

Summary of Existing Guidelines for Hydrologic Safety of Dams

FEMA P-919 / July 2012

FEMA

Preface

In September 2010, the Federal Emergency Management Agency's National Dam Safety Program sponsored development of this document under the supervision of James E. Demby, Jr., P.E. The primary authors of this document are Dr. Arthur Miller, P.E. (AECOM); and Paul Schweiger, P.E.; Amanda Hess, P.E.; Rod Holderbaum, P.E.; Bob Kline, P.E.; Don Roarabaugh, P.E.; and Gregory Richards, E.I.T. (Gannett Fleming).

The quality and scope of this report has been significantly improved by the efforts and knowledge of the Steering Committee and Research Work Group composed of the following dam safety experts:

Steering Committee:

James Gallagher, P.E.
Chief Engineer, Dam Bureau
New Hampshire Department of Environmental Services

Brian Long
Manager, Division of Water & Waste Management, Dam Safety Section
West Virginia Department of Environmental Protection

Dan Mahoney, P.E.
Director, Division of Dam Safety and Inspections
Federal Energy Regulatory Commission

John H. Moyle, P.E.
Manager, Bureau of Dam Safety and Flood Control
New Jersey Department of Environmental Protection

Laurence Siroky, P.E.
Bureau Chief, Water Operations
Montana Department of Natural Resources and Conservation

Research Work Group:

Brian Becker
Chief, Dam Safety Office, Bureau of Reclamation
U.S. Department of the Interior

Jason Boyle, P.E.
State Dam Safety Engineer
Minnesota Department of Natural Resources

Robert H. Dalton
Vasconcelles Engineering Corporation

James Demby
Assessment and Planning Section, Risk Analysis Branch, Mitigation Division
Department of Homeland Security/Federal Emergency Management Agency

Patrick Diederich
Chief of Dam Safety
Nebraska Department of Natural Resources

Greg Hanson
Research Leader, Hydraulic Engineering Research Unit, Agricultural Research Service
U.S. Department of Agriculture

Lisa Krosley
Denver Federal Center, Bureau of Reclamation
U.S. Department of the Interior

Dan Mahoney, P.E.
Director, Division of Dam Safety and Inspections
Federal Energy Regulatory Commission

John Ritchey
Bureau of Dam Safety of Flood Control
New Jersey Department of Environmental Protection

Michael K. Sharp
Engineer Research and Development Center
U.S. Army Corps of Engineers

Hal Van Aller
Dam Safety Division
Maryland Department of the Environment

Eugene P. Zeizel
Assessment and Planning Section, Risk Analysis Branch, Mitigation Division
Department of Homeland Security/Federal Emergency Management Agency

Summary of Existing Guidelines for Hydrologic Safety of Dams

The authors extend their appreciation to the following agencies and individuals for graciously providing information and permission to use their materials in this publication:

Association of State Dam Safety Officials, Sarah McCubbin-Cain
Canadian Dam Association
Queensland Department of Environment and Resource Management
United States Society on Dams, Larry Stephens
United States Army Corps of Engineers
United States Bureau of Reclamation

The authors caution readers of this document that sound engineering judgment should always be applied when using technical references. This publication is intended solely for use by professional personnel who are competent to evaluate the significance and limitations of the information provided herein, and who will accept total responsibility for the application of this information. Anyone making use of this information assumes all liability from such use.

Suggestions for changes, corrections, or updates to this document should be directed to:

Paul G. Schweiger, P.E.
Assistant Manager, Dams and Hydraulics Section
Gannett Fleming, Inc.
207 Senate Avenue
Camp Hill, PA 17011-2316
Fax: 717-763-1140
pschweiger@gfnet.com

Please reference specific pages, paragraphs, or figures within the document, together with proposed new material in any convenient format. Sources of proposed new material should be completely cited. Submission of material signifies permission for use in future revised editions of this document, but credit for such new material will be given where appropriate.

F.1. Size Classification Schemes

F.2. Hazard Classification Schemes

Executive Summary

Background

There is a need for updated guidelines for evaluating the hydrologic safety of dams, and in particular, for determining the appropriate Inflow Design Flood (IDF) and freeboard requirements. The existing hydrologic guidelines of some states and federal agencies were written in the late 1970s. Since that time, significant technological and analytical advances have been made along with better watershed and rainfall information that improve the analysis of extreme floods and quantification of incremental dam failure consequences. Many existing dams that were constructed before dam safety rules existed still do not meet regulatory guidelines for safely passing the IDF. Existing guidelines often do not treat new and existing dams the same in recognition of the fact that upgrading older dams to pass the IDF can be difficult and expensive.

There continues to be much debate with the current criteria, both within the engineering profession and among dam owners and others involved with dam safety. Several states and federal agencies have recently updated their dam regulations, including the sections relating to hydrologic safety; however, there appears to be considerable inconsistencies and non-uniformity in the dam classification systems and spillway capacity criteria being specified.

The overriding purpose of this report is to document the available data and to present the state of the practice for evaluating the hydrologic safety of dams, including inventorying current practices used by state and federal agencies. This work included a review of hydrologic guidelines currently used in each state and federal agency that regulates dams, and was guided by an independent steering committee and reviewed by the Research Work Group. A subsequent publication will include new federal guidelines for the evaluation of the hydrologic safety of dams that could be applied nationwide.

United States Dam Inventory

The current National Inventory of Dams, developed and maintained by the U.S. Army Corps of Engineers (USACE), contains data on nearly 84,000 dams within the United States. Approximately 11,000 of these dams are considered High Hazard, another 11,000 dams are considered Significant Hazard, and the remaining are considered Low Hazard. Most of the dams (over 65,000) are regulated by the states and owned by a variety of private or municipal entities. Federal agencies own or regulate approximately 6 percent of dams [FEMA, 2010].

Evolution of Design Flood Selection for Spillways

An understanding of the timeframe of the development of the methodologies for selecting the Spillway Design Flood (SDF) in the United States is helpful to understanding the history of dam safety guidelines since each type of design flood selection methodology must first be introduced and evaluated by the dam safety community before it becomes accepted and included in the

guidelines. While laws related to the performance of dams have existed since before 1700 BC, dam designs during the early period of dam building in the United States were based solely on the judgment of the engineer. By about 1900, however, the field of surface water measurement had advanced enough to support the development of empirical equations to transpose maximum regional discharges to the drainage area of interest in order to predict peak flood discharges.

Systematic nationwide collection of surface water data began in earnest by the U.S. Geologic Survey in 1934 when the New Deal Federal Public Works Administration obtained funds to perform detailed studies of floods, rainfall, and runoff. The 1930s and 1940s saw many significant advances in hydrology including the innovation of the unit hydrograph which made it possible to estimate flood flows from storm rainfall.

The years following 1950 saw the development of elegant theoretical and mathematical approaches to solve hydrologic problems. This along with the advancement of computers to perform computationally demanding analyses led to greater use of watershed modeling using unit hydrographs and precipitation. During this period, engineers turned to meteorologists to establish limiting rates of precipitation for design purposes. Between 1963 and 1984, a series of Hydrometeorological Reports were subsequently developed to establish Probable Maximum Precipitation (PMP) estimates for the majority of the country.

While deterministic approaches to the hydrologic design of dams have been overwhelmingly supported over the past few decades, there has also been an increased interest in the application of risk analysis. The U.S. Bureau of Reclamation (Reclamation) appears to be the first agency to seriously apply risk-based decision making to dam safety. Beginning around 1995, Reclamation adopted the use of risk analysis as the primary support to their dam safety decision-making. In 1997, the USACE replaced the Probable Maximum Flood standard with an incremental procedure to provide a framework for evaluating the benefits of mitigating hazards presented by hydrologic deficiencies in high hazard situations.

Today, many professionals consider risk assessment to be a useful way to ensure dam safety as it requires dam owners to investigate failure modes in detail and understand where the greatest risks lie. However, the main drawback of this approach is that it is technically challenging, time consuming, and difficult to administer, and so the traditional standards based approach is generally still adopted by the states.

Origins of Dam Safety Design Guidelines

Thus far, the methodology used to determine spillway adequacy has been described without regard for the actual regulatory framework. Prior to 1950, regulatory guidelines and design standards for the hydrologic safety of dams were based mainly on judgment and experience. As of 1964, a fourth of the states exercised no supervision over dams at all, and a third exercised no responsibility over operation and maintenance of a dam once it was constructed. This same year, Franklin F. Snyder,

Hydraulic Engineer with the Office of the Chief of Engineers, published a dam classification and spillway design flood matrix that considered dam height, storage, and damage potential.

In the early 1970s a series of dam safety incidents occurred resulting in significant loss of life including the failure of Buffalo Creek Dam (West Virginia) in February 1972 and Canyon Lake Dam (South Dakota) in June 1972. Following these events, the Congress enacted the National Dam Inspection Act (PL 92-367) which became law on August 8, 1972. The Mine Safety and Health Administration (MSHA) also gained regulatory jurisdiction of coal refuse impoundments at this time. In the early 1970s, many states did not have laws regarding dam safety and often did not require a review of the dam design prior to construction or require construction inspection or post-construction inspection. It was also found that dam safety in most states was inadequate with a wide variation of practices, regulations and capabilities of all agencies supervising dam safety. There was also little or no overall coordination of dam safety efforts.

Dams subject to PL 92-367 were those having a height 25 feet or greater, or a maximum impounding capacity greater than 50-acre-feet. Dams less than six feet high or storing less than 15 acre-feet were excluded. Congress charged the USACE with implementing the provisions of the Act. In addition to carrying out a national program of inspection of dams for the purpose of protecting human life and property, the act also required: (1) an inventory of all dams located in the United States; (2) a review of each inspection made; and (3) recommendations for a comprehensive national program for the inspection and regulation of dams, and the respective responsibilities which should be assumed by Federal, State, and local governments and by public and private interests.

Because of the scale of the program, the USACE developed a classification system to screen the adequacy of spillway capacity. The selected classification system was quite similar to that proposed by Snyder in 1964 and closely resembles the current classification criteria used by many states.

In 1979, the Federal Emergency Management Agency (FEMA) and the *ad hoc* Interagency Committee on Dam Safety issued "Federal Guidelines for Dam Safety." This document provided the first guidelines for federal agency dam owners and dam owners regulated by federal agencies. For flood selection design or evaluation, the federal guidelines supported the use of risk analysis. The guidelines were clear, however, that the spillway design standard to be adopted for dams where loss of life or major property damage could be significant was the Probable Maximum Flood (PMF).

In 1986, FEMA published "Federal Guidelines for Selecting and Accommodating Inflow Design Floods for Dams" as a supplement to the "Federal Guidelines for Dam Safety." The primary purpose of the document was to provide general guidelines on procedures for selecting and accommodating inflow design floods for use by federal agencies in developing agency criteria and to ensure more nationwide uniformity in application.

Several other guidance documents relating to the hydrologic safety of dams were published in the decades that followed by agencies such as FEMA, the American Society of Civil Engineers (ASCE), and the National Research Council. These documents included numerous recommendations supporting both deterministic and risk-based approaches to spillway design. The guidance documents also identified several inconsistencies in the state-of-the-practice.

Pertinent International Guidelines

While the scope of this study specifically addresses guidelines for hydrologic safety of dams within the United States, there are several developments in the international arena that are particularly relevant to the study. Recently updated guidelines in Australia and Canada were reviewed and are summarized to provide a glimpse of how other countries' guidelines are changing. The Australian National Committee on Large Dams (ANCOLD) led the way internationally in the development of acceptable risk criteria in dam safety and published *Guidelines on Risk Assessment* in 1994. This was followed with *ANCOLD Guidelines on Selection of Acceptable Flood Capacity for Dams* which was published in 2000 to provide more appropriate and consistent guidance within a risk process for dam safety evaluation under floods. These guidelines provided a basis for integrating risk assessment into dam safety. Guidelines published by the Canadian Dam Association (CDA) in 2007 include a dam classification system based on failure consequences and discuss both the traditional standards-based approach and the risk-based approach to dam safety decision making. Selecting the IDF using quantitative risk analyses is not discussed in CDA's guidelines and appears to be discouraged because of the inability to accurately assign a probability to extreme floods.

2011 Hydrologic Safety of Dams Survey and Summary of State and Federal Guidelines

In order to document the present state of the practice for evaluating the hydrologic safety of dams and inventory current practices used by state and federal agencies within the United States, a detailed questionnaire was prepared and distributed to all state dam safety agencies as well as any federal agencies which own, regulate, or assist in the design of dams. The questionnaire addressed many important issues related to the hydrologic safety of dams including dam classification criteria, determination of the spillway design flood, allowable methodologies and software, consideration of future development, incremental damage assessment, use of early warning systems, current practices related to risk analysis, and agencies' ability and receptiveness to perform risk analysis.

Surveys were completed by the appropriate dam safety agency from all 50 states as well as Puerto Rico with exception of Alabama and Florida. Of the federal agencies, respondents included the Bureau of Indian Affairs, Federal Energy Regulatory Commission (FERC), Mine Safety and Health Administration, Natural Resources Conservation Service, Tennessee Valley Authority (TVA), U.S. Army Corps of Engineers, U.S. Bureau of Reclamation, U.S. Forest Service, and the U.S. Fish and Wildlife Service. A comparison of survey results with past documented surveys allows the identification of trends and changes related to the hydrologic safety of dams over the past 40 years.

The Current State of the Practice

The existing hydrologic guidelines of many states and federal agencies were written in the 1970s or 1980s. Since that time, significant technological and analytical advances have been made along with better watershed and rainfall information that have improved the analysis of extreme floods and quantification of incremental dam failure consequences. Review of the published policy and guidelines for each state as well as the responses to the detailed survey completed as part of this study have revealed several important findings that can be used to define the current state of the practice regarding the hydrologic safety of dams.

In general, the guidelines for the hydrologic safety of dams are not consistent and vary widely from state-to-state and between federal agencies in many respects. Although some states and agencies have recently updated their guidelines, many states and agencies have not significantly changed their guidelines since their development. Some of those who have changed their guidelines have incorporated some form of risk-based analyses, but the requirements and methodology differ widely.

Some of the most notable inconsistencies in the existing guidelines relate to classification systems. From the most basic criteria for what defines a regulatory or a jurisdictional dam to whether the dam is classified by size, hazard, or not at all, there is no overwhelming majority of configuration for these classification systems. While size classification is used by many states and hazard classification is used by all states, the number of classifications and the distinctions between the classes vary. There is also no consensus on distinctions between new dams and existing dams.

In determining the magnitude of the SDF, most states follow a prescriptive approach in which the design flood is specified based upon the dam's classification (size, hazard, or both). Both probabilistic and deterministic (based on PMP or PMF estimates) criteria are used for the prescriptive approach by the states and agencies. Many of the criteria in prescriptive approaches are arbitrary with no apparent scientific rationale, and the prescribed SDFs for identical dams in different states have varying magnitudes.

Historically, a few important federal agencies have led the way in the development of dam safety regulations and design standards, and the trend among these agencies is toward incorporating a risk-based approach rather than the prescriptive approach. The USACE is currently partnering with Reclamation, FERC, and TVA to achieve a common risk management framework and guidelines. This trend toward risk-based design is also apparent in the international practice.

The transition to risk-based analyses in some states has also begun. The methodologies developed by California, Washington, and Montana reflect an initial movement to make site-specific, cost-effective, and risk-based designs. They also demonstrate how the complexities of risk analysis can be applied in a simplified, standard-based system. Comparison of these three recently developed, risk-based approaches indicates a lack of consistency regarding the criteria used among the systems, the weights assigned to the criteria, and the resultant risk tolerances.

Although the trend appears to be the incorporation of risk-based approaches into guidelines for the hydrologic safety of dams, there are many obstacles to widespread acceptance by state regulatory agencies. The budgets, staff availability, and technical ability of many dam safety state agencies are very limited. Many respondents indicated that they have concerns regarding risk-based analyses to determine spillway capacity requirements due to review requirements and the lack of widely acceptable and defensible guidelines.

It should also be noted that the federal agencies who have led the way in developing risk analysis procedures and tolerances are owners of a significant number of dams. These agencies have been able to utilize the prioritization and ranking aspects of risk analysis to manage their respective portfolios in addition to using quantitative risk analysis in design. The administrative processes and reviews of regulatory agencies, such as FERC, MSHA, and most of the states, differ significantly from that of dam owners like USACE and Reclamation. The application of quantitative risk analysis for dam design in regulatory agencies may be burdensome or even unnecessary. The state dam regulatory agencies of California, Washington and Montana have recently developed risk-based indices to determine acceptable flood capacity; however, none of the states use quantitative risk assessment.

There are many differing opinions regarding the need for uniformity of design criteria between states and federal agencies. It is generally recognized that the implementation of strictly uniform criteria is not a possibility. Instead, a flexible framework of criteria may be required to provide for the specific requirements, budget, and technical ability of each state. While leading federal agencies and a few states have recently transitioned from strictly prescriptive to risk-based criteria, it is evident that a large portion of the dam safety community has significant reservations concerning the validity and practicality of risk analysis. Having one set of federal dam safety standards for risk determination may help to promote the use of risk-based analysis by states and potentially encourage increased uniformity of state guidelines.

The survey responses also indicate that a significant portion of the dam safety community is unaware of current and even long-standing landmark publications regarding guidelines for the hydrologic safety of dams. A quarter of respondents were unaware of FEMA's 2004 federal guidelines for "Selecting and Accommodating Inflow Design Floods for Dams," and approximately half were not familiar with the most recently published USACE, Reclamation, and ASCE inflow design and dam safety guidelines. It is therefore apparent that any attempt to encourage the adoption of more uniform guidelines and consideration of adopting risk-based criteria will require a more effective outreach and educational effort.

Although the literature search identified several studies that provided information on state practices related to selecting inflow design floods for dams, none of the studies provided a comprehensive compilation of this data. In addition to providing background information for developing new federal guidelines for the hydrologic safety of dams, this report and the associated database provide a comprehensive compilation of current federal and state guidelines that can be used by individual

states to evaluate and compare their current guidelines with those of other agencies. As individual states revise their guidelines, this information will provide them with important information that will help them to make informed decisions that should result in more uniformity.

1. Introduction

1.1. Authorization

There is a need for updated guidelines for evaluating the hydrologic safety of dams, and in particular, for determining the appropriate Inflow Design Flood (also referred to as Spillway Design Flood) and freeboard requirements. The existing hydrologic guidelines of many states and federal agencies were written in the late 1970s. Since that time, significant technological and analytical advances have been made along with better watershed and rainfall information that improve the analysis of extreme floods and quantification of incremental dam failure consequences. Many existing dams that were constructed before dam safety rules existed still do not meet regulatory guidelines for safely passing the Inflow Design Flood (IDF). Existing guidelines often do not treat new dams and existing dams the same in recognition of the fact that upgrading older dams to pass the IDF can be difficult and expensive.

There continues to be much debate with the current criteria, both within the engineering profession and among dam owners and others involved with dam safety. Several states and federal agencies have recently updated their dam regulations, including the sections relating to hydrologic safety, however, there appears to be considerable inconsistencies and non-uniformity in the dam classification systems and spillway capacity criteria being specified.

In September 2010, the Federal Emergency Management Agency (FEMA) authorized a new study titled: "*Development of Guidelines for the Evaluation of Risk-Based Hydrologic Safety of Dams.*" The objective of this study is to develop and publish a guidance document for the evaluation of the hydrologic safety of dams, including guidelines for determining the IDF for new and existing dams that could be applied nationwide. This project is being completed under the direction of Dr. Art Miller with management and execution of the project by the BakerAECOM Risk MAP Professional Technical Services (PTS) Team comprised of Gannett Fleming, AECOM, Michael Baker, Jr., Inc., and Taylor Engineering. The project team includes an Independent Steering Committee comprised of Dan Mahoney (FERC), John Moyle (NJ), Brian Long (WV), Jim Gallagher (NH), and Lawrence Siroky (MT).

1.2. Purpose

Prior to developing the guidance document for the risk-based evaluation of the hydrologic safety of dams, the study team was tasked with reviewing and documenting the hydrologic guidelines currently used by each state and federal agency that regulates dams. Previous publications and technical papers that contain hydrologic safety guidelines for dams were reviewed. Organizations dealing with dam safety were contacted to determine what guidelines and support materials exist, including the Australian National Committee on Large Dams (ANCOLD), the American Society of Civil Engineers (ASCE), the Association of State Dam Safety Officials (ASDSO), the Canadian

Dam Association (CDA), FEMA, the Interagency Committee on Dam Safety (ICODS), the National Research Council (NRC), U.S. Society on Dams (USSD), and others. This initial task also included conducting a survey to gather information from every state dam safety program and federal agency that owns or regulates dams.

The overriding purpose of this report is to document the available data and to present the state of the practice for evaluating the hydrologic safety of dams, including inventorying current practices used by state and federal agencies.

1.3. Scope of Work

The scope of work for developing the guidelines for the hydrologic safety of dams was divided into five tasks. Tasks 1 and 2 relate to the current document which summarizes the existing guidelines while Tasks 3 and 4 relate to preparing the new guidance document. Task 5 relates to monthly reporting. The scope of work for the first two tasks, covering the primary purpose and scope of this reports' effort, is as follows:

> *"Task 1: Data Search – The contractor will review and gather the hydrologic guidelines currently used in each state and federal agency that regulate dams. The contractor shall also review the ASCE publication titled, 'Evaluation Procedures for Hydrologic Safety of Dams,' as well as identifying and reviewing other publications that may contain hydrologic safety guidelines. The contractor shall also contact organizations dealing with dam safety to determine what existing guidelines may exist, such as ICODS, ASDSO and its 'Model State Dam Safety Program,' and FEMA's 'Selecting and Accommodating Inflow Design Floods for Dams.'*
>
> *"Task 2: Compile Data – Within 6 months of contract start-up, the contractor will compile available data and present a draft report which incorporates findings from Task 1. The draft report should include a state of the practice of evaluating the hydrologic safety of dams. The draft report will be submitted to the Research Work Group and an independent steering committee recommended by the contractor and approved by the Research Work Group for review. The Research Work Group and steering committee will provide comments on the draft report within 30 days of submission. The contractor will submit a revised Report incorporating the comments within 30 days of receipt of comments."*

2. United States Dam Inventory Data

2.1. Background

The purpose of this section is to provide a summary of basic information related to the inventory of dams within the United States. This data is helpful for establishing new guidelines for the hydrologic safety of existing and new dams as it provides general information on the location, age, ownership, hazard classification and size of dams in the United States. This summary of dams is based on information cataloged and reported by the Association of State Dam Safety Officials (ASDSO), the US Army Corps of Engineers (USACE), the American Society of Civil Engineers (ASCE) and the Federal Emergency Management Agency (FEMA) as described in the following paragraphs. Data from each of these entities does vary; therefore, there are inconsistencies in the data presented from various sources in this chapter.

National Inventory of Dams

The National Inventory of Dams (NID) is a database of dams in the United States which was developed and is maintained by the USACE. Congress authorized the USACE to inventory dams as part of the 1972 National Dam Inspection Act. Several subsequent acts have authorized maintenance of the NID and provided funding. The USACE collaborates with FEMA and state regulatory offices to collect data on dams. The goal of the NID is to include all dams in the United States which meet at least one of the following criteria:

1. High hazard classification - loss of at least one human life is likely if the dam fails
2. Significant hazard classification - possible loss of human life and likely significant property or environmental destruction
3. Equal or exceed 25 feet in height and exceed 15 acre-feet in storage
4. Equal or exceed 50 acre-feet storage and exceed 6 feet in height

Low hazard dams which do not meet the criteria specified in number 3 or 4 are not included in the NID even if they are regulated according to state criteria. In some states, the number of these dams is several times the number of dams included in the NID.

Association of State Dam Safety Officials

In addition to using information collected as part of the NID, ASDSO annually collects additional information on dams in the United States by survey for their State Dam Safety Program Performance Information Report. ASDSO data focuses on dams within the jurisdiction of each state regardless of whether or not they are included in the NID.

American Society of Civil Engineers

Since 1998, ASCE has issued four reports titled “Report Card for America’s Infrastructure.” These reports depict the condition and performance of the nation’s infrastructure, including dams, and

were prepared by an advisory panel of the nation's leading civil engineers. This panel analyzed hundreds of reports and studies in the process of assigning grades as well as surveying thousands of engineers.

Federal Emergency Management Agency

As part of the U.S. Department of Homeland Security, FEMA also has an interest in dam safety in the United States. In their 2010 biennial report to Congress, "Dam Safety in the United States, A Progress Report on the National Dam Safety Program," FEMA describes the achievements of the states, the federal agencies, and their partners in Fiscal Year (FY) 2008 and FY 2009 in meeting the vision, mission, and objectives of the National Dam Safety Program. This document contains many interesting statistics and graphics that are useful in summarizing the dam inventory of the United States.

2.2. Summary of Significant Statistics for Dams in the United States

Dam construction in the United States began in earnest in the second half of the 19th century and peaked with the surge in the American economy and population following World War II. The current NID contains data on nearly 84,000 dams. The average age of these dams is over 50 years. Figure 2.1 shows the relative construction date of dams based on data in the NID.

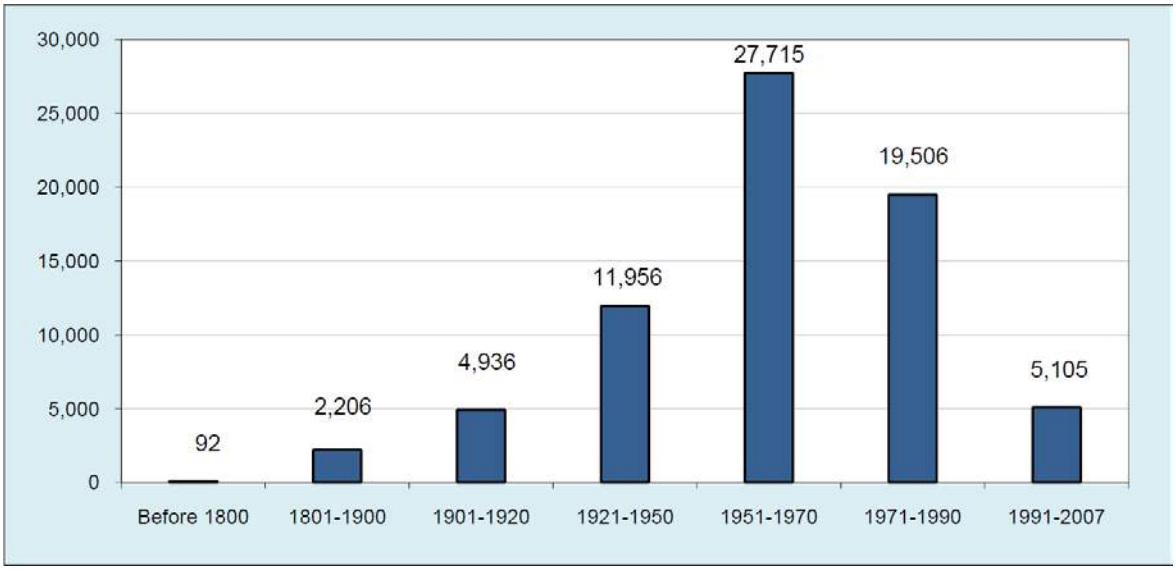

Figure 2.1 Year Dams Were Completed in the United States [USACE, 2009]

The 2009 Report Card for America's Infrastructure on Dams, prepared by ASCE, indicates that age has a two-fold effect on the determination of deficiency of a dam. First, the age of a dam contributes to deterioration. Second, design criteria and loadings which were considered

appropriate at the time of design, may now be considered insufficient, leading to dams being considered unsafe or deficient. The same publication reports that the number of dams determined to be unsafe or deficient is rising and now stands at more than 4,400 dams. ASCE's 2009 Report Card states, "Over the past six years, for every deficient, high hazard potential dam repaired, nearly two more were declared deficient."

Not only are dams in the United States aging and being declared deficient, but, at the same time, the number of high hazard potential dams is also increasing at a significant rate. According to statistics maintained by ASDSO, for the 10-year period from 2000 through 2009, the number of dams listed in the NID increased by about 9 percent. During this same period, the number of high-hazard, state-regulated dams increased by almost 14 percent. ASCE's 2009 Report Card on Dams states that the trend of increasing number of high hazard dams is a result of higher consequences of failure spurred by new downstream development. Development both upstream and downstream of dams is a widespread concern.

Within the United States, dams are owned and regulated by a variety of organizations. Most dams are privately or municipally-owned and are state-regulated. Figure 2.2 is a map of the United States showing the distribution of low, significant and high hazard potential dams. Figure 2.3 is a similar map showing only state-regulated high hazard potential dams.

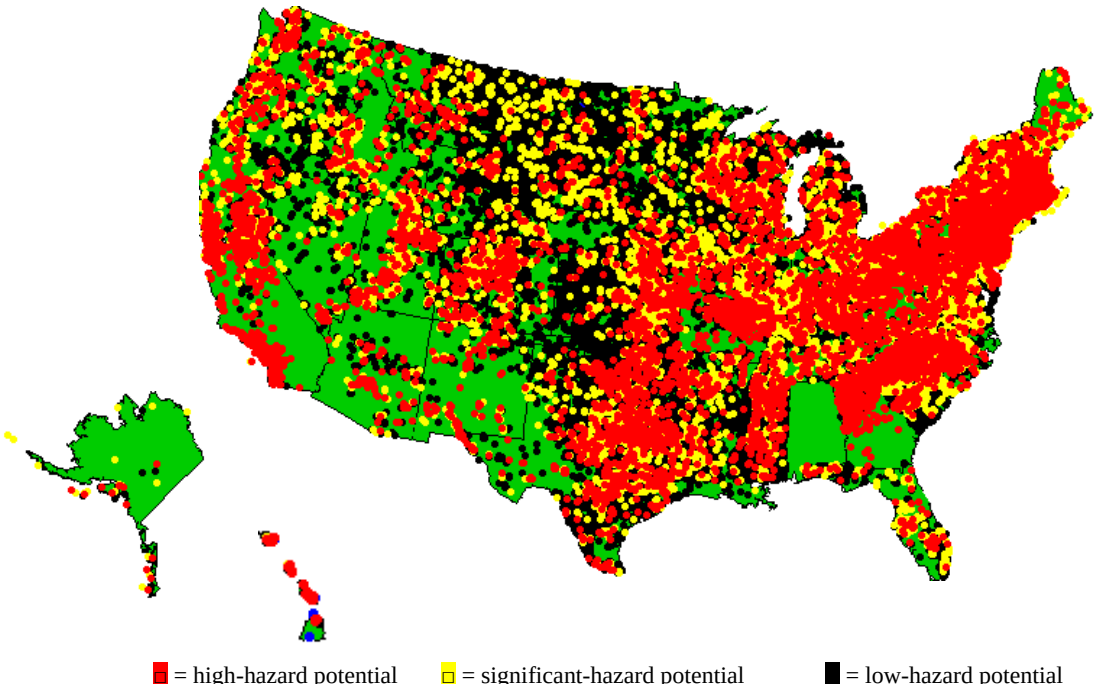

Figure 2.2 State-Regulated Dams in the United States According to Hazard Potential [FEMA, 2010]

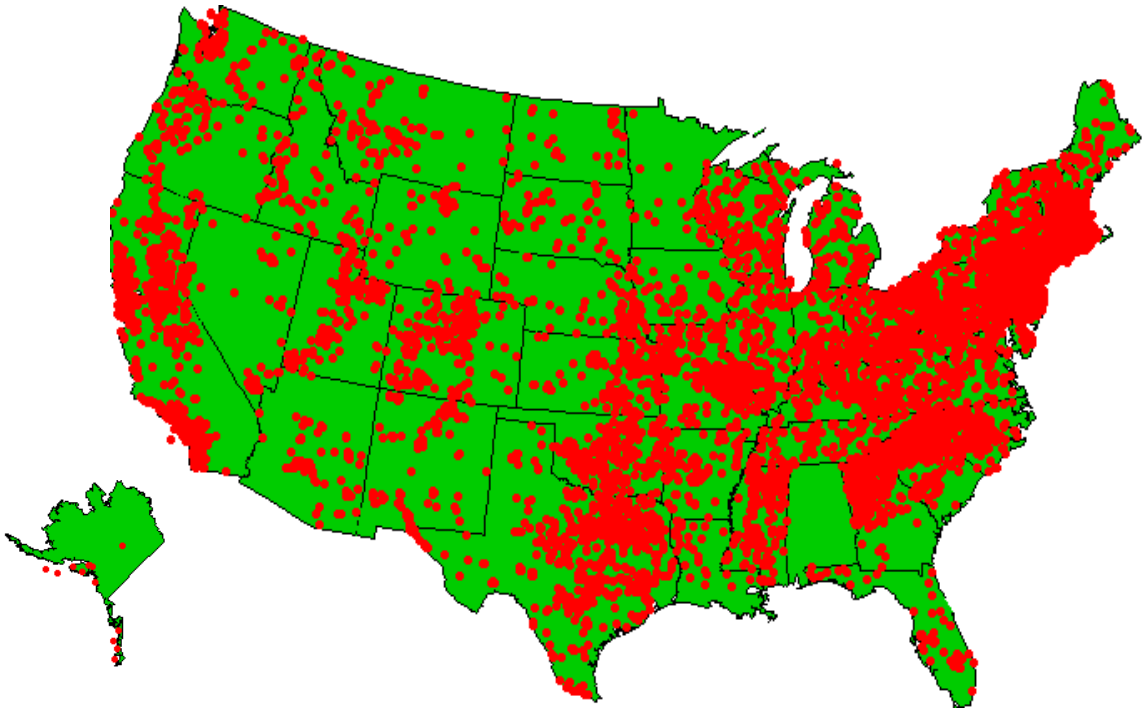

Figure 2.3 Map Showing Only State-Regulated High-Hazard Potential Dams [FEMA, 2010]

According to the FEMA biennial report to Congress, the federal government owns or regulates approximately 6 percent of the dams in the United States, and many of these dams are considerable in terms of size, function and hazard potential. The rest of the dams are within the jurisdiction of state dam safety programs. A summary of dams by state and hazard classification are summarized in Table 2-1 and Table 2-2. Figure 2.4 is a map showing the location of dams reported to the NID by the federal agencies. Table 2-3 is a summary of federal dam ownership by hazard classification.

Table 2-1 Dam Safety Statistics from the NID [USACE, 2009; ASDSO, 2008]

Hazard Potential	State Regulated Dams Listed in the NID	Total State Regulated Dams
High	10,856	10,993
Significant	11,163	10,931

[3] Five USACE dams need to have a hazard classification determined.
[4] Three Navy dams need to have a hazard classification determined.
[5] Includes only main dam projects. Total, including associated saddle dams and dikes, is 84.

3. Evolution of Design Flood Selection for Spillways

3.1. Background

This Chapter focuses on the history and development of various methodologies for selecting the Spillway Design Flood (SDF) in the United States. The regulatory framework of dam safety guidelines and regulations is discussed in Chapter 4. An understanding of the timeframe of the development of the methodologies is helpful to understanding the history of dam safety guidelines since each type of design flood selection methodology must first be introduced and evaluated by the dam safety community before it becomes accepted and included in the guidelines.

3.2. Pre-United States Dam Building

Laws related to the performance of dams have existed since before 1700 BC. The Babylonian Code of Hammurabi is the earliest discovered example of a set of written laws, two of which (Law Nos. 53 and 54) specifically address the responsibility of dam owners to maintain their dams and provide restitution should their dam fail and flood downstream fields [King, 1910]. Engineers up until the 1800s appear to have had no known rationale for their spillway designs [Schnitter, 1994]. Many early Roman dams, mostly of modest height and of masonry with a stepped downstream face, appear to have been designed to be overtopped.

3.3. The Early Period (Before ~1900)

In the United States, few notable dams were constructed until the second half of the 19th century. In this early period, the design engineer had to rely on his own judgment as little or no streamflow or rainfall data were available. Usually the only available information was historical or anecdotal in terms of a past peak flood stage (high water mark) information. The corresponding flood discharge rates at a site were subsequently estimated from the high water mark or from past recorded flood levels transposed from adjacent streams. Early reports seem to provide a sense that the less cautious engineer had a confidence that the flood record was somewhat stable and that nature had shown what could be expected on a particular stream in terms of maximum flood potential in relatively few decades. Others believed the evaluation of major floods was impossible given the accepted techniques and resources available at that time [Myers, 1967].

During this early period, it should be recognized that the consequences of a dam failure were generally less severe than they are today. Early dams were typically constructed to limited heights. They were often constructed using rock-filled timber-cribs, stone masonry, or concrete and were resistant to erosion from overtopping. Many dams were constructed for the purpose of providing irrigation or power in remote areas where downstream development was insignificant. There may also have been an acceptance of the idea that some natural events are so extreme that man is not responsible for their consequences. The degree of conservatism of the design was generally

unknown. In 1889, 2,209 lives were lost when South Fork Dam, an earth embankment dam near Johnstown, Pennsylvania, overtopped and breached. The 72-foot-high structure was initially constructed between 1838 and 1853. This man-made catastrophe focused much needed attention on the importance of adequate spillway design capacity.

During the period between 1800 and 1900, several governmental agencies with an interest in hydrology were founded in the United States, including the Army Corps of Engineers (1802), the Fish and Wildlife Service (1871), the Geological Survey (1879), the Weather Bureau under the Department of Agriculture (1891), and the Mississippi River Commission (1893). These organizations helped to advance the field of surface water measurement and ushered in the beginning of stream gauging and precipitation gauging data collection [Chow, 1964]. Significant flow measurements were made in many rivers, and a comprehensive program to perform topographical and hydrographical surveys throughout the United States was initiated. The American Society of Civil Engineers and Architects (1852) was also founded during the Croton Aqueduct project for the City of New York, and soon emerged as a leading organization for organizing lectures and publishing technical papers on dam engineering.

3.4. Period of Empiricism or the Regional Discharge Period (1900-1930)

During the last part of the 19th century and the first 30 years of the 20th century, many formulas were developed to predict peak flood discharge based on the size and hydrologic characteristics of the drainage basin [Schnitter, 1994]. Ven Te Chow notes that although much work on the modernization of hydrology had been started, the development of quantitative hydrology was still immature. He refers to this period as the "Period of Empiricism." Hundreds of empirical formulas were proposed and the selection of their coefficients and parameters depended mainly on judgment and experience [Chow, 1964].

By analyzing the maximum discharges observed at hundreds of streams regionally rather than at a single stream, regional flood frequency formulas were developed. The concepts of *extrapolation*, *transposition* and *envelopment* were applied in the development of the formulas and recognized the random-chance nature of major storms occurring over a watershed. These concepts also recognized that hydrologic data observed at one location could serve as a basis for estimates at other locations. The most famous and widely used enveloping formula was the Myers' and Jarvis' ratings in which peak discharges are proportional to the square root of the drainage area and a coefficient that varies with region and geology. By transposing the largest observed values of peak discharge to drainage area within a particular geological and climatological area, it was assumed that these values approached the largest that could occur, or that they provided an adequate degree of safety [Myers, 1967].

One example of a dam designed during this period is the Gilboa Dam (Schoharie County, New York) which was designed and constructed during the period of 1917 to 1926 to impound a water

supply storage reservoir for New York City. With a height of 183.0 feet and a normal pool storage of approximately 60,000 acre-feet, the dam's construction was a noteworthy achievement in dam engineering during this period. For the hydrologic design of Gilboa Dam, regional floods were analyzed and the maximum event was transposed to the 314 square mile drainage area of the dam. This transposed flood event was then multiplied by a factor of three to provide a margin of safety per the engineer's judgment. The resulting flood flow of 168,000 cubic feet per second was referred to in 1917 design documents as the "probable maximum flood." This design flood compares favorably to current industry standards for calculating the probable maximum event [USACE, 1978].

Additional major governmental agencies were founded in the United States during this period that relied on hydrologic investigations to perform their functions including the Bureau of Reclamation (1902), the Forest Service (1906), the Miami Conservancy District (1914), and the U.S. Army Engineers Waterways Experiment Station (1928). The National Research Council of the National Academy of Sciences (1919), the Federal Power Commission (1920) the International Commission on Large Dams (1928), and USCOLD (1928), now the United States Society on Dams (2001), were also established during this period.

3.5. Period of Rationalization or Period of Statistical Frequency Analysis and Storm Transposition (1930-1950)

During this period, additional important government agencies were organized in the United States such as the Tennessee Valley Authority (1933), the Soil Conservation Service (1935), now known as the Natural Resources Conservation Service (1994), and the Weather Bureau (1940).

Systematic nationwide collection of surface water data began in earnest by the Geologic Survey in 1934 when the New Deal Federal Public Works Administration obtained funds to perform detailed studies of floods, rainfall, and runoff. The publication *Floods in the United States* provided information on floods, flood peaks, and river discharges for most of the major rivers in the country while the publication *Rainfall and Run-Off in the United States* provided minimum, maximum, and other precipitation statistics from precipitation stations throughout the country. Together, the two volumes covered the major areas of surface water hydrology as it was understood and significantly increased the data available to dam engineers [Reuss, 2002].

Several great hydrologists emerged during this period who used rational analysis instead of empiricism to solve hydrologic problems. In 1932, L. K. Sherman demonstrated the use of the unit hydrograph for translating rainfall excess into a runoff hydrograph. In 1933, R. E. Horton developed an approach to determine rainfall excess based on infiltration theory. In 1941, E. J. Gumbell proposed the use of the extreme-value distribution for frequency analysis of hydrologic data, and along with many others promoted the use of statistics in hydrology [Chow, 1964].

During a brief portion of this period, flood-frequency curves were extrapolated to estimate flood flows with return periods as large as 10,000 years. The flood selected for setting the spillway design capacity depended on the judgment of the engineer [ASCE, 1988]. Developing a SDF for a dam by straight frequency analysis of discharges from a long record initially showed great promise. After several major floods, however, the recorded peak discharges were found to exceed maximum recorded floods by several orders of magnitude and fall far outside of the defined flood frequency relationships. In 1942, the Boston Society of Civil Engineers examined the use of flood frequency relationships developed from flood records extending back 100 years, and concluded that it was difficult and uncertain to assign return periods to extreme observed floods. They also concluded that it would be even more difficult and uncertain to extrapolate to the long return period that would be required for a SDF [Myers, 1967].

Figure 3.1 provides an example of the difficulties in using statistics alone, and shows the maximum annual peak discharge for the Pecos River near Comstock, Texas for the 54-year period from 1900 to 1954. Based on the observed annual peak discharges at this gaging station no one could have predicted the observed peak discharge for the 1954 flood by extrapolating prior flood frequency data (statistics) alone.

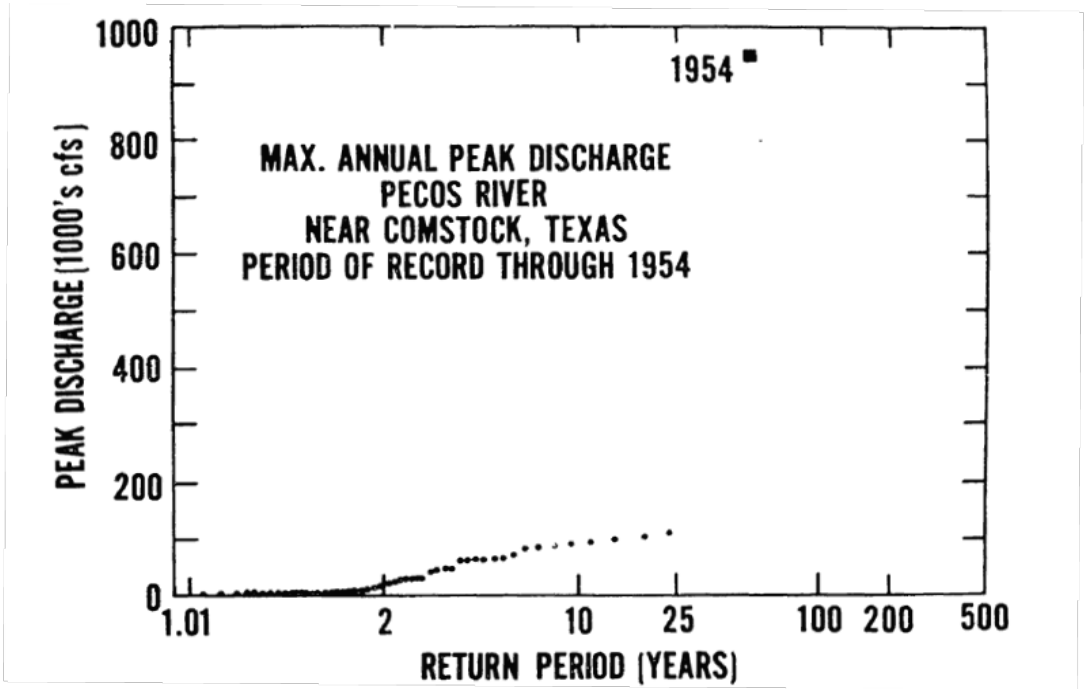

Figure 3.1 Maximum Annual Peak Discharge, Pecos River near Comstock [Myers, 1967]

With the innovation of the unit hydrograph, it became possible to estimate flood flows from storm rainfall. This led to storm transposition whereby precipitation recorded from major storms within a

region are transposed or centered over the basin under study. Runoff is then computed using unit hydrograph theory. This method was developed and advocated by members of the Corps of Engineers and Weather Bureau as a powerful tool for engineers in determining events which "could happen" over basins, but cautioned that this does not necessarily yield a "limiting storm." In the late 1930s, the Tennessee Valley Authority used the Myer's rating to establish the peak design discharge (plus generous freeboard) and storm transposition for flood volume [Myers, 1967].

3.6. The Probable Maximum Precipitation Period Using Prescriptive Standards (1950-~2000)

After 1950, the Agricultural Research Service (1953) was established, the Federal Power Commission was reorganized to form the Federal Energy Regulatory Commission (1978), and the federal government's disaster-recovery efforts were consolidated to form the Federal Emergency Management Agency (1979). Under FEMA's leadership, the Interagency Committee on Dam Safety (1980) was formed and the National Dam Safety Program was established (1980). In March 2003, FEMA joined 22 other federal agencies, programs, and offices in becoming the Department of Homeland Security (2003).

The Association of Dam Safety Officials (1983) was also formed during this period and initially had 34 member states. Today ASDSO is a leading non-profit organization with more than 3,000 members representing every state dam safety regulatory agency, federal and local governments, academia, dam owners, consultants, contractors, manufacturers and suppliers.

The development of elegant theoretical and mathematical approaches to solve hydrologic problems along with the advancement of computers to perform computationally demanding analyses led to greater use of watershed modeling using unit hydrographs and precipitation. This period also coincided with a rapid increase in population and the greatest period of dam building in the United States, where dam building passed from a project-by-project emphasis to a continuous program. During this period, engineers turned to meteorologists to establish limiting rates of precipitation for design purposes. By performing air mass analyses, limits on the amount of precipitation from a storm were estimated using humidity of the incoming air, wind velocity, and the percent of water vapor that could be precipitated. In 1959, the definition of the term Probable Maximum Precipitation appeared in the Glossary of Meteorology published by the American Meteorological Society as follows [Meyers, 1967]:

> *"The theoretical greatest depth of precipitation for a given duration that is physically possible over a particular drainage area at a certain time of year"* [American Meteorological Society, 1959].

The resulting Probable Maximum Flood was defined as:

> *"The flood that may be expected from the most severe combination of critical meteorologic and hydrologic conditions that are reasonably possible in the drainage basin under study"* [FEMA, 2004].

In the early years the terms “maximum possible precipitation (MPP)” and “maximum possible flood (MPF)” were sometimes used. In 1956 this terminology was changed to probable maximum precipitation (PMP) and probable maximum flood (PMF) to recognize the uncertainties in the precipitation and runoff estimates, and that the worst combination of events was not assumed when translating rainfall into runoff [ASCE, 1988; Tomlinson & Kappel, 2009]. PMP was viewed as an estimate as there remain unknowns and unmeasured atmospheric parameters that are important to extreme rain storms [NRC, 1985]. Similarly, the PMF is less than the maximum possible flood to the extent that the combinations of natural factors assumed in the determination are less than a theoretical maximum, and the reduction tends to vary depending on the person performing the analysis and/or agency or company policy [ASCE, 1988].

Between 1963 and 1984, a series of Hydrometeorological Reports (HMR) were subsequently developed for the Continental United States by the U.S. Weather Bureau, now the National Weather Service (NWS). The oldest of these reports is HMR 39 prepared for Hawaii in 1963. The most recent is HMR 59 for California which was updated in 1999. Figure 3.2 illustrates the coverage of the HMR studies.

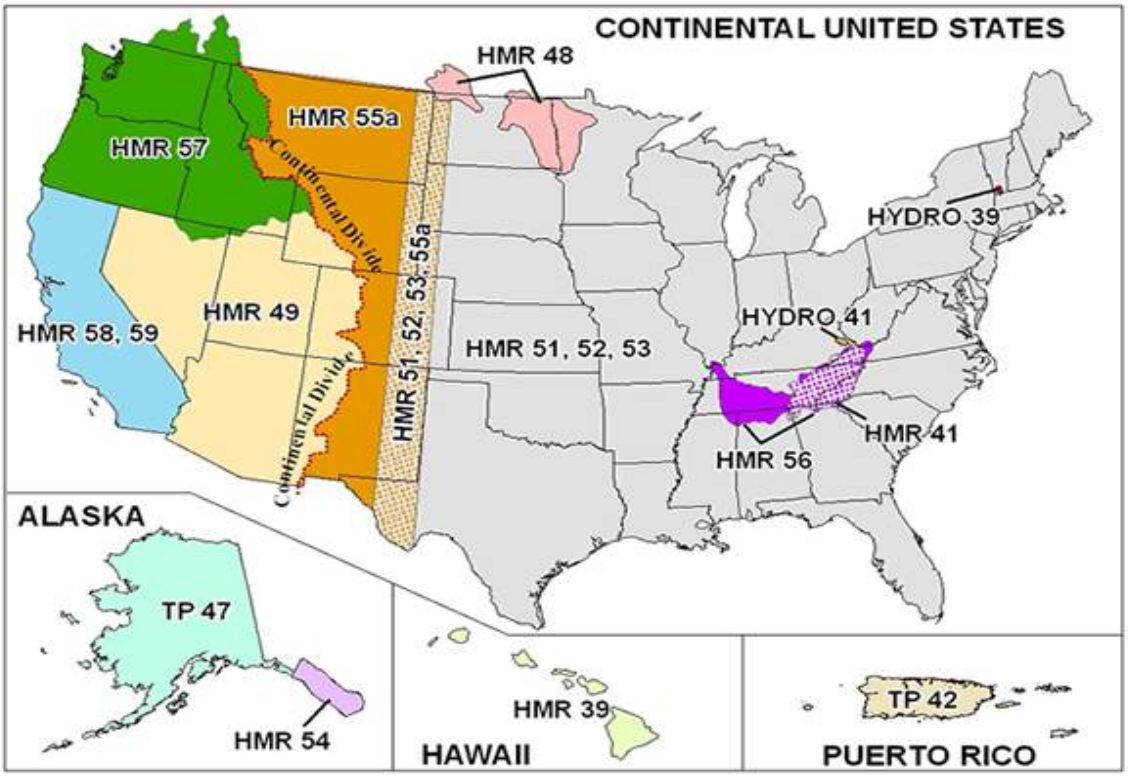

Figure 3.2 Hydrometeorological Reports prepared by the NWS for the Continental United States [NOAA, 2011]

Most of the HMRs use analyses of individual storm depth-area-duration rainfall patterns to evaluate spatial and temporal rainfall distributions and include a multiplication factor to address orographic effects. HMR 51, which covers the eastern two-thirds of the U.S., does not include any orographic adjustments but identifies two "stippled regions" in which the authors of the HMRs acknowledged that terrain effects were not evaluated and suggest that future NWS studies examine these regions more closely.

PMP estimates developed using HMRs and site specific studies in conjunction with watershed models to compute flood runoff, have been widely accepted as the basis for design of spillways for dams where failure of the structure by overtopping cannot be tolerated, and has resulted in progressively more conservative design requirements for spillways. The adoption of this standard has raised difficult questions as to what should be done with existing dams constructed before this standard where the spillways do not satisfy this criterion.

Site specific PMP studies have also been performed by private contractors recognizing the fact that the published HMRs provide generalized rainfall values that are not basin-specific and tend to represent the largest PMP values across broad regions. Many recent site-specific studies have produced PMP values significantly different from the HMR values. Reasons for the differences (mostly reductions) are attributed to using basin characteristics that are specific to the topography and local climate of the watershed being studied, new storm data like NWS NEXRAD, improved analysis procedures, and technology advances such as new computer models, weather radar, and geographic information system (GIS) software to analyze depth-area-duration tables. Site specific PMP study values are generally 5 to 15 percent lower than values from the published HMRs, although some studies have shown minimal reductions. The largest PMP reductions from site specific studies have been for long duration storms for large drainage areas, and have been greater than 50 percent lower [Tomlinson & Kappel, 2009; Applied Weather Associates, 2008].

Statewide studies of extreme storm events have also been performed in an effort to support risk-based design criteria for spillways. The states of Washington, Montana, California and Wisconsin have authorized statewide studies. For example, beginning in 1981, the state of Washington began collecting and analyzing data to define the characteristics of extreme storms for use in developing risk-based criteria for spillway design. This work was led by Dr. Mel Shaefer and resulted in the publication of "*Technical Note 3*" in 1993 which provided engineering guidance for developing design storms for use in computing IDFs using rainfall-runoff computer models. This document was updated in 2009 using more than 700 precipitation gages and high resolution mapping techniques within a GIS framework, and includes probabilistic based procedures for generating precipitation magnitude-frequency relationships for any location within the state [MGS Engineering Consultants, 2009].

In a letter dated June 1, 1984 to the NRC Committee on Safety Criteria for Dams, the NWS provided some additional information regarding the extensive material on PMP estimates and

techniques that they developed to provide the basis for the most conservative criteria for spillway design. The following is extracted from their letter to the NRC Committee:

> *"Theoretically the PMP has zero probability of actual occurrence. A report (Riedel, J. T., and Shreiner, L. C. 1980) compares the greatest known storm rainfall depths with generalized PMP estimates for the United States east of the 105th meridian and west of the Continental Divide. This was done for rainfall depths averaged over six area sizes (10, 200, 1,000, 5,000, 10,000, and 20,000 mi^2) each for durations (6, 12, 24, 48 and 72 hours) covering the eastern United States. A similar comparison was made for the western United States, but with fewer combinations. A summary of the results is presented in [Table 3-1]."*

Another comparison shows that for the eastern and western United States there were 170 and 66 separate storms that occurred from 1819 to 1979 which had depths exceeding 50% of PMP for at least one area size and duration, respectively. Riedel and Schreiner also pointed out that the greatest rainfall amount in a storm may not have been observed and documented, especially in the west. In a few recorded storms, total rainfall amounts have exceeded 100% of the PMP. These include the Smethport, PA storm of July 17-18, 1942 in which 30.8 inches of rain fell in 4.5 hours, and the Cherry Creek, CO storm of May 30-31, 1935 where 24 inches of rain was observed in a period of less than 6 hours [Huffman, 1999].

Table 3-1 Comparison of Greatest Known Storm Rainfall Depths with Generalized PMP Estimates within the United States [Riedel & Shreiner, 1980]

Location	Number of Storms Exceeding Various Percentages of PMP		
	70%	80%	90%
East of the 105th Meridian	160	49	4
West of the Continental Divide	16	5	0

3.7. Risk-Informed Decision Making Period (2000-Present)

Although the period of time beginning in 2000 can be considered the period of risk-informed decision making, several advances and publications prior to 2000 paved the way for the introduction of risk into SDF selection. The earliest reference to using risk-based analyses to determine the SDF appears to be in a 1964 manual prepared by the American Water Works Association (AWWA) titled: *Manual M13 – Spillway Design Practice*. The AWWA guidelines presented in this manual stress that for water supply dams, "the selection of a spillway capacity less than the maximum probable flood is a very serious decision for the designer and for management," and recommends the use of a "thorough cost study to evaluate the variable costs of (1) repairs to the dam and spillway, (2) lost water during periods of repairs, (3) damages caused by insufficient

spillway, and (4) construction of spillways of specific capacity" [AWWA, 1964]. Although the concepts of risk, flood probability, and consequences are discussed in the manual, procedures for performing a formal risk analysis and establishing decision criteria are not addressed in Manual M13. The AWWA guidelines indicate that this type of cost analysis is largely subjective and almost entirely a matter of judgment.

In 1973, an ASCE Task Committee on the Reevaluation of the Adequacy of Spillways of Existing Dams published a report in the Journal of the Hydraulics Division [ASCE, 1973]. In the report, the Task Committee advocated "risk taking" in spillway capacity design and recommended that spillway capacities for new and existing dams of all sizes be based on a thorough economic analysis of the "social cost of risks and the cost of modification" computed on an average annual basis. An evaluated level of risk at which the total of all social costs will be at a minimum was proposed. The Task Committee recommended use of a monetary value for human life and injury in the analysis based on practices of courts in awarding damages in cases involving accidental deaths and injury. The ASCE Task Committee's report generated much controversy and their recommended approach was viewed as a "radical departure" from accepted standards [Williams, 1973]. The recommendation to place a monetary value on human life and suffering in the economic analysis was ultimately not accepted by the engineering profession or by regulatory agencies. Other factors contributing to the lack of interest for the recommended approach included the need to select an interest rate for the analysis of equivalent present-day costs, and the problem of assigning probabilities for extreme flood events.

From the time the ASCE Task Committee on the Reevaluation of the Adequacy of Spillways of Existing Dams published their report in 1973 through the present, there has been much discussion, debate and controversy on the use of risk-based analyses for dams. Between 1979 and 2000, several studies and guidelines on selecting acceptable flood capacity for dams were published by various individuals and agencies including the following:

1979 – *Federal Guidelines for Dam Safety*, FEMA ad hoc ICODS (Reprinted 2004)
1985 – *Flood and Earthquake Criteria,* NRC Committee on Safety Criteria for Dams
1986 – *Federal Guidelines for Selecting and Accommodating Inflow Design Floods for Dams,* FEMA (ICODS)
1988 – *Evaluation Procedures for Hydrologic Safety of Dams,* ASCE Task Committee on Spillway Design Flood Selection
1996 – *Dam Safety Policy for Spillway Design Floods,* Dubler, James & Neil S. Grigg
1998 – *Selecting and Accommodating Inflow Design Floods for Dams,* FEMA Federal Guidelines for Dam Safety (Reprinted 2004)

Summaries of each of these documents as well as the aforementioned AWWA manual and the ASCE Task Committee report as they relate to spillway flood design criteria are presented in Chapter 4. Each of the documents listed above make reference to the use of risk-based analyses for selection of SDFs for dams. Most of these documents provide general guidelines and discussions

on the issues involved in the decision analysis procedures. None of the documents provide risk tolerance criteria for making a final safety design decision.

The U.S. Bureau of Reclamation (Reclamation) appears to be the first agency to seriously apply risk-based decision making to dam safety and have emerged as world leaders in this approach. Beginning around 1995, Reclamation adopted the use of risk analysis as the primary support for their dam safety decision-making and have developed several important publications related to risk analysis including the following:

1998 – *Implementation of Risk Analysis Principles into the Bureau of Reclamation's Dam Safety Program Actions*
1999 – *A Framework for Characterizing Extreme Floods for Dam Safety Risk Assessment*
2000 – *Risk Based Profiling System*
2003 – *Guidelines for Achieving Public Protection in Dam Safety Decision-making*
2006 – *Guidelines for Evaluating Hydrologic Hazards*
2010 – *Dam Safety Risk Analysis Best Practices Training Manual*

Reclamation has devoted significant resources to the development of risk-based hydrologic hazard methods and guidelines related to extreme rainfall probabilities. A framework for the characterization of extreme flood events has also been developed which considers various types of flood estimation procedures ranging from paleoflood hydrology to regional precipitation frequency with L-Moments. The resultant reports and guidelines created by Reclamation facilitate the incorporation of hydrologic data in risk analysis.

In 2003, because of the growing interest in the use of risk assessment methods for dam safety, the USSD published a white paper titled *"Dam Safety Risk Assessment: What Is It?, Who Is Using It and Why?, Where Should We Be Going With It?"* [USSD, 2003]. The paper represented a consensus position of a diverse group of USSD members and other dam safety professionals at that time. The overall purpose of the paper was to assess the state-of-the-practice in dam safety risk assessment, and to provide commentary on appropriate types of applications and ways to facilitate and strengthen its use [USSD, 2003].

The USSD paper identified and described four risk assessment application categories: (1) Failure Modes Identification; (2) Index Prioritization; (3) Portfolio Risk Assessment; and (4) Quantitative Risk Assessment. Of the four risk assessment application categories, only the Quantitative Risk Assessment approach has been used as an analytical method to help select acceptable spillway design capacity for dams. The other three methods have been used primarily as a means of identifying dam deficiencies and prioritizing their repair or resolution. The USSD white paper emphasizes that limitations must be fully considered and that risk assessment approaches should be used only as a supplement and not as a replacement for the traditional approach. The USSD white paper concluded that this "risk-enhanced" approach provides a way for the benefits of improved

understanding and management of dam safety risks to be realized, while maintaining a reference to established practice [Bowles et al, 2003].

Another leader in the forefront of risk-based methods is the U.S. Army Corps of Engineers (USACE). In the 1990s, USACE held workshops and invested research to evaluate risk analysis frameworks and began publishing regulations and documents supporting the use of risk analysis including the following:

1996 – *Risk Analysis for Dam Safety Evaluation: Hydrologic Risk*
1996 – *Risk-Based Analysis for Flood Damage Reduction Studies, EM 1110-2-1619*
1997 – *Dam Safety Assurance Program, Regulation No. 1110-2-1155*
2001 – *Hydrologic Research Needs for Dam Safety*
2003 – *Application of Paleohydrology to Corps Flood Frequency Analysis*
2007 – *Updated Principles for Risk Analysis*
2007 – *Draft Inflow Hydrographs Toolbox*
2007 – *Interim Risk Reduction Measures for Dam Safety*
2009 – *Interim Tolerable Risk Guidelines for US Army Corps of Engineers Dams*
2010 – *Safety of Dams – Policy and Procedures, ER 1110-2-1156 (DRAFT)*

In 1997, USACE replaced the PMF standard with an incremental procedure to provide a framework for evaluating the benefits of mitigating hazards presented by hydrologic deficiencies in high hazard situations, as described in their *Dam Safety Assurance Program, Regulation No. 1110-2-1155* [USACE, 1997]. The PMF standard was replaced because it did not provide analysis of the benefits versus costs of design as compared to a lesser flood and recognition of the fact that the PMF design does not result in zero risk [Eiker et al, 1998]. The new USACE policy was a compromise between the desire to provide a risk-based analysis of the benefits gained from mitigating the hazard and the traditional approach of requiring a design that is capable of safely passing the PMF.

The incremental procedure required by the 1997 USACE policy included two phases. Phase I was used to determine the Base Safety Conditions (BSC) as follows:

> *"…. A comparative hazard analysis in which the threshold flood (TF) and the BSC are established. The TF is the flood that fully utilizes the existing dam, i.e., the flood that just exceeds the design maximum water surface elevation at the dam (top of dam minus freeboard). The BSC is determined by comparing the loss of life for various floods, expressed as percentages of the PMF, with and without dam failure. PMF is determined in accordance with standard Hydrometeorological procedures. The flood, expressed as a percentage of PMF for which loss of life is not different for with and without dam failure conditions, is the BSC, but should never be more than 100% of the PMF"* [USACE, 1997].

Phase II was the risk-cost analysis required if modifications for a flood greater than the BSC were recommended. An important aspect of the new USACE policy was the focus on loss of life as the

criteria for determining the BSC in the incremental analysis. Economic damage was not considered.

Although the USACE's incremental analysis represented a significant advance in developing an IDF for dam design, it was recognized by the USACE that it did not provide a means for comparing the benefits and costs to mitigate spillway capacity deficiencies within their portfolio of dams. Given the limitations on annual funding available for mitigating dam deficiencies, the USACE subsequently adopted the use of Risk Assessment to provide decision variables that relate the hazard and remediate measures for a particular dam deficiency to other dams. This approach was pursued as it allowed decision makers to develop a ranking system for prioritizing the implementation of the remediation measures. The remediation of the hazard would then depend on the ranking and funding available for implementing the remediation measure [Eiker et al, 1998].

The USACE later began working closely with Reclamation, the Federal Energy Regulatory Commission (FERC), and the Tennessee Valley Authority (TVA) to develop a common dam safety risk management framework and policies for its portfolio of dams that includes tolerable risk guidelines. In 2010, the USACE published a draft form of *ER 1110-2-1156; Safety of Dams – Policy and Procedures.* This document prescribes the guiding principles, policy, organization, responsibilities, and procedures for implementation of risk-informed dam safety program activities and a dam safety portfolio risk management process within the USACE and represents a significant paradigm shift. As explained in the *Guidelines on Risk Assessment* prepared by the Australian National Committee on Large Dams (ANCOLD) in 2003,

> "*The USACE is moving from a solely standards-based approach for its dam safety program to a dam safety portfolio risk management approach. The standards-based or essential guidelines approach is included in the risk-informed approach to the dam safety program and dam safety program decisions will now be risk-informed. One of the bases for a risk-informed decision, and prioritization of the work, is a consideration of the achievement of tolerable risk guidelines following implementation of risk reduction measures. In addition, it should be recognized that other non-quantitative factors will influence practical decision making for the dam safety program.*
>
> *"There was previously a view in some quarters that risk assessment was a means to justify less costly safety upgrades of dams than those required by the traditional approach. It is now recognized that such a view seriously misunderstands the true aim of risk assessment, which is more informed decision-making than would be possible from reliance on the traditional approach alone. It may be that the additional understanding that comes from the risk assessment process, will reveal that a less costly solution to a dam safety problem could be justified, though a decision that way should be made with great care and having regard to all of the community risk and business risk considerations. But it could as easily be the case that risk assessment shows that a more stringent safety level, and thus a more costly solution, ought to be implemented."*

The USACE's tolerable risk guidelines are based on an adaptation of the 2003 Reclamation guidelines, the risk evaluation guidelines published by the Australian National Committee on Large Dams [ANCOLD, 2003], and adaptations of the ANCOLD guidance implemented by the New South Wales Government Dam Safety Committee (NSW DSC) Risk Management Policy Framework for Dam Safety [NSW DSC, 2006]. According to the Tolerable Risk Guidelines, a dam is considered to be "Adequately Safe" (DSAC Class V) when residual risk is considered tolerable and meets all essential USACE guidelines with no dam safety issues. A summary of these guidelines is included in Chapter 8.

For determining the probability associated with the PMF and lesser events, the current interim USACE procedure is to perform statistical smoothing as described in EM 1110-2-1415 Hydrologic Frequency Analysis and the Draft Inflow Hydrographs Toolbox [USACE, 2007]. The PMF is assigned a probability of 1 in 10,000 (0.0001) per year.

Today, many professionals consider risk assessment to be a useful way to provide dam safety as it requires dam owners to investigate failure modes in detail and understand where the greatest risks lie. However, the main drawback of this approach is that it is technically challenging, time-consuming, and difficult to administer. Because of this, the traditional standards based approach is generally still adopted by the states. Note that the federal agencies who have led the way in developing risk analysis procedures and tolerances are owners of a significant number of dams. The administrative processes and reviews of regulatory agencies, such as FERC and most of the states, differ significant from that of dam owners like USACE and Reclamation. The application of quantitative risk analysis for dam design by regulatory agencies may be burdensome or even unnecessary. The state dam regulatory agencies of California, Washington and Montana have recently developed risk-based indices to determine acceptable flood capacity; however, none of the states use quantitative risk assessment.

4. Origins of Dam Safety Design Guidelines

4.1. Overview

Chapter 3 presented a history of SDF selection for dams in the United States without regard for the actual regulatory framework. That chapter described the state of the practice as far as methodology used to evaluate SDFs. Chapter 4 focuses on the application of the methodology in formal guidelines within the United States.

4.2. General Standard of Practice Prior to 1950

Prior to approximately 1950, hydrologic design standards for dams were based mainly on judgment and experience. In general, the probable maximum flood, as best determined at that time, was generally accepted as the standard for dams where the consequences of failure required the greatest conservatism. Pennsylvania enacted the first known dam safety legislation in the United States in 1913, and California's Division of Safety of Dams was created in 1929. Both states were prompted to action by catastrophic dam failures that occurred in their respective states. A U.S. Committee on Large Dams (USCOLD) survey on practices and regulations within the United States found that as of 1964, a fourth of the states exercised no supervision over dams at all, and a third exercised no responsibility over operation and maintenance of a dam once it was constructed. USCOLD then organized a committee to draft a model law to be considered by states for enactment. In 1968, the committee completed a proposed law that was modeled after the 1929 California law [Golze, 1973].

4.3. ASCE Task Force on Spillway Design Floods (1955)

The first organized effort to document SDF policy and criteria in the United States appears to have occurred in June 1955 when the first ASCE Task Force on Spillway Design Floods was organized. This committee attempted to formulate a questionnaire for submission to government agencies, utilities, private engineering firms, and technical groups with an interest in dam design in order to review and summarize existing spillway design policy and criteria. The task force was unsuccessful in developing a questionnaire and collecting the data; however, they developed the following three classifications of spillway requirements for dams [ASCE, 1988]:

Class 1: Dams where failure cannot be tolerated
Class 2: Dams where failure would result in serious economic loss
Class 3: Dams where structural failure would result in minor damage

The task force's final report was presented in four papers in a symposium on the Hydrology of Spillway Design on May 16, 1962 as part of the first ASCE Water Resources Engineering Conference. The papers were published in the Journal of the Hydraulics Division in May 1964 and summarized the existing practice for designing new dams. With respect to Class 1 dams, Mr. Franklin Snyder, a member of the task force, made the following statement:

> *"For large major structures that would be subject to possible failure if the selected capacity were exceeded, there would be few instances, if any, where anything less than the provision for the probable maximum flood can be justified"* [Snyder, 1964].

Snyder also published a dam classification and suggested the matrix as presented in Table 4-1 be used to select the minimum SDF. It is interesting to note that Snyder's suggested classification matrix closely resembles the current classification criteria used by many states (See Chapter 9).

Table 4-1 Snyder's Classification of Dams [Snyder, 1964]

Failure Category	Danger Potential		Damage Potential		SDF
	Storage (Acre-Feet)	Height (Feet)	Loss of Life	Damage	
Minor	<1,000	<50	None	Cost of Dam	50-100 Year
Intermediate	1,000 – 50,000	40 to 100	Possible/small	Within Capacity of Owner	SPF(1)
Intolerable	>50,000	>60	Considerable	Excessive	PMF

(1) The SPF is the Standard Project Flood which is the most severe storm "reasonably characteristic" of the region.

4.4. AWWA Spillway Design Practice – Manual M13 (1964)

In 1964, the AWWA published *Manual M13 – Spillway Design Practice*. The manual was intended to be a general reference for engineers in the water utility practice, and provides procedures for selecting SDFs for dams constructed on drainage areas less than 1,000 square miles. The guidelines stress that for water supply dams, "the selection of a spillway capacity less than the maximum probable flood is a very serious decision for the designer and for management" and recommends the use of a "thorough cost study to evaluate the variable costs of (1) repairs to the dam and spillway, (2) lost water during periods of repairs, (3) damages caused by insufficient spillway, and (4) construction of spillways of specific capacity" [AWWA, 1964]. The manual goes on to state that this type of cost analysis is largely subjective and almost entirely a matter of judgment.

As shown in Table 4-2, the AWWA manual presents three classifications of dams based on possible damages from overtopping to select the SDF. It is interesting to note that the AWWA criteria include an assessment of the anticipated damage to the dam following overtopping. The guidelines note that for smaller watersheds, the peak discharge computed from PMP may be ten or more times the maximum observed peak streamflow. In addition to the SDF requirements shown in Table 4-2, the AWWA indicated that "even under the most advantageous circumstances, the total freeboard above the maximum water level in the reservoir should not be less than 3-5 feet" [AWWA, 1964].

Table 4-2 Summary of 1964 AWWA Spillway Design Flood Guidelines [AWWA, 1964]

Possible Damages from Overtopping	Spillway Design Flood
Destruction of dam and catastrophic losses at downstream urban areas	Probable maximum precipitation (PMP) on very wet ground
Moderate damage to dam and little loss at downstream urban areas	Greatest known storm on another watershed that can be transposed to the study watershed
Minor damage to dam or other structures and no losses possible downstream	Storm obtained by applying a reduction factor to the probable maximum precipitation, or frequency studies to past floods

4.5. USCOLD Workgroup on Criteria and Practices Utilized in Determining the Required Capacity of Spillways (1970)

In 1967, a USCOLD workgroup was formed to compile information and to prepare a report regarding criteria and practices used in the United States for determining the required capacity of spillways. The national survey titled "*Criteria and Practices Utilized in Determining the Required Capacity of Spillways"* was published in 1970. The workgroup surveyed the USACE, Reclamation, TVA, Soil Conservation Service, state agencies, investor-owned utility companies and private engineering firms using a questionnaire. Only two state agencies (Pennsylvania and California) were surveyed. The final report summarized spillway requirements or "standards" for new dams for four hazard categories.

The workgroup indicated that all respondents stated that their current policies were consistent with the following statements:

> *"… The policy of deliberately accepting a recognizable major risk in the design of a high dam simply to reduce the cost of the structure has been generally discredited from the ethical and public welfare standpoint, if the results of a failure would imperil the lives and lifesavings of the populace of the downstream floodplain. Legal and financial capability to compensate for economic losses associated with major dam failures are generally considered as inadequate justifications for accepting such risks, particularly when severe hazards to life are involved. Accordingly, it is the policy of this agency that high dams impounding large volumes of water be designed to conform with Security Standard 1"* (design the dam and spillway large enough to assure that the dam will not be overtopped by floods up to the probable maximum) [USCOLD, 1970].

The workgroup also compared current (1970) criteria with past criteria and policies and concluded:

> *"The policies which are now generally accepted are not radically different from those followed 20 or more years ago by the responding organizations, even though procedures and techniques have been changed and improved and have been adopted rather uniformly as they have been developed. Accordingly, differences that do exist result largely from variations in interpretation of the policies, some differences in analytical technique, and designer's judgment"* [USCOLD, 1970].

The USCOLD report also provided a general summary of freeboard criteria and starting reservoir levels assumed in the SDF analyses, and identified erosion of spillway channels that could lead to breaching the spillway or eroding the toe of embankment dams as a common design concern.

4.6. National Dam Inspection Act, PL 92-367 and USACE Guidelines for Existing Dams (1972)

In the early 1970s a series of dam safety incidents occurred resulting in significant loss of life including the failure of Buffalo Creek Dam (West Virginia) in February 1972 and Canyon Lake Dam (South Dakota) in June 1972. In June of 1972, severe flooding caused by Hurricane Agnes endangered many dams. Large areas in Pennsylvania and New York experienced rainfall rates that were within 90 percent of PMP values [Riedel, 1973]. The Black Hills, South Dakota storm of June 1972 resulted in rainfalls that were 75 percent of the PMP [Riedel, 1973]. Following these events, the Congress enacted the National Dam Inspection Act (PL 92-367) and it became law on August 8, 1972. At that time many states did not have laws regarding dam safety and often did not require a review of the dam design prior to construction or require construction inspection or post-construction inspection. It was also found that dam safety in most states was inadequate with a wide variation of practices, regulations and capabilities of all agencies supervising dam safety. There was also little or no overall coordination of dam safety efforts.

Dams subject to PL 92-367 were those having a height 25 feet or greater, or a maximum impounding capacity greater than 50-acre-feet. Dams less than six feet high or storing less than 15 acre-feet were excluded. Congress charged the USACE with implementing the provisions of the Act. In addition to carrying out a national program of inspection of dams for the purpose of protecting human life and property, the act also required: (1) an inventory of all dams located in the United States; (2) a review of each inspection made; and (3) recommendations for a comprehensive national program for the inspection and regulation of dams, and the respective responsibilities which should be assumed by Federal, State, and local governments and by public and private interests.

Because of the scale of the program, the USACE developed a classification system to screen the adequacy of spillway capacity. The selected classification system used the dam size based on dam height and impoundment volume as shown in Table 4-3, and the hazard potential based on loss of life and economic loss as presented in Table 4-4. Table 4-5 presents the USACE's recommended SDF based on the Hazard and Size classification. A comparison of the criteria in the Tables 4-3 through 4-5 with that proposed by Snyder in 1964 in Table 4-1 shows remarkable similarities.

Where a range of SDF is indicated, the USACE guidelines specify that the magnitude that most closely relates to the involved risk should be selected. The use of partial PMF values are not discussed. For "Significant Hazard" dams, no more than six single-family type inhabitable structures were permitted in the downstream and upstream inundation zones, and consideration was

to be given to probable future development in order to select a conservative but realistic category [Hagen, 1973]. The original USACE guidelines also contained freeboard criteria, but these were deleted from the final guidance documents. The decision on freeboard allowance for each project was left to the inspection team [Hagen, 1973]. The USACE guidelines were reported to be based on a professional consensus [Dubler, 1995].

Table 4-3 USACE Dam Classification [USACE, 1979]

Category	Impoundment	
	Storage (Acre-Feet)	Height (Feet)
Small	<1,000 and 50	<40 and 25
Intermediate	1,000 and < 50,000	40 and <100
Large	50,000	100

Table 4-4 USACE Hazard Potential [USACE, 1979]

Category	Loss of Life (Extent of Development)	Economic Loss (Extent of Development)
Low	None expected	Minimal
Significant	Few	Appreciable
High	More than a few	Excessive

Table 4-5 USACE Hydrologic Evaluation Guidelines Recommended Spillway Design Floods [USACE, 1979]

Hazard Potential	Size	Spillway Design Flood (SDF)
Low	Small Intermediate Large	50 to 100-Year Flood 100-Year to ½ PMF PMF
Significant	Small Intermediate Large	100-year to PMF ½ PMF to PMF PMF
High	Small Intermediate Large	½ PMF to PMF PMF PMF

In developing the spillway capacity guidelines, the USACE made a distinction between new and existing dams and emphasized that the proposed guidelines were intended for existing dams. As stated in a discussion paper presented by the USACE, the "analysis of hydrologic and hydraulic

competency of existing structures should not be as rigorous as the design requirements for new dams. Costs associated with extra conservatism in a new project are almost always a small fraction of the cost required to modify an existing structure" [Hagen, 1973].

4.7. ASCE Task Committee on the Reevaluation of the Adequacy of Spillways of Existing Dams (1973)

In 1973, following four years of study, the ASCE Task Committee on the Reevaluation of the Adequacy of Spillways of Existing Dams published their report in the Journal of the Hydraulics Division [ASCE, 1973]. In the report, the Task Committee advocated "risk taking" in spillway capacity design and recommended that spillway capacities for new and existing dams of all sizes be based on a thorough economic analysis of the "social cost of risks and the cost of modification" computed on an average annual basis. An evaluated level of risk at which the total of all social costs will be at a minimum was proposed. The Task Committee recommended use of a monetary value for human life and injury in the analysis. Mr. Bob Buehler, Chief of the Flood Control Branch of the TVA and member of the committee, subsequently published a paper on "The Monetary Value of Life and Health" [Buehler, 1973]. Values assigned by Mr. Buehler in an example economic analysis presented in a paper titled *Reevaluation Spillway Adequacy of Existing Dams* showed values of $150,000, $200,000, and $10,000 for deaths, disabling injuries, and non-disabling injuries, respectively [Buehler, 1973].

Assigning a probability to extreme floods was a concern expressed by engineers reviewing the report. For expediency, the ASCE Task Committee's solution to the problem of assigning probability to extreme events was to arbitrarily assign an average return interval of 10,000 years to the PMF. This was considered by the committee to be a conservatively low return period, yet high enough to accomplish the purposes of the analysis process. Assigning a 10,000-year probability to the PMF at that time was suggested and supported by others as well [Beard, 1973]. With the upper extreme fixed arbitrarily at 10,000 years and the lower extreme defined by observed data, a curve on probability paper provided probabilities for all in-between floods.

An interesting and intriguing argument presented by the committee, and demonstrated with analysis examples, was that risk costs can increase as additional dam safety is provided, since improved safety is often provided by raising the dam and/or increasing spillway capacity with a resulting increase in downstream flood flow. The economic analysis approach was recommended to avoid mistakes where circumstances exist in which modification to reduce failure probability would increase rather than decrease potential average annual losses, and that "modification with good intent to increase safety would be an incorrect move" [Buehler, 1973].

The ASCE Task Committee's report generated much controversy and 13 published discussions which was said to be a record number. The discussions were equally divided in favor and against the proposed approach [Buehler, 1973]. The recommendation to place a monetary value on human life and suffering in the economic analysis was ultimately not accepted by the engineering

profession or by regulatory agencies. The approach was viewed as a "radical departure" from accepted standards [Williams, 1973]. For dams where loss of life was not expected, the risk-based economic analysis proposed by the ASCE Task Committee was supported by the Bureau of Reclamation with the provision that the public be kept aware of the possibility of failure, that a land use plan be enforced that ensured the minimum hazard to life, and that a periodic re-examination must be scheduled and made to verify that the downstream hazard and damage assumptions continue to be valid [Bertle, 1973]. The economic analysis proposed by the ASCE Task Committee was also viewed as impractical for smaller dam projects as the cost to perform the analysis could approach the cost of the structural modifications [Williams, 1973].

4.8. FEMA ad hoc ICODS – Federal Guidelines for Dam Safety (1979, Reprinted 2004)

In 1979, the *ad hoc* Interagency Committee on Dam Safety (ICODS) issued "Federal Guidelines for Dam Safety." This document provided the first guidelines for federal agency dam owners and dam owners regulated by federal agencies. As stated in the preface:

> *"These guidelines apply to Federal practices for dams with a direct Federal interest and are not intended to supplant or otherwise conflict with State or local government responsibilities for safety of dams under their jurisdiction."*

For flood selection for design or evaluation, the federal guidelines supported the use of risk analysis, and stated:

> *"The selection of the design flood should be based on an evaluation of the relative risks and consequences of flooding, under both present and future conditions. Higher risks may have to be accepted for some existing structures because of irreconcilable conditions"* [FEMA, 1979].

The guidelines were clear, however, that the spillway design standard to be adopted for dams where loss of life or major property damage could be significant was the PMF. The following statement concerning selection of the flood for design for spillways is in the 1979 guidelines:

> *"When flooding could cause significant hazards to life or major property damage, the flood selected for design should have virtually no chance of being exceeded. If lesser hazards are involved, a smaller flood may be selected for design. However, all dams should be designed to withstand a relatively large flood without failure even when there is apparently no downstream hazard involved under present conditions of development"* [FEMA, 1979].

For existing dams, "risk-based analyses should be considered in establishing priorities for examining and rehabilitating the dams, or for improving their safety" [FEMA, 1979]. The guidelines did not provide a specific framework for classifying dams or for assigning SDFs using risk-based analyses.

4.9. National Research Council Committee on Safety Criteria for Dams, Safety of Dams – Flood and Earthquake Criteria (1985)

In response to a request by the Assistant Secretary of the Interior for Water and Science and the Assistant Secretary of the Army for Civil Works, the National Research Council (NRC) established an *ad hoc* Committee on Safety Criteria for Dams to prepare an inventory of currently used criteria for dams relating to safety from hazards of extreme floods and earthquakes, and to identify and evaluate alternative criteria for safety of federal dams. The committee was made up of experts in risk assessment, regulation of dams, law, science, and engineering. A comprehensive survey of design criteria in use for dams relative to hazards of extreme floods was performed for 35 states, 10 federal agencies, four technical societies (ASCE, ICOLD, and USCOLD), nine firms, and one foreign country (England).

The following key findings were made by the Committee as they relate to selecting spillway inflows for dams:

- Current dam practices reflect a great variety of standards used to classify dams relative to hazards and in the criteria for evaluation of safety from extreme floods.
- While simple hazard rating categories based on downstream development may be useful for identifying dams for high-priority safety evaluation and study, they do not reflect the potential for incremental loss of life and damage caused by failure of a dam due to an inadequate spillway when a river is already in flood.
- More uniformity is needed among the several federal and state agencies establishing size and hazard definitions and correlative design standards.
- New concepts and improved methods for estimating floods have resulted in generally larger flood estimates and future estimates of magnitude for extreme floods can be expected to increase. However, unless the runoff characteristics of the watershed were to change, increments in future flood estimates should be less than those noted in the past. There have been instances where more intensive hydrometeorological studies have resulted in reductions in estimates of PMP by earlier investigations.
- A dam designed for the PMF using the PMP does not provide absolute assurance that the dam is safe for every possible flood.
- The federal government has become increasingly involved in risk management issues and a number of federal agencies have developed various risk management standards, but these are not applicable to risk management for dams. Adaptation of these concepts to dam safety requires research.
- Court decisions relating to dam failures in general have held the owner liable for the damages resulting from a failure.

The Committee made the following recommendations:

- To the extent practicable, reservoir safety evaluations should strike a balance among project benefits, construction costs, social costs, and public safety. Currently available technology does not permit this balancing with full confidence in the results.
- Safety evaluation standards for existing dams and new dams do not need to be the same.
- The use of PMFs based on estimated PMP as the general design standard for new high-hazard dams should be continued. Instances may be encountered where a lower standard may be justified if failure of a dam during floods of PMF magnitude would cause no significant increase in potential loss of life or property damage.
- For existing high-hazard dams, the adopted SDF should take into account estimated flood probabilities, expected project performance, and incremental damages that would result from dam failure for a range of floods up to and including the PMF.
- In the design of new dams and spillways when design alternatives of approximately equal cost are available, a selection among these alternatives should give consideration to potential future needs for increased safety against floods.
- Periodic reviews of hazard determinations and safety decisions for all dams should be required, especially when safety evaluations are based on criteria less conservative than the PMF.
- As advances occur in hydrology, meteorology, and the relevant databases, and as changes are noted in public attitudes toward risk, federal agencies should periodically undertake a review of dam safety practices and standards by an independent body representing the professions involved in engineering for dams and experts from other relevant disciplines.

For new high-hazard dams, the Committee recommended the PMF be adopted for the SDF unless risk analyses that examine the incremental impact of overtopping and dam failure during an extraordinary flood demonstrate that little or nothing is gained by such a high standard. The SDF would be the smallest value that ensures that a dam breach results in no significant increase in potential for loss of life or major property damage.

For existing high-hazard dams, the Committee concluded that there was no universally satisfactory approach to establishing spillway capacity criteria. The Committee therefore recommended that risk-based analysis be considered for existing high-hazard dams "for which the PMF is not required." A section describing risk-based analyses was included in the report.

No specific recommendations were made by the Committee for spillway design requirements for intermediate hazard and low hazard dams.

4.10. FEMA (ICODS) – Federal Guidelines for Selecting and Accommodating Inflow Design Floods for Dams (1986)

This publication was prepared by an ICODS working group on inflow design floods to supplement the *FEMA Federal Guidelines for Dam Safety* which was published in 1979. The primary purpose

of the document was to provide general guidelines on procedures for selecting and accommodating inflow design floods for use by federal agencies in developing agency criteria and to ensure more nationwide uniformity in application. The guidelines apply to both proposed and existing dams.

For existing and proposed dams where failure is expected to result in loss of life or extensive property damage, the guidelines specified using the PMF as the IDF. The evaluation dam failure impacts are based on both existing and future conditions. Key statements made in the guidelines with respect to evaluating dam failure impacts and selection of the IDF follow:

> *"The PMF should be adopted as the IDF in those situations where consequences attributable to dam failure from overtopping are unacceptable. The determination of unacceptability exists when the area affected is evaluated and factors indicate loss of human life, extensive property and environmental damage, or serious social impact may be expected as a result of dam failure"* [FEMA, 1986].
>
> "*Dams and their appurtenant structures should be designed to give satisfactory performance and to practically eliminate the probability of failure"* [FEMA 1986].
>
> *"The presence of public facilities within the potential area inundated by dam failure that would attract people on a temporary basis (e.g., campgrounds, State or National parks, etc.) requires special consideration"* [FEMA, 1986].
>
> *"The presence of an emergency action plan and/or a warning system should not be substituted for safe design practice or for use in reducing the potential for loss of life in the analysis for selecting the IDF"* [FEMA, 1986].
>
> *"Re-evaluation of an existing dam with respect to selecting and accommodating the IDF should normally be based on the same basic guidelines as for proposed dams"* [FEMA, 1986].

The guidelines make a specific distinction between service, auxiliary, and emergency spillways. For the design of auxiliary and emergency spillways, infrequent limited damage during passage of the IDF is acceptable provided the damage does not endanger the dam or usefulness of the service spillway and the control section of the spillway is not degraded to the extent it results in an unacceptable loss of storage or uncontrolled discharges which exceed the peak inflow. According to the guidelines, emergency spillways may be permitted to sustain significant damage when used and may be designed to a lower structural standard than auxiliary spillways.

Consideration for floods less than the PMF were permitted only when there were no existing permanent human habitations, commercial or industrial development, or such developments that were projected to occur within the foreseeable future, and transient population was not expected to be affected within the hazard area. An exception was made for a few permanent human habitations located within the flood hazard area provided there was no significant increase in the hazard resulting from the occurrence of floods larger than the proposed IDF up to the PMF (for example, where failure would not add appreciable volume to the outflow hydrograph and the downstream

inundation would be essentially the same with or without failure). For selection of the IDF less than the PMF, "the spillway capacity should be not less than some minimum standard to reduce the risk of loss of benefits during the life of the project; to hold O&M costs to a reasonable level; to maintain public confidence in agencies responsible for dam design, construction, and operation; and to be in compliance with local, State, or other regulations applicable to the facility" [FEMA, 1986].

The guidelines also made provisions for Federal agencies to develop agency-specific criteria and allowed the use of risk analyses as an approach to evaluating spillway inflow requirements less than the PMF on a case-by-case basis for existing dams.

> "*It is recognized that for some existing dams which do not meet current hydrologic design criteria but have been soundly designed and well constructed, it may be prudent to select an IDF smaller than the PMF. … However, any relaxation of design criteria should be undertaken on a case-by-case basis after the consequences of dam failure have been thoroughly evaluated and quantified. … Local interests should be made aware of the possibility of larger floods occurring when a flood smaller than the PMF is selected as the IDF*" [FEMA, 1986].

A section describing risk-based analyses was included in the guidelines.

4.11. ASCE Task Committee on Spillway Design Flood Selection (1988)

This ASCE Task Committee was formed in 1984 in response to the growing national concern for dam safety and the lack of uniformity in the hydrologic procedures used in dam safety evaluation. The charge of the Task Committee was to develop standards for selecting SDFs which could be readily implemented and applied nationwide. Their objective was to identify an acceptable procedure for selecting the SDF which, in addition to the traditional economic analysis, would permit the inclusion of loss of life, owner liability, social disruption, and the magnitude of destruction. The committee consisted of 14 persons. The final report was submitted to nearly 60 outside peer reviewers and was revised six times.

The ASCE Committee developed a quantitative risk assessment approach for selecting the SDF that applies to both new and existing dams. The Committee's design selection process was based on dividing dams into three categories depending on their failure consequences as summarized in Table 4-6.

The quantitative risk assessment proposed by the Committee for Category 2 dams does not provide specific risk guidelines or thresholds for the potential for loss of life and economic damage but assumes them to be "a matter of judgment." The Committee provides a tabulation of population at risk (PAR) from dam failure versus warning time for use in the initial screening of Category 1 dams. The values range from a PAR of 50 for a flood wave arrival time less than 2 hours to a PAR of 1,000 or more for a time of flood wave arrival of less than 12 hours.

Table 4-6 Summary of ASCE Committee's Spillway Design Flood Selection Process [ASCE, 1988]

Category	Description	Spillway Design Flood
1	Dams where failure consequences include loss of life or other social and economic losses that warrant the use of the PMF as the spillway design flood.	PMF
2	Dams where the social and economic consequences of failure are not large enough to require use of the PMF as the spillway design flood.	PMF unless quantitative risk assessment shows smaller flood is justified
3	Small dams where the cost of construction is small and the failure damage is low and confined to the owner.	10- to 100-year flood[1]

1 *The committee suggests that the owner may benefit from a quantitative risk assessment to determine the spillway design flood. However, it may not warrant the cost of the analysis. Guidelines adapted from the SCS were offered with the provision that the owner should consider the chances the investment will be lost during the planned project life.*

It is unclear how loss of life is to be addressed for a Category 2 dam since there is no explicit accounting for loss of life in the proposed quantitative risk assessment or in the examples provided; only economic losses that can be quantified in dollars are explicitly considered, although loss of life estimates are shown in the summary of consequences. The committee does state that "the relative weighing of nonmonetary consequences and their comparison to dollar savings is a matter of judgment which will vary among decision makers for each site examined."

A requirement attached to adopting a SDF less than the PMF for Category 2 dams is that the dam owner must consider the cost of indemnifying possible victims of dam failure against financial losses. The cost of indemnification, rather than the flood damage, is taken as the proper measure of damage sustained by parties other than the dam owner. In addition to the loss of project benefits and physical damages created by the dam failure, the indemnification costs include income losses, emergency response, flood fighting, disaster assistance, reoccupation, cleanup, personal trauma, and post-disaster studies. The ASCE Committee concluded that the procedure requires a regulatory mechanism to make sure that the dam owner maintains the capability throughout the project life to fully compensate all victims should the dam fail.

A criticism of the ASCE Task Committee's proposed procedure is that the relative weighing of non-monetary consequences and their comparison to dollar savings were assumed to be a matter of judgment, and no criteria were provided for making a final design decision [Graham, 2000].

4.12. FEMA Federal Guidelines for Dam Safety – Selecting and Accommodating Inflow Design Floods for Dams (1998 – Reprinted 2004)

In 1994, an ICODS subcommittee was formed to review and update the existing Federal Guidelines for Dam Safety to meet current dam safety challenges and to ensure consistency across agencies and users. With the passage of the National Dam Safety Program Act in 1996 (Public Law 104-303), ICODS and its Subcommittees were reorganized to reflect the objectives and requirements of

Public Law 104-303. In 1998, the newly convened ICODS Subcommittees completed work on the update of the *Federal Guidelines for Dam Safety: Selecting and Accommodating Inflow Design Floods for Dams*. The ICODS Subcommittees were also made responsible for maintaining the guidelines to help achieve the objectives of the National Dam Safety Program.

The current (1998 – reprinted 2004) *Federal Guidelines for Dam Safety: Selecting and Accommodating Inflow Design Floods for Dams* places an emphasis on basing the selection of the SDF on an accurate hazard potential determination that evaluates the consequences of dam failure based on the dam being in place, and comparing the impacts of with-failure and without-failure conditions on existing development and prospective future development. The guidelines stipulate that the flood wave created by a dam failure should be routed downstream to the point where the incremental effect of a failure no longer results in unacceptable consequences. The IDF is then selected based on the results of the incremental hazard evaluation. This evaluation involves simulating a flood event during existing and dam failure conditions. The additional downstream consequences due to the incremental increase in flood flows downstream are assessed for each dam failure scenario. The above procedure is to be repeated until the flood inflow condition is identified such that a failure at that flow or larger flows (up to the PMF) will no longer result in unacceptable additional consequences. The resultant flow is the IDF for the dam. The maximum IDF is always the PMF. The guidelines provide specific guidance and procedures, including a comprehensive flowchart, for conducting an incremental hazard evaluation to select the appropriate IDF.

The guidelines stipulate that the PMF should be adopted as the IDF in those situations where consequences of a dam failure for floods less than the PMF are unacceptable. A flood less than the PMF may be adopted as the IDF in situations where the consequences of dam failure at flood flows larger than the selected IDF are acceptable as determined by the incremental hazard evaluation. When an IDF less than the PMF is selected, the consequences of a dam failure resulting from floods in excess of the IDF must be limited to the dam owner's facilities. The guidelines stipulate that acceptable consequences exist when evaluation of the area affected indicates either of the following two conditions:

1. There are no permanent human habitations, known national security installations, or commercial or individual developments, nor are such habitations or commercial or industrial developments projected to occur within the potential hazard area in the foreseeable future.
2. There are permanent human habitations within the potential hazard area that would be affected by failure of the dam, but there would be no significant incremental increase in the threat to life or property resulting from the occurrence of a failure during floods larger than the proposed IDF.

The guidelines indicate that when a dam break analysis shows downstream incremental effects of approximately two feet or more, engineering judgment and further analysis are necessary to finally evaluate the need for modification of the dam. In general, the consequences of failure are considered acceptable when the incremental effects (depth) of failure on downstream structures are

less than two feet. The consequence analysis should also include consideration of impacts to vital community services such a municipal water or energy supply and may require increasing the spillway capacity to ensure those services are continued during and following extreme flood conditions. The guidelines suggest that it would not be appropriate to set the IDF for a spillway with an exceedance flood frequency less than the 100-year flood, including low-hazard dams.

The guidelines note that "there are times when selection (of the IDF) becomes difficult and it may be necessary to conduct further analyses with a risk-based approach," but follows by stating that "incremental hazard evaluation is, in essence, a risk-based approach." No guidelines were provided for performing an alternate type of risk-based analysis.

The guidelines indicate that it may be appropriate to perform site-specific PMP studies or regional PMP studies to better define existing NWS HMR estimates, provided the additional analysis costs are warranted.

The guidelines address minimum freeboard requirements (the difference between the top of dam and the maximum pool elevation during the IDF) and note that it is generally not necessary to prevent splashing or occasional overtopping of a dam by waves under extreme conditions, however, the number and duration of such occurrences should not threaten the structural integrity of the dam. The guidelines for minimum freeboard allowance do, however, recommend consideration of combinations of components that have a reasonable probability of simultaneous occurrence including: wind-generated wave run-up, effects of possible malfunction of the spillway and outlet works, settlement of the embankment, and landslide-generated waves.

4.13. FEMA Federal Guidelines for Dam Safety – Hazard Potential Classification System for Dams (1998 – Reprinted 2004)

The ICODS Subcommittee on Federal/Non-Federal Dam Safety Coordination was also tasked to develop a new guideline, *Hazard Potential Classification System for Dams*, which was subsequently published in 1998 and reprinted in 2004. Three classification levels were adopted: Low, Significant, and High. The hazard potential classification system categorizes dams based on the probable loss of human life and the impacts on economic, environmental, and lifeline interests and is summarized in Table 4-7. The assigned classification of a dam is based on failure consequences that will result in the assignment of the highest hazard potential classification of all probable failure and misoperation scenarios. The guidelines state that the probable scenarios considered are to be reasonable, justifiable, and consistent with the FEMA *Federal Guidelines for Dam Safety: Selecting and Accommodating Inflow Design Floods for Dams*.

Table 4-7 Summary of Proposed ICODS Hazard Potential Classification System for Dams [FEMA, 1998]

Hazard Potential Classification	Loss of Human Life	Economic, Environmental, Lifeline Losses
Low	None expected	Low and generally limited to owner
Significant	None expected	Yes
High	Probable. One or more expected.	Yes (but not necessary for this classification)

The ICODS Subcommittee recommended that the proposed Hazard Potential Classification System be adopted in lieu of existing numerical and alphabetical systems to eliminate confusion in the dam safety community and to educate the public on the importance of dam safety. The guidelines do not establish how the system should be used, such as prescribing specific spillway design criteria.

4.14. FEMA Model State Dam Safety Program (2007)

This document was prepared by ASDSO to outline key components of an effective dam safety program. The first edition of this document was published in 1987 with amendments in 1998 to reflect the experience of state programs. Spillway design criteria for dams are not provided in this document.

5. Relevant International Guidelines

5.1. Introduction to Summaries of International Guidelines

While the scope of this study specifically addresses guidelines for hydrologic safety of dams within the United States, there are several developments in the international arena that are particularly relevant to the study. Recently updated guidelines in Australia and Canada were reviewed and are summarized in the following sections to provide a glimpse of how other countries' guidelines are changing. This literature review is by no means intended to be a comprehensive overview of international guidelines.

5.2. ANCOLD Guidelines on Selection of Acceptable Flood Capacity for Dams

In Australia, there is no federal legislation on dam safety. Therefore, Australian jurisdictions that have dam safety regulations in place including Victoria, New South Wales, Queensland, and the Australian Capital Territory (ACT) are responsible for developing their own dam safety guidelines. In order to provide a basis for consistency throughout Australia in the assessment of hydrologic safety of dams, the Australian National Committee on Large Dams (ANCOLD) established a Working Party in 1994 to revise the existing standards based guidelines in light of moves to integrate risk assessment into dam safety procedures.

The prior *1986 ANCOLD Guidelines on Design Floods for Dams* introduced the concept of incremental flood hazard categories for ranking the recommended design flood against consequences of a dam failure. At that time risk analysis was being considered; however, the methodology was not well developed. As a result, the 1986 guidelines did not propose the use of risk analyses for dams where lives were at risk. In 1987, the guidelines were revised to include *Australian Rainfall and Runoff*, which included a chapter on estimation of extreme floods.

ANCOLD then led the way internationally in the development of acceptable risk criteria in dam safety and published *Guidelines on Risk Assessment* in 1994. These guidelines provided a basis for integrating risk assessment into dam safety. At that time it became apparent that procedures for risk-based dam safety evaluation were still in the development phase worldwide, and the 1994 risk guidelines needed review. In addition flood estimation procedures for risk-based dam safety evaluation were required to provide flood probabilities for application in risk assessment.

In 2000, *ANCOLD Guidelines on Selection of Acceptable Flood Capacity for Dams* was published to provide more appropriate and consistent guidance within a risk process for dam safety evaluation under floods. The 2000 guidelines superseded the 1986 guidelines in accordance with the ANCOLD aim for integration of risk assessment into the guidelines. The estimation of extreme floods and associated assigned probabilities are based on the procedures developed for Australia in 1999. A point reiterated in the 2000 ANCOLD guidelines is that spillway capacity should be

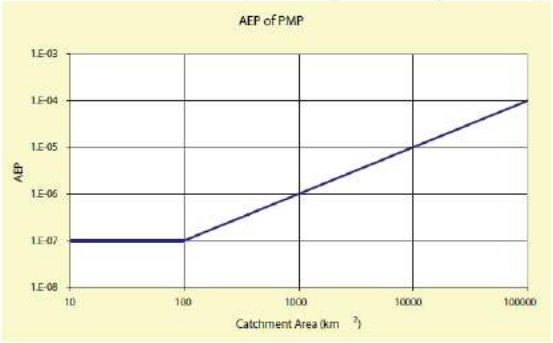
assessed within the total load context and not as a separate case so that all safety issues can be identified and an optimum solution can be developed.

The guidelines include a deterministic "fall-back option" that the owner can adopt instead of the quantitative risk assessment approach. The fall-back option is intended to be more conservative and result in a higher design requirement and cost to bring the dam up to the required standard than the alternative risk assessment procedure. The fall-back option involves first determining the Hazard Category based on consequences and then assigning the acceptable flood capacity based on the assigned return period for the selected Hazard Category rating. The hazard category rating system adopted by Queensland in 2007 based on the ANCOLD Guidelines as well as the corresponding range of acceptable flood capacities for the different hazard categories are presented in Table 5-1. The guidelines also specify flood surcharge "wet" and "dry" freeboard requirements.

Table 5-1 Queensland Hazard Category Rating System [State of Queensland, 2007]

Incremental Population at Risk (PAR)	Severity of Damage and Loss			
	Negligible	Minor	Medium	Major
$2 \le PAR \le 10$	Low: 5.0×10^{-4} / 5.0×10^{-4}	Significant: 5.0×10^{-4} / 1.0×10^{-4}	Significant: 1.0×10^{-4} / 1.0×10^{-4}	High C: 1.0×10^{-5} / C
$10 < PAR \le 100$	5.0×10^{-4} / 1.0×10^{-4}	Significant: 1.0×10^{-4} / 1.0×10^{-4}	High C: C / C	High B: B / B
$100 < PAR \le 1000$	A / A	High A: A / A	High A: A / A	A / A
$PAR > 1000$	If in this region, go to the next highest severity of Damage and Loss category for the same PAR		PMF / PMF	Extreme: PMF / PMF

Where



A = PMP Design Flood

B = PMP Design Flood or 10^{-6}, whichever is the smaller flood event

C = PMP Design Flood or 10^{-5} whichever is the smaller flood event

Note that the probability of the PMP Design Flood is a function of the catchment area.

Table 2: Required range of A cceptable Flood Capacities for different hazard categories

© State of Queensland (Department of Environment and Resource Management) 2011

The ANCOLD *Guidelines on Risk Assessment* was revised in 2003. Victoria, New South Wales, Queensland subsequently adopted the ANCOLD guidelines with minor differences in the limits for tolerability of risk and other provisions. The Victorian regulations require risk assessments for high hazard dams. Risk assessments are optional for the Queensland and New South Wales regulations [Sih et al, 2010]. Reclamation and USACE have recently revised and adopted elements of the ANCOLD guidelines in the formulation of their new risk-based guidelines.

5.3. Canadian Dam Association Guidelines (2007)

Regulation of dams in Canada is primarily a provincial responsibility. Federal agencies have limited jurisdiction related to international boundary waters with the United States and some responsibility for security of critical infrastructure. In 1995, after three years of effort by working groups, the Canadian Dam Safety Association (CDA) published *Dam Safety Guidelines*. In 1999, the CDA issued a revision, and in 2007, the CDA published its most recent guidelines that include a companion series of technical bulletins on dam safety. The technical bulletins suggest methodologies and procedures for use by qualified professionals as they perform dam analyses and safety assessments.

The CDA guidelines include a dam classification system based on failure consequences and discuss both the traditional standards-based approach and the risk-based approach to dam safety decision making. However, IDF requirements are only specified using a deterministic assessment. *Technical Bulletin 6 – Hydrotechnical Considerations for Dam Safety* presents details of the CDA guidelines for selecting the inflow design flood (IDF) and freeboard. The suggested CDA IDF for use in deterministic assessments is presented in Table 5-2. The suggested CDA dam classification scheme is shown in Table 5-3. The IDFs presented in Table 5-2 make reference to the 1 in 1,000-year flood, and ratios of 1/3 and 2/3 between the 1 in 1,000-year flood and the PMF. The CDA guidelines indicate that beyond the 1 in 1,000-year flood, floods cannot be obtained by flood statistics methods. The proposed method consists of interpolating the flood hydrographs rather than the flood peaks or volumes since experience has shown unacceptable distortions using these parameters.

Selecting the IDF using quantitative risk analyses is not discussed and appears to be discouraged because of the inability to accurately assign a probability to extreme floods. As noted in Table 5-2, “extrapolation of flood statistics beyond the 1 in 1,000 year flood is discouraged.”

Provinces, like British Columbia, have adopted the CDA guidelines with only minor modifications. Table 5-4 shows the downstream consequence classification system presented in the 2009 *British Columbia Dam Safety Guidelines*. Minimum design standards for determining the IDF for dams constructed after 2008 are identical to those shown in Table 5-2. The British Columbia guidelines note that the 1999 CDA dam safety guidelines were updated in 2007 and that this update resulted in, among other things, a more stringent suggested annual exceedance probability (AEP) for determining the IDF. For dams constructed prior to 2008, the British Columbia Dam Safety

Program allows dam design engineers to use the 1999 CDA Dam Safety Guidelines. Since the 2007 CDA guidelines use a different dam classification table than the British Columbia Dam Safety Regulations, design engineers are instructed to contact their Dam Safety Officer for the policy on how to use the two classification tables together.

Table 5-2 Suggested CDA Inflow Design Flood for Use in Deterministic Assessments [CDA, 2007]

Consequence Class	IDF
Low	1/100-year
Significant	Between 1/100 and 1/1000-year (Note 1)
High	1/3 between 1/1000-year and PMF (Note 2)
Very High	2/3 between 1/1000-year and PMF Note 2)
Extreme	PMF

Note 1. Selected on basis of incremental flood analysis, exposure and consequence of failure.
Note 2. Extrapolation of flood statistics beyond 1/1000-year flood (10^{-3} AEP) is generally discouraged. The PMF has no asssociated AEP. The flood defined as "1/3 between 1/1000-year and PMF" or "2/3 between 1/1000 year and PMF" has no defined AEP.

Table 5-3 Suggested CDA Dam Classification System [CDA, 2007]

Dam class	Population at risk [note 1]	Incremental losses		
		Loss of life [note 2]	Environmental and cultural values	Infrastructure and economics
Low	None	0	Minimal short-term loss No long-term loss	Low economic losses; area contains limited infrastructure or services
Significant	Temporary only	Unspecified	No significant loss or deterioration of fish or wildlife habitat Loss of marginal habitat only Restoration or compensation in kind highly possible	Losses to recreational facilities, seasonal workplaces, and infrequently used transportation routes
High	Permanent	10 or fewer	Significant loss or deterioration of *important* fish or wildlife habitat Restoration or compensation in kind highly possible	High economic losses affecting infrastructure, public transportation, and commercial facilities
Very high	Permanent	100 or fewer	Significant loss or deterioration of *critical* fish or wildlife habitat Restoration or compensation in kind possible but impractical	Very high economic losses affecting important infrastructure or services (e.g., highway, industrial facility, storage facilities for dangerous substances)
Extreme	Permanent	More than 100	Major loss of *critical* fish or wildlife habitat Restoration or compensation in kind impossible	Extreme losses affecting critical infrastructure or services (e.g., hospital, major industrial complex, major storage facilities for dangerous substances)

Note 1. Definitions for population at risk:

None—There is no identifiable population at risk, so there is no possibility of loss of life other than through unforeseeable misadventure.

Temporary—People are only temporarily in the dam-breach inundation zone (e.g., seasonal cottage use, passing through on transportation routes, participating in recreational activities).

Permanent—The population at risk is ordinarily located in the dam-breach inundation zone (e.g., as permanent residents); three consequence classes (high, very high, extreme) are proposed to allow for more detailed estimates of potential loss of life (to assist in decision-making if the appropriate analysis is carried out).

Note 2. Implications for loss of life:

Unspecified—The appropriate level of safety required at a dam where people are temporarily at risk depends on the number of people, the exposure time, the nature of their activity, and other conditions. A higher class could be appropriate, depending on the requirements. However, the design flood requirement, for example, might not be higher if the temporary population is not likely to be present during the flood season.

Table 5-4 British Columbia Dam Safety Dam Classification System [British Columbia, 2009]

Rating	Loss of Life	Economic and Social Loss	Environmental and Cultural Losses
VERY HIGH	Large potential for multiple loss of life involving residents and working, travelling and/or recreating public. Development within inundation area (the area that could be flooded if the dam fails) typically includes communities, extensive commercial and work areas, main highways, railways, and locations of concentrated recreational activity. Estimated fatalities could exceed 100.	Very high economic losses affecting infrastructure, public and commercial facilities in and beyond inundation area. Typically includes destruction of or extensive damage to large residential areas, concentrated commercial land uses, highways, railways, power lines, pipelines and other utilities. Estimated direct and indirect (interruption of service) costs could exceed $100 million.	Loss or significant deterioration of nationally or provincially important fisheries habitat (including water quality), wildlife habitat, rare and/or endangered species, unique landscapes or sites of cultural significance. Feasibility and/or practicality of restoration and/or compensation is low.
HIGH	Some potential for multiple loss of life involving residents, and working, travelling and or recreating public. Development within inundation area typically includes highways and railways, commercial and work areas, locations of concentrated recreational activity and scattered residences. Estimated fatalities less than 100.	Substantial economic losses affecting infrastructure, public and commercial facilities in and beyond inundation area. Typically includes destruction of or extensive damage to concentrated commercial land uses (highways, railways, power lines, pipelines and other utilities). Scattered residences may be destroyed or severely damaged. Estimated direct and indirect (interruption of service) costs could exceed $1 million.	Loss or significant deterioration of nationally or provincially important fisheries habitat (including water quality), wildlife habitat, rare and/or endangered species, unique landscapes or sites of cultural significance. Feasibility and practicality of restoration and/or compensation is high.
LOW	Low potential for multiple loss of life. Inundation area is typically undeveloped except for minor roads, temporarily inhabited or non- residential farms and rural activities. There must be a reliable element of natural warning if larger development exists.	Low economic losses to limited infrastructure, public and commercial activities. Estimated direct and indirect (interruption of service) costs could exceed $100,000.	Loss or significant deterioration of regional important fisheries habitat (including water quality), wildlife habitat, rare and endangered species, unique landscapes or sites of cultural significance. Feasibility and practicality of restoration and/or compensation is high. Includes situations where recovery would occur with time without restoration.
VERY LOW	Minimal potential for any loss of life. The inundation area is typically undeveloped	Minimal economic losses typically limited to owners property and do not exceed $100,000. Virtually no potential for future development of other land uses within the foreseeable future.	No significant loss or deterioration of fisheries habitat, wildlife habitat, rare or endangered species, unique landscapes or sites of cultural significance.

6. Prior State and Federal Surveys Related to Design Flood Selection

6.1. Background

As design practices and regulatory guidelines relating to the selection of a design flood have developed over the past several decades, multiple organizations and individuals have striven to understand what the industry standard was at a particular point in time. The use of surveys has been a common tool in identifying current dam safety practices. Several past surveys regarding design flood selection are summarized in this chapter. Each survey provides a snapshot in time of dam safety practices and regulations as well as common opinions and ideologies of the dam safety community. A careful review of each of the surveys is helpful in identifying the trends and changes regarding the hydrologic safety of dams over the past 40 years.

6.2. USCOLD – 1970

In the late 1960s, the U.S. Committee on Large Dams performed a survey of dam design practices for sizing spillways in the United States. Surveys were solicited from both federal and state dam safety agencies, and results were published in a 1970 report "Criteria and Practices Utilized in Determining the Required Capacity of Spillways."

It was reported that all respondents to the survey followed policies discouraging the use of risk analysis when designing high hazard dams. Without exception, respondents agreed that the prevention of overtopping during extreme flood events is of such importance that the required cost is justified. It was also noted that the policies generally accepted at the time were not radically different from those from 20 or more years previous to the study, although procedures and techniques had improved.

6.3. National Research Council – 1985

As part of a study entitled "Safety of Dams: Flood and Earthquake Criteria" performed by the Committee on Safety Criteria for Dams of the Water Science and Technology Board of the NRC's Commission on Engineering and Technical Systems, inquiries regarding current dam safety provisions were made to federal agencies most concerned with dams, state dam safety units, several prominent dam engineering firms, and other organizations with interests in dam safety. The data from 10 federal agencies, 35 state and local agencies, 9 private firms, and 4 professional engineering societies were used to determine the state of the practice in 1985.

The survey found a broad range of classification criteria being used at the time. Most dam classification systems were based on dam height, volume of water impounded, the extent of

development in the downstream dam failure hazard area, or a combination of the preceding characteristics. The summary notes that:

> *"While it appears that many of the differences in dam classification systems are the result of arbitrary choices of regulatory authorities, it also appears that most of the classification systems have been structured to meet the perceived needs of the issuing agency or state government"* [NRC, 1985].

In regards to spillway capacity, the survey found that the majority of design criteria were based on deterministic estimates of the PMP or PMF, some percentage of the PMP or PMF, and probabilistic flood events with a return period of 100 years or less frequent. The Soil Conservation District and the state of West Virginia reported using mixed criteria based upon both probabilistic and deterministic estimates. The only reports of probabilistic floods less frequent than the 100-year event occurred in California (1,000 year flood event) and Michigan (200-year flood event). A summary of spillway capacity criteria used by various U.S. states and agencies in 1985 is included in Table 6-1.

Table 6-1 Spillway Capacity Criteria Reported to Be in Use by Various U.S. Agencies in 1985 [NRC, 1985]

Deterministic Criteria	Mixed Criteria	Probabilistic Criteria
Criteria specifying rainfalls		
PMP	P100 + 0.40 (PMP – P100)	2.25 P100
0.90 PMP	P100 + 0.26 (PMP – P100)	1.50 P100
0.80 PMP	P100 + 0.12 (PMP – P100)	P100
0.75 PMP	P100 + 0.06 (PMP – P100)	P50
0.50 PMP		P10
0.45 PMP		
0.40 PMP		
0.33 PMP		
0.30 PMP		
0.25 PMP		
0.225 PMP		
0.20 PMP		
0.10 PMP		
Criteria specifying floods		
PMF		1,000-year flood
0.75 PMF		200-year flood
0.50 PMF		100-year flood
0.40 PMF		50-year flood
0.30 PMF		
0.25 PMF		
0.20 PMF		

Criteria specific to each agency included in this study are published within the report. The following key points regarding spillway capacity design were noted:

- There was a fair consensus on the spillway requirements for large, high-hazard dams. The use of PMP or PMF estimates for such dams predominated, although many state regulatory agencies indicated that their standards did not require the full PMP or PMF.
- There was a much greater diversity of hydrologic criteria for the safety of classes of dams other than large, high hazard dams.
- While simple hazard rating categories based on downstream development may be useful for identifying dams for high-priority safety evaluation and study, they do not reflect the potential for incremental loss of life and damage caused by failure of a dam due to an inadequate spillway when a river is already in flood.
- Though not included in most published criteria, the use of incremental damage assessments was growing in acceptance and used to establish the required spillway capacity.
- New concepts and improved methods for estimating floods have resulted in generally larger flood estimates and future estimates of magnitude for extreme floods can be expected to increase. However, unless the runoff characteristics of the watershed were to change, increments in future flood estimates should be less than those noted in the past. There have been instances where more intensive hydrometeorological studies have resulted in reductions in estimates of PMP by earlier investigations.
- A dam designed for the PMF using the PMP does not provide absolute assurance that the dam is safe for every possible flood.
- The study noted that the use of arbitrary criteria such as a percentage of the 100-year storm, fraction of the PMF, or combinations of the PMF and probability based floods was common, even though there is no documented scientific rationale for such approaches.

For new high-hazard dams, the Committee recommended the PMF be adopted for the SDF unless risk analyses that examine the incremental impact of overtopping and dam failure during an extraordinary flood demonstrate that little or nothing is gained by such a high standard. The SDF would be the smallest value that ensures that a dam breach results in no significant increase in potential for loss of life or major property damage.

For existing high-hazard dams, the Committee concluded that there was no universally satisfactory approach to establishing spillway capacity criteria. The Committee therefore recommended that risk-based analysis be considered for existing high-hazard dams “for which the PMF is not required.” A section describing risk-based analyses was included in the report.

No specific recommendations were made by the Committee for spillway design requirements for intermediate hazard and low hazard dams.

Additional recommendations made by the Committee are summarized in Section 4.9.

6.4. Dubler Thesis, Colorado State University – 1995

James R. Dubler published the thesis "Dam Safety Policy for Spillway Design Floods" as part of his Master of Science degree at Colorado State University in 1995. Representatives of 46 state dam safety agencies provided responses to a survey included in the thesis.

The study found that disagreement concerning the selection of the SDF among professionals still existed. At the time of the survey, risk analysis was not popular in the professional community, and most states' guidelines for the selection of the SDF were based on a prescriptive approach. The survey also explored a variety of topics related to the SDF and risk analysis including incremental damage analysis, early warning systems, the development of probable maximum flood estimates, downstream development controls, advantages and disadvantages concerning risk analysis, and opinions regarding the level of conservatism required for spillway design.

Dubler made the following conclusions in his thesis:

- The use of prescriptive standards for important structures usually implies adoption of the "no-risk" stance. This is inappropriate. That is not to say use of the PMP/PMF as a design criterion is necessarily inappropriate, but it is inappropriate to make that selection on the basis of "no-risk."
- It is not reasonable to have different probabilities of failure for different aspects of dam design.
- It is not reasonable to have different degrees of conservatism for different sorts of risks facing society.
- The risk analysis approach is not popular in the professional community. Perhaps this is partly because "risk" is a bad word. Perhaps we need a more appealing label, such as "balanced design."
- There are those who believe it is wrong for public policy to explicitly acknowledge that for some stated endeavor a certain degree of risk exists. The unfortunate fact is that risks do exist and accidental deaths do occur. We as a society must decide what portion of our resources we are willing to allocate to reduce such deaths. Clearly, certain expenditures involving construction or retrofitting of spillways are not justifiable. It is the moral duty of the engineer, and in fact of everyone, to make optimum use of resources.

6.5. Paxson and Harrison – 2003

In 2003, Greg Paxson and John Harrison of Schnabel Engineering, Inc. performed an independent survey of state dam safety officials as part of a technical paper entitled "Hydrology and Hydraulics for Dams: State of the Practice or Practice of States?" All 50 states were included in the study which placed an emphasis on the hydrologic and hydraulic methods and models used.

The survey revealed that a total of 76 percent of the states would allow the development of site specific PMP studies. Eighty-eight percent of the states would allow the use of incremental damage

assessment to establish the SDF. Only 43 percent would allow the use of rigorous risk-based analysis. It was noted that the allowance of these practices did not necessarily equate to their common use.

The authors of the technical paper commented that standardization of certain practices not dependent upon regional conditions would likely be beneficial to the dam safety community. Standard criteria could include approved hydrologic models, freeboard requirements, reservoir inflow and initial water surface elevation criteria for dam failure inundation analyses, and criteria for incremental damage analysis.

6.6. ASDSO Surveys

The Association of State Dam Safety Officials has performed numerous surveys of the state dam safety agencies over the past decade. Recent material includes the "State Dam Safety Dam Size Classification Schemes" and "State Dam Safety Hazard Potential Classification" which were both published in 2010 and are included in Appendix F. On an annual basis, ASDSO collects information on states' public awareness, education, staffing, training, budgets, legislation/regulations, program improvements, litigation, dam failures/incidents, dam removals, research, and other activities.

7. 2011 Hydrologic Safety of Dams Survey and Database

7.1. Questionnaire Distribution and Database Compilation

The purpose of this report is to document the present state of the practice for evaluating the hydrologic safety of dams, including inventorying current practices used by state and federal agencies. As a significant portion of this effort, a detailed questionnaire was prepared and distributed to all state dam safety agencies as well as any federal agencies which own, regulate, or assist in the design of dams. Members of the research team initially reviewed each agency's published policies and guidelines and completed applicable portions of the questionnaire. Respondents were requested to complete the survey and verify any responses initially completed by the research team. Electronic copies of the questionnaire were distributed to potential respondents in February 2011. Questionnaires were completed by respondents and returned to the research team by May 2011.

As questionnaires were returned, a member of the research team reviewed each response to ensure its accuracy and completeness. If needed, the respondent was contacted to clarify their responses. In a few cases, questionnaires were edited to create consistency between responses, thereby enabling comparison and analysis of the results. For example, when asked if the agency had hazard classification criteria, the survey allowed several responses including "Yes (High, Significant, and Low)." Several agencies responded "Yes (Other)" and commented that they utilized classification system consisting of high, moderate, and low hazards. In these cases, the terms "moderate" and "significant" were judged to be equivalent and interchangeable and the response was edited by the research team accordingly. All responses were incorporated into an electronic database which facilitated analysis of the survey results.

The questionnaire addressed many important issues related to the hydrologic safety of dams including dam classification criteria, determination of the SDF, allowable methodologies and software, consideration of future development, incremental damage assessment, use of early warning systems, current practices related to risk analysis, and agencies' ability and receptiveness to perform risk analysis. Thirteen questions were included in an "off-the-record" or anonymous portion of the survey due to their potentially sensitive nature. A copy of the survey questionnaire and corresponding answer choices is included in Appendix C.

7.2. Response

Of the 63 surveys distributed, a total of 58 were completed. Surveys were completed by the appropriate dam safety agency from all 50 states, as well as Puerto Rico, with exception of Alabama and Florida. The State of Alabama does not currently have a dam safety program and therefore did not provide a response. Florida's Dam Safety Program elected to not complete the

questionnaire due to the fact that dams within the state are regulated separately by each water management district. Each of the five districts within the state has different spillway design standards.

Of the federal agencies, respondents included:

- Bureau of Indian Affairs
- Federal Energy Regulatory Commission
- Mine Safety and Health Administration
- Natural Resources Conservation Service
- Tennessee Valley Authority
- U.S. Army Corps of Engineers
- U.S. Bureau of Reclamation
- U.S. Forest Service
- U.S. Fish and Wildlife Service

The National Park Service declined to participate. The Bureau of Land Management and U.S. Nuclear Regulatory Commission did not respond to the survey request.

Chapters 8 and 9 of this report present the key findings of this survey effort in relation to current hydrologic design practices of both the federal and the state agencies, respectively. "On-the-record" portions of questionnaires completed by respondents and finalized by the Research Team are included in Appendix C.

8. Summary of Current Federal Hydrologic Design Guidelines

8.1. Background

Historically, a few key federal agencies have led the way in developing dam safety regulations and design standards. Agencies that have typically been at the forefront of dam safety include the Federal Emergency Management Agency, Bureau of Reclamation, Army Corps of Engineers, and the Natural Resources Conservation Service. Summaries of the hydrologic design practices of these agencies are provided in this chapter. A compilation of pertinent federal publications and guidance documents are included in Appendix D. Policies of other federal agencies who responded to the Hydrologic Safety of Dams Survey are also reviewed.

8.2. Overview of Dam Classification and Spillway Design Criteria

8.2.1. Definition of Regulatory Dam

In identifying non-jurisdictional or non-inventory dams, all federal agencies other than FERC and the Mine Safety and Health Administration (MSHA) follow the definition outlined in FEMA's Federal Guidelines for Dam Safety. FEMA's guidelines specify that a dam is:

> *"…any artificial barrier, including appurtenant works, which impounds or diverts water and which (1) is twenty-five feet or more in height from the natural bed of the stream or watercourse measured at the downstream toe of the barrier or from the lowest elevation of the outside limit of the barrier if it is not across a stream channel or water course, to the maximum water storage elevation or (2) has an impounding capacity at a maximum water storage elevation of fifty acre-feet or more. These guidelines do not apply to any such barrier which is not in excess of six feet in height regardless of storage capacity, or which has a storage capacity at maximum water storage elevation not in excess of fifteen acre-feet regardless of height. This lower size limitation should be waived if there is a potentially significant downstream hazard"* [FEMA, 2004].

The MSHA's non-coal program area also follows these guidelines; however, for the coal program, any impoundment less than 5 feet high or less than 20 feet high with a storage volume of less than 20 acre-feet is considered non-jurisdictional. FERC considers any dam included in a FERC license to be a jurisdictional dam.

8.2.2. Dam Classifications and Selection of the Spillway Design Flood

All of the federal agencies responding to the survey indicated the use of hazard classification criteria. All of these agencies use a three-class system consisting of high, significant, and low hazard. Most of the agencies defined "Significant Hazard" as having *no potential for loss of life,*

though extensive economic losses would be expected. Under these agencies, any dam creating a hazard to human life would be classified as "High Hazard." The Bureau of Indian Affairs (BIA) definition of a significant hazard dam states that between 1 and 6 lives would be at risk or significant property damage could occur if the dam failed. USACE indicated that loss of life is "not probable" during the failure of a significant hazard dam.

The only federal agencies indicating the use of size classification criteria were the U.S. Fish and Wildlife Service (USFWS) and MSHA. Both of these agencies use a combination of hazard and size classification to determine the SDF. Most of the other federal agencies prescriptively assign the SDF based on hazard classification only. The only exceptions to this are USACE and Reclamation who are leading the way in developing spillway design criteria using risk analysis. Additionally, the BIA indicated that the use of risk analysis in connection with its prescriptive hazard classification system was acceptable.

With the exception of the Bureau of Reclamation, all federal agencies use the same criteria for both the design of new dams and the evaluation and rehabilitation of existing dams. Reclamation indicated that the application of updated design guidelines to an existing dam would vary by project after considering the amount of risk reduction, feasibility of the modification, and cost/benefit analysis results.

8.2.3. Design Criteria

By way of the 2011 Hydrologic Safety of Dams survey, several key points were identified concerning the practices of federal agencies. These are as follows:

- For PMP/PMF designs, most federal agencies determine the necessity for freeboard on a case-by-case basis. The Natural Resources Conservation Service (NRCS), TVA, and U.S. Forest Service (USFS) do not require freeboard for such designs.
- Most federal agencies either allow or encourage the use of early warning systems on Significant and High Hazard structures; however, they will not consider an early warning system as an alternative to designing a dam for the regulatory SDF. MSHA will allow storm runoff flood control dams to be designed to low hazard criteria if an early warning system is provided to prompt the evacuation of downstream personnel.
- All federal agencies permit the use of site specific PMP studies.
- The only federal agency that does not allow the use of an incremental damage assessment to establish the SDF is the TVA.
- While not all federal agencies have reviewed a risk-based design, there are no federal guidelines or regulations that forbid such designs. Federal agencies that have reviewed risk-based designs include the BIA, NRCS, USACE, Reclamation, and USFWS.

8.3. Summary of Guidelines from Select Federal Agencies

8.3.1. U.S. Bureau of Reclamation

As noted in Section 3.7, Reclamation appears to be the first federal agency worldwide to seriously apply risk-based decision making to dam safety. The Bureau began applying principles of risk analysis to dam safety as early as the 1980s. In 1985, the NRC Committee on Safety Criteria for Dams reported that while many Reclamation dams were held to the industry standard PMF, the concepts of incremental damage analysis and even the beginnings of full-fledged risk analysis (including consideration of social, environmental, and political effects of dam failure in additional to incremental damage and loss of life) were incorporated in Reclamation design criteria.

Since that time, Reclamation has moved away from deterministic design flood standards and has emerged as a major promoter of risk analysis. In utilizing risk analysis, each dam site and structure is considered individually with the SDF being determined on a case-by-case basis. Under current Reclamation practice, any modifications to spillway design capacity would follow a risk-based approach using Reclamation's Risk Analysis Best Practices Manual and would vary by project. Modifications to existing structures must consider the amount of risk reduction, feasibility of modification, and cost/benefit analysis when selecting the design criteria. Reclamation's recommended guidelines for evaluating the need and urgency to implement risk reduction activities based on the estimated risk are shown in Table 8-1 and Figure 8.1. Incremental damage analysis is used when appropriate but not required.

In 2006, Robert E. Swain, John F. England, Jr., and Kenneth L. Bullard of Reclamation published Guidelines for Evaluating Hydrologic Hazards as a guidance document for generating hydrologic hazard information to be used in evaluating the hydrologic risk at dams. This document outlines a procedure for developing hydrologic hazard curves using a combination of seven hydrologic methods. These methods include the use of flood frequency analysis with historical and paleoflood data as well as the development of a PMF using published HMR and Reclamation guidelines. Other significant contributions and guidelines that Reclamation has published over the past two decades to facilitate application of risk analysis to dam safety are noted in Section 3.7.

Table 8-1 Bureau of Reclamation Risk Reduction Guidance [Adapted from Reclamation, 2003]

Guidance for Estimated Risk	
Estimated risk is portrayed to be greater than 0.01 lives per year	Reclamation considers that there is justification for taking expedited action to reduce risk. While there is a full range of possible risk reduction actions that can be taken, Reclamation should focus on those that can quickly reduce risk or improve understanding of the uncertainties associated with the risk. As confidence increases that the risk is in this range, actions considered should concentrate more on reducing the risk than reducing the uncertainties. Any reassessment of the risk should be done prior to increased storage if at all possible, and every effort should be made to complete the reassessment within 90 days of determining the need for expedited risk reduction action.
Estimated risk is portrayed between 0.01 and .001 lives per year	Reclamation considers that there is justification for taking action to reduce risk. When the range of risk estimates falls in this range, there are a wide variety of possible actions which may be appropriate. However, the actions can be scheduled into the dam safety program and coordinated with other needs at the facility or at other facilities. Actions to reduce risks should be implemented on a schedule that is consistent with budgeting and appropriations processes. Typically, risk reduction should be accomplished within 7 years of a decision that risks need to be reduced. When there is an indicated need for risk reduction, the time spent on additional loading definition, data collection, and risk assessment should be completed in a reasonable timeframe. While it is desirable for this timeframe to be within a year, other times may be considered reasonable by decision makers based on the severity of the identified risks. Decisions on adequate time frames should be documented in appropriate decision documents.
Estimated risk is portrayed to be less than 0.001 lives per year	The justification to implement risk reduction actions or conduct additional studies diminishes as estimated risks become smaller than .001. Risk reduction action costs, uncertainties in the risk estimates, scope of consequences, operational and other water resources management issues play an increased role in decision making. Actions considered reasonable and prudent should be considered for implementation when the risk is in this range.

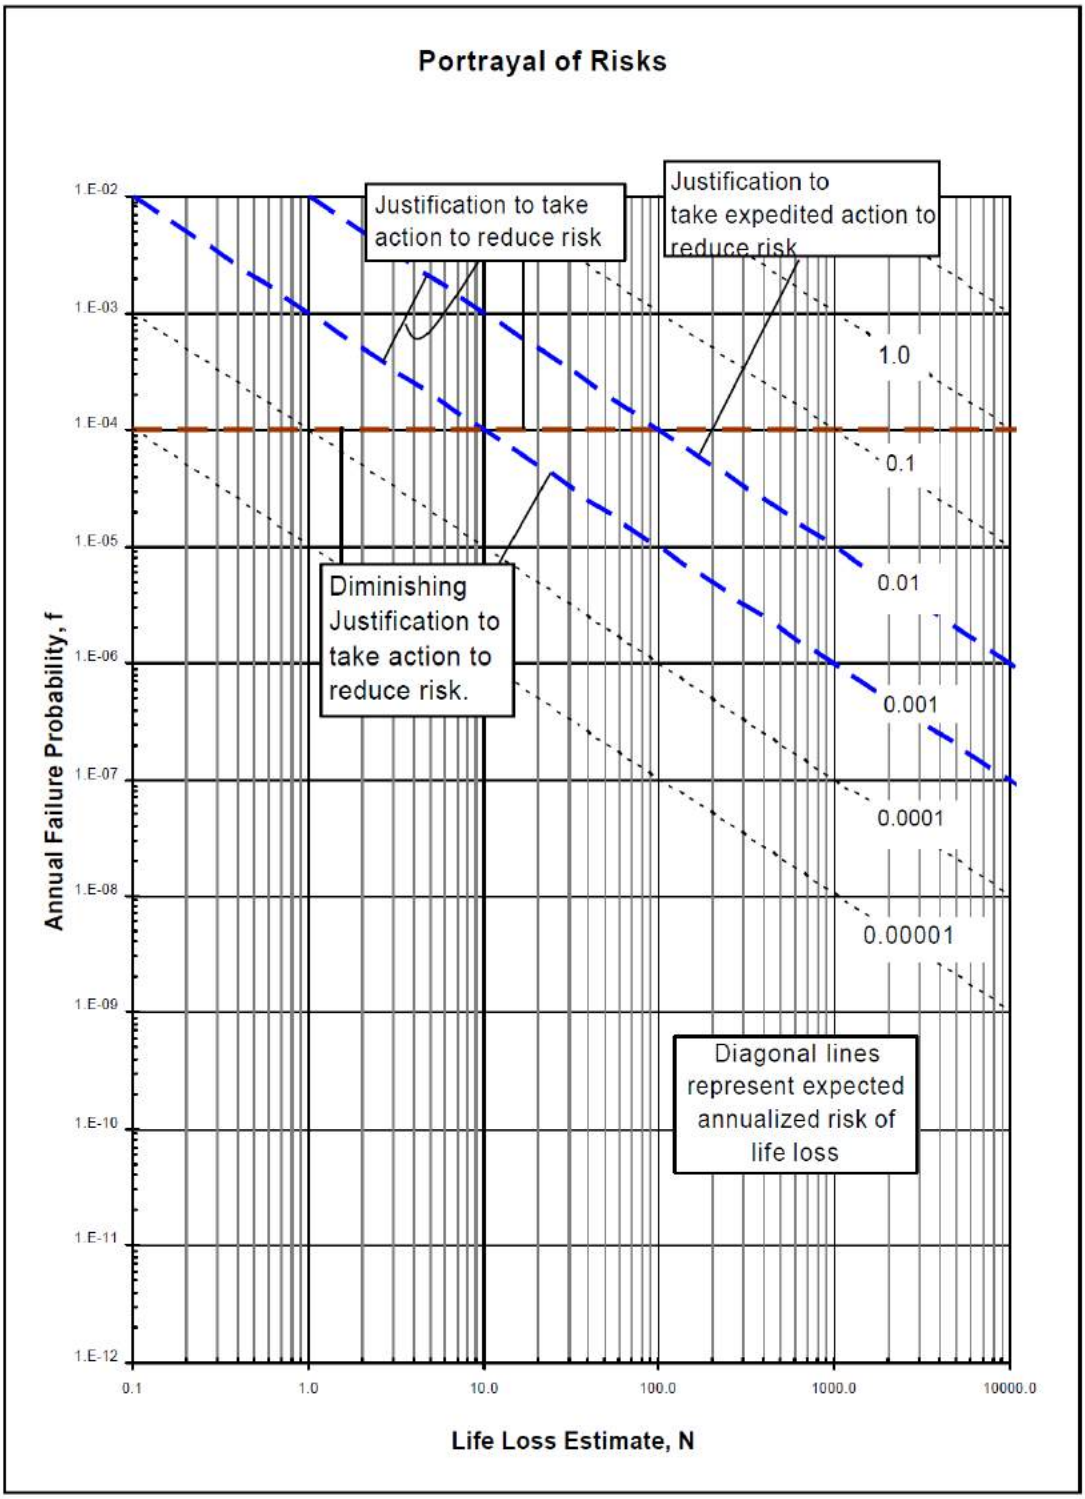

Figure 8.1 Reclamation f-N Chart for Displaying Probability of Failure, Life Loss, and Risk Estimates [Reclamation, 2003]

8.3.2. U.S. Army Corps of Engineers

The other major contributor to the development of risk-based dam safety standards in the United States has been the U.S. Army Corps of Engineers. USACE has published numerous guidance documents outlining policy and procedures related to dam safety. Under current guidelines, High hazard dams with potential life loss must pass 100% of the PMF per Standard 1 of ER 1110-8-2. Significant hazard dams with no probable life loss must pass major floods typical of the region without excessive damage or loss of operability per Standard 2 of ER 1110-8-2. Significant hazard dams with no incremental life loss due to dam failure must pass a minimum of 1/2 PMF per Standard 3 of ER 1110-8-2. Low hazard dams typically fall under Standard 4 of ER 1110-8-2 which requires rainfall-runoff probability analyses with no specific minimum requirement. These design standards are consistent with those that were utilized at the time of the 1985 NRC report.

One of the most recent USACE publications is ER 1110-2-1156 which is in draft form and is dated September 30, 2010. This publication provides an overview of the Dam Safety Program, provides guidelines and procedures for decisions, and discusses periodic assessments, inspections, and other items.

Some of the most relevant and state-of-the-art portions in ER 1110-2-1156 are the guidelines for assessing tolerable risk. The overall goal is to lower the residual risk to a tolerable level while also meeting project-specific requirements for what is practicable. The project-specific limits defined for what is practicable are termed “ALARP” which stands for “As Low As Reasonably Practicable.”

ER 1110-2-1156 presents the state-of-the-art guidelines for assessing tolerable risk including the application of the following concepts: “Tolerable Risk,” “Broadly Acceptable Risk,” “Tolerable Risk Range,” and “As-Low-As-Reasonably-Practicable” in a generalized and project specific tolerability of risk framework. A schematic illustrating these concepts is shown in Figure 8.2. Determining ALARP is ultimately a matter of judgment. General guidance is provided in ER 1110-2-1156 on how to satisfy the ALARP requirement.

The following four risk measures are evaluated under the USACE tolerable risk guidelines:

1. Annual Probability of Failure (APF)
2. Life Safety Risk
3. Economic Risk
4. Environmental and Other Non-Monetary Risk

Incremental consequences (consequences resulting from dam failure vs. consequences resulting without dam failure) are to be considered when performing quantitative risk analysis.

The USACE’s policy for the estimated annual probability of failure (APF) is that it is unacceptable to be greater than 1 in 10,000 (0.0001). An APF will be considered tolerable when it is less than 1 in 10,000 (0.0001) per year provided the other tolerable risk guidelines are met.

The USACE has identified three types of risk safety guidelines; (1) individual incremental life safety risk using probability of life loss, (2) societal incremental life safety risk expressed as a probability distribution of potential life loss (F-N chart), and (3) societal incremental life safety risk expressed as an Annualized Life Loss (ALL). For existing and new dams, the individual incremental life safety risk probability of life loss should be less than 1 in 10,000 and 1 in 100,000 per year, respectively. For existing dams the societal risk should be less than the tolerable risk limit line shown on Figure 8.3 and satisfy the ALARP requirements. Dams with failure risks that plot above a tolerable risk limit shown on Figure 8.3 are considered to have an unacceptable level of risk, except in exceptional circumstances. Annualized incremental societal life loss is evaluated based on the guidelines presented in Figure 8.4.

Risk informed hydrologic designs are permitted for flood damage reduction studies (e.g. levees, channel improvements, etc) per ER 1105-2-101. However, despite the significant efforts given to developing risk analysis for dam safety, risk-informed hydrologic designs are not permitted for dams under current USACE guidelines. Risk-informed hydrologic analyses for dams are used to prioritize risk reduction actions for dams in the USACE inventory and to inform decisions on incremental risk reduction actions for specific projects.

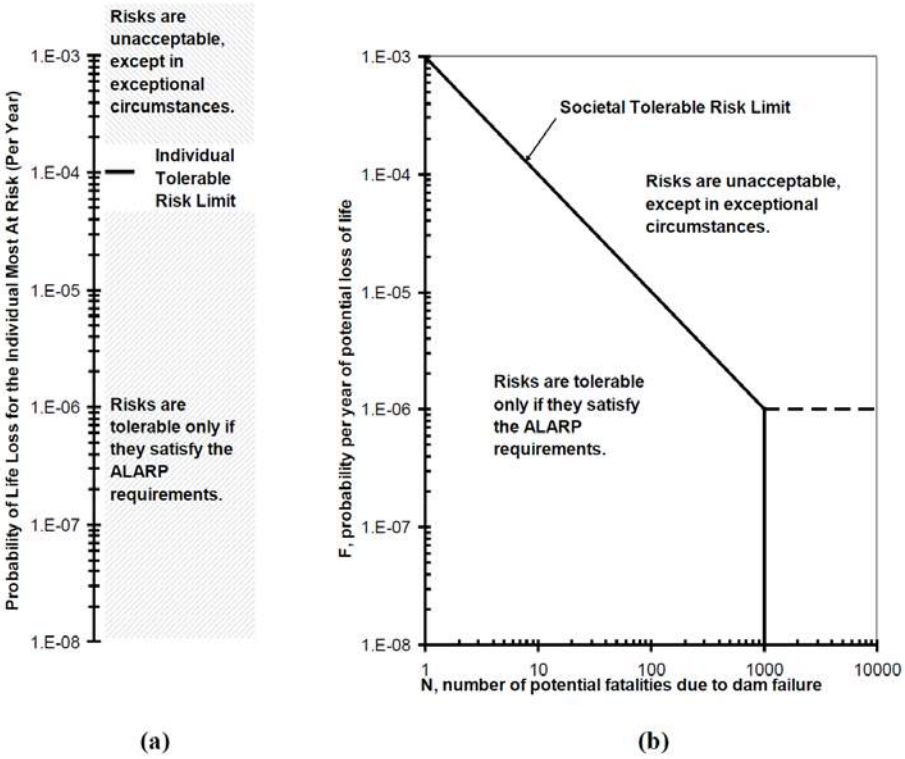

Figure 8.3 Individual Risk Guidelines (a) and Societal Risk Guidelines (b) for Existing Dams [USACE, 2010]

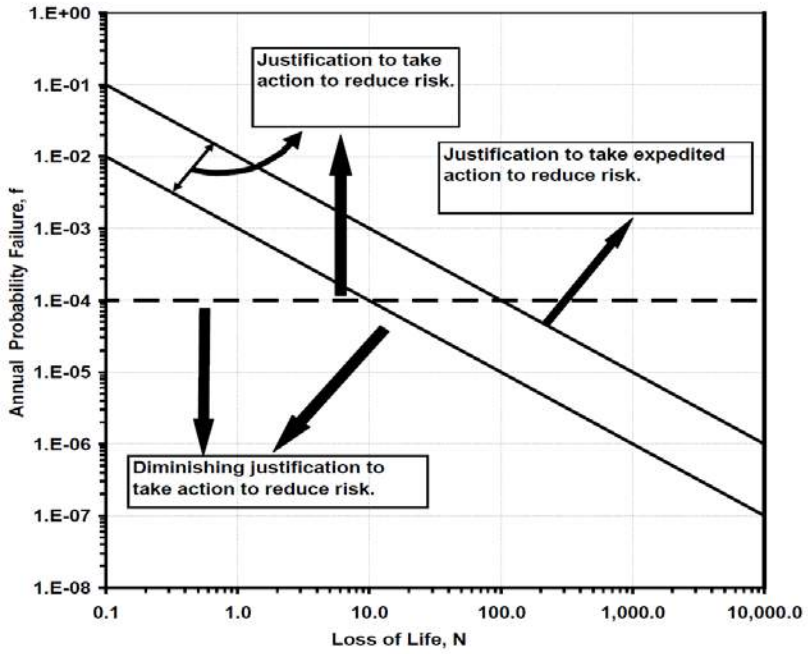

Figure 8.4 F-N Chart for Displaying Annual Probability of Failure and Annualized Life Loss [USACE, 2010]

8.3.3. Natural Resources Conservation Service

NRCS (previously known as the Soil Conservation Service or SCS) is not a regulatory agency, but rather an agency that provides financial and technical assistance to landowners and project sponsors in the evaluation, design, and installation of dams. SCS/NRCS guidelines were first developed in the 1930s. Since then the guidelines have evolved and are reviewed and updated on a continual basis. The NRCS has adopted a nationwide standard and allows state NRCS offices to revise the standards to make them more restrictive, but not less restrictive. Additionally, NRCS dams must meet all state and local regulations.

The NRCS has published numerous guidelines regarding the design and safety of dams. Technical Release 60 (TR-60) contains design requirements for earth dams and their associated spillways; National Engineering Handbook Part 630, Chapter 21 contains procedures for developing inflow hydrographs; and the National Conservation Practice Standard No. 378 contains design requirements for ponds and their associated spillways. NRCS design flood criteria from the TR-60 publication are listed in Table 8-2. These criteria are identical to those used by the NRCS in 1985 [NRC, 1985]. About 60 percent of NRCS dams are small, low hazard structures that provide water for livestock, fish and wildlife, recreation, fire control, or other related uses. Design criteria for these structures are listed in Table 8-3 as described in the National Conservation Practice Standard No. 378 for ponds.

NRCS encourages the use of a site-specific PMP where information is available. Where limiting physical site constraints exist, the NRCS does allow the use of incremental damage assessment in the rehabilitation of existing dams provided downstream land use controls are put in place to prevent voiding incremental risk assumptions [Hoeft et al, 2010]. NRCS will consider risk-based designs, but they are not a part of design guidelines.

Table 8-2 Minimum Auxiliary Spillway Capacity Criteria for Dams of the Natural Resources Conservation Service [NRCS, 2005]

Class of Dam	Product of storage X effective height	Existing or planned upstream dams	Precipitation data for [1]	
			Auxiliary spillway hydrograph	Freeboard hydrograph
Low [2]	less than 30,000	none	P_{100}	$P_{100} + 0.12(PMP - P_{100})$
	greater than 30,000		$P_{100} + 0.06(PMP - P_{100})$	$P_{100} + 0.26(PMP - P_{100})$
	all	any [3]	$P_{100} + 0.12(PMP - P_{100})$	$P_{100} + 0.40(PMP - P_{100})$
Significant	all	none or any	$P_{100} + 0.12(PMP - P_{100})$	$P_{100} + 0.40(PMP - P_{100})$
High	all	none or any	$P_{100} + 0.26(PMP - P_{100})$	PMP

[1] P_{100} = Precipitation for 100-year return period. PMP = Probable maximum precipitation
[2] Dams involving industrial or municipal water are to use minimum criteria equivalent to that of Significant Hazard Class.
[3] Applies when the upstream dam is located so that its failure could endanger the lower dam

Table 8-3 Minimum Auxiliary Spillway Capacity Criteria for Ponds of the Natural Resources Conservation Service [NRCS, 2002]

Drainage area (Ac.)	Effective height of dam[1] (Ft.)	Storage (Ac-Ft)	Minimum design storm[2] Frequency (Years)	Minimum design storm[2] Minimum duration (Hours)
20 or less	20 or less	< than 50	10	24
20 or less	> than 20	< than 50	25	24
> than 20		< than 50	25	24
All others			50	24

1. As defined under "Conditions where Practice Applies".
2. Select rain distribution based on climatological region.

8.3.4. Federal Energy Regulatory Commission

FERC guidelines for the hydrologic safety of dams are consistent with FEMA's "Federal Guidelines for Dam Safety: Selecting and Accommodating Inflow Design Floods for Dams." These guidelines emphasize hazard evaluation as the primary means of determining the SDF. This emphasis includes the use of incremental damage analysis. FERC has also used information obtained from risk-based hydrologic analysis to aid in reviewing spillway designs. Although FERC has not utilized or developed risk analysis as fully as USACE or Reclamation, they have transitioned from a very deterministic and prescriptive approach to placing increasing emphasis on risk-related practices such as incremental damage analysis. A complete summary of FERC/FEMA's guidelines is included in Section 4.12.

8.3.5. Mine Safety and Health Administration

MSHA guidelines for the hydrologic safety of dams are based upon FEMA's "Federal Guidelines for Dam Safety: Selecting and Accommodating Inflow Design Floods for Dams." As noted previously, MSHA also utilizes a size classification system in conjunction with hazard classification to determine the appropriate SDF.

8.3.6. Tennessee Valley Authority

TVA guidelines are based upon FEMA's Federal Guidelines for Dam Safety as well as self-imposed criteria that TVA has developed over time. At present, TVA regulates 49 dams. They are in the process of creating a Dam Safety Governance organization which will implement guidelines for any impoundment within the TVA system which meets the definition of a dam within FEMA's Federal Guidelines for Dam Safety.

TVA typically selects the PMF as the appropriate SDF for dams with a high hazard classification. Significant and low hazard dams must pass the "TVA precipitation" as defined by a hydrometeorological design basis report developed for TVA by the National Weather Service. This precipitation is significantly less than the PMP. These SDF criteria are very similar to those used by the Authority in 1985 [NRC, 1985].

8.3.7. Bureau of Indian Affairs

BIA has custom developed dam safety guidelines based upon those published by Reclamation. In following with Reclamation guidelines, BIA determines the SDF using a combination of risk analysis and hazard classification. Under these guidelines, the SDF is typically defined as the largest flood which will cause incremental dam failure flooding. However, BIA reserves the right to select something smaller based on downstream conditions. Normally, the IDF will not be greater than a 10,000-year storm.

8.3.8. U.S. Forest Service

Both FEMA and USACE guidelines were consulted in the development of revised USFS dam safety guidelines. It is anticipated that the new guidelines will be completed in summer 2011. With the adoption of new guidelines, the Forest Service will discontinue the use of design flood criteria based upon a combination of size and hazard classification. SDF standards will be based entirely upon hazard classification. High Hazard dams will be required to pass the PMF, significant hazard dams will be required to pass 50% of the PMF, and low hazard dams will be required to pass the 100-year flood. Incremental damage analysis may allow spillway capacity to be reduced, but not any lower than the minimum thresholds which are as follows: 50% PMF (High Hazard), 100-year event (Significant Hazard), 50-year event (Low Hazard). Other than its use of incremental damage analysis, the revised USFS guidelines do not address risk analysis.

8.3.9. U.S. Fish and Wildlife Service

USFWS owns and self-regulates over 250 dams. SDF standards for these dams are based upon a combination of size and hazard classification. SDF criteria for varying size and hazard classes are as follows: all sizes of High Hazard dams (100% PMF); large, Significant Hazard dams (50-100% PMF); small or intermediate, Significant Hazard dams (50% PMF); large, Low Hazard dams (100-year to 500-year event); and small or intermediate, Low Hazard dams (100-year event). Incremental damage analysis may allow spillway capacity to be reduced, but not any lower than the 100-year flood. The Service indicated that risk-based hydrologic designs are permitted and have been used in the past.

9. Summary of Current State Hydrologic Design Guidelines

9.1. Introduction to State Guidelines

This chapter provides a summary of current state hydrologic design guidelines based on survey results, an examination of the actual guidelines, and review of prior state and federal surveys related to design flood selection. The information available from these sources was abundant, and only the most important and relevant findings are reviewed within this Chapter. Appendix C contains the completed surveys. A compilation of pertinent state regulations and guidance documents are included in Appendix E.

9.2. Origins and Status of State Guidelines

Most state dam safety officials who responded to the questionnaire indicated that their agency utilizes some sort of hydrologic design guidelines. Such guidelines are often published in the form of state administrative code, agency regulations and guidance documents, or a combination of both. Guidelines often hold the force of law. While guidelines are typically custom suited to each state and geographic region, the majority of state guidance documents draw heavily from federal dam safety regulations and design practices. The federal guidelines most commonly utilized by the states include those of FEMA, Reclamation, USACE, NRCS, and MSHA. A summary of when states adopted SDF criteria throughout the last century is shown in Figure 9.1 and shows that most states established SDF criteria prior to 1990.

In many states, dam safety guidelines are updated or revised on either a continual or recurring basis. However, of the 49 responding states, 31 indicated that they do not have any plans to update or revise their guidelines in the near future. At least 12 of the states had not updated spillway design guidelines in more than 15 years. It is noted that some states may consider altering requirements to be unfavorable due to potential cost consequences for dam owners in compliance with previous standards, potential for weakening of the overall standards due to lobbying, or the possible perception by the public that lives downstream are not worth the cost of protection.

In following with federal programs of the 1970s and 1980s, most states use a prescriptive approach to spillway design capacity. However, in the past few decades, a few states have adopted a more detailed, risk-based approach.

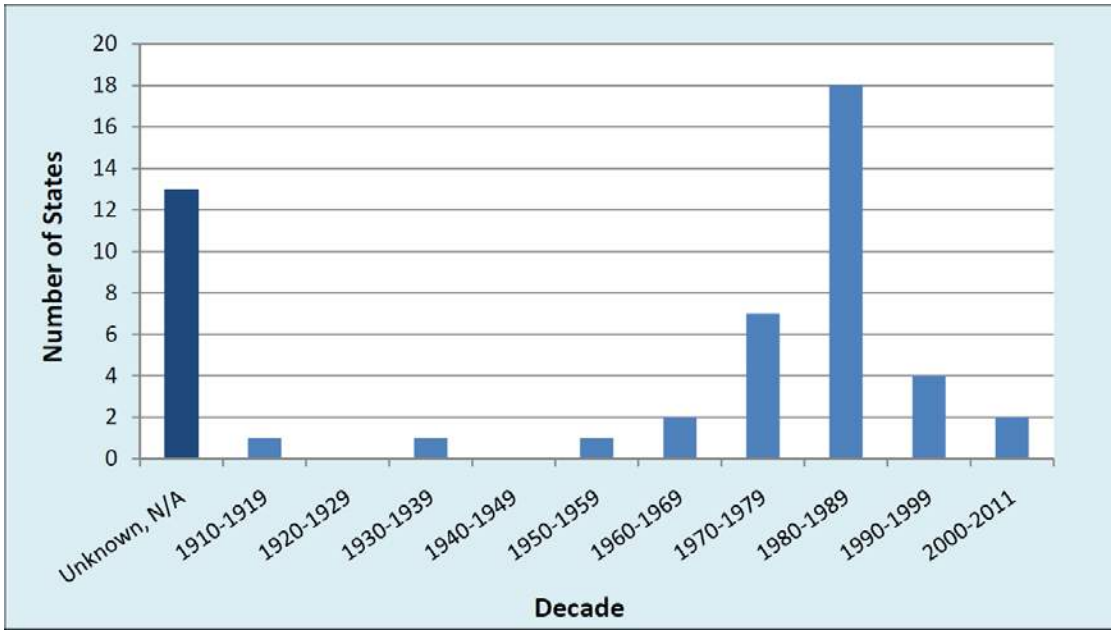

Figure 9.1 State Adoption of Spillway Design Flood Criteria by Decade

9.3. Dam Classification

States use many methods to identify and regulate dams within their jurisdiction. It appears that methods of dam classification have changed very little since the NRC's evaluation of flood design criteria in 1985. As noted in that report:

> *"There is considerable variety in the classification systems that have been adopted, and this variety often makes difficult any precise comparisons between criteria used by different agencies. Most systems for classifying dams specifically utilize dam height, volume of water impounded, and character of the development in the relevant downstream area as parameters in regard to probable effects of dam failure…*
>
> *"While it appears that many of the differences in dam classification systems are the result of arbitrary choices of regulatory authorities, it also appears that most of the classification systems have been structured to meet the perceived needs of the issuing agency or state government"* [NRC, 1985].

This broad variance of size, hazard, and other classification criteria is described in Sections 9.3.1 thru 9.3.4. Since these criteria are often used in prescribing the SDF, classification criteria is a very important aspect of the hydrologic safety of dams.

9.3.1. Regulatory Dam

The definition of a regulatory or jurisdictional dam varies greatly from one state to another. Most states determine the status of an impoundment based either loosely or entirely upon the similar

definitions outlined in both the NID and FEMA's Federal Guidelines for Dam Safety (See Section 8.2.1). A total of 92% of the states define a jurisdictional dam by considering the storage volume of the impoundment. For 88% of the states, the height of the dam is also considered. Only 27% of the states mentioned the consideration of downstream hazard potential when determining if a dam is jurisdictional. Eight percent of states regulations included the drainage area in determining the regulatory status of an impoundment.

A few exceptions were also cited in determining the status of a dam. Under these exceptions, some states have defined farm ponds, road fills that do not normally impound water, dams associated with cranberry operations, dams used for manure storage, and dams not on watercourses as non-jurisdictional structures.

In the questionnaire, respondents were asked how their agency defines a "non-inventory or non-jurisdictional" dam. It is noted that in some states these two terms are distinctly defined. These states typically maintain an inventory of many small, limited hazard dams that do not necessarily fall under their regulatory jurisdiction.

9.3.2. Size Classification

In order to prescribe design standards or other regulations related to dams, several states utilize size classification criteria. Of the 49 surveys received, 29 states indicated that they utilize some sort of size classification system (See Figure 9.2). The names, number of size categories, and range limits vary extensively throughout the country. For example, depending on the state, a small-sized dam may be identified as a Class III, Class A, Class C, or small dam.

With respect to the number of size categories, the majority of size classification systems utilized by the states have only 3 classes (typically small, medium or intermediate, and large). Six states (Georgia, Kansas, Maryland, North Carolina, Ohio, and South Carolina) use size classification systems with 4 categories (either very large or very small in addition to the typical 3-class system). Four state/territories (Montana, New York, Puerto Rico, and Wisconsin) use size classification systems with only 2 categories (typically large and small). North Dakota is the only state that indicated a size classification system with 5 categories.

Size classification of a dam is typically based upon the height of the dam, the volume of storage, or some combination or product of the two values. The height and volume ranges vary dramatically. For example, the upper limit defining a small dam range anywhere from 10 feet high to 50 feet high and 12.5 acre-feet to 10,000 acre-feet. The most common definition of a small dam is less than 40 feet high storing less than 1,000 acre-feet. The lower limit defining a large dam is also extremely varied with the height ranging between 25 to 100 feet and the storage volume ranging between 50 acre-feet and 50,000 acre-feet. The most commonly used definition of a large dam is one having a height greater than 100 feet and storage greater than 50,000 acre-feet.

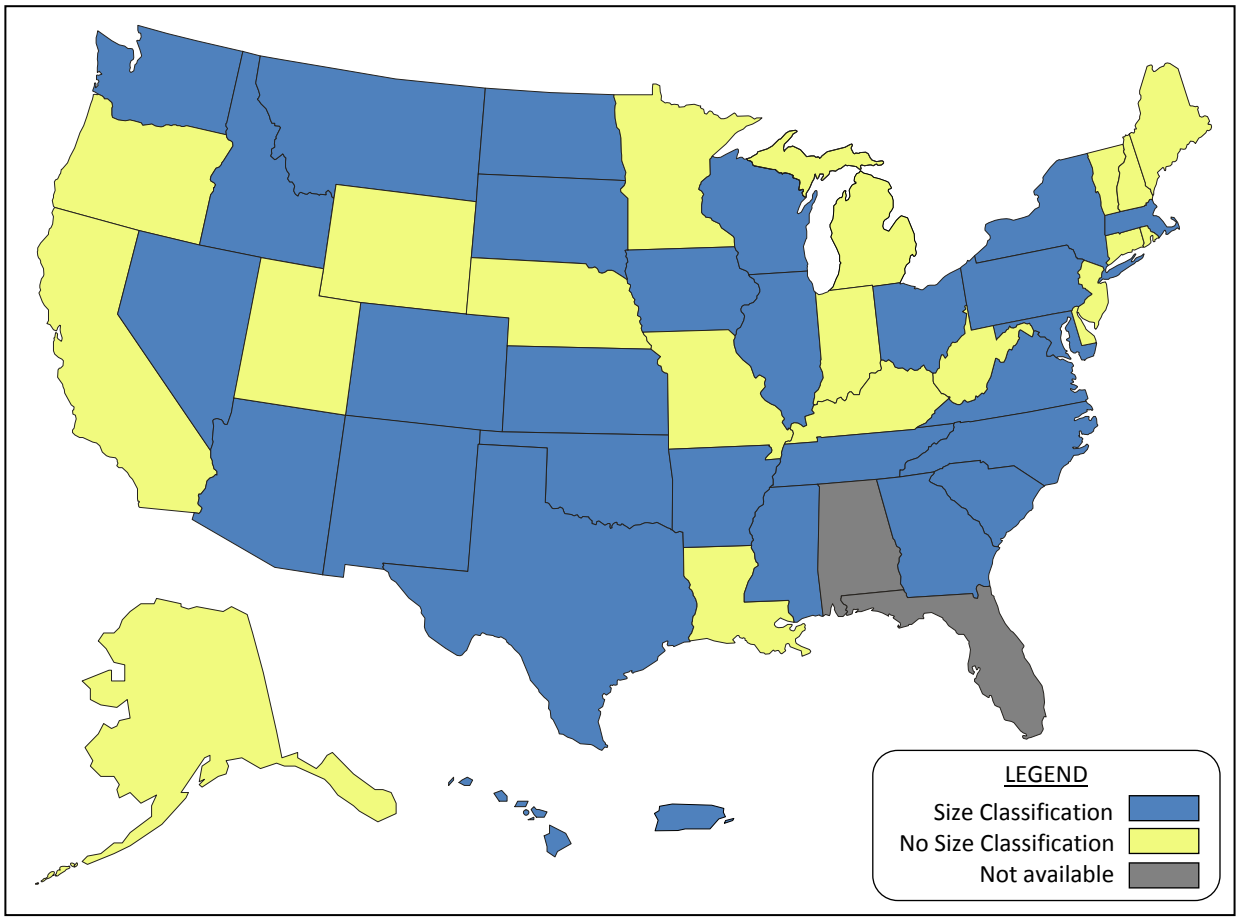

Figure 9.2 Size Classification Criteria within the United States and Puerto Rico

9.3.3. Hazard Classification

All of the states responding to the survey indicated the use of hazard classification criteria by their agency. A majority of 73% of respondents (36 states) use a three-class system consisting of high, significant, and low hazards. An additional 20% (10 states) have implemented a four-class system which typically includes a "Limited Hazard" classification below the "Low Hazard" class. Among the states using a three- or four-class system, there is a significant amount of disagreement concerning the definition of significant and high hazard dams. The key point of divergence is whether the probable loss of human life constitutes a high hazard rating. Sixty-five percent of the states have defined "Significant Hazard" as having *no potential* for loss of life, though extensive economic losses are expected. In these states, any dam creating a hazard to human life would be classified as "High Hazard." For the remaining 35% of the states, there are several ways that potential for loss of human life has been included in the definition of significant hazard. Some states define the loss of life potential as "few" or even designate a population at risk threshold for a significant hazard dam (such as 1 to 6 people or 1 or 2 habitable structures). Other states designate

that the failure or misoperation of a significant hazard dam will cause "possible loss of human life" (as opposed to "probable loss of human life" for a high hazard dam). Others state that the failure of a significant hazard dam has a "low probability" of causing loss of human life.

Georgia and Montana utilize a similar hazard classification system that is entirely based upon the likelihood of loss of human life. Dams are divided into two categories: those that will cause probable loss of life and those that will not. Connecticut is the only state to use a 5-class hazard classification system (Negligible, Low, Moderate, Significant, and High). Figure 9.3 illustrates the number of hazard classes used by each state.

9.3.4. Additional Class Distinctions

Since new spillway requirements are often more conservative, upgrading an existing dam to meet current requirements each time the criteria are changed can be costly. For this reason, many states allow a reduction of SDF or even exemption from the updated criteria for dams existing prior to adoption of the criteria. Fifty-one percent of the responding states indicated that their guidelines for new and existing dams differ. The other 49% of the states hold all dams to the same standard, regardless of when they were constructed.

In addition to distinction between new and existing dams, several states require that mine tailings and coal ash dams be held to a different design standard. Fourteen percent of the respondents stated that their guidelines include additional design criteria for such dams.

In Alaska, the protection of anadromous fish habitat has been included in the hazard potential classification system. Missouri specifies varying hazard criteria based on dam type (conventional or industrial), stage of construction, and environmental class.

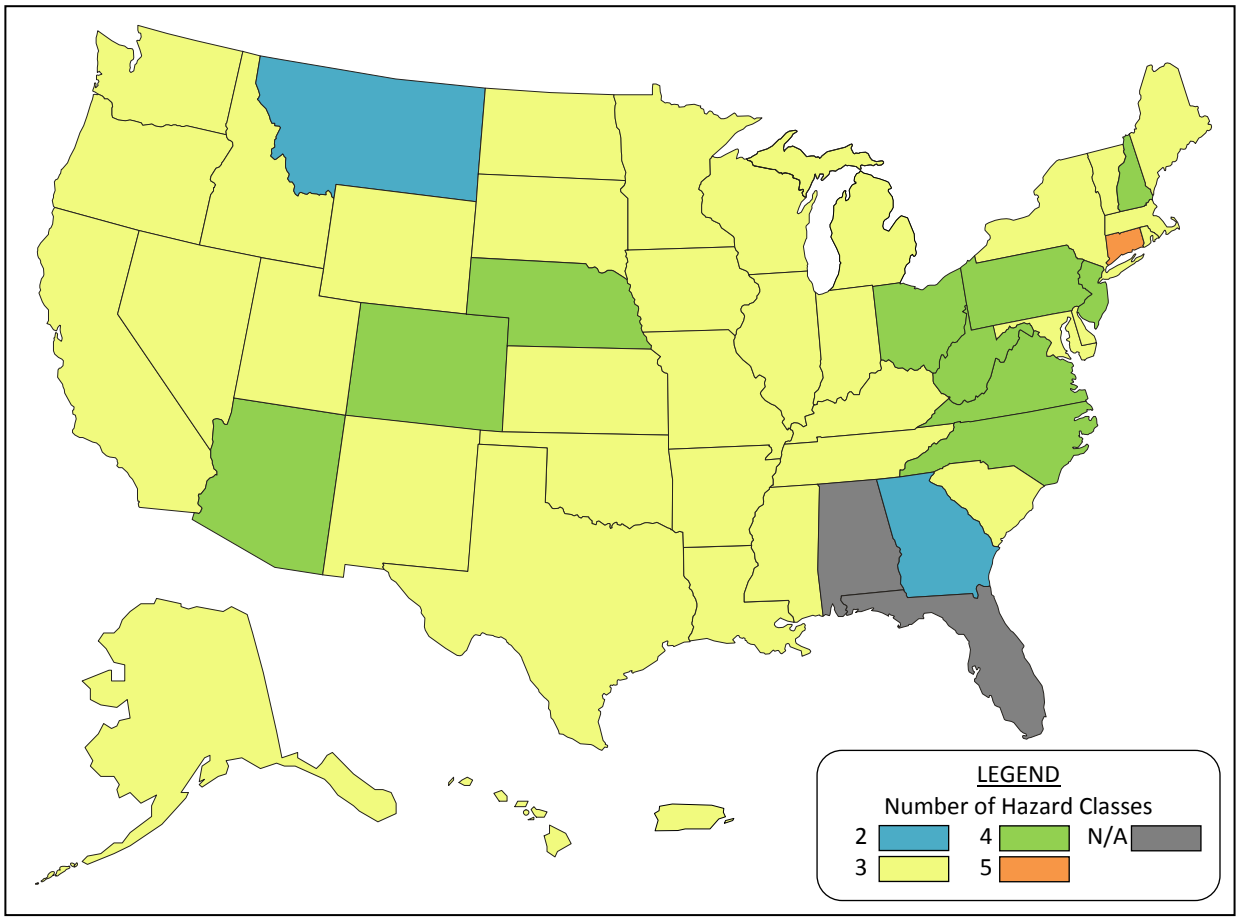

Figure 9.3 Hazard Classification Criteria within the United States and Puerto Rico

9.4. Determining the Spillway Design Flood

In determining the magnitude of the SDF, most states follow a prescriptive approach. Under a prescriptive approach, a design flood would be specified based upon the dam's classification (size, hazard, or both). Of the states using a prescriptive approach for SDF selection, most criteria are based upon either the hazard classification or a combination of size and hazard classifications. Georgia is the only state where the SDF is determined using only size classification criteria. Figure 9.4 shows a summary of each state's current approach to determining the SDF.

In the past few decades, a few states (including California, Washington, and Montana) have developed risked-based spillway design criteria. These methods are typically simpler than a rigorous risk analysis yet more complex than the typical hazard classification system. These criteria often determine the SDF using probabilistic loss of life estimates or consequence rating evaluation. The design flood in a risk-based system is often determined using a sliding scale between some lower threshold flood event and the maximum theoretical event. A few examples of such criteria are discussed in greater depth in Section 9.13 of this chapter.

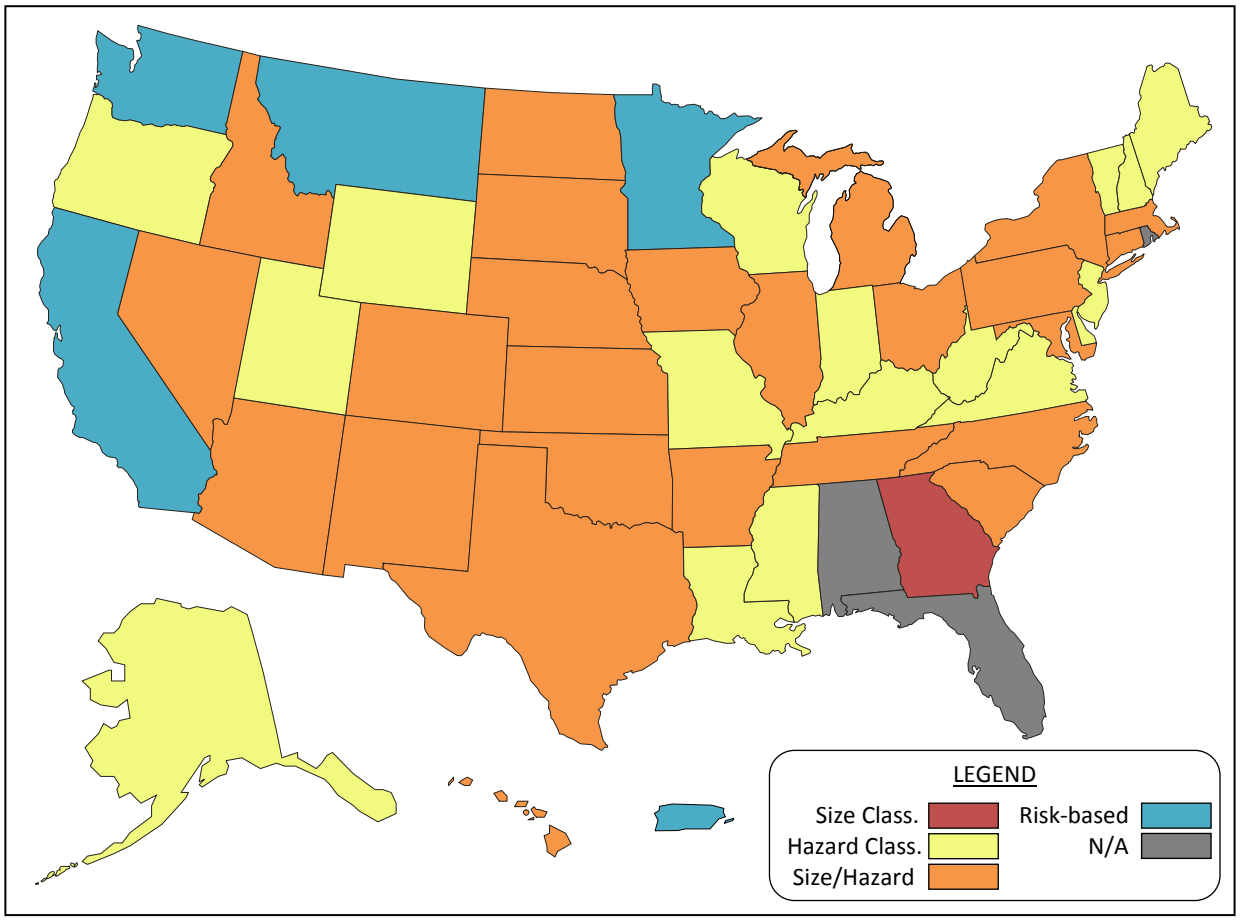

Figure 9.4 Approach to Selecting the SDF within the United States and Puerto Rico

Criteria for determining the SDF can be classified further as either probabilistic or deterministic. Probabilistic criteria are based on either floods or rainfall events which have specified probabilities or return periods. Deterministic criteria are based on PMP estimates or PMF estimates which are a derivative of the PMP. Of the states that utilize a deterministic approach, 33% define criteria with relation to the PMP while 67% are defined with relation to the PMF.

The variance in SDF criteria for new dams is significant as illustrated in Figures 9.5, 9.6, and 9.7. These figures represent the ranges of events specified by each state for low, significant, and high hazard dams. As described previously, there are many differences in the dam classification systems used by various states. In states where a High, Significant, and Low hazard rating system does not apply, classification systems were generalized to allow the comparison of SDF criteria. Also note that although probability events are shown on the figures, their plotted locations are not representative of their magnitude with relation to the probable maximum event. Tables 9-1 thru 9-3 provide additional analysis of spillway design criteria for both new and existing dams.

For new High Hazard dams, nearly half of the responding states indicated that the SDF should be no less than the probable maximum event. Eighty-two percent of the states use criteria extending up to the probable maximum event, usually dependent on size or hazard. A few states require only a fraction of the probable maximum event including Missouri (50 to 75% PMP depending on stage of construction), Colorado (45 to 90% PMP), Kansas (40% PMP), and Michigan (200-year event to 50% PMF). Wisconsin specifies that the SDF for a High Hazard dam is the 1000-year event. Idaho and Alaska specify that a SDF of 100-year magnitude is sufficient in some instances.

For new Significant Hazard dams, the range of SDF criteria is increasingly varied with acceptable design ranges stretching from the full probable maximum event down to the 100-year event. Thirteen states specify 50% of the probable maximum event as the SDF for a significant hazard dam. Several other states use the 50% mark as either an upper or lower limit.

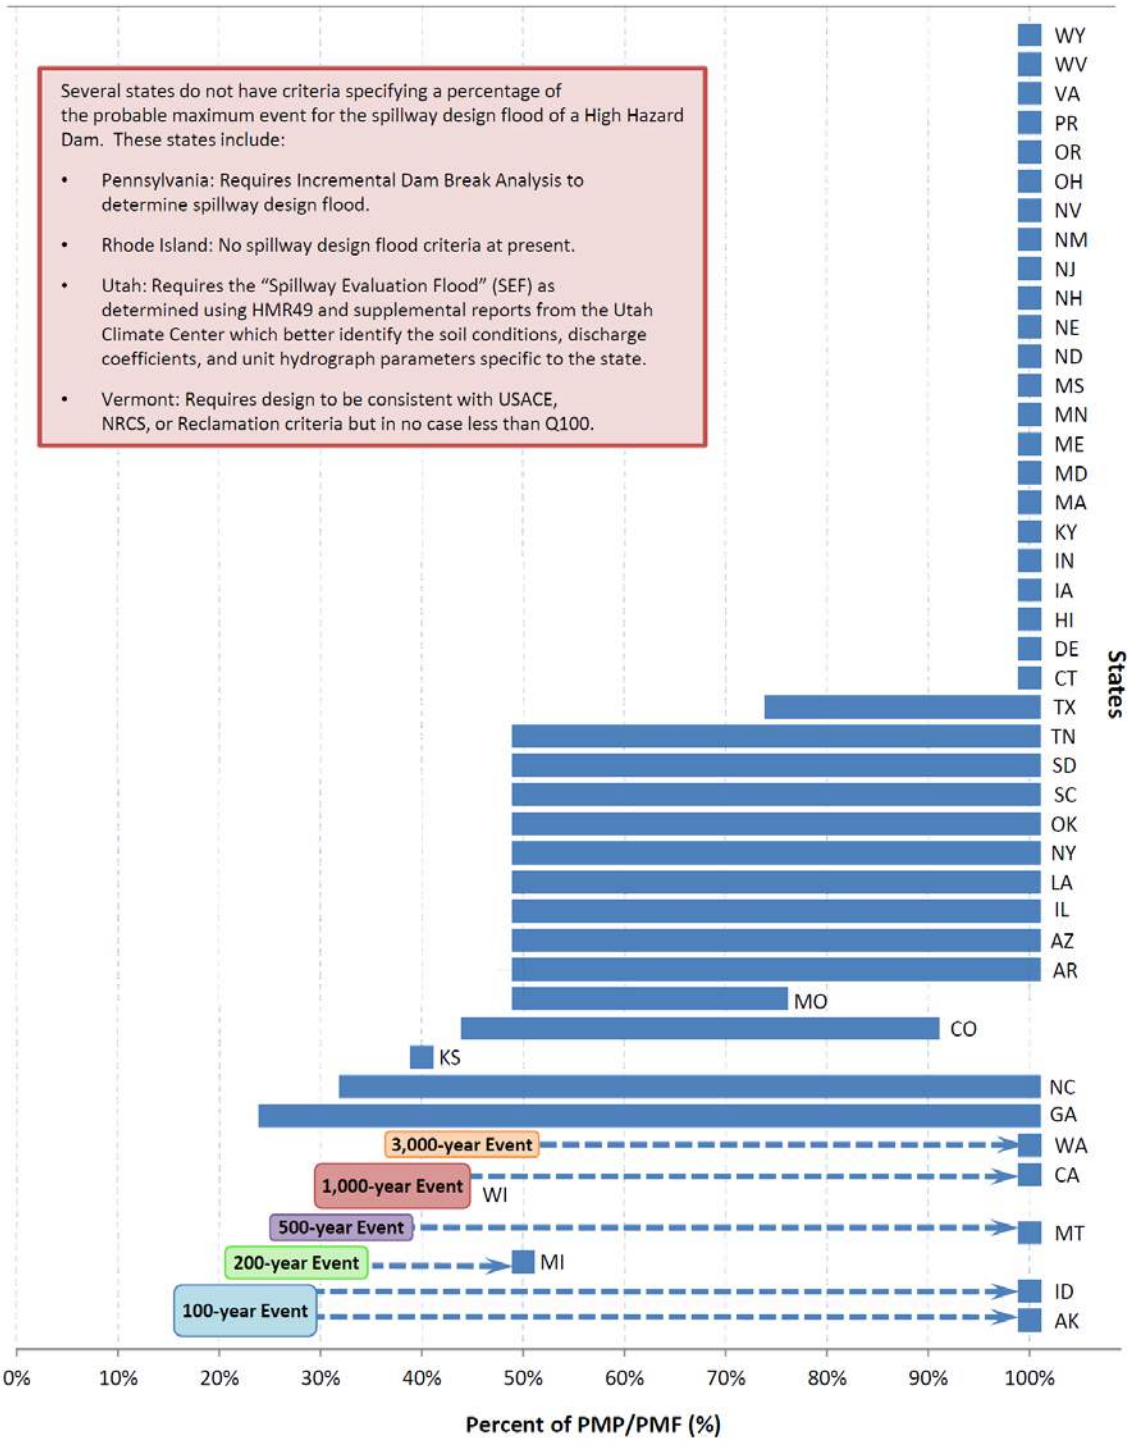
For new Low Hazard dams, 15 states specify the 100-year event for spillway design. Eight additional states specify the 100-year event as a lower design limit. Low hazard spillway design in 11 states extends down to the 50-year flood. North Dakota is the only state allowing the 25-year event as a low hazard design event. For some large, low hazard dams, South Carolina and Tennessee require that the spillway pass the full probable maximum event. California's minimum design event is the 1000-year flood.

In Colorado, the spillway design ranges shown in Figures 9.5 thru 9.7 relate to a standard design using percentage of the PMP as developed using the appropriate HMR. Colorado has also specified SDF criteria for special cases such as high elevation dams and site specific PMP studies. For dams at elevations higher than 5,000 feet above MSL, PMP estimates can be decreased by an additional 5% or more depending on elevation [Colorado DNR, 2007].

In Virginia, the past few years have seen significant changes with regard to the hydrologic safety of dams. In response to revised regulations containing stricter hazard classification criteria, a dam owner recently led an effort to pass legislation that would provide relief to existing dam owners [Zamensky, 2010]. Multiple bills were subsequently passed. Under the new laws, the maximum design storm event to be required of existing dams is 90% of the PMP (formerly 100% of the PMP). Further reduction to 60% of the PMP was also permitted if certain conditions were met. These conditions include performing daily inspections, having an approved Emergency Action Plan, and obtaining insurance in an amount that would cover all losses due to dam failure. With regards to incremental damage analysis, the new laws also reduced the allowable lower limit of the SDF from 50% of the PMF to the 100-year flood [Commonwealth of Virginia, 2010].

Overall, it appears that current state SDF criteria for all dam hazard classes are similar to those reported in 1985 by the NRC. The following observations made in 1985 are equally applicable today:

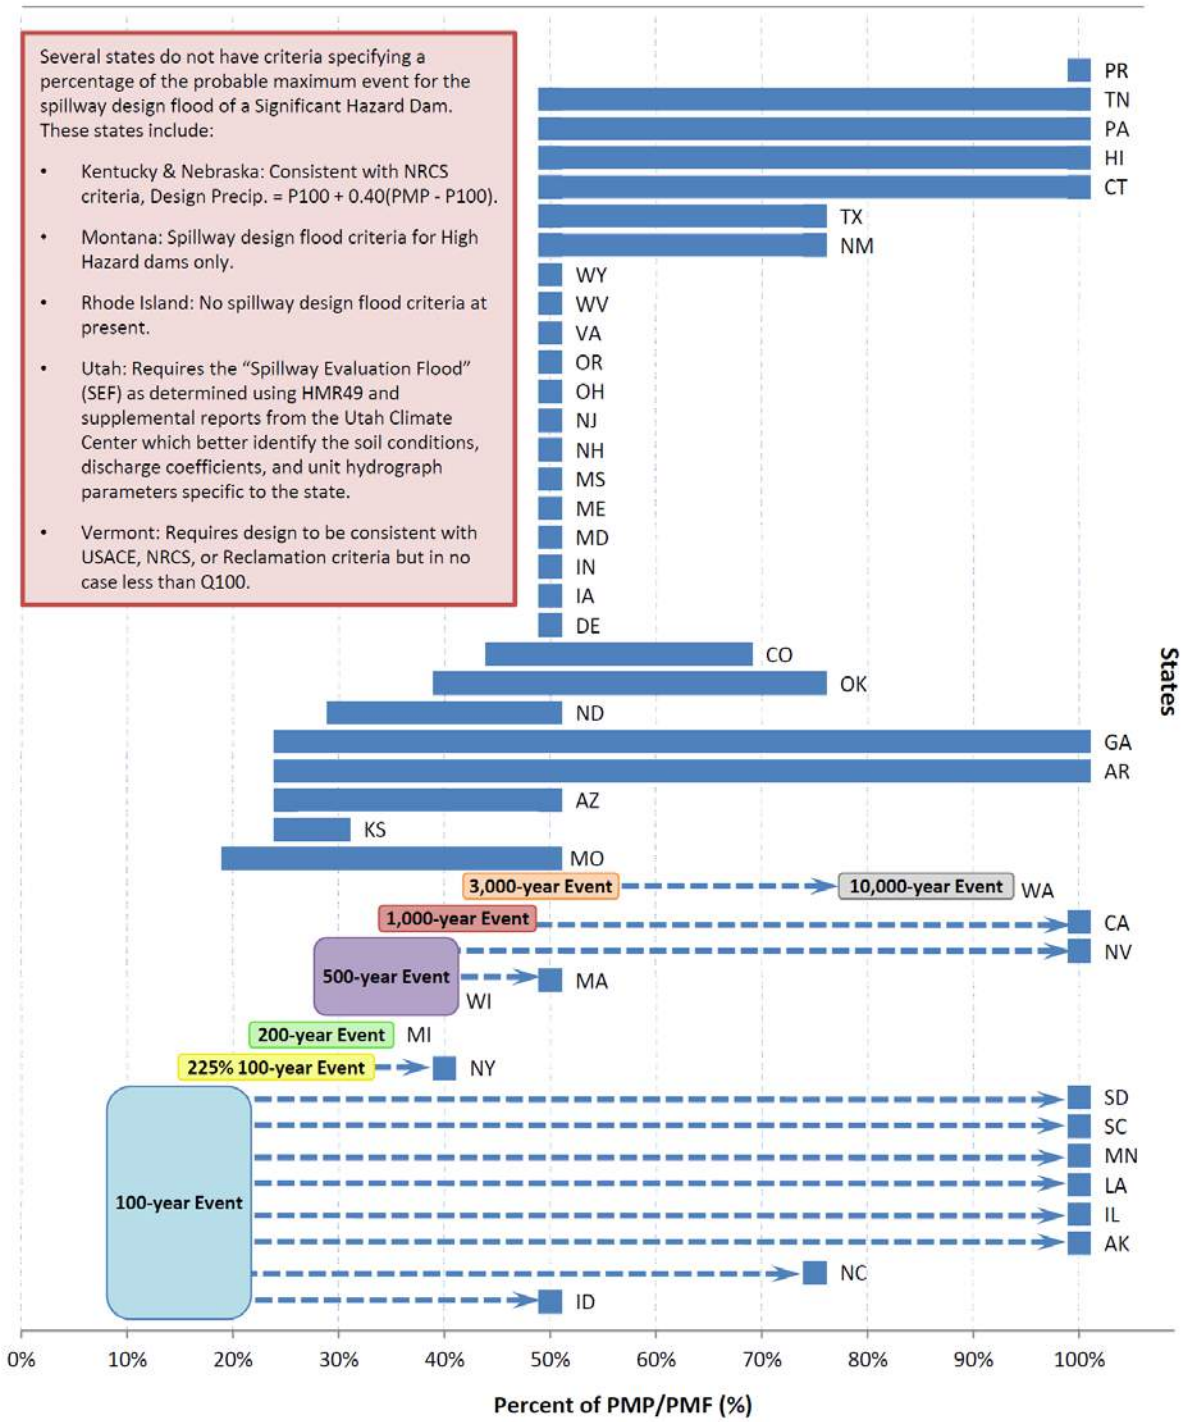
- "Use of PMP estimates for evaluating spillway capacity requirements for large, high-hazard dams predominates, although a number of state agencies have indicated that their standards do not require that such dams pass the full estimated PMF based on the PMP.



- "The influence of the practices of the principal federal dam-building agencies is evident in the majority of the standards for large, high-hazard dams, but the practices of those agencies have had less effect on current state standards for small dams in less hazardous situations.
- "Apparently as a result of the National Dam Inspection Program for nonfederal dams carried out by the Corps of Engineers in the 1977-1981 period, several state dam safety agencies have adopted the spillway capacity criteria used in those inspections.
- "Several states have adapted the standards used by the Soil Conservation Service (now NRCS) for the design of the tens of thousands of smaller dams constructed under that agency's programs.
- "Current practices include use of arbitrary criteria (such as 150 percent of the 100-year flood, fractions of the PMF, and combinations of the PMF with probability based floods) for which there is no apparent scientific rationale."

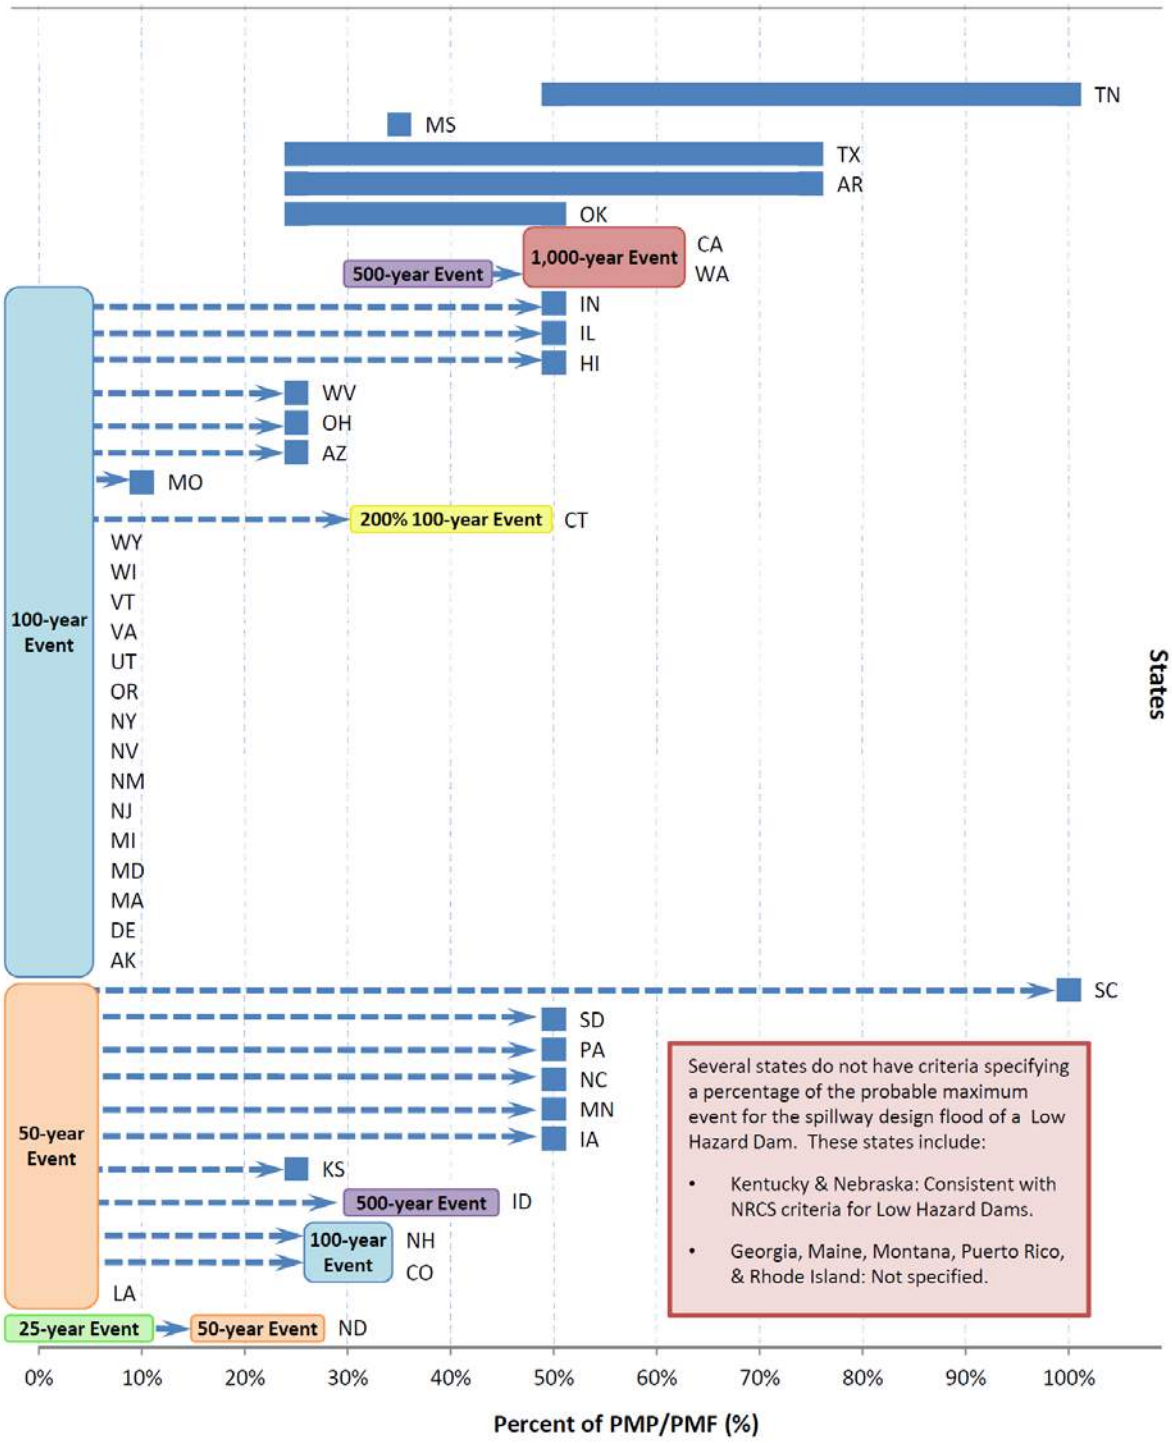
Note that the NRC's Committee on Safety Criteria for Dams questioned the use of composite criteria (combining flow frequency concepts with PMF concepts) as well as specifying percentages of the PMP, PMF, or various frequency events. "The problem with such a criterion, based on an arbitrary percentage of a derived flood or an arbitrary combination of floods developed from differing concepts, is that it permits no direct evaluation of the relative degree of safety provided." [NRC, 1985] The issue was further expounded upon in 1988 by the ASCE Task Committee on Spillway Design Flood Selection who stated:

> *"Studies by the National Weather Service indicate that the occurrence of a storm producing PMP is not equally probable nationwide. Thus, using a fraction of the PMF results in selecting a safety design flood which varies widely in exceedance probability… As long as the PMF is used to define a probable upper limit to flooding for use in a safety design, this is not a major concern. The exceedance probability of the PMF, assuming it is correctly defined, is essentially zero. When selecting a safety design flood less than the PMF, use of a fraction of the PMF produces a variation in exceedance probability that results in an inconsistent national safety standard"* [ASCE, 1988].



In light of technological advances which aid in calculating and assessing failure consequences, the ASCE Committee continued on to also question the practice of grouping dams based on size except for "projects too small and damages too low to warrant the expense of a specific failure analysis" [ASCE, 1988].

Although these concepts were disputed by experts in the mid- to late-1980s, the majority of state dam safety agencies continue to utilize such criteria multiple decades later. The NRC Committee did recognize that regional differences in climate, geography, and urbanization could justify differences in spillway design criteria. However, they also noted that not all criteria "could be efficient in limiting risks of dam failures to acceptable limits or in protecting the public interest" and recommended that more uniform approaches to specifying spillway capacity be considered.



Note: For probability events (such as the 100-year flood), the corresponding percentage of the probable maximum event varies significantly in different areas of the country. The plotted location of probability events do not, therefore, represent the corresponding PMP/PMF percentage.

Figure 9.5 Range of Spillway Design Flood Criteria for New High Hazard Dams

Note: For probability events (such as the 100-year flood), the corresponding percentage of the probable maximum event varies significantly in different areas of the country. The plotted location of probability events do not, therefore, represent the corresponding PMP/PMF percentage.

Figure 9.6 Range of Spillway Design Flood Criteria for New Significant Hazard Dams

Note: For probability events (such as the 100-year flood), the corresponding percentage of the probable maximum event varies significantly in different areas of the country. The plotted location of probability events do not, therefore, represent the corresponding PMP/PMF percentage.

9.5. Storm Duration and Distribution

Thirty-seven percent of the states do not specify design storm duration within their hydrologic design guidelines. Of the 63% that do provide specific guidance regarding storm duration, it is typical to base the duration on the watershed's time of concentration or consider durations ranging from 6 hours to 72 hours. It should be noted that time of concentration is not the only determining factor in selecting the appropriate storm duration. For example, a reservoir with a large amount of available storage may not be significantly impacted by a short duration storm. A longer duration event yielding a larger volume of runoff could, therefore, govern the hydrologic design. Caution should be used when applying limiting or specific design criteria. Such criteria should allow for deference to a competent design engineer. The respondent in Alaska noted that hydrologic design criteria have specifically been excluded from their regulations to allow engineers to develop reasonable designs.

For the temporal distribution of the design storm, 57% of the states do not provide guidance. Of the 43% that do define the temporal distribution, about half indicate that the HMRs published by the National Weather Service should be used. Other commonly used temporal distributions include those developed by the NRCS as well as regional or custom distributions developed by the states.

One respondent noted that the duration and temporal distribution of a rainfall design event can have considerable impact on the required hydrologic design of a dam. Prior to 2005, the NRCS 6-hour design storm distribution was the basis for design of NRCS dams. The 6-hour rainfall amount and storm distribution has been used by the NRCS for over 50 years to set the top of dam and spillway requirements and is well established. Longer storm durations were considered only if the time of concentration exceeded six hours or the contributing drainage area exceeded 100 square miles. For dams with contributing drainage areas exceeding 100 square miles, the NRCS recommended that individual watershed PMP studies be performed by the NWS to take into account orographic features that are smoothed in the generalized precipitation studies.

In 2005, the NRCS revised TR-60 to require the analysis of both the 6-hour and 24-hour duration with the most critical results used for checking the discharge capacity and the integrity of the auxiliary spillway. It should be noted that although the 6- and 24-hour PMP rainfall amounts are obtained from NWS Hydrometeorological Reports, the rainfall distributions presented in TR-60 are used by the NRCS rather than the rainfall distributions presented in the hydrometeorological reports. For example, in the eastern United States, the rainfall distribution for the 24-hour duration PMP storm is not the same "critically stacked" rainfall distribution obtained using HMR-52, as it does not include critically stacking shorter duration rainfalls within the peak 6-hour rainfall. The NRCS approach to constructing the 24-hour storm is to critically stack incremental rainfall amounts of successive 6-, 12- and 24-hour durations, but distributing each 6-hour PMP depth uniformly over each six-hour period. This distribution is referred to by the NRCS as the 5-point storm distribution. The aforementioned 24-hour rainfall distribution was adopted primarily for checking the integrity

of the auxiliary spillway since it produces a greater runoff volume and longer spillway flows as compared to the 6-hour PMP storm.

A comprehensive discussion of temporal rainfall distributions for near PMP storm events for design of NRCS dams is presented in a paper by James N. Moore et al. (2001). Based on an evaluation 72 NRCS dams, use of the 24-hour 5-point rainfall distribution would require 54 percent of the dam heights to increase with 61 percent within plus or minus one foot of the 6-hour design criteria. The HMR-52 rainfall distribution would require 97 percent of the dam heights to increase with 47 percent within plus or minus one foot of the 6-hour design criteria.

Montana and Washington have developed regional precipitation-frequency analyses to determine the return period of extreme events [Fischer & Lemieux, 2010; MGS Engineering Consultants, Inc., 2009]. Nebraska has had a site-specific PMP study performed for the entire state which resulted in PMP reductions ranging from 3 to 56 percent [Applied Weather Associates, 2008].

The majority of states do not provide guidance regarding the spatial distribution of a storm. The few states that do include it in their guidelines indicate that spatial distribution should only be used in cases where the drainage area is greater than 10 square miles.

9.6. Antecedent Moisture Conditions and Initial Reservoir Pool Levels

In developing the SDF and designing the dam, initial assumptions such as antecedent moisture conditions (AMC) and the initial reservoir pool level can have a significant impact on the results. Twenty-nine of the forty-nine states (59%) surveyed do not specify or provide direction regarding either of these variables in their guidelines. Of the states that do specify antecedent moisture conditions, most use either SCS AMC-II or AMC-III criteria. Several states also have specific directives regarding the consideration of snowmelt and frozen ground conditions.

For initial reservoir pool level criteria, most states specify that normal water surface elevation be used as an initial routing condition. Others specify similar criteria such as the “lowest uncontrolled spillway inlet” or “at the crest of the spillway for permanent water storage.”

9.7. Freeboard Requirements

For a PMP/PMF design, 37% of the surveyed states do not require freeboard above the peak PMP/PMF reservoir level. The remaining states use many varying criteria based on dam type, wave run-up calculations, dam size or hazard classification, and case-by-case evaluations. The following comments from survey respondents illustrate several of these varying criteria:

- Oklahoma – “Minimum freeboard varies from 1 to 3 feet based on both hazard and size classification.”

- Illinois – Freeboard is determined on a "case-by-case basis considering many factors including duration of high water levels during the design flood, the effective wind fetch and reservoir depth available to support wave generation, the probability of high wind speed occurring from a critical direction, the potential wave run up based on roughness and slope, and the ability of the dam to resist erosion from overtopping waves."
- Iowa – "For dams with emergency spillways, the top of dam elevation after settlement shall not be less than the highest peak pool elevation reached during the freeboard design flood. For dams without an emergency spillway, the top of dam elevation shall be 2 feet higher than the peak flood elevation expected to occur during passage of the freeboard design flood, unless it is specifically designed to withstand the overflow."
- Nevada – "'Rule of thumb' is 3 feet. Wave run up calculations are preferred and required if the owner is requesting a smaller freeboard. Exceptions are tailings facilities for deposition (beach) side embankments and Storm Water detention facilities."
- Colorado – "The minimum freeboard requirements for new or enlarged dams shall be based upon the dam height required to prevent overtopping by wave action, or the sum of the IDF maximum water surface level plus 1 foot of residual freeboard, but not less than 5 feet unless the State Engineer approves a lesser amount. Except for concrete dams where the design engineer has demonstrated that overtopping of the dam will not be detrimental to the safety of the dam, the IDF can be accommodated with zero residual freeboard or the overtopping depth at which the dam still meets the stability and stress requirements of Rule 5.9.5."
- Georgia – Based on wave run up computations with a "3-foot maximum."
- New York – "One foot minimum for small dam, 2 foot minimum for large dam."

This sampling of criteria as well as the large percentage of states that do not require freeboard demonstrates the variation that exists in current freeboard criteria. It is also apparent that there is a significant variation in the level of detail required for freeboard analysis among the states.

9.8. Applicable Methodologies and Software

The majority of state agencies will allow the use of any analysis methodologies, procedures, or computer software as long as results are verifiable and applied using good engineering practice. There are, however, several states which stipulate a specific methodology (i.e. using HMRs to develop the PMP) or approved computer software (i.e. HEC applications, NWS DAMBRK, SITES, etc.). The states of Mississippi, New York, and Pennsylvania specifically do not allow the use of the rational method in any case.

9.9. Provisions for Future Development

One common issue faced by regulatory agencies is development both upstream and downstream of existing dams. Development within a watershed can cause increased runoff and peak inflows higher than those used to design a dam. In some cases, development extends into the flood pool of a structure which poses a risk to those developments.

The development of an area downstream of a dam often causes a condition called "hazard creep." Low or significant hazard dams which are oftentimes built in rural areas are reclassified as high hazard dams due to development that occurs after construction of the dam. These reclassified dams are then subject to increasingly conservative design standards and usually need to be upgraded to pass flood events of a greater magnitude.

Figure 9.8 illustrates the percentage of states that specifically require consideration of future development when determining the SDF. Note that 22 states (45%) do not require the designer to consider upstream or downstream development when designing a dam, and only 6 states (12%) require the consideration of development upstream of the dam. Sixty-nine percent of states surveyed felt that hazard creep due to development was a problem, though only twelve percent considered it a major problem.

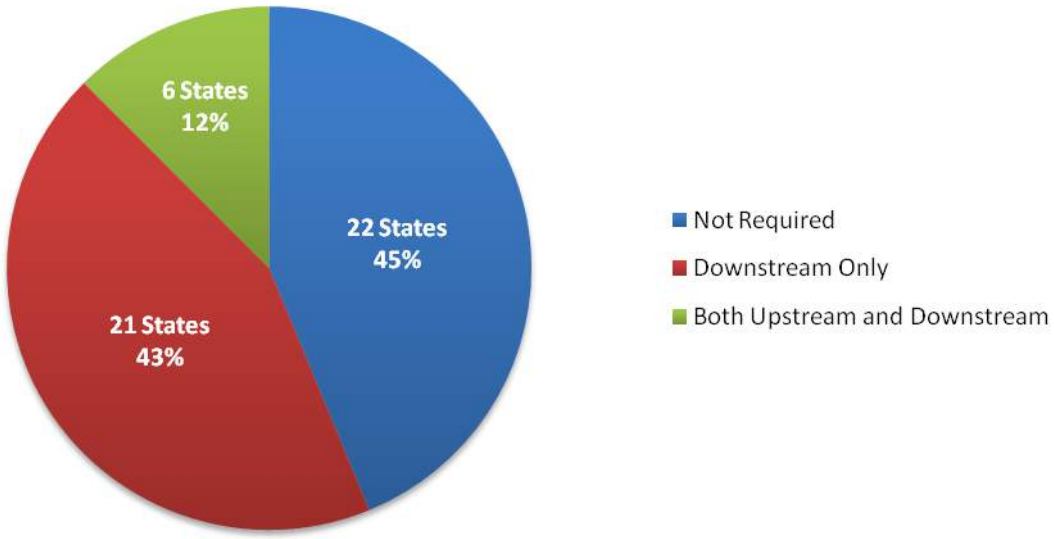

Figure 9.8 Consideration of Future Development for Spillway Design Flood Criteria

In Illinois, Delaware, and New Jersey, all Low and Significant Hazard dams must incorporate alternatives in the proposed design for increasing the total spillway capacity if the downstream hazard potential increases. Future downstream land use, land use controls, and growth projections are considered in the review of the spillway capacity design.

9.10. Early Warning Systems

When asked if an early warning system would be considered as an alternative to designing a high hazard dam for the regulatory SDF, the majority of states indicated that such an alternative would not be acceptable. Many noted that a safe design should be passive and not require significant maintenance or operation. Of the 10 states that would consider this as a viable alternative, most

required significant justification and additional protective measures to be included with the early warning system. Most of these agencies would only consider this as an alternative for existing dams or as a temporary solution until structural modifications are made.

In 1995, Dubler asked state dam safety officials a similar question and found that about 15 states would allow the use of an early warning system on a case-by-case basis. This indicates a slight trend away from the use of these systems over the past 15 years.

9.11. Incremental Damage Analysis

As described in Chapter 3, incremental damage analysis is a comparative hazard approach that creates a compromise between the desire to provide a risk-based analysis of the benefits gained from mitigating the hazard and the traditional approach of requiring a design capable of safely passing the PMF. Of the responding states, 67% indicated that they allow the use of incremental damage analysis to establish the SDF (See Figure 9.9). A few allowed this type of analysis only in evaluating existing dams. Of those who allow incremental damage analysis, less than half require that future downstream conditions within the dam failure inundation zone be considered in the incremental damage analysis.

It is interesting to note that in the survey performed in 2003 by Paxson and Harrison, 88% of survey participants responded that their state would allow incremental damage analysis as opposed to 65% in 2011. The reason for this discrepancy is unknown; however, the 2011 response seems to correspond more closely to Dubler's 1995 survey in which 59% of respondents indicated that incremental damage analysis was utilized. In any case, it appears that the use of incremental damage analyses has become more common in the past decade.

Since incremental damage analysis is typically used to decrease the SDF, some states place a minimum limit on the SDF regardless of downstream consequences. Eighteen states indicated that they have restrictions or guidelines on the use of incremental damage assessments or risk analyses. Table 9-4 summarizes most of these criteria.

While most states perform incremental damage analysis in the downstream dam failure inundation zone to establish the magnitude of the SDF, some have also applied the concept to the mitigation of flooding due to spillway discharge. This would apply in situations where gate operators or fuse plugs provide the dam owner some control over spillway discharge. In Arizona, spillways are required to be constructed in a manner that avoids flooding in excess of that which would have occurred under the same conditions before construction. Other states have expressed similar interest in regulating flooding due to spillway discharge.

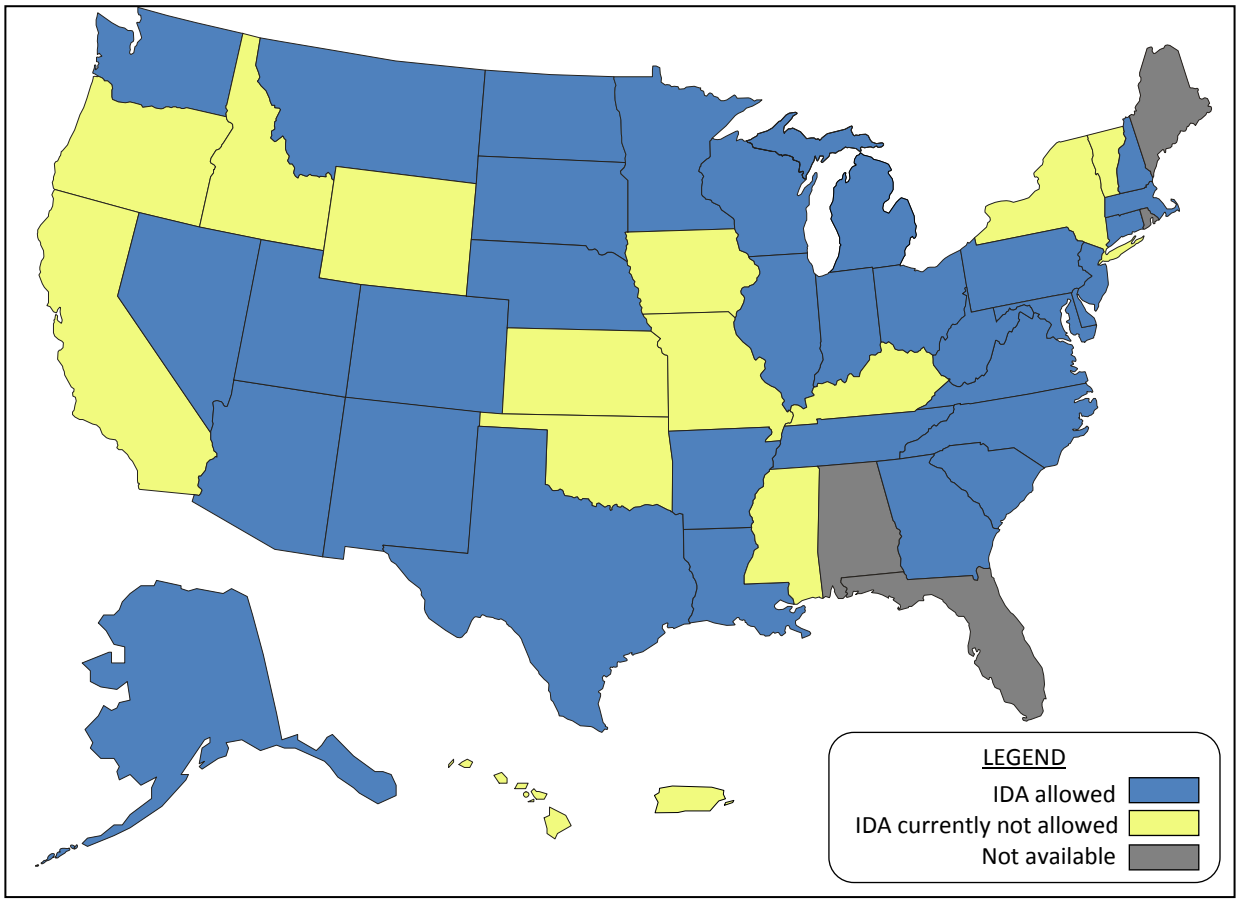

Figure 9.9 Use of Incremental Damage Analysis in the United States and Puerto Rico

Table 9-4 Minimum Design Event when Incremental Damage Analysis is Applied

Criteria	States Using this Criteria
Minimum SDF: 100-year flood (High and Significant Hazards); 50-year Flood (Low Hazard)	VA
Minimum SDF: 100-year frequency flood or storm event	AK, CO, DE, IL, NC, NJ, NM, NV, PA, SD, UT
Minimum SDF: 200-year flood or flood of record, whichever is greater	MI
Minimum SDF: 40% PMF (High Hazard); 20% PMF (Significant Hazard); 100-year flood (Low Hazard)	OH
Minimum SDF: 50% PMP (High Hazard); 100-year flood (Low Hazard)	IN
Minimum SDF: 70% PMP (High Hazard); 25% PMP (Significant Hazard); P100 (Low Hazard)	WV
SDF can only be reduced by up to 10%	GA

9.12. Provisions for Developing Site Specific PMP

The practice of developing a site specific PMP for a dam design is allowed in 32 states (65%). It is restricted in 6 states (12%). Permission to perform a site specific study in the remaining 11 states (22%) has never been requested (See Figure 9.10). It is important to note that of the 32 states allowing site specific PMP studies, more than half (17 states) have no guidelines, requirements, or restrictions regarding this practice.

Those that do have guidelines, requirements, or restrictions utilize a variety of criteria. Several states require a site specific design to pass through special levels of review or even be overseen by a board of consultants. Mississippi will only consider a site specific study if the drainage area is greater than 10 square miles. New Jersey only allows the use of site specific PMP's for existing structures. Colorado has a completely separate requirements matrix for site specific analyses. Using this guideline, a dam is required to pass a higher percentage of the site specific PMP/PMF than is required if the SDF has been developed following the HMR approach.

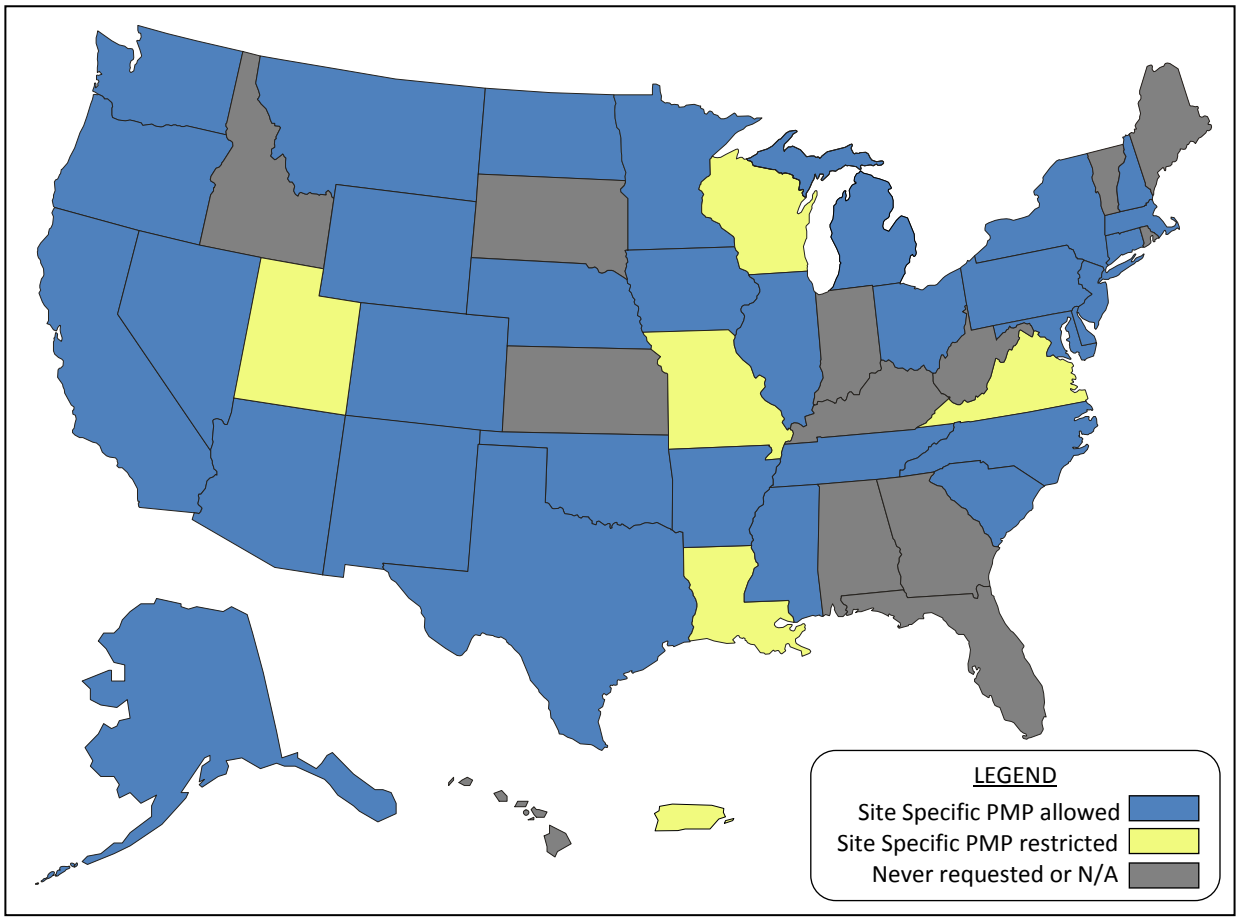

Figure 9.10 Use of Site Specific PMP Studies in the United States and Puerto Rico

9.13. Risk-based Criteria

Within the 1988 report published by ASCE, the Task Committee on Spillway Design Flood Selection concluded that the only standard which "could be applied consistently both today and in the future would be a selection based upon a site-specific evaluation of the likelihood of failure and the social, economic, and environmental consequences of failure – a quantitative risk assessment. A quantitative risk assessment provides the decision maker at each level of the decision making process – the engineer, the dam owner, and the regulator – with the information needed to select a safety design flood" [ASCE, 1988]. States tend to look toward the federal agencies to initiate changes in regulations, and the majority of federal agencies have made policy shifts toward the use of risk analysis (See Chapter 8). The level of acceptance continues to be greatly varied. It appears that the Bureau of Reclamation has fully embraced the use of quantitative risk analysis for the hydrologic design of dams. Several other state and federal agencies are taking a more gradual approach to adopting risk-based designs. In these agencies, the use of incremental damage analysis is a common way to introduce components of risk analysis into design criteria. It should be noted that the establishment of any guidelines introduces some sort of risk assessment. States that currently base dam design standards on size or hazard classification systems are effectively performing very generalized and informal risk analysis.

9.13.1. Current Use of Risk-based Criteria by the States

Of the 49 states surveyed, 15 (31%) indicated that they permit or review risk-based designs. Seven states (14%) indicated that risk-based designs are either forbidden by regulation or will not be considered due to administrative decision. The remaining 27 states (55%) indicated that their regulations do not specifically address the topic of risk analysis and it has never come up for consideration.

The same question regarding risk-based hydrologic designs was asked in Dubler's survey. In 1995, 43% indicated that they either permitted or reviewed risk-based designs on a case-by-case basis. The 2003 survey by Paxson and Harrison also indicated that 43% of states would allow the use of risk-based analysis. This decrease indicates that over the past decade, a number of states have stopped allowing the use of risk analysis. Chapter 10 provides a discussion of several trends which may have caused this reduction in the allowance of risk analysis.

In contrast to the current trend, a few states have dedicated significant resources over the past 30 years to develop risk-based design criteria for dams. Generally speaking, these risk-based guidelines do not comprise rigorous or quantitative risk analysis. Rather, they incorporate both principles of risk with some sort of hazard classification or consequence rating system. The design flood in a risk-based system is often determined using a sliding scale between a lower threshold flood event and the maximum theoretical event. California, Washington, and Montana each have unique risk-based criteria for the hydrologic design of dams.

9.13.2. California

In 1981, the State of California became the first state to adopt a risk-based methodology that could be applied to any spillway in the state [Calzascia & Fitzpatrick, 1987]. One challenge of devising such a method is that it must be able to be applied both rationally and consistently across a broad range of dam types and sizes. Under this methodology, a dam's hazard classification is determined by considering reservoir capacity, dam height, estimated number of people evacuated in anticipation of failure, and potential downstream damage.

> *"Each factor is categorized as low, moderate, high or extreme. The method produces a composite numerical rating termed the Total Class Weight (TCW)… With this system, small remote dams generally have a TCW of 2, while large urban dams might have a TCW of 36. The capacity of the reservoir and height of the dam are clearly defined. Estimated evacuation and potential downstream damage are uncertain and require an investigation of the potentially flooded area. This investigation includes estimating the population at risk, the possible loss of life, the physical property damage, the social consequences and the environmental impact. Through application to the many dams under its jurisdiction, [California's Division of Safety of Dams] has developed a coherent and uniform approach to conducting the damage investigations so that consistent total class weights are found"* [Calzascia & Fitzpatrick, 1987].

Figure 9.11 illustrates the weighting system used in California to determine the TCW. California considers the TCW criteria as an adequate assessment of risk; therefore, they do not allow the use of quantitative risk analysis. Once the TCW has been determined, the appropriate design storm is selected.

> *"The minimum allowable design event required is a 1000 year storm which corresponds with a TCW of 4. The maximum event is a storm derived from the Probable Maximum Precipitation and is equated with a TCW of 30. The design event is interpolated between these limits at the computed TCW"* [Calzascia & Fitzpatrick, 1987].

By applying these risk-based criteria, less than 8% of California's dams are required to pass the full PMF [Calzascia & Fitzpatrick, 1987].

DAMAGE POTENTIAL CLASSIFICATION FOR

FLOOD ESTIMATE AND SPILLWAY ANALYSIS

Name of Dam _____ Type of Dam _____Dam No. _____

County _____ Located on _____

	Damage Potential Rating			
	Extreme	High	Moderate	Low
Capacity _____ AF	100,000 & Over	1,000-99,999	100-999	15-99
(circle weight)	6	4	2	0
Height _____ Ft.	150 & Over	100-149	50-99	6-49
(circle weight)	6	4	2	0
Estimated Evacuation _____	1,000 & Over	100-999	1-99	None
(circle weight)	12	8	4	0
Potential D/S Damage	High	Moderate	Low	None
(circle weight)	12	8	4	0

Total Class Weight _____

Figure 9.11 Total Class Weight and Hazard Potential Classification in California [Calzascia & Fitzpatrick, 1987]

9.13.3. Washington

In 1990, Washington State adopted an approach to dam safety that "can be characterized as employing risk concepts in a standards-based framework" [Johnson, 2000]. The state's approach utilizes what it calls the "Design Step Format." Under this format, a range of failure consequences are divided into 8 steps. For Design Step 1, the annual exceedance probability of the design event is 1 in 500. This step would apply "when the downstream consequences of a dam failure would be minimal and there would be no potential for loss of life" [Washington State Department of Ecology, 1993]. In situations where the consequences of failure would be "catastrophic," the theoretical maximum design event (PMP/PMF) is applied under Design Step 8. This maximum theoretical event is assumed to have an annual exceedance probability of 10^{-6}. In order to utilize probability-based hydrologic events, Washington has performed regional precipitation-frequency analyses to determine the return period of extreme events.

Table 9-5 outlines the range of consequence rating points assigned to several hazard indicating parameters. Using a cumulative total of consequence rating points, the designer can determine both the design step and the required annual exceedance probability for design as shown in Figure 9.12. This annual exceedance probability will apply to all aspects of the dam design (hydrologic, seismic, etc.) in an effort to provide "balanced protection." Table 9-6 relates the Washington State's design step criteria to typical downstream hazard classifications.

By adopting this approach to dam safety, the state has been able to apply risk concepts in a format that is fairly simple and easy to use. A similar ranking system has been applied to evaluate existing dams, thus allowing a prioritization of compliance efforts. "Of the 46 dams inspected under the National Dam Inspection Program still listed as unsafe in 1990, 40 had been repaired by 1999 [under this standard]. In addition, 78 of the 101 additional dams identified by the state dam safety program since 1985 have been repaired" [Johnson, 2000].

Table 9-5 Numerical Rating Format for Additive Weighting Scheme for Assessing Consequences of Dam Failure [Adapted from Washington Department of Ecology, 1993]

Consequence Categories	Consequence Rating Points	Indicator Parameter	Considerations
CAPITAL VALUE OF PROJECT	0 – 150	DAM HEIGHT	Capital Value of Dam
	0 – 75	PROJECT BENEFITS	Revenue Generation or Value of Reservoir Contents
POTENTIAL FOR LOSS OF LIFE	0 – 75	CATASTROPHIC INDEX	Ratio of Dam Breach Peak Discharge to 100-Year Flood
	0 – 300	POPULATION AT RISK	Population at Risk Potential for Future Development
	0 – 100	ADEQUACY OF WARNING	Likely Adequacy of Warning in Event of Dam Failure
POTENTIAL FOR PROPERTY DAMAGE	0 – 250	ITEMS DAMAGED	Residential and Commercial Property
		OR	Roads, Bridges, Transportation Facilities
		SERVICES	Lifeline Facilities Community Services
		DISRUPTED	Environmental Degradation from Reservoir Contents (Tailings/Wastes/etc.)

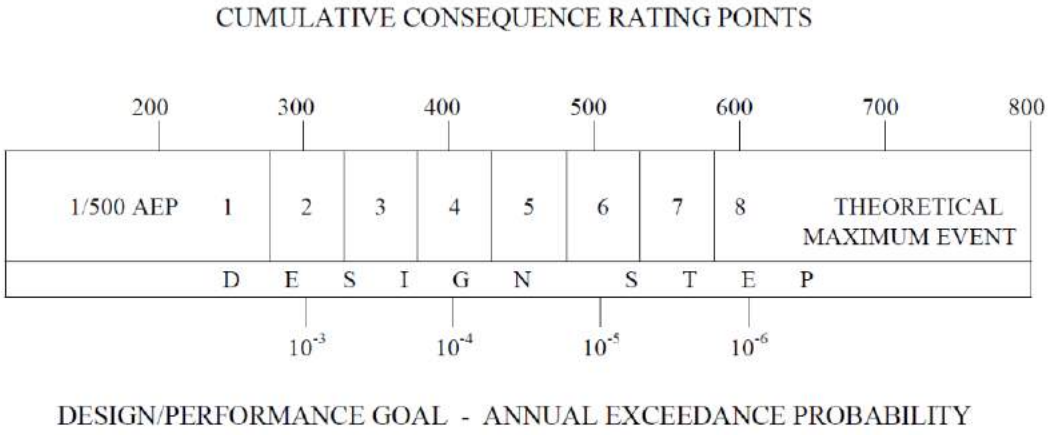

Figure 9.12 Design Step Format and Consequence Rating Points [Washington Department of Ecology, 1993]

Table 9-6 Relationship of Design Step to Downstream Hazard Classification [Adapted from Washington Department of Ecology, 1993]

Downstream Hazard Potential	Downstream Hazard Classification	Population at Risk	Economic Loss	Environmental Damages	Typical Design Step
LOW	3	0	Minimal: No inhabited structures; Limited agriculture development.	No deleterious materials in reservoir	1 – 2
SIGNIFICANT	2	1 to 6	Appreciable: 1 or 2 inhabited structures; Notable agriculture or work sites; Secondary highway and/or rail lines.	Limited water quality: Degradation from reservoir contents and only short term consequences	3 – 4
HIGH	1C	7 to 30	Major: 3 to 10 inhabited structures; Low density suburban area with some industry and work sites; Primary highways and rail lines.	Severe water quality: Degradation potential from reservoir contents and long term effects on aquatic and human life	3 – 6
HIGH	1B	31 to 300	Extreme: 11 to 100 inhabited structures; Medium density suburban or urban area with associated industry; property and transportation features.		4 – 8
HIGH	1A	More than 300	Extreme: More than 100 inhabited structures; Highly developed, densely populated suburban or urban area with associated industry, property, transportation, and community life line features.		8

9.13.4. Montana

Prior to 1999, Montana's Dam Safety Rules established spillway design criteria based on dam height and storage. After recognizing that the required spillway capacity was disproportionate to the level of downstream development, the state developed new hydrologic design criteria based upon estimated loss of life (LOL). Similar to Washington State, Montana has performed regional precipitation-frequency analyses to determine the return period of precipitation events having recurrence intervals up to 5,000 years [Fischer & Lemieux, 2010].

LOL estimates are obtained by considering three factors: 1) PAR or population occupying the area inundated by a dam failure flood, 2) the warning time given to PAR exposed to the resultant flood wave, and 3) the severity of the flood. In general, LOL is significantly less than PAR. The Montana DCNR publication titled "Technical Note 2, Loss of Life Determination for Spillway Capacity Analysis" describes in detail how to calculate LOL.

> *"If the estimated LOL is equal to or less than 0.5, the minimum IDF is the 500-year recurrence interval… If the LOL is greater than 0.5 and less than or equal to 5, the minimum IDF recurrence interval is determined by multiplying the LOL by 1,000* (i.e. a dam with estimated LOL of 2 would be required to pass the 2,000-year flood event)… *If the LOL is greater than 5 and less than 1,000, the precipitation depth for determining the IDF is calculated with equations that effectively interpolate between depths for the 5,000-year storm and the PMP... The IDF for an LOL greater than or equal to 1,000 is the probable maximum flood, or PMF. The PMF is runoff produced by the PMP"* [Hydrometrics, Inc., 2008].

Montana's SDF determination process is illustrated by a flowchart in Figure 9.13.

9.13.5. Inconsistencies with Current Risk-Based Criteria

Within the past few decades, the use of risk analysis and risk-based design criteria has increased. The methodologies developed by California, Washington, and Montana reflect a growing desire for site-specific, cost-effective, and risk-based designs. They also demonstrate how the complexities of risk analysis can be applied in a simplified, standard-based system. Due to a lack of resources and staff in many state dam safety offices, such simplification would likely be necessary if broad application were to be successful. There is also a general lack of region-specific precipitation-frequency analyses, thus making it difficult for states desiring to adopt risk-based criteria to assign annual exceedance probabilities to extreme events.

Perhaps the most apparent observation regarding these recently developed, risk-based approaches is the lack of both consistency between the states as well as defensible risk tolerance criteria. California's weighting criteria are based entirely on the storage volume and height of the dam, the estimated evacuation, and potential downstream damage. Washington's consequence rating points are determined based on similar criteria (capital value of project, potential for loss of life, potential for property damage); however, in Washington's system, loss of life accounts for 50% of the entire

design weight while it accounts for only 33% of the total weight in California. Montana alternatively bases the design entirely (100%) on potential loss of life and completely disregards the value or size of the project as well as potential property damage due to dam failure.

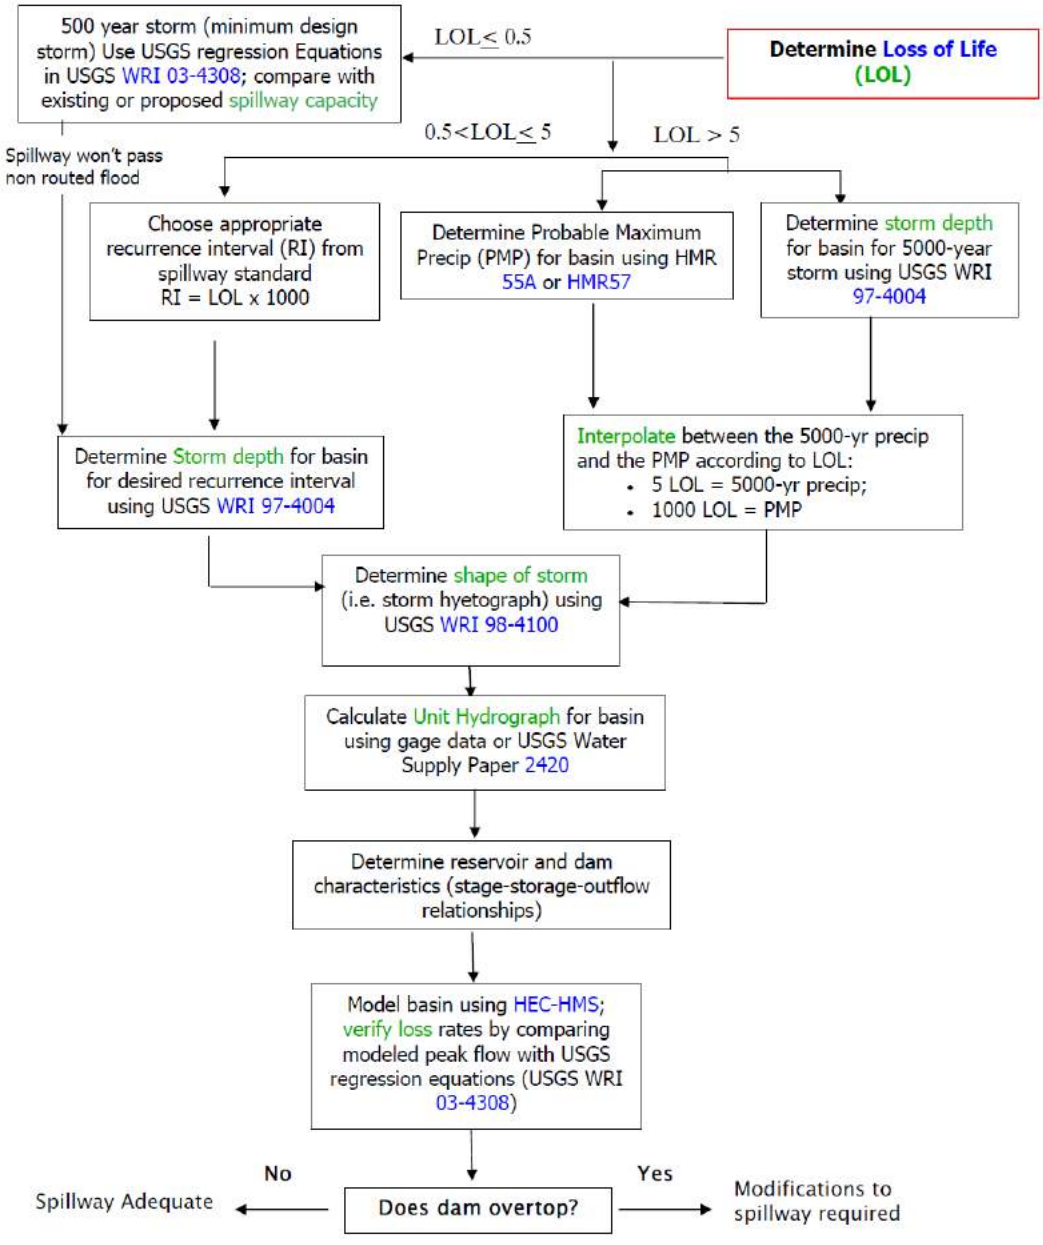

Figure 9.13 Procedure for Determining Spillway Adequacy [Montana DNRC, 2008]

Also inconsistent in the states' approaches are the probabilities of spillway design events required. In California, the minimum SDF is the 1,000-year event while Washington and Montana both allow a minimum of the 500-year event. Even though all three indicate that the PMP/PMF is the maximum event, the different weighting systems, loss of life determination, and other varying criteria could introduce significant deviation in spillway capacity requirements from one state to another.

It may be that risk-based criteria have been structured to meet the perceived needs or societal demands of the issuing agency or state. However, it is also possible that these differences are the result of somewhat subjective choices made by regulatory authorities. In either case, the considerable variety in risk-based criteria will complicate any precise comparisons between criteria used by different agencies. It will also result in a variation or imbalance of risk tolerances with regards to dam safety throughout the country.

9.14. Agency Review

The role of state dam safety agencies in determining the SDF varies from state to state. Only 8 of the 49 state agencies perform an independent verification of all submitted designs. An additional 15 agencies perform both limited detail reviews and in depth verifications as they deem fit (case-by-case basis). Most other agencies perform reviews of the hydrologic design, but do not verify the design independently. A few agencies also act as the designer/engineer for work done on state-owned dams.

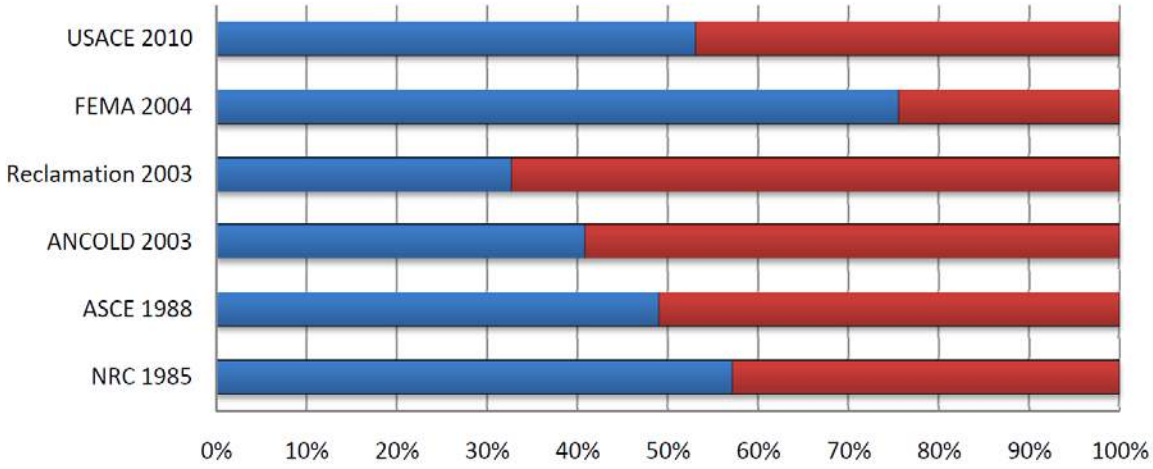
10. Receptiveness of States to Changing Guidelines

10.1. The Need for Uniformity

There are many differing opinions regarding the need for uniformity of design criteria between states and federal agencies. It is generally recognized that the implementation of strictly uniform criteria is not a possibility. A flexible framework of criteria would be required to provide for the specific requirements, budget, and technical ability of each state. The NRC Committee's critique of the state-of-the-practice summarizes this issue in the following:

> *"The goal of dam safety is to limit the risks from dam failures to acceptable levels. Probability of failure is controlled partly by design standards and partly by quality of design, construction, inspection, operation, and maintenance. Ideally, hazard failure probability, and acceptable damage would be quantified for the site-specific conditions of each individual existing or proposed dam in order to establish site-specific standards for achieving this goal. With few exceptions, current practices do not involve quantification of these three critical elements for each dam.*
>
> *"Instead, the most widespread current practice is to classify dams in three broad, not well-defined, qualitative damage potential categories (i.e. high, intermediate, and low hazard) and to somewhat arbitrarily assign one of three or four grades or ranges of design standards to each dam depending on its height, storage capacity, and qualitative hazard rating. Current practice treats all of the elements needed for selecting design standards in a generalized way; thus, the appropriateness of the design standards as applied to individual dams is generally unknown.*
>
> *"In defense of this current general practice, it must be recognized that most of the scores of federal and state regulatory agencies each have hundreds to thousands of dams under their jurisdictions. Given their limited resources, as a practical matter, they must use a generalized system of assigning design standards according to generalized hazard and size classifications, at least as an interim step until more detailed site-specific studies can be made. However, the wide range of hazard versus size versus design standards among various agencies reflects a lack of uniformity even within the generalized current practice.*
>
> *"This lack of uniformity in dam classification and safety design standards appears to result from three main factors: (1) lack of interagency and intergovernmental communication, (2) variations in engineering judgment in selecting the generalized standards, and (3) variations in public policy attitudes at the times the standards were selected. In any case, a critique of present practices must point out that, though a generalized approach to selecting design standards is justified as a practical interim step, there is a need for more uniformity among the various federal and state agencies in establishing size and hazard definitions and correlative design standards"* [NRC, 1985].

10.2. Awareness of Existing Federal Guidelines



As noted in Section 9.1, the majority of states adopted guidelines or regulations regarding the SDF in the 1970s and 1980s. Since then, each state dam safety agency has had varying degrees of success in updating these guidelines. Some states have recently revised their guidelines or maintain a continuous process of revision and are very aware of current research and recommendations regarding dam safety. Other agencies which are under-staffed or under-funded have limited time to give to such activities. As part of the survey, all agency representatives were asked if they were aware of several documents published on the federal and international levels regarding spillway design criteria. These documents are as follows:

1. Safety of Dams: Policy and Procedures (ER 1110-2-1156), *Draft Version* – U.S. Army Corps of Engineers [USACE, 2010]
2. Federal Guidelines for Dam Safety – Selecting and Accommodating Inflow Design Floods for Dams – Federal Emergency Management Agency [FEMA, 2004]
3. Guidelines for Achieving Public Protection in Dam Safety Decision-making - U.S. Bureau of Reclamation [Reclamation, 2003]
4. Guidelines on Selection of Acceptable Flood Capacity for Dam & Guidelines on Risk Assessment – Australian National Committee on Large Dams [ANCOLD, 2000 & 2003]
5. Evaluation Procedures of Hydrologic Safety of Dams – Prepared by the Task Committee on Spillway Design Flood Selection of the Committee on Surface Water Hydrology of the Hydraulics Division of the American Society of Civil Engineers [ASCE, 1988]
6. Safety of Dams: Flood and Earthquake Criteria – Prepared by the Committee on Safety Criteria for Dams, National Research Council [NRC, 1985]

The results are shown in Figure 10.1 and indicate that a significant portion of the dam safety community is unaware of current and even long-standing publications regarding the hydrologic safety of dams. A quarter of respondents were unaware of FEMA's federal guidelines for inflow design. It is apparent that any attempt to encourage the adoption of more uniform guidelines would require a significant outreach and educational effort on the part of FEMA.

10.3. Perception of PMP and PMF Criteria

When asked if they thought that designing for the PMP/PMF is unreasonably conservative, 31% of the respondents agreed. Fifty-one percent indicated that the PMP/PMF is a reasonable design criterion. The remaining 18% were either neutral or undecided (See Figure 10.2). This is interesting when considering that about half of the states require a full PMP/PMF design for high hazard structures, and in over 80% of the states, the SDF range extends up to the full PMP/PMF. It is also interesting to note that in Dubler's 1995 survey, only 17% of the states agreed that the PMP/PMF was unreasonably conservative, and none of those respondents strongly agreed. Conversely, 76% of states indicated in the 1995 survey that the PMP/PMF was a reasonable design criterion (59% indicated strongly disagreeing that the PMP/PMF was unreasonable).

	NRC 1985	ASCE 1988	ANCOLD 2003	Reclamation 2003	FEMA 2004	USACE 2010
Aware	57%	49%	41%	33%	76%	53%
Unaware	43%	51%	59%	67%	24%	47%

Figure 10.1 Awareness of Previously Published Spillway Design Guidelines

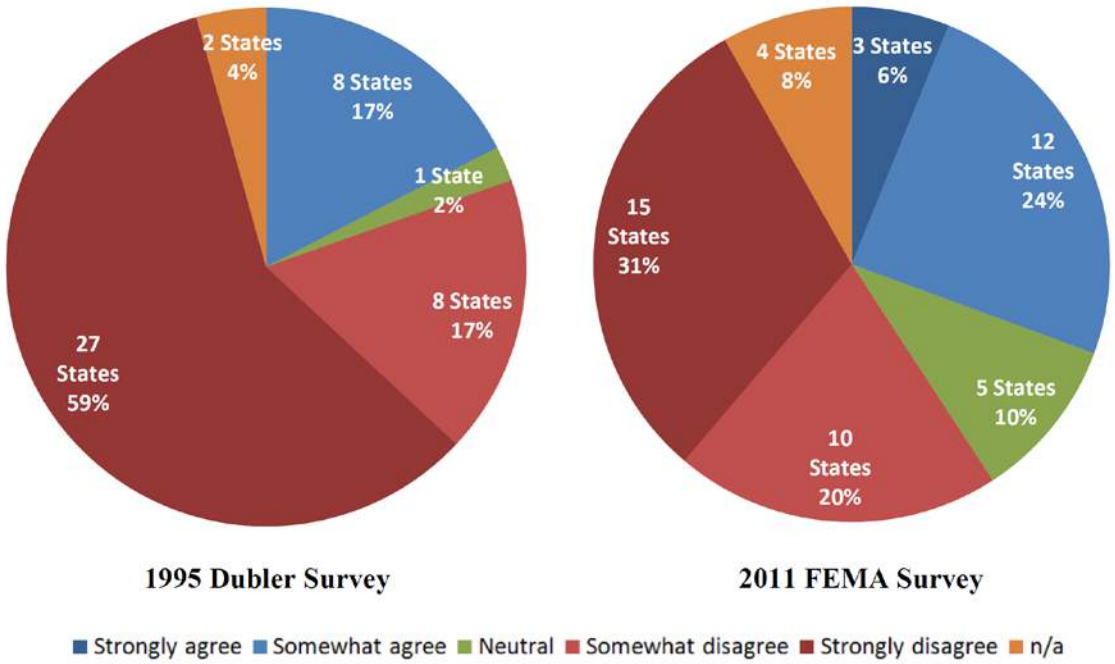


Figure 10.2 Do you agree that designing for the PMF is unreasonably conservative?

While these opinions indicate that a slight majority of the professional community supports design for the PMP/PMF, it also indicates that existing guidelines and spillway design criteria do not align with the current views of all dam safety professionals. Over the past 15 years, support for the PMP/PMF design in general appears to have diminished.

10.4. Concerns Regarding Consistency of Hydrologic Analyses

Many different design methods and models are currently used by dam designers. Twenty-six of the states indicated that they have concerns regarding the consistency of hydrologic and hydraulic analyses. Many of these concerns seem to stem from a general lack of training and experience of consultants as well as varying levels of detail given to the analyses. The variability of inputs into models, the various models used, and the inherent uncertainty in the computational methods and data are common sources of variability in analysis results.

10.5. Perception and Concerns Regarding Risk-Based Criteria

While leading federal agencies and a few states have transitioned from strictly prescriptive to risk-based criteria, it is evident that a large portion of the dam safety community doubts the validity and practicality of risk analysis. Fifty-one percent of respondents indicated that they have concerns regarding either the use of risk analyses or incremental damage analysis to determine spillway capacity requirements. Respondents indicated a number of concerns with these approaches to spillway design including the following:

- The complexity of risk analysis makes it expensive and time consuming to either perform or review.
- There is a general lack of minimum design criteria available. Current methodologies are still under development and are neither mature nor proven.
- Risk-based analyses lack consistency.
- Any argument can be justified using risk analysis if data are selectively analyzed and evaluated.
- There are currently no clear or acceptable guidelines for evaluating incremental damage.
- Many dam safety personnel lack training necessary to perform or review such designs.
- Risk analysis is too subjective and could be problematic over time with new development downstream of a dam.
- Risk analysis does not adequately address the worth of human life. "The potential adverse effects of a dam failure make 'allowing' a risk threshold somewhat unsettling both morally and politically."
- Results of such a design may not be defensible during a lawsuit.

Figure 10.3 illustrates the current opinions of state dam safety officials regarding risk analysis, its usefulness, and constraints. This figure also shows the responses to the same survey questions as

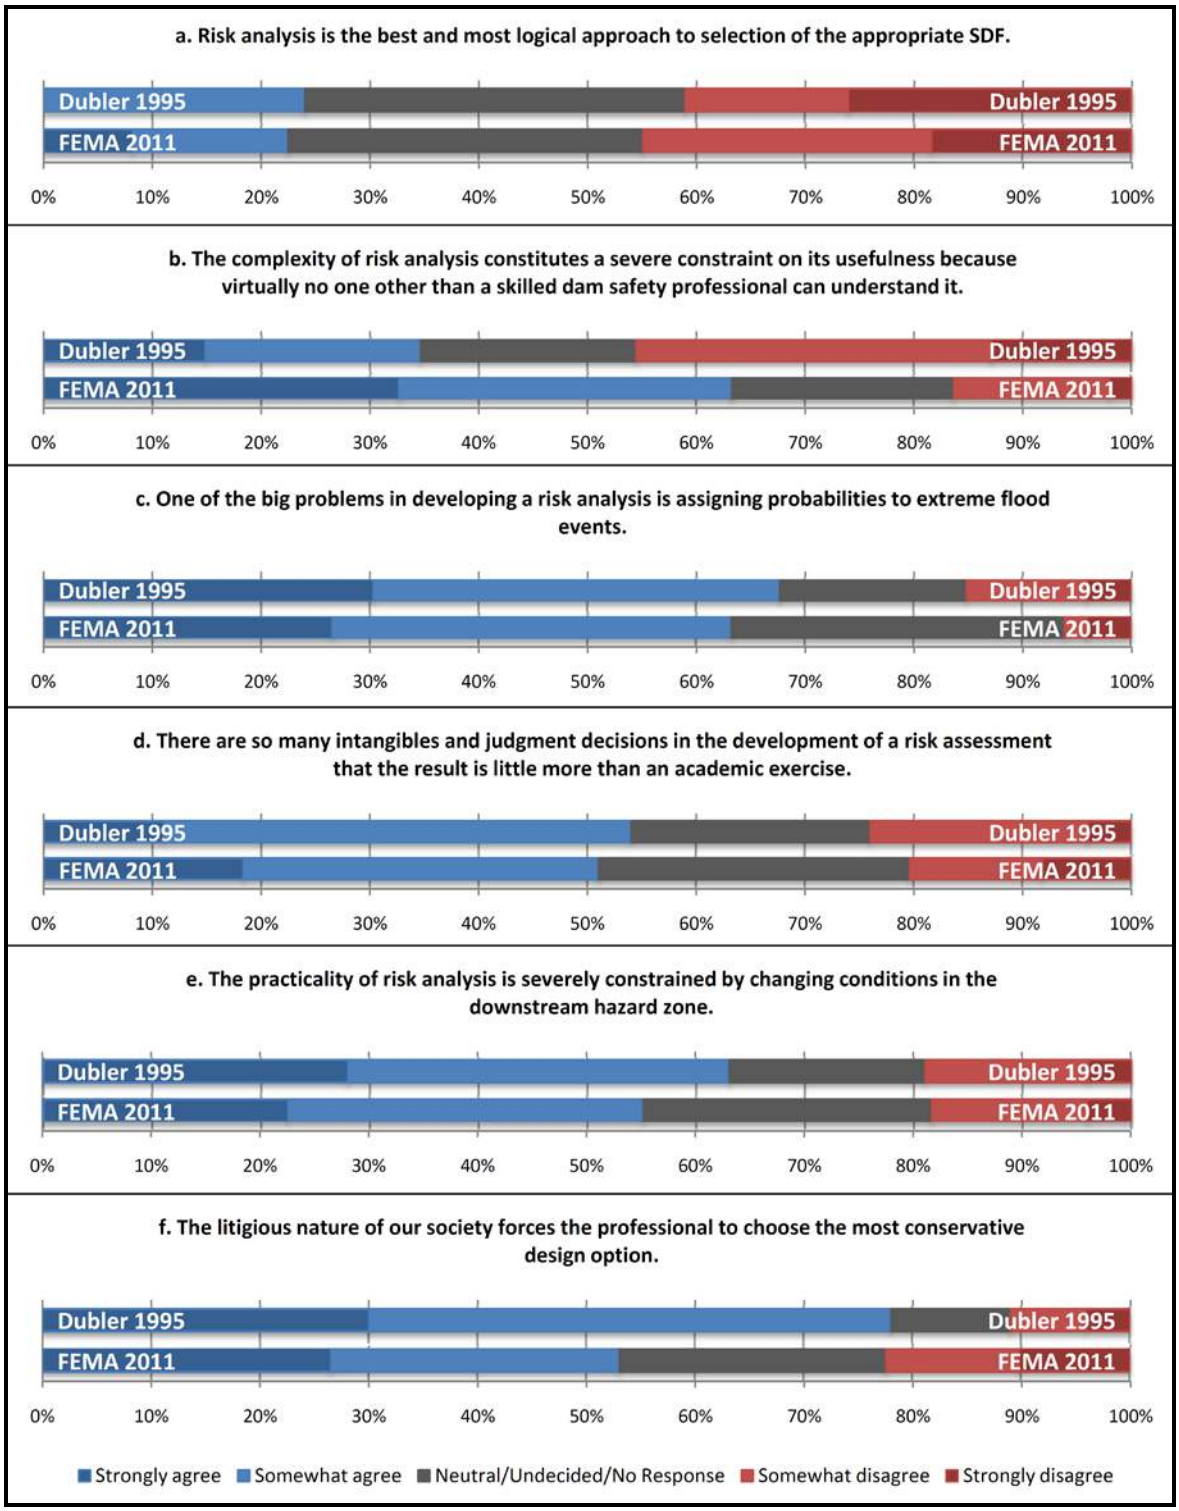

Figure 10.3 Opinions regarding risk analysis: 1995 vs. 2011

collected by Dubler in 1995. While there are significant differences of opinions regarding the complexity of risk analysis as well as the litigious nature of society and its implications for dam design, the overall views of state dam safety officials appear to be very similar to those found in the 1995 survey. The past 15 years have seen little change in opinion regarding risk-based analysis for the hydrologic safety of dams.

10.6. Technical Ability and Availability of Staff to Implement and Enforce Guidelines

The training and resources available to state dam safety agencies oftentimes determines the level of enforcement of dam safety guidelines. This also impacts an agency's ability to implement state-of-the-art practices in their state. Survey respondents were asked if they felt their agency and personnel had the resources (availability and budget) and technical ability to review several more recent advances that relate to the hydrologic safety of dams (See Table 10-1). The majority of agencies felt that they lacked both the technical ability and resources to review rigorous risk analyses. With regard to site specific PMP studies, a majority believed they had the technical ability required but lacked the necessary resources. The majority of states have the necessary resources and training to review incremental damage analyses. There are significant percentages of state regulatory agencies which feel they lack both the training and the resources required to review these state-of-the-art practices.

Table 10-1 Resources and Technical Ability of State Dam Safety Agencies

		Site Specific PMP	Incremental Damage Analysis	Rigorous Risk Analysis
Technical Ability	*Yes*	59%	78%	31%
	No	41%	22%	69%
Availability and Budget	*Yes*	41%	57%	22%
	No	59%	43%	78%

10.7. Overall Receptiveness and Obstacles to Changing Existing Guidelines

Fifty-seven percent of the surveyed states believe that increased uniformity in state dam safety guidelines across the country would be beneficial; thirty-nine percent believed that increased

uniformity would not be beneficial; and four percent did not respond to this question. Many indicated that it would be difficult to implement uniformity of the guidelines without eliminating many necessary regional distinctions that are currently in place. A solution would be to provide a uniform framework of guidelines that also provides for the specific requirements, budget, and technical ability of each state.

In general, dam safety officials were more receptive to adopting new recommended guidelines if they resulted in lower SDF criteria as opposed to higher SDF criteria. When asked how difficult it would be to change current regulations, the majority of states responded that it would be difficult. All others indicated a moderate level of difficulty. For many, such changes are expensive and time consuming, often extending over a period of years. Several respondents indicated that the current partisan political climate would also cause difficulty in changing regulations.

Many state representatives indicated that before the states attempt to standardize their guidelines, the major federal agencies who have traditionally led the effort to develop acceptable dam safety standards need to come to agreement. If these federal players could agree on basic items such as condition assessment, spillway standards, and risk determination, then the states would certainly be more receptive to adopting similar criteria.

11. The Current State of the Practice

11.1. Summary

This document, the "Summary of Existing Guidelines for the Hydrologic Safety of Dams," is the first of two documents commissioned by FEMA related to the Hydrologic Safety of Dams. The purpose of this document is to compile available data and to summarize the state of the practice of evaluating the hydrologic safety of dams. The second document will be in the form of guidelines which will assist dam safety programs in evaluating the adequacy of their current hydrologic guidelines.

At the root of this study is the acknowledgement of the basic need for adequate guidelines for evaluating the hydrologic safety of dams. The inventory of United States dams is large, aging and increasing in hazard as the United States becomes more and more developed. This Summary of Existing Guidelines has traced the evolution and history of design flood practice for dams as well as the application of the methodology in formal dam safety guidelines. The existing hydrologic guidelines of many states and federal agencies were written in the 1970s or 1980s. Since that time, significant technological and analytical advances have been made along with better watershed and rainfall information that have improved the analysis of extreme floods and quantification of incremental dam failure consequences. Review of the published policy and guidelines for each state as well as the responses to the detailed survey completed as part of this study have revealed several important findings that can be used to define the current state of the practice regarding the hydrologic safety of dams.

In general, the guidelines for the hydrologic safety of dams are not consistent and vary widely from state-to-state and between federal agencies in many respects. Although some states and agencies have recently updated their guidelines, many states and agencies have not significantly changed their guidelines since their development. Some of those who have changed their guidelines have incorporated some form of risk-based analyses, but the requirements and methodology differ widely.

Some of the most notable inconsistencies in the existing guidelines relate to classification systems. From the most basic criteria for what defines a regulatory or a jurisdictional dam to whether the dam is classified by size, hazard, or not at all, there is no overwhelming majority of configurations for these classification systems. While size classification is used by many states and hazard classification is used by all states, the number of classifications and the distinctions between the classes vary. There is also no consensus on distinctions between new dams and existing dams.

In determining the magnitude of the SDF, most states follow a prescriptive approach in which the design flood is specified based upon the dam's classification (size, hazard, or both). Both probabilistic and deterministic (based on PMP or PMF estimates) criteria are used for the prescriptive approach by the states and agencies. Many of the criteria in prescriptive approaches

are arbitrary with no apparent scientific rationale [NRC, 1985], and the prescribed SDFs for identical dams in different states would have drastically varying magnitudes.

Historically, a few important federal agencies have led the way in the development of dam safety regulations and design standards, and the trend among these agencies is toward incorporating a risk-based approach rather than the prescriptive approach. In fact, USACE is currently partnering with Reclamation, FERC, and TVA to achieve a common risk management framework and guidelines. Internationally, the trend is also toward integrating risk assessment into dam safety procedures. Recent changes to guidelines in Australia and Canada have addressed risk-based approaches.

The transition to risk-based analyses in some states has also begun. The methodologies developed by California, Washington, and Montana reflect an initial movement to make site-specific, cost-effective, and risk-based designs. They also demonstrate how the complexities of risk analysis can be applied in a simplified, standard-based system. Comparison of these three recently developed, risk-based approaches indicates a lack of consistency regarding the criteria used among the systems, the weights assigned to the criteria, and the resultant risk tolerances.

Although the trend appears to be the incorporation of risk-based approaches into guidelines for the hydrologic safety of dams, there are many obstacles to widespread acceptance by state regulatory agencies. The budgets, staff availability, and technical ability of many state dam safety agencies are very limited. Many respondents indicated that they have concerns regarding risk-based analyses to determine spillway capacity requirements due to review requirements and the lack of widely acceptable and defensible guidelines.

It should also be noted that the federal agencies who have led the way in developing risk analysis procedures and tolerances are owners of a significant number of dams. These agencies have been able to utilize the prioritization and ranking aspects of risk analysis to manage their respective portfolios in addition to using quantitative risk analysis in design. The administrative processes and reviews of regulatory agencies, such as FERC, MSHA, and most of the states, differ significantly from that of dam owners like USACE and Reclamation. The application of quantitative risk analysis for dam design in regulatory agencies may be burdensome or even unnecessary. The state dam regulatory agencies of California, Washington and Montana have recently developed risk-based indices to determine acceptable flood capacity; however, none of the states use quantitative risk assessment.

There are many differing opinions regarding the need for uniformity of design criteria between states and federal agencies. It is generally recognized that the implementation of strictly uniform criteria is not a possibility. Instead, a flexible framework of criteria may be required to provide for the specific requirements, budget, and technical ability of each state. While leading federal agencies and a few states have recently transitioned from strictly prescriptive to risk-based criteria, it is evident that a large portion of the dam safety community has significant reservations concerning the validity and practicality of risk analysis. Having one set of federal dam safety

standards for risk determination may help to promote the use of risk-based analysis by states and potentially encourage increased uniformity of state guidelines.

The survey responses also indicate that a significant portion of the dam safety community is unaware of current and even long-standing landmark publications regarding guidelines for the hydrologic safety of dams. A quarter of respondents were unaware of FEMA's 2004 federal guidelines for "Selecting and Accommodating Inflow Design Floods for Dams," and approximately half were not familiar with the most recently published USACE, Reclamation, and ASCE inflow design and dam safety guidelines. It is therefore apparent that any attempt to encourage the adoption of more uniform guidelines and consideration of adopting risk-based criteria will require a more effective outreach and educational effort.

Although the literature search identified several studies that provided information on state practices related to selecting inflow design floods for dams, none of the studies provided a comprehensive compilation of this data. In addition to providing background information for developing new federal guidelines for the hydrologic safety of dams, this report and the associated database provide a comprehensive compilation of current federal and state guidelines that can be used by individual states to evaluate and compare their current guidelines with those of other agencies. As individual states revise their guidelines, this information will provide them with important information that will help them to make informed decisions that should result in more uniformity.

Appendix A. Glossary and Acronyms

A.1 Glossary
A.2 Acronyms

FEMA

A.1. Glossary

Below is a listing of terms used within this report. Many of these definitions were taken from FEMA's Federal Guidelines for Dam Safety, Glossary of Terms, April 2004.

Appurtenant structure. Ancillary features of a dam such as outlets, spillways, power plants, tunnels, etc.

Breach. An opening through a dam that allows the uncontrolled draining of a reservoir. A controlled breach is a constructed opening. An uncontrolled breach is an unintentional opening caused by discharge from the reservoir. A breach is generally associated with the partial or total failure of the dam.

Consequences. Potential loss of life or property damage downstream of a dam caused by floodwaters released at the dam or by waters released by partial or complete failure of dam. Also effects of landslides upstream of the dam on property located around the reservoir.

Dam. An artificial barrier that has the ability to impound water, wastewater, or any liquid-borne material, for the purpose of storage or control of water.

Dam failure. Catastrophic type of failure characterized by the sudden, rapid, and uncontrolled release of impounded water or the likelihood of such an uncontrolled release It is recognized that there are lesser degrees of failure and that any malfunction or abnormality outside the design assumptions and parameters that adversely affect a dam's primary function of impounding water is properly considered a failure. These lesser degrees of failure can progressively lead to or heighten the risk of a catastrophic failure. They are, however, normally amenable to corrective action.

Dam safety. Dam safety is the art and science of ensuring the integrity and viability of dams such that they do not present unacceptable risks to the public, property, and the environment. It requires the collective application of engineering principles and experience, and a philosophy of risk management that recognizes that a dam is a structure whose safe function is not explicitly determined by its original design and construction. It also includes all actions taken to identify or predict deficiencies and consequences related to failure, and to document, publicize, and reduce, eliminate, or remediate to the extent reasonably possible, any unacceptable risks.

Deterministic methodology. A method in which the chance of occurrence of the variable involved is ignored and the method or model used is considered to follow a definite law of certainty, and not probability.

Emergency Action Plan (EAP) Exercise. An activity designed to promote emergency preparedness; test or evaluate EAPs, procedures, or facilities; train personnel in emergency management duties; and demonstrate operational capability. Exercises consist of the performance of duties, tasks, or operations very similar to the way they would be performed in a real emergency. However, the exercise performance is in response to a simulated event.

Exceedance Probability. The likelihood that a random event will exceed a specified magnitude in a given time period, usually 1 year unless otherwise indicated.

Failure mode. A potential failure mode is a physically plausible process for dam failure resulting from an existing inadequacy or defect related to a natural foundation condition, the dam or appurtenant structures design, the construction, the materials incorporated, the operations and maintenance, or aging process, which can lead to an uncontrolled release of the reservoir.

Flood. A temporary rise in water surface elevation resulting in inundation of areas not normally covered by water. Hypothetical floods may be expressed in terms of average probability of exceedance per year such as one-percent-chance-flood, or expressed as a fraction of the probable maximum flood or other reference flood.

> **Flood, Inflow Design (IDF).** The flood flow above which the incremental increase in downstream water surface elevation due to failure of a dam or other water impounding structure is no longer considered to present an unacceptable threat to downstream life or property. The flood hydrograph used in the design of a dam and its appurtenant works particularly for sizing the spillway and outlet works and for determining maximum storage, height of dam, and freeboard requirements.
>
> **Flood, Probable Maximum (PMF).** The flood that may be expected from the most severe combination of critical meteorologic and hydrologic conditions that are reasonably possible in the drainage basin under study.

Flood plain. An area adjoining a body of water or natural stream that may be covered by floodwater. Also, the downstream area that would be inundated or otherwise affected by the failure of a dam or by large flood flows. The area of the flood plain is generally delineated by a frequency (or size) of flood.

Hazard. A situation that creates the potential for adverse consequences such as loss of life, property damage, or other adverse impacts.

> **Hazard potential.** The possible adverse incremental consequences that result from the release of water or stored contents due to failure of the dam or misoperation of the dam or appurtenances. Impacts may be for a defined area downstream of a dam from flood waters released through spillways and outlet works of the dam or waters released by partial or complete failure of the dam. There may also be impacts for an area upstream of the dam from effects of backwater flooding or landslides around the reservoir perimeter.
>
> **Hazard potential classification.** A system that categorizes dams according to the degree of adverse incremental consequences of a failure or misoperation of a dam. The hazard
>
> potential classification does not reflect in any way on the current condition of the dam (i.e., safety, structural integrity, flood routing capacity).

Hydrograph, breach or dam failure. A flood hydrograph resulting from a dam breach.

Hydrograph, flood. A graph showing, for a given point on a stream, the discharge, height, or other characteristic of a flood with respect to time.

Hydrograph, unit. A hydrograph with a volume of one inch of runoff resulting from a storm of a specified duration and areal distribution. Hydrographs from other storms of the same duration and distribution are assumed to have the same time base but with ordinates of flow in proportion to the runoff volumes.

Hydrology. One of the earth sciences that encompasses the natural occurrence, distribution, movement, and properties of the waters of the earth and their environmental relationships.

Indemnification Cost. The present cost to provide sufficient security against all claims of loss or damage in the event of a future dam failure.

Population at Risk. All those persons who could be in the flooded area below a dam attributable to the failure of the dam at the time of failure.

Probable Maximum Flood (PMF). See Flood. **Probable Maximum Precipitation (PMP).** Theoretically, the greatest depth of precipitation for a given duration that is physically possible over a given size storm area at a particular geographical location during a certain time of the year.

Reservoir. A body of water impounded by a dam and in which water can be stored.

Risk. A measure of the likelihood and severity of adverse consequences (National Research Council 1983). Risk is estimated by the mathematical expectation of the consequences of an adverse event occurring, i.e., the product of the probability of occurrence and the consequence, or alternatively, by the triplet of scenario, probability of occurrence, and the consequence.

Risk analysis. A procedure to identify and quantify risks by establishing potential failure modes, providing numerical estimates of the likelihood of an event in a specified time period, and estimating the magnitude of the consequences. The risk analysis should include all potential events that would cause unintentional release of stored water from the reservoir.

Risk assessment. The process of deciding whether existing risks are tolerable and present risk control measures are adequate and, if not, whether alternative risk control measures are justified. Risk assessment incorporates the risk analysis and risk evaluation phases.

Spillway. A structure over or through which flow is discharged from a reservoir. If the rate of flow is controlled by mechanical means, such as gates, it is considered a controlled spillway. If the geometry of the spillway is the only control, it is considered an uncontrolled spillway.

Spillway, auxiliary. Any secondary spillway that is designed to be operated infrequently, possibly in anticipation of some degree of structural damage or erosion to the spillway that would occur during operation.

Spillway, emergency. See Spillway, auxiliary.

Spillway, service. A spillway that is designed to provide continuous or frequent regulated or unregulated releases from a reservoir, without significant damage to either the dam or its appurtenant structures. This is also referred to as principal spillway.

Spillway capacity. The maximum spillway outflow that a dam can safely pass with the reservoir at its maximum level.

Spillway channel. An open channel or closed conduit conveying water from the spillway inlet downstream.

Spillway chute. A steeply sloping spillway channel that conveys discharges at super-critical velocities.

Spillway crest. The lowest level at which water can flow over or through the spillway.

Spillway Design Flood (SDF). The flood flow above which the incremental increase in downstream water surface elevation due to failure of a dam or other water impounding structure is no longer considered to present an unacceptable threat to downstream life or property. The flood hydrograph used in the design of a dam and its appurtenant works particularly for sizing the spillway and outlet works and for determining maximum storage, height of dam, and freeboard requirements.

Storage. The retention of water or delay of runoff either by planned operation, as in a reservoir, or by temporary filling of overflow areas, as in the progression of a flood wave through a natural stream channel.

Surcharge. The volume or space in a reservoir between the controlled retention water level and the maximum water level. Flood surcharge cannot be retained in the reservoir but will flow out of the reservoir until the controlled retention water level is reached.

Watershed. The area drained by a river or river system or portion thereof. The watershed for a dam is the drainage area upstream of the dam.

A.2. Acronyms

ACT. Australian Capital Territory

HYDROLOGIC SAFETY OF DAMS

QUESTIONNAIRE

On the Record

1. Respondent information:
   - State/Federal Dam Safety Organization _____
   - Name of Representative _____
   - Title of Representative _____
   - Phone number(s) _____
   - Email address _____

2. Number of dams under Organization's jurisdiction by type:
   - Total Dams _____
   - Total Regulated Dams _____
   - High Hazard Dams _____
   - Significant Hazard Dams _____
   - Low Hazard Dams _____
   - Unregulated Dams _____
   - Other _____

3. What year did your Agency adopt minimum Inflow Design Flood criteria? _____

4. How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:
   - ☐ Less than 25 feet high (from streambed) and 15 acre-feet of storage (top of dam)
   - ☐ Less than 6 feet high (from streambed) and 50 acre-feet of storage (top of dam)
   - ☐ Both of the above
   - ☐ Less than 50 acre-feet of storage (top of dam)
   - ☐ Other (Please specify) _____

5. Are there types/categories of dams (other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)
   - ☐ Yes (Please explain)
   - ☐ No

6. Does the Organization have published size classification criteria?
   - ☐ Yes
   - ☐ No

   If "Yes", check and complete as appropriate:
   - Class A (Small) =<_____ feet high and stores =< _____ acre-feet
   - Class B (Medium)
   - Class C (Large) =>_____ feet high and stores => _____ acre-feet
   - Other (Specify) _____

7. Does the Organization have published hazard classification criteria?
   - ☐ Yes (High, Significant, and Low)
   - ☐ Yes (High, Significant, Low, Limited Hazard)
   - ☐ Yes (Other)
   - ☐ No

   If "Yes" and Significant Hazard is defined, how is Significant Hazard defined?
   - ☐ Loss of life potential is "few" with "appreciable" economic loss
   - ☐ No potential for loss of life with significant but not excessive economic loss
   - ☐ Other (Please specify) _____

8. Does the Organization have guidelines for determining the spillway design flood?
   - ☐ Yes
   - ☐ No

   If "Yes", what is the status of the guidelines; do they have the force of law?
   - ☐ Published within State Laws
   - ☐ Published guidelines/regulations that are required
   - ☐ Published guidelines/regulations for consideration by the engineer/designer
   - ☐ Unpublished guidelines that are required
   - ☐ Unpublished guidelines for consideration by the engineer/designer
   - ☐ Other (Please specify) _____

9. What is the origin of the guidelines?
   - ☐ Custom developed by Organization
   - ☐ USBR guidelines
   - ☐ NRCS guidelines
   - ☐ FEMA/FERC federal guidelines
   - ☐ USACE guidelines (including Phase I Study guidelines)
   - ☐ Combination of the above (Please specify) _____
   - ☐ Other (Please specify) _____
   - ☐ Unknown

10. When were the guidelines last revised (MM/DD/YYYY)? _____

11. Are there any plans to update or revise the guidelines in the near future?
   - ☐ Yes (Please specify) _____
   - ☐ No

12. Are the guidelines different for new and existing dams?
   - ☐ Yes (Please elaborate) _____
   - ☐ No

13. Which of the following best describes your agency's role in determining the spillway design flood:
   - ☐ Agency does not review any technical information, but ensures that design is performed by qualified professionals
   - ☐ Agency reviews submitted designs
   - ☐ Agency performs independent verification of submitted designs
   - ☐ Agency acts as designer/engineer
   - ☐ Agency utilizes a combination of the above approaches, possibly on a case-by-case basis
   - ☐ Other (Please explain) _____

14. How are the guidelines applied?
   - ☐ Based on both size and hazard classification
   - ☐ Based on size classification only
   - ☐ Based on hazard classification
   - ☐ Based on risk analysis
   - ☐ Based on a combination of risk analysis and hazard/size classification
   - ☐ Based on other criteria (Please specify) _____

15. For PMP/PMF designs, is freeboard required?
   - ☐ No
   - ☐ Based on wave run up computations
   - ☐ 1.0'
   - ☐ 1.5'
   - ☐ 2.0'
   - ☐ 3.0' or more
   - ☐ Other (Please specify) _____

16. Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that must be used?
    - ☐ Yes
    - ☐ No

    If "Yes", what are the specific analysis methodologies, procedures, or computer software that must be used?
    - ☐ Must use HMRs for developing PMP
    - ☐ Must use SCS unit hydrograph
    - ☐ Must use HEC-1
    - ☐ Must use HEC-HMS
    - ☐ Must use SITES
    - ☐ Other (Please specify) _____

17. Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?
    - ☐ Yes (Please specify) _____
    - ☐ No

18. Do the guidelines specify any criteria for storm duration?
    - ☐ Yes (6-hour)
    - ☐ Yes (24-hour)
    - ☐ Yes (48-hour)
    - ☐ Yes (72-hour)
    - ☐ Yes (Based on Tc)
    - ☐ No
    - ☐ Other (Please specify) _____

19. Do the guidelines specify any criteria for temporal storm distribution?
    - ☐ Yes (HMR)
    - ☐ Yes (NRCS Standard)
    - ☐ Yes (Regional)
    - ☐ Yes (Other, Please specify) _____
    - ☐ No

20. Do the guidelines specify any criteria for spatial storm distribution?
    - ☐ Yes (Please specify) _____ _____
    - ☐ No

21. Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?
    - ☐ Yes (Please specify) _____
    - ☐ No

22. Does the organization allow development of a site specific PMP?
    - ☐ Yes
    - ☐ No
    - ☐ Unknown (never requested)

    If "Yes", are there any restrictions, requirements, or guidelines for performing a site specific PMP?
    - ☐ Yes (Please specify) _____
    - ☐ No

23. Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?
    - ☐ Yes, a major problem
    - ☐ Yes, a moderate problem
    - ☐ Yes, a minor problem
    - ☐ No
    - ☐ Unsure

24. Do guidelines require consideration or analysis of future development?
    - ☐ Yes (Impacts of development on watershed hydrology)
    - ☐ Yes (Impacts of development on hazard classification or failure consequences)
    - ☐ Yes (Both of the above)
    - ☐ Yes (Other; please specify) _____
    - ☐ No

25. Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?
    - ☐ Yes (Please specify) _____
    - ☐ No

26. Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?
    - ☐ Yes
    - ☐ No

    If "Yes", do guidelines require analyses to include future downstream conditions within the dam failure inundation zone?
    - ☐ Yes
    - ☐ No

27. Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?
    - ☐ Yes (Please specify) _____
    - ☐ No

28. Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF? If "Yes", complete as appropriate. If "No", describe below how spillway design capacity is determined. _____

New High Hazard Dams must pass	_____ % of PMP, or	_____ % of PMF
Existing High Hazard Dams must pass	_____ % of PMP, or	_____ % of PMF
New Significant Hazard Dams	_____ % of PMP, or	_____ % of PMF
Existing Significant Hazard Dams	_____ % of PMP, or	_____ % of PMF

29. For low hazard dams, the spillway design requirement is:
    - ☐ 25-year flood
    - ☐ 50-year flood
    - ☐ 100-year flood
    - ☐ 500-year flood
    - ☐ Not specified
    - ☐ Other (Please specify) _____

30. Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?
    - ☐ Yes
    - ☐ No

31. Does your organization permit risk based hydrologic designs?
    - ☐ Yes; our regulations permit them
    - ☐ Yes; although our regulations do not specifically address this topic, we review risk-based designs on a case-by-case basis
    - ☐ No; our regulations forbid them
    - ☐ No; our regulations address this topic and we have made an administrative decision not to consider risk-based designs
    - ☐ Our regulations do not specifically address this topic and it has never come up for consideration
    - ☐ Other (Please explain) _____

32. Has your agency ever reviewed a risk-based hydrologic analysis?
    - ☐ Yes (Reviewed and approved)
    - ☐ Yes (Reviewed and rejected)
    - ☐ Yes (Both approved and rejected)
    - ☐ No
    - ☐ Unsure
    - ☐ Other (Please explain)

33. How difficult would it be to change your regulations? Please explain. _____
    - ☐ Difficult
    - ☐ Moderate
    - ☐ Easy

34. Are they any unique provisions in your regulations?
    - ☐ Yes (Please explain) _____
    - ☐ No

Off the Record

35. Do you agree that designing for the PMF is unreasonably conservative?
    - ☐ Strongly agree
    - ☐ Somewhat agree
    - ☐ Neutral
    - ☐ Somewhat disagree
    - ☐ Strongly disagree
    - ☐ Undecided

36. In your opinion, does the general public believe that the PMF is unreasonably conservative?
    - ☐ Yes, the general public strongly opposes the PMF design
    - ☐ Yes, the general public somewhat opposes the PMF design
    - ☐ No, the general public strongly favors the PMF design
    - ☐ No, the general public somewhat favors the PMF design
    - ☐ Undecided
    - ☐ No opinion
    - ☐ Other (Please explain) _____

37. Do you have any concerns regarding the consistency of hydrologic and hydraulic analyses?
    - ☐ Yes (Please specify) _____
    - ☐ No

38. Are you aware of the guidelines in the following documents?
    a. Safety of Dams: Flood and Earthquake Criteria – Prepared by the Committee on Safety Criteria for Dams, National Research Council (1985) ☐ Yes ☐ No
    b. Evaluation Procedures of Hydrologic Safety of Dams – Prepared by the Task Committee on Spillway Design Flood Selection of the Committee on Surface Water Hydrology of the Hydraulics Division of the American Society of Civil Engineers (1988) ☐ Yes ☐ No
    c. Guidelines on Selection of Acceptable Flood Capacity for Dams, and Guidelines on Risk Assessment – ANCOLD (2000, 2003) ☐ Yes ☐ No
    d. Guidelines for Achieving Public Protection in Dam Safety Decisionmaking - US Bureau of Reclamation (2003) ☐ Yes ☐ No
    e. Federal Guidelines for Dam Safety – Selecting and Accommodating Inflow Design Floods for Dams – FEMA (2004) ☐ Yes ☐ No
    f. Safety of Dams: Policy and Procedures (ER 1110-2-1156) – US Army Corps of Engineers (2010) ☐ Yes ☐ No

39. Do you have any concerns regarding the use of risk analyses or incremental damage assessments to determine spillway capacity requirements?
    - ☐ Yes (Please specify) _____
    - ☐ No

40. Do you agree or disagree with the following statements:

a.	Risk analysis is the best and most logical approach to selection of the appropriate SDF.	☐ Strongly agree ☐ Neutral ☐ Undecided	☐ Somewhat agree ☐ Somewhat disagree ☐ Strongly disagree
b.	The complexity of risk analysis constitutes a severe constraint on its usefulness because virtually no one other than a skilled dam safety professional can understand it.	☐ Strongly agree ☐ Neutral ☐ Undecided	☐ Somewhat agree ☐ Somewhat disagree ☐ Strongly disagree
c.	One of the big problems in developing a risk analysis is assigning probabilities to extreme flood events.	☐ Strongly agree ☐ Neutral ☐ Undecided	☐ Somewhat agree ☐ Somewhat disagree ☐ Strongly disagree
d.	There are so many intangibles and judgment decisions in the development of a risk assessment that the result is little more than an academic exercise.	☐ Strongly agree ☐ Neutral ☐ Undecided	☐ Somewhat agree ☐ Somewhat disagree ☐ Strongly disagree
e.	The practicality of risk analysis is severely constrained by changing conditions in the downstream hazard zone.	☐ Strongly agree ☐ Neutral ☐ Undecided	☐ Somewhat agree ☐ Somewhat disagree ☐ Strongly disagree
f.	The litigious nature of our society forces the professional to choose the most conservative design option.	☐ Strongly agree ☐ Neutral ☐ Undecided	☐ Somewhat agree ☐ Somewhat disagree ☐ Strongly disagree

41. Do you believe your agency has the technical ability to review the following:

Site Specific PMP Studies	☐ Yes	☐ No
Incremental Damage Assessments	☐ Yes	☐ No
Rigorous Risk Analyses	☐ Yes	☐ No

42. Do you believe your agency has the resources (availability and budget) to review the following:

Site Specific PMP Studies	☐ Yes	☐ No
Incremental Damage Assessments	☐ Yes	☐ No
Rigorous Risk Analyses	☐ Yes	☐ No

43. Would you like to see any changes in your current guidelines?
    - ☐ Yes (Please specify) _____
    - ☐ No

44. Do you believe that increased uniformity in state dam safety guidelines across the country would be beneficial?
    - ☐ Yes
    - ☐ No

45. Would you be receptive to adopting new recommended guidelines if they resulted in lower spillway design flood criteria for existing and new dams?
    - ☐ Yes
    - ☐ No

46. Would you be receptive to adopting new recommended guidelines if they resulted in higher spillway design flood criteria for existing and new dams?
    - ☐ Yes
    - ☐ No

47. Do you have any other comments? _____

C.2. Completed Federal Surveys

FEMA

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	Bureau of Indian Affairs
Name of Representative	John Anevski
Title of Representative	Chief, Division of Water and Power
Phone number(s)	(202) 208-5480
Email address	john.anevski@bia.gov

2 Number of dams under Organization's jurisdiction by type:

Total Dams	900
Total Regulated Dams	900
High Hazard Dams	91
Significant Hazard Dams	45
Low Hazard Dams	764
Unregulated Dams	0
Other	0

3 What year did your Agency adopt minimum Inflow Design Flood criteria? 2006

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Both of the above

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

No

6 Does the Organization have published size classification criteria?

No

7 Does the Organization have published hazard classification criteria?

Yes (High, Significant, and Low)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

Loss of life potential is "few" with "appreciable" economic loss

Comments: Based on Indian Dam Safety Act of 1994 (P.L. 103-302)--Between 1 and 6 lives would be at risk or significant property damage could occur if the dam failed.

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Published guidelines/regulations for consideration by the engineer/designer

Comments: The current BIA Handbook calls for the Base Safety Condition to be determined and this is the largest flood which will cause incremental dam failure flooding. However, BIA reserves the right to select something smaller based on downstream conditions. Normally, the IDF will not be greater than a 10,000 year storm.

9 What is the origin of the guidelines?

Combination of the above (Please specify)

Comments: Custom based on Bureau and USBR Guidelines

10 When were the guidelines last revised (MM/DD/YYYY)? 07/08/2007

11 Are there any plans to update or revise the guidelines in the near future?

Yes (Please specify)

Comments: Plan to include revised current guidelines in BIA Safety of Dams Handbook in FY 2012

12 Are the guidelines different for new and existing dams?

No

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency utilizes a combination of the above approaches, possibly on a case-by-case basis

14 How are the guidelines applied?

Based on a combination of risk analysis and hazard/size classification

15 For PMP/PMF designs, is freeboard required?

Based on wave run up computations

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

No

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

No

18 Do the guidelines specify any criteria for storm duration?

No

19 Do the guidelines specify any criteria for temporal storm distribution?

No

20 Do the guidelines specify any criteria for spatial storm distribution?

No

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

No

22 Does the organization allow development of a site specific PMP?

Yes

If "Yes", are there any restrictions, requirements, or guidelines for performing a site specific PMP?

No

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

No

24 Do guidelines require consideration or analysis of future development?

No

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

No

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

Yes

If "Yes", do guidelines require analyses to include future downstream conditions within the dam failure inundation zone?

No

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

No

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

No

Comments: The current BIA Handbook calls for the Base Safety Condition to be determined and this is the largest flood which will cause incremental dam failure flooding. However, BIA

29 For low hazard dams, the spillway design requirement is:

Not specified

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

Yes

Comments: EWS instrumentation will be installed, operated, and maintained at High or Significant Hazard dams and in the upstream basin when early detection of hydrologic events would provide additional time needed for emergency management activities.

31 Does your organization permit risk-based hydrologic designs?

Yes; although our regulations do not specifically address this topic, we review risk-based designs o

32 Has your agency ever reviewed a risk-based hydrologic analysis?

Yes (Reviewed and approved)

33 How difficult would it be to change your regulations? Please explain.

Easy

Comments: Most of our criteria for IDF development is in the form of guidelines/standards and is not found in regulations. However, we would normally consult with Tribal organizations if and when revisions occur.

34 Are there any unique provisions in your regulations?

No

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	Federal Energy Regulatory Commission
Name of Representative	Daniel J. Mahoney
Title of Representative	Director, Dam Safety and Inspection
Phone number(s)	(202) 502-6743
Email address	daniel.mahoney@ferc.gov

2 Number of dams under Organization's jurisdiction by type:

Total Dams	2530
Total Regulated Dams	2530
High Hazard Dams	780
Significant Hazard Dams	192
Low Hazard Dams	1558
Unregulated Dams	0
Other	0

3 When did your Organization adopt minimum Inflow Design Flood criteria? 1981

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Other (Please specify)

Comments: Every dam included in a FERC license

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

No

6 Does the Organization have published size classification criteria?

No

7 Does the Organization have published hazard classification criteria?

Yes (High, Significant, and Low)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

No potential for loss of life with significant but not excessive economic loss

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Published guidelines/regulations that are required

Comments: They have the force of law.

9 What is the origin of the guidelines?

FEMA/FERC federal guidelines

10 When were the guidelines last revised (MM/DD/YYYY)?

Comments: FERC Engineering Guidelines are constantly updated and revised

11 Are there any plans to update or revise the guidelines in the near future?

Yes (Please specify)

Comments: Continually revised as necessary.

12 Are the guidelines different for new and existing dams?

No

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency utilizes a combination of the above approaches, possibly on a case-by-case basis

Comments: We review all of them, but when necessary we perform an independent verification

14 How are the guidelines applied?

Based on hazard classification only

15 For PMP/PMF designs, is freeboard required?

Other (Please specify)

Comments: On a case by case basis, anticipated wave run-up and engineering judgement

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

No

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

No

18 Do the guidelines specify any criteria for storm duration?

No

19 Do the guidelines specify any criteria for temporal storm distribution?

No

20 Do the guidelines specify any criteria for spatial storm distribution?

No

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

Yes (Please specify)

Comments: Outlet works and service spillways should be designed for frequent use and should by highly reliable. Auxiliary spillways are usually designed for infrequent use and it is acceptable to sustain limited damage during passage of the IDF. Emergency spillway may be used to obtain a high degree of hydrologic safety with minimal additional cost. Because of their infrequent use, it is acceptable for them to sustain significant damage when use and they may be designed with lower structural standards than those used for auxiliary spillways.

22 Does the organization allow development of a site specific PMP?

Yes

If "Yes", are there any restrictions, requirements, or guidelines for performing a site specific PMP?

Yes (Please specify)

Comments: A BOC is normally required to oversee the development of the PMP/PMF

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

No

Comments:

24 Do guidelines require consideration or analysis of future development?

Yes (Impacts of development on hazard classification or failure consequences)

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

Yes (Please specify)

Comments: In general, if there is no allocated or planned flood control storage (i.e., run-of-river), the flood routing usually begins with the reservoir at the normal maximum pool elevation. If regulation studies show that pool levels would be lower than the normal maximum pool elevation during the critical inflow design flood (IDF) season, then the results of those specific regulation studies should be analyzed to determine the appropriate initial pool level for routing the IDF.

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

Yes

If "Yes", do guidelines require analyses to include future downstream conditions within the dam failure inundation zone?

Yes

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

No

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

No

Comments: Follow FEMA's "Federal Guidelines for Dam Safety: Selecting and Accomodating Inflow Design Floods for Dams" (April 2004)

29 For low hazard dams, the spillway design requirement is:

100-year flood

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

No

31 Does your organization permit risk-based hydrologic designs?

Our regulations do not specifically address this topic and it has never come up for consideration

32 Has your agency ever reviewed a risk-based hydrologic analysis?

Other (Please explain)

Comments: We have considered risk based hydrologic analysis as another bit of information when reviewing IDFs

33 How difficult would it be to change your regulations? Please explain.

Moderate

34 Are there any unique provisions in your regulations?

No

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	DOL - Mine Safety and Health Administration
Name of Representative	Stanley Michalek
Title of Representative	Acting Dam Safety Officer
Phone number(s)	412-386-6974 (202-693-9476 until 4/4/11)
Email address	michalek.stanley@dol.gov

2 Number of dams under Organization's jurisdiction by type:

Total Dams	2089
Total Regulated Dams	2089
High Hazard Dams	429
Significant Hazard Dams	266
Low Hazard Dams	1394
Unregulated Dams	unknown
Other	n/a

3 What year did your Agency adopt minimum Inflow Design Flood criteria? approx. 1975

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Other (Please specify)

Comments: < 5 feet high; or < 20 feet high and < 20 ac-ft. This is criteria used by Agency's coal program area. For the non-coal program area, the size criteria specified by NID is used.

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

Yes (Please explain)

Comments: In some cases, flood control dams that would be classified as high hazard potential are allowed to be designed to low hazard storm event with warning system.

6 Does the Organization have published size classification criteria?

Yes

If "Yes", check and complete as appropriate:

Class A (Small)	=<	<40	feet high and stores =<	<1000	acre-feet
Class B (Medium)					
Class C (Large)	=>	40	feet high and stores =>	1,000	acre-feet
Other (Specify)					

7 Does the Organization have published hazard classification criteria?

Yes (High, Significant, and Low)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

No potential for loss of life with significant but not excessive economic loss

Comments: Facilties where failure would likely not result in loss of human life, but can cause economic loss, environmental damage, or disruption of lifeline facilities.

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Published guidelines/regulations that are required

Comments: MSHA guidelines use the inflow design flood in the design (freeboard design flood).

9 What is the origin of the guidelines?

FEMA/FERC federal guidelines

10 When were the guidelines last revised (MM/DD/YYYY)? 10/01/2007

Comments: "Coal Mine Impoundment Inspection and Plan Review Handbook"

11 Are there any plans to update or revise the guidelines in the near future?

No

12 Are the guidelines different for new and existing dams?

No

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency reviews submitted designs

MSHA uses inflow design flood.

14 How are the guidelines applied?

Based on both size and hazard classification

15 For PMP/PMF designs, is freeboard required?

3.0' or more

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

No

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

No

18 Do the guidelines specify any criteria for storm duration?

Other (Please specify)

Comments: Designer must consider most severe storm duration up to 72 hours.

19 Do the guidelines specify any criteria for temporal storm distribution?

Yes (HMR)

Comments: Storm must be temporally and spatially distributed to produce the most severe conditions with respect to freeboard and spillway discharge.

20 Do the guidelines specify any criteria for spatial storm distribution?

No

Comments: Storm must be temporally and spatially distributed to produce the most severe conditions with respect to freeboard and spillway discharge.

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

No

22 Does the organization allow development of a site specific PMP?

Yes

If "Yes", are there any restrictions, requirements, or guidelines for performing a site specific PMP?

No

Comments: While we allow it, we've never seen it done.

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

No

24 Do guidelines require consideration or analysis of future development?

Yes (Both of the above)

Comments: Question poorly worded. We do not require consideration of future development in the design plan, but do require consideration/analysis after the development takes place.

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

Yes (Please specify)

Comments: AMC III for PMF; pool at elevation of lowest ungated outlet.

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

Yes

If "Yes", do guidelines require analyses to include future downstream conditions within the dam failure inundation zone?

No

Comments: inflow design flood or freeboard design flood.

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

Yes (Please specify)

Comments: Once hazard potential rating would be determined using incremental damage assessment, design storm is defined by guidelines.

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

Yes

If "Yes", complete as appropriate. If "No", describe below how spillway design capacity is determined.

New High Hazard Dam must pass	100	% of the	PMF
Existing High Hazard Dam must pass	100	% of the	PMF
New Significant Hazard Dam must pass	50-100	% of the	PMF
Existing Significant Hazard Dam must pass	50-100	% of the	PMF

Comments: For significant hazard potential, storm depends on size classification of dam.

29 For low hazard dams, the spillway design requirement is:

Other (Please specify)

Comments: For small reservoir - 100 year, 24 hour
For large reservoir - 1/2 PMF

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

Yes

Comments: Dams constructed to control floods due to storm runoff may be designed to low hazard storm criteria and use an early warning system to evacuate downstream personnel.

31 Does your organization permit risk-based hydrologic designs?

Other (Please explain)

Comments: We do not forbid risk-based designs. We have not seen one submitted. There is some question whether our regulations would allow them.

32 Has your agency ever reviewed a risk-based hydrologic analysis?

No

33 How difficult would it be to change your regulations? Please explain.

Difficult

34 Are there any unique provisions in your regulations?

Yes (Please explain)

Comments: Not with regard to hydrologic issues. We do allow low hazard impoundments to be "abandoned" as live dams if specific criteria are met.

FEMA

HYDROLOGIC SAFETY OF DAMS QUESTIONNAIRE

Gannett Fleming
Your Trusted Advisor Since 1915

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	USDA - Natural Resources Conservation Service
Name of Representative	Noller P. Herbert
Title of Representative	Director, Conservation Engineering Division
Phone number(s)	(202) 720-2520
Email address	noller.herbert@wdc.usda.gov

2 Number of dams under Organization's jurisdiction by type:

Total Dams	
Total Regulated Dams	27254
High Hazard Dams	2233
Significant Hazard Dams	2299
Low Hazard Dams	22722
Unregulated Dams	
Other	

3 What year did your Agency adopt minimum Inflow Design Flood criteria? 1930's

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Both of the above

Comments: Defined in "USDA - NRCS National Engineering Manual (NEM) Part 520, Subpart C Section F." http://directives.sc.egov.usda.gov/viewDirective.aspx?hid=27493

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

No

Comments: Regardless of structure purpose or type of dam, it is subject to either TR-60 or Conservation Practice Standard 378 design standards.

6 Does the Organization have published size classification criteria?

No

Comments: Design standards are based on hazard classification criteria, not size classification.

7 Does the Organization have published hazard classification criteria?

Yes (High, Significant, and Low)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

No potential for loss of life with significant but not excessive economic loss

Comments: Significant Hazard - Dams in predeominately rural or agriclutural areas where failure may damage isolated homes, main highways, or minor railroads, or interrupt service of relatively important utilities.

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Published guidelines/regulations that are required

Comments: TR-60 contains policy on storm size; National Engineering Handbook Part 630, Chapter 21 contains procedure for developing inflow hydrograph.

9 What is the origin of the guidelines?

NRCS guidelines

Comments: SCS/NRCS guidelines were first developed in the 1930s when the first floodwater retarding dams were installed under the pilot watershed program. Since then the guidelines have evolved and are reviewed and updated on a continual basis.

10 When were the guidelines last revised (MM/DD/YYYY)? 07/01/2005

Comments: They are continually under revision and we are trying to get to the point again that they are reviewed every 5 years.

11 Are there any plans to update or revise the guidelines in the near future?

Yes (Please specify)

Comments: We are currently in the process of updating a number of standards and guidelines used in dam design and dam safety activities

12 Are the guidelines different for new and existing dams?

No

Comments: The guidelines are the same for new and existing dams except in the case of rehabilitation of structures where site constraints prohibit the use of the existing guidelines. For those situations, FEMA 94 guidelines on Inflow Design Flood is allowed.

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency utilizes a combination of the above approaches, possibly on a case-by-case basis

Approach dependent upon time and resources available as determined by NRCS State Conservationists.

14 How are the guidelines applied?

Based on hazard classification only

Comments: Based upon size, various types of materials may be allowed for certain appurtenances (for example principal spillway pipes may be either corrugated metal, pvc, steel or concrete depending upon structure size).

15 For PMP/PMF designs, is freeboard required?

No

Comments: PMP/PMF is used to set the top of dam elevation. NRCS does not include additional freeboard.

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

Yes

If "Yes", what are the specific analysis methodologies, procedures, or computer software that must be used?

Must use SITES

Comments: SITES must be used for TR-60 structures. Conservation Practice Standards 378 designs may use other analyses/methodologies/procedures/computer software dependent upon NRCS state conservation engineer guidance.

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

No

Comments: This is based on the professional judgment of the designer, reviewer and approver.

18 Do the guidelines specify any criteria for storm duration?

Other (Please specify)

Comments: Both a short duration (6 hour or longer) and a long duration (24 hour or longer) storm shall be analyzed and the most critical results used to check the capacity and the integrity of the auxiliary spillway.

19 Do the guidelines specify any criteria for temporal storm distribution?

Yes (Other - please specify)

Comments: Principal spillway design hydrographs use NRCS standard distributions. Spillway design hydrographs (used for auxiliary spillway design) use type B or standard distributions. PMP/PMF uses PMP distribution as defined in HMR 52 or 5-point distribution (developed based on HMR 52 methodologies).

20 Do the guidelines specify any criteria for spatial storm distribution?

No

Comments: Uniform rainfall depth assumed over the entire watershed. Rainfall depth may be adjusted based on watershed drainage area.

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

Yes (Please specify)

Comments: Spillway frequency of use criteria are provided. Also, earth and vegetated auxiliary spillways are designed on the basis that some erosion or scour will occur during passage of infrequent storms, but the spillway will not breach during passage of the freeboard storm.

22 Does the organization allow development of a site specific PMP?

Yes

If "Yes", are there any restrictions, requirements, or guidelines for performing a site specific PMP?

No

Comments: NRCS encourages the use of a site-specific PMP where information is available. Site specific PMP studies must be performed by a qualified professional.

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

Yes, a major problem

Comments: NRCS does not regulate any of the dams for which it provides technical or financial assistance. Changing dam classifications is a problem for our customers and sponsors.

24 Do guidelines require consideration or analysis of future development?

Yes (Both of the above)

Comments: TR-60 requires that consideration must be given to the damage that might occur to existing and future developments.

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

Yes (Please specify)

Comments: Use average antecedent runoff conditions (ARC II) or greater unless a special study shows that a different condition is justified. The initial reservoir stage for principal spillway hydrograph routing shall be at the crest of the lowest ungated inlet or (if not subtracted from the stage-storage curve) the anticipated elevation of the sediment storage, whichever is higher, except as provided below. For dams with significant base flow, principal spillway hydrograph routings must start not lower than the elevation of the water surface associated with the base flow. Significant base flow is average annual or seasonal flow that would produce at least 0.5 feet of head over the lowest principal spillway inlet immediately prior to a flood or occupy more than 10 percent of the floodwater storage capacity. For dams with joint use storage capacity, when one of the uses is floodwater detention, routing of the principal spillway hydrograph may begin at the lowest anticipated elevation of the joint use pool in accordance with the operation plan. Single purpose, low hazard class irrigation dams with gated outlets and earth or vegetated auxiliary spillways, which are located on ephemeral streams in areas where the average annual precipitation is less than 25 inches, may be considered to have discharged up to 70 percent of the storage, exclusive of sediment storage in determining the elevation to start routing. For auxiliary spillway and freeboard hydrographs, routings start at the 10-day draw-down elevation or the principal spillway hydrograph.

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

Yes

If "Yes", do guidelines require analyses to include future downstream conditions within the dam failure inundation zone?

Yes

Comments: Methods in the Federal Guidelines for Dam Safety - Inflow Design Floods, FEMA 94, may alternately be used to proportion the embankment and auxiliary spillway, provided downstream land use controls exist to prevent voiding incremental risk assumptions after the dam is completed. Only for rehabiliation projects. Not allowable for new projects.

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

Yes (Please specify)

Comments: Only allowed for rehabilitation projects - not allowed for new projects. For high hazard dams, when using an IDF (FEMA 94) analysis, the minimum storm that can be used can be no less than the freeboard design storm for a significant hazard dam. (P100+0.4(PMP-P100))

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

Yes

If "Yes", complete as appropriate. If "No", describe below how spillway design capacity is determined.

New High Hazard Dam must pass	100	% of the	PMP
Existing High Hazard Dam must pass	100	% of the	PMP
New Significant Hazard Dam must pass		% of the	
Existing Significant Hazard Dam must pass		% of the	

Comments: Significant Freeboard Design Hydrograph: P100 + 0.40(PMP - P100)

29 For low hazard dams, the spillway design requirement is:

Other (Please specify)

Comments: If product of storage and effective height is less than 30,000 and there are no upstream dams: P100 + 0.12(PMP - P100); if product of storage and effective height is greater than 30,000 and there are no upstream dams: P100 + 0.26(PMP - P100); if there is an existing or planned upstream dam: P100 + 0.40(PMP - P100)

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

No

Comments: NRCS might consider an early warning system as alternative, but it is not a part of design guidelines.

31 Does your organization permit risk-based hydrologic designs?

Yes; although our regulations do not specifically address this topic, we review risk-based designs o

Comments: NRCS will consider risk based designs, but they are not a part of design guidelines.

32 Has your agency ever reviewed a risk-based hydrologic analysis?

Yes (Both approved and rejected)

Comments: NRCS has both approved and rejected designs based on FEMA 94 guidelines.

33 How difficult would it be to change your regulations? Please explain.

Moderate

Comments: It takes time for review and coordination but we do not have to get any legislative approval for a change

34 Are there any unique provisions in your regulations?

No

Comments: NRCS tries to apply standards nationwide. States are allowed to revise the standards to make them more restrictive, but not less restrictive. Additionally, NRCS must meet all state and local regulations.

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	Tennessee Valley Authority
Name of Representative	Michael T. Scott
Title of Representative	Dam Safety Officer
Phone number(s)	423.751.6995
Email address	mtscott2@tva.gov

2 Number of dams under Organization's jurisdiction by type:

Total Dams	
Total Regulated Dams	49
High Hazard Dams	36
Significant Hazard Dams	10
Low Hazard Dams	3
Unregulated Dams	
Other	

3 What year did your Agency adopt minimum Inflow Design Flood criteria? circa 1978

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Both of the above

Comments: This survey has been completed for TVA's 49 regulated dams. TVA is currently creating a Dam Safety Governance organization which will implement guidelines for any impoundment within the TVA system which meets the definition of dam given in FEMA 93.

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

No

Comments: TVA is currently creating a Dam Safety Governance organization which will implement dam safety guidelines for any impoundment (tailings, coal combustion products, etc.) which meet the definition of a dam as given in FEMA 93.

6 Does the Organization have published size classification criteria?

No

7 Does the Organization have published hazard classification criteria?

Yes (High, Significant, and Low)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

No potential for loss of life with significant but not excessive economic loss

Comments: TVA follows FEMA 333 for assigning hazard classifications.

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Published guidelines/regulations that are required

Comments: Our historic practice has been to select the PMF as the appropriate spillway design flood for TVA dams with a high hazard classification.

9 What is the origin of the guidelines?

Combination of the above (Please specify)

Comments: FEMA (Federal Guidelines) and self imposed criteria that TVA has historically adopted

10 When were the guidelines last revised (MM/DD/YYYY)? 1/1/2008

Comments: Note that the date is approximate. TVA's self imposed criteria changed based on new information including: operating guides, orifice flow coefficients, etc.

11 Are there any plans to update or revise the guidelines in the near future?

Yes (Please specify)

Comments: TVA Dam Safety Governance organization will issue guidelines and each business unit will create implementing procedures.

12 Are the guidelines different for new and existing dams?

No

Comments: It is not expected that the hydrologic safety of dams guidelines will be different for new and existing dams.

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency acts as designer/engineer

14 How are the guidelines applied?

Based on hazard classification only

15 For PMP/PMF designs, is freeboard required?

No

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

No

Comments: TVA has followed specific methodologies which were not stipulated. TVA uses rainfall design basis developed by NWS under contract with TVA, estimated watershed response (inflows) using TVA developed tools used to schedule the reservoir system, and routed those inflows through the system using hydrologic models developed by TVA.

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

No

18 Do the guidelines specify any criteria for storm duration?

Other (Please specify)

Comments: TVA uses a 9-day sequence specified by a hydrometeorological design basis report developed by NWS (contracted work).

19 Do the guidelines specify any criteria for temporal storm distribution?

Yes (Other - please specify)

Comments: TVA uses a distribution specified by a hydrometeorological design basis report developed by NWS (contracted work).

20 Do the guidelines specify any criteria for spatial storm distribution?

Yes (Please specify)

Comments: TVA uses a distribution specified by a hydrometeorological design basis report developed by NWS (contracted work).

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

No

22 Does the organization allow development of a site specific PMP?

Yes

If "Yes", are there any restrictions, requirements, or guidelines for performing a site specific PMP?

Yes (Please specify)

Comments: TVA uses the hydrometeorological design basis report developed by NWS (contracted work).

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

No

Comments: Historically, this has not been a problem for TVA.

24 Do guidelines require consideration or analysis of future development?

No

Comments: Most communities downstream of TVA dams participate in the FEMA flood insurance program, and so they are somewhat self-regulating.

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

Yes (Please specify)

Comments: Historic practice includes median moisture conditions and conservatively high initial reservoir pool levels.

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

No

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

Yes (Please specify)

Comments: 100-year frequency event minimum

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

No

If "Yes", complete as appropriate. If "No", describe below how spillway design capacity is determined.

New High Hazard Dam must pass		% of the	
Existing High Hazard Dam must pass		% of the	
New Significant Hazard Dam must pass		% of the	
Existing Significant Hazard Dam must pass		% of the	

Comments: Our historic practice has been to select the PMF as the appropriate spillway design flood for TVA dams with a high hazard classification. Significant hazard dams must pass the "TVA precipitation" as defined by the NWS study. This precipitation is significantly less than the PMP.

29 For low hazard dams, the spillway design requirement is:

Other (Please specify)

Comments: TVA practice is that Low hazard dams must pass the "TVA precipitation" as defined by the NWS study. This precipitation is significantly less than the PMP.

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

Yes

Comments: This practice has been adopted by TVA in the past, but was not used as the permanent solution (used as an interim measure).

31 Does your organization permit risk-based hydrologic designs?

Other (Please explain)

Comments: TVA has not practiced risk-basd hydrologic designs. However, the topic has been considered with no firm conclusions.

32 Has your agency ever reviewed a risk-based hydrologic analysis?

No

33 How difficult would it be to change your regulations? Please explain.

Moderate

Comments: Changes to Dam Safety Guidelines would have to be approved by the Dam Safety Officer, Chief Operating Officer, and possibly the TVA Board of Directors/Chief Executive Officer.

34 Are there any unique provisions in your regulations?

No

FEMA

HYDROLOGIC SAFETY OF DAMS QUESTIONNAIRE

Gannett Fleming
Your Trusted Advisor Since 1915

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	Army Corps of Engineers
Name of Representative	Eric C. Halpin
Title of Representative	Special Assistant for Dam and Levee Safety
Phone number(s)	202-761-7662
Email address	Eric.C.Halpin@usace.army.mil

2 Number of dams under Organization's jurisdiction by type:

Total Dams	
Total Regulated Dams	697
High Hazard Dams	525
Significant Hazard Dams	138
Low Hazard Dams	34
Unregulated Dams	
Other	

3 What year did your Agency adopt minimum Inflow Design Flood criteria? Procedures Pertaining to Deter

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Both of the above

Comments: Criteria is per the National Dam Safety Program Act.

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

No

6 Does the Organization have published size classification criteria?

Yes

If "Yes", check and complete as appropriate:

Class A (Small)	=<	40	feet high and stores =<	1,000	acre-feet
Class B (Medium)					
Class C (Large)	=>	100	feet high and stores =>	50,000	acre-feet
Other (Specify)					

Comments: ER 1110-2-106, "Recommended Guidelines for Safety Inspection of Dams", 26 September 1979. This regulation is no longer valid. Current USACE guidance classifies dams by hazard potential and not size.

7 Does the Organization have published hazard classification criteria?

Yes (High, Significant, and Low)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

Loss of life potential is "few" with "appreciable" economic loss

Comments: Loss of life not probable.

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Published guidelines/regulations that are required

Comments: ER 1110-8-2(FR), "Inflow Design Floods for Dams and Reservoirs", 1 March 1991.

9 What is the origin of the guidelines?

USACE guidelines (including Phase I Study guidelines)

10 When were the guidelines last revised (MM/DD/YYYY)? 03/01/1991

11 Are there any plans to update or revise the guidelines in the near future?

Yes (Please specify)

Comments: USACE has a program for updating guidance but there are no specific dates established for this regulation.

12 Are the guidelines different for new and existing dams?

No

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency acts as designer/engineer

14 How are the guidelines applied?

Based on other criteria (Please specify)

Comments: Standard 1: Risk to life and property; Standard 2: Run of river projects; Standard 3: Base safety condition, negligible incremental impacts due to failure; Standard 4: Small Dams

15 For PMP/PMF designs, is freeboard required?

Other (Please specify)

Comments: Three feet minimum for concrete dams. Three feet minimum for embankment dams unless pool is within three feet of the maximum pool for more than 36 hours in which case the minimum is five feet. Required freeboard may be greater than the minimum based on wind setup, wave action, uncertainty in analysis procedures, or uncertainty in project function.

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

Yes

If "Yes", what are the specific analysis methodologies, procedures, or computer software that must be used?

Must use HMRs for developing PMP

Comments: Development of site specific PMPs is allowed. EM 1110-2-1417, "Flood Runoff Analysis", 31 August 1994.

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

Yes (Please specify)

Comments: USACE maintains software lists that classify software as follows: Required, Recommended, Ok to use, Retired, Not Allowed for Use.

18 Do the guidelines specify any criteria for storm duration?

Yes (Based on Tc)

19 Do the guidelines specify any criteria for temporal storm distribution?

Yes (HMR)

20 Do the guidelines specify any criteria for spatial storm distribution?

Yes (Please specify)

Comments: HMR spatial distribution with orientation adjusted to maximize peak discharge.

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

No

22 Does the organization allow development of a site specific PMP?

Yes

If "Yes", are there any restrictions, requirements, or guidelines for performing a site specific PMP?

Yes (Please specify)

Comments: Site specific PMPs require approval by HQUSACE.

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

Yes, a moderate problem

Comments: Although downstream development can change hazard potential classification and inflow design flood requirements, this has not been an issue for USACE dams. A more common issue relates to changes in routine operation due to downstream development. Hazard potential classification affects frequency of dam safety exercises.

24 Do guidelines require consideration or analysis of future development?

Yes (Other; please specify)

Comments: Analysis of new projects requires consideration of most likely future conditions. Existing projects based on existing conditions. Design of spillways requires consideration of potential for hazardous flow regardless of current or future development (ER 1110-2-1451).

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

Yes (Please specify)

Comments: ER 1110-8-2(FR) provides requirements for antecedent reservoir pool conditions. EM 1110-2-1417 provides guidelines for antecedent moisture conditions. Criteria can be modified at the regional (MSC) level based on regional conditions.

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

Yes

If "Yes", do guidelines require analyses to include future downstream conditions within the dam failure inundation zone?

No

Comments: Applies to Standard 3 dams per ER 1110-8-2(FR).

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

Yes (Please specify)

Comments: Minimum 1/2 PMF for Standard 3 dams per ER 1110-8-2(FR).

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

Yes

If "Yes", complete as appropriate. If "No", describe below how spillway design capacity is determined.

New High Hazard Dam must pass	100	% of the	PMF
Existing High Hazard Dam must pass	100	% of the	PMF
New Significant Hazard Dam must pass		% of the	
Existing Significant Hazard Dam must pass		% of the	

Comments: High hazard dams with potential life loss must pass 100% of the PMF per Standard 1 of ER 1110-8-2(FR). Significant hazard dams with no probable life loss must pass major floods typical of the region without excessive damage or loss of operability per Standard 2 of ER 1110-8-2(FR). Significant hazard dams with no incremental life loss due to dam failure must pass a minimum of 1/2 PMF per Standard 3 of ER 1110-8-2(FR).

29 For low hazard dams, the spillway design requirement is:

Other (Please specify)

Comments: Low hazard dams typically fall under Standard 4 of ER 1110-8-2(FR) which requires rainfall-runoff probability analyses with no specific minimum requirement.

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

No

Comments: Early warning can be considered as a risk reduction measure but would not be accepted in lieu of meeting minimum essential guidelines for the inflow design flood.

31 Does your organization permit risk-based hydrologic designs?

Other (Please explain)

Comments: Risk informed hydrologic designs are permitted for flood damage reduction studies (e.g. levees, channel improvements, etc) per ER 1105-2-101. Risk informed hydrologic designs are not permitted for dams. Risk informed hydrologic analyses for dams are used to prioritize risk reduction actions for dams in the USACE inventory and to inform decisions on incremental risk reduction actions for specific projects.

32 Has your agency ever reviewed a risk-based hydrologic analysis?

Yes (Both approved and rejected)

33 How difficult would it be to change your regulations? Please explain.

Difficult

Comments: A significant challenge would be establishing appropriate new/revised essential guidelines. Updating USACE regulations is a well defined process but usually takes 2-5 years to complete.

34 Are there any unique provisions in your regulations?

Yes (Please explain)

Comments: There are numerous guidelines that address/allow consideration of site-specific circumstances, regional considerations, and portfolio prioritization.

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	US Bureau of Reclamation
Name of Representative	Brian Becker
Title of Representative	Chief, Dam Safety Office
Phone number(s)	303-445-2776
Email address	bbecker@usbr.gov

2 Number of dams under Organization's jurisdiction by type:

Total Dams	587
Total Regulated Dams	468
High Hazard Dams	332
Significant Hazard Dams	38
Low Hazard Dams	98
Unregulated Dams	
Other	119

3 What year did your Agency adopt minimum Inflow Design Flood criteria? Around 1951.

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Other (Please specify)

Comments: Reclamation follows definition in the Federal Guidelines for Dam Safety (FGDS). (Your pull downs use the word "and" between the 2 dimensions, when the FGDS uses "or" and your pull-downs incorrectly mixing the 2 dimensions. The way the FGDS reads is 25ft and 50 ac-ft for one jurisdiction test and 6' and 15ac-ft for the other test.)\

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

No

6 Does the Organization have published size classification criteria?

No

7 Does the Organization have published hazard classification criteria?

Yes (High, Significant, and Low)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

No potential for loss of life with significant but not excessive economic loss

Comments: Prior to adopting FEMA 333, Reclamation Dam Safety Program used the following definition for Significant: "Few Loss of Life is defined as 1 to 6 lives in jeopardy. Appreciable economics is defined as rural area with notable agriculture, industry, or worksites, or outstanding natural resources." While we now follow FEMA 333 definitions, dams that were assigned a hazard class of significant by following our 1988 guidelines and have potential life loss, these facilities have not been changed to high-hazard. It is the Reclamation's Dam Safety view that since these significant-hazard dams are treated as high-hazard.

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Published guidelines/regulations for consideration by the engineer/designer

Comments: Reclamation uses the Reclamation Flood Hydrology Manual and the Reclamation Public Protection Guidelines (PPG) and uses a risk based approach.

9 What is the origin of the guidelines?

USBR guidelines

Comments: The risk assessment methodology of 1999 is superceded by the current Best Practices and used in coordination with the PPG. Reclamation has moved away from deterministic design flood standards and now uses risk-based approach. (Reclamation prefers the acronym of "Reclamation" instead of USBR or BOR.)

10 When were the guidelines last revised (MM/DD/YYYY)? 04/04/2011

Comments: Dam Safety Risk Analysis Best Practices Manual is updated as needed; approximately once or twice a year. PPG was last updated in 2010.

11 Are there any plans to update or revise the guidelines in the near future?

Yes (Please specify)

Comments: Dam Safety Risk Analysis Best Practices Manual is updated as needed; approximately once or twice a year. PPG was last updated in 2010.

12 Are the guidelines different for new and existing dams?

Yes (Please elaborate)

Comments: The application of updated design guidelines, or state-of-the-art, will vary by project. Modifications to existing structures must consider the amount of risk reduction, feasibility of the modification, and the cost/benefit when trying to apply state-of-the art.

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency acts as designer/engineer

In determining the spillway design flood, we set spillway design as case by case. It's very structure/site specific.

14 How are the guidelines applied?

Based on risk analysis

15 For PMP/PMF designs, is freeboard required?

Other (Please specify)

Comments: Following the Federal Guidelines for Dam Safety, freeboard conditions include consideration factors that can reasonably occur at the given project site but include, wave height based on fetch and wind velocity assumptions, settlement, allowance for improper gate operation, landslide-generated wave potential, and perphaps an arbitrary allowance for contingencies to provide an increased factor of safety.

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

No

Comments: The Dam Safety Risk Analysis Best Practice was written to guide the engineer but also allows for deviation if justifiable.

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

No

Comments: Duration of flood overtopping is a critical element in determining the failure probability; however, it is difficult to accurately estimate.

18 Do the guidelines specify any criteria for storm duration?

No

Comments: Basis for storm duration is the PMP hydromet reports and is dependant upon site conditions. Type of spillway is a critical factor as well size of reservoir.

19 Do the guidelines specify any criteria for temporal storm distribution?

Yes (Other - please specify)

Comments: The Reclamation Flood Hydrology Manual specifies a 2/3 PMP distribution. We vary this based on site conditions and individual extreme storms according to Reclamations's

20 Do the guidelines specify any criteria for spatial storm distribution?

Yes (Please specify)

Comments: The Flood Hydrology Manual specifies a successive subtraction for PMP over watershed subbasins. We vary this based on site conditions and individual extreme storms according to Reclamations's guidelines for estimating hydrologic hazard curves.

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

Yes (Please specify)

Comments: Reclamation uses risk analysis but most likely freeboard would be integrated with other analysis, such as gate operations.

22 Does the organization allow development of a site specific PMP?

Yes

If "Yes", are there any restrictions, requirements, or guidelines for performing a site specific PMP?

No

Comments: PMPs are obtained for moderate level of effort studies such as Issue Evaluations, Corrective Action Studies, and Final Design. Reclamation uses generalized PMPs from the HMRs and according to Reclamation Flood Hydrology Manual and the Hydrologic Hazard Guidelines. Instead of site specific PMPs, Reclamation uses risk analysis.

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

No

Comments: It is not a regulatory problem since changes in downstream development are reviewed during facility exams.

24 Do guidelines require consideration or analysis of future development?

Yes (Both of the above)

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

Yes (Please specify)

Comments: The risk analysis decision tree evaluates loads at various reservoir elevations. Antecedent moisture conditions are a parameter in modeling and are considered during the risk analysis process.

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

Yes

If "Yes", do guidelines require analyses to include future downstream conditions within the dam failure inundation zone?

No

Comments: The Guidelines do not require an incremental damage assessment but are used if appropriate.

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

No

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

No

Comments: Any modifications to spillway design capacity would follow a risk-based approach using Reclamation's Risk Analysis Best Practices Manual.

29 For low hazard dams, the spillway design requirement is:

Not specified

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

No

Comments: For new design of high hazard dam, an EWS would probably not be allowed as an alternative for the regulatory spillway design flood. In cases of risk reduction, the cost to modify up to state-of-the-art may require the use of an EWS.

31 Does your organization permit risk-based hydrologic designs?

Yes; our regulations permit them

Comments: A better answer is Yes, our guidelines permit them.

32 Has your agency ever reviewed a risk-based hydrologic analysis?

Yes (Both approved and rejected)

33 How difficult would it be to change your regulations? Please explain.

Moderate

34 Are there any unique provisions in your regulations?

No

HYDROLOGIC SAFETY OF DAMS QUESTIONNAIRE

FEMA

Gannett Fleming
Your Trusted Advisor Since 1915

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	US Fish and Wildlife Service
Name of Representative	Brad Iarossi
Title of Representative	Chief, Dam Bridge and Seismic Safety Branch
Phone number(s)	703-358-2211
Email address	Brad_Iarossi@fws.gov

2 Number of dams under Organization's jurisdiction by type:

Total Dams	
Total Regulated Dams	259
High Hazard Dams	17
Significant Hazard Dams	18
Low Hazard Dams	224
Unregulated Dams	
Other	

3 What year did your Agency adopt minimum Inflow Design Flood criteria? 1991

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Both of the above

Comments: The U.S. Fish and Wildlife Service uses the definition of a dam found in the National Dam Safety Program Act to define a dam as "inventory dam". Impundment structures that do not meet these size/hazard criteria are considered "non-inventory" and are not subject to dam safety inspections etc.

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

No

6 Does the Organization have published size classification criteria?

Yes

If "Yes", check and complete as appropriate:

Class A (Small)	=<	40	feet high and stores =<	1,000	acre-feet
Class B (Medium)					
Class C (Large)	=>	100	feet high and stores =>	50,000	acre-feet
Other (Specify)					

Comments: Intermediate (Medium) 40-100 feet high; 1000 - 50,000 acre feet

7 Does the Organization have published hazard classification criteria?

Yes (High, Significant, and Low)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

No potential for loss of life with significant but not excessive economic loss

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Published guidelines/regulations that are required

Comments: The U.S. Fish and Wildlife Service self regulates our dams, therefore the design guidelines are followed, but are not in statute as we are not a regulator.

9 What is the origin of the guidelines?

Unknown

10 When were the guidelines last revised (MM/DD/YYYY)? 09/12/2008

11 Are there any plans to update or revise the guidelines in the near future?

Yes (Please specify)

Comments: The guidelines will likely be revised to incorporate risk assessments and updates to the EAP format.

12 Are the guidelines different for new and existing dams?

No

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency reviews submitted designs

Incremental damage assessments are often used to establish inflow design floods.

14 How are the guidelines applied?

Based on both size and hazard classification

15 For PMP/PMF designs, is freeboard required?

Other (Please specify)

Comments: Evaluated on a case by case basis

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

No

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

No

18 Do the guidelines specify any criteria for storm duration?

No

19 Do the guidelines specify any criteria for temporal storm distribution?

No

20 Do the guidelines specify any criteria for spatial storm distribution?

No

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

No

22 Does the organization allow development of a site specific PMP?

Yes

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

Yes, a major problem

Comments: It is not a regulatory problem as we are not a regulator, however, as a responsible dam owner, we modify our dams appropriately based on hazard classification.

24 Do guidelines require consideration or analysis of future development?

Yes (Impacts of development on hazard classification or failure consequences)

Comments: If data is available

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

No

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

Yes

If "Yes", do guidelines require analyses to include future downstream conditions within the dam failure inundation zone?

Yes

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

Yes (Please specify)

Comments: Minimum inflow design is the 100-year flood.

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

Yes

If "Yes", complete as appropriate. If "No", describe below how spillway design capacity is determined.

New High Hazard Dam must pass	100	% of the	PMF
Existing High Hazard Dam must pass	100	% of the	PMF
New Significant Hazard Dam must pass	50-100	% of the	PMF
Existing Significant Hazard Dam must pass	50-100	% of the	PMF

Comments: Significant: Small (50% PMF), Intermediate (50% PMF), Large (50-100% PMF)

29 For low hazard dams, the spillway design requirement is:

Other (Please specify)

Comments: Small (100-year), Intermediate (100-year), Large (100-year to 500-year)

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

No

Comments: Absolutely NOT!

31 Does your organization permit risk-based hydrologic designs?

Yes; our regulations permit them

32 Has your agency ever reviewed a risk-based hydrologic analysis?

Yes (Reviewed and approved)

33 How difficult would it be to change your regulations? Please explain.

Easy

34 Are there any unique provisions in your regulations?

No

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	Forest Service
Name of Representative	Clifford Denning
Title of Representative	Program Manager, Geotech and Dams
Phone number(s)	414-297-3305
Email address	cdenning@fs.fed.us

2 Number of dams under Organization's jurisdiction by type:

Total Dams	
Total Regulated Dams	437
High Hazard Dams	31
Significant Hazard Dams	83
Low Hazard Dams	323
Unregulated Dams	
Other	

3 What year did your Agency adopt minimum Inflow Design Flood criteria? s dated 1993 and minimum inf

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Both of the above

Comments: Non-inventory dams are dams with a low or undertermined hazard potential classification that do not meet: a) Equal or exceed 25 feet in height and exceed 15 acre-feet in storage or b) Exceed 6 feet in height and equal or exceed 50 acre-feet in storage.

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

No

6 Does the Organization have published size classification criteria?

No

Comments: New Forest Service Manual does not have published size classification criteria.

7 Does the Organization have published hazard classification criteria?

Yes (High, Significant, and Low)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

No potential for loss of life with significant but not excessive economic loss

Comments: Would result in no probable loss of human life but could cause economic loss, disruption of lifeline facilities, or other significant impacts and would result in non-recoverable environmental damage.

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Published guidelines/regulations that are required

Comments: The level of design detail increases from preliminary to final design and with increasing size, value, and hazard potential classification of the structure. The level of detail of the geological and geotechnical investigation, design, design reports, and drawings must be adequate to construct the dam within acceptable safety parameters for its size and hazard potential classification. Utilize current U. S. Army Corps of Engineers or Bureau of Reclamation standards and procedures for dams in planning, investigating, and designing dams on National Forest System lands.

9 What is the origin of the guidelines?

Combination of the above (Please specify)

Comments: FEMA and USACE guidelines were consulted in the revision of our direction.

10 When were the guidelines last revised (MM/DD/YYYY)? 05/01/2011

Comments: The Forest Service guidelines are currently being revised and the above date is an estimated date of completion.

11 Are there any plans to update or revise the guidelines in the near future?

Yes (Please specify)

Comments: They are currently being revised

12 Are the guidelines different for new and existing dams?

No

Comments: Existing dams which can accommodate at least 75 percent of the inflow design flood do not need to be modified to increase spillway capacity to the minimum requirements , until the dams undergo major reconstruction.

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency utilizes a combination of the above approaches, possibly on a case-by-case basis

14 How are the guidelines applied?

Based on hazard classification only

15 For PMP/PMF designs, is freeboard required?

No

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

No

Comments: At a minimum, utilize standards and procedures established by the Bureau or Reclamation, U. S. Army Corps of Engineers, or Natural Resources Conservation Service for determining the design storm event and sizing the spillway. Any appropriate Federal and State standards may be used case by case. Conduct site-specific evaluations to develop the inflow design hydrographs.

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

No

Comments: At a minimum, utilize standards and procedures established by the Bureau or Reclamation, U. S. Army Corps of Engineers, or Natural Resources Conservation Service for determining the design storm event and sizing the spillway. Any appropriate Federal and State standards may be used case by case. Conduct site-specific evaluations to develop the inflow design hydrographs.

18 Do the guidelines specify any criteria for storm duration?

No

Comments: At a minimum, utilize standards and procedures established by the Bureau or Reclamation, U. S. Army Corps of Engineers, or Natural Resources Conservation Service for determining the design storm event and sizing the spillway. Any appropriate Federal and State standards may be used case by case. Conduct site-specific evaluations to develop the inflow design hydrographs.

19 Do the guidelines specify any criteria for temporal storm distribution?

No

Comments: At a minimum, utilize standards and procedures established by the Bureau or Reclamation, U. S. Army Corps of Engineers, or Natural Resources Conservation Service for determining the design storm event and sizing the spillway. Any appropriate Federal and State standards may be used case by case. Conduct site-specific evaluations to develop the inflow design hydrographs.

20 Do the guidelines specify any criteria for spatial storm distribution?

No

Comments: At a minimum, utilize standards and procedures established by the Bureau or Reclamation, U. S. Army Corps of Engineers, or Natural Resources Conservation Service for determining the design storm event and sizing the spillway. Any appropriate Federal and State standards may be used case by case. Conduct site-specific evaluations to develop the inflow design hydrographs.

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

No

22 Does the organization allow development of a site specific PMP?

Yes

If "Yes", are there any restrictions, requirements, or guidelines for performing a site specific PMP?

No

Comments: Conduct site-specific evaluations to develop the inflow design hydrographs.

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

Yes, a moderate problem

Comments: We have had several dams change classifications because of downstream development due to lack of zoning requirements.

24 Do guidelines require consideration or analysis of future development?

Yes (Impacts of development on hazard classification or failure consequences)

Comments: Consider and document reasonably foreseeable downstream development as well as existing development in the assessment.

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

No

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

Yes

If "Yes", do guidelines require analyses to include future downstream conditions within the dam failure inundation zone?

No

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

Yes (Please specify)

Comments: Under no circumstances should the spillway capacity be reduced below the applicable minimum threshold (High=0.5PMF, Significant=100-year RP, Low=50-year RP).

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

Yes

If "Yes", complete as appropriate. If "No", describe below how spillway design capacity is determined.

New High Hazard Dam must pass	100	% of the	PMF
Existing High Hazard Dam must pass	100	% of the	PMF
New Significant Hazard Dam must pass	50	% of the	PMF
Existing Significant Hazard Dam must pass	50	% of the	PMF

Comments: Incremental Damage Analysis may allow spillway capacity to be reduced, but not any lower than the minimum threshold stated in question 27.

29 For low hazard dams, the spillway design requirement is:

100-year flood

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

No

Comments: While we would not accept as an alternative the new direction states "To afford the maximum opportunity to alleviate problems that could threaten the integrity or operation of a dam remote sensing is required on all Forest Service operated dams with a high hazard potential classification."

31 Does your organization permit risk-based hydrologic designs?

Our regulations do not specifically address this topic and it has never come up for consideration

32 Has your agency ever reviewed a risk-based hydrologic analysis?

Unsure

33 How difficult would it be to change your regulations? Please explain.

Moderate

Comments: While not impossible, changes require review and edits at different levels.

34 Are there any unique provisions in your regulations?

No

C.3. Completed State Surveys

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	Alaska
Name of Representative	Charles Cobb
Title of Representative	State Dam Safety Engineer
Phone number(s)	(907) 269-8636
Email address	charles.cobb@alaska.gov

2 Number of dams under Organization's jurisdiction by type:

Total Dams	171
Total Regulated Dams	79
High Hazard Dams	19
Significant Hazard Dams	30
Low Hazard Dams	30
Unregulated Dams	57
Other	35

3 What year did your Agency adopt minimum Inflow Design Flood criteria? 2004

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Other (Please specify)

Comments: Less than 10 feet in height and poses no threat to lives and property; less than 20 feet in height, impounding less than 50 acre-feet and poses no threat to lives and property.

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

Yes (Please explain)

Comments: Certain tailings dams must meet highest design standard

6 Does the Organization have published size classification criteria?

No

If "Yes", check and complete as appropriate:

Class A (Small) =< _____ feet high and stores =< _____ acre-feet

Class B (Medium)

Class C (Large) => _____ feet high and stores => _____ acre-feet

Other (Specify) _____

Comments:

7 Does the Organization have published hazard classification criteria?

Yes (High, Significant, and Low)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

Other (Please specify)

Comments: failure or improper operation of the barrier will result in: Significant danger to public health; Probable loss of or probable signifcant damage to homes, occupied structures, commercial property, high-value property, major highways, primary roads, railroads or public utilities, except those which belong to the barrier owner; other probable significant property losses or damage; probable loss of or significant damage to waters identified as important for the spawning, rearing or migration of anadromous fish.

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Other (Please specify)

Comments: State published guidelines which do not have the force of law, and reference to FEMA 94 (1998) in published regulations (Alaska Administrative Code) which does have the force of law.

9 What is the origin of the guidelines?

Custom developed by Organization

Comments: Alaska Dam Safety Program

10 When were the guidelines last revised (MM/DD/YYYY)? 06/01/2005

Comments:

11 Are there any plans to update or revise the guidelines in the near future?

No

Comments:

12 Are the guidelines different for new and existing dams?

Yes (Please elaborate)

Comments: Depends

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency utilizes a combination of the above approaches, possibly on a case-by-case basis

The department will at a minimum review submitted designs, and depending on the hazard potential of the structure will on a case-by-case basis perform an independent verification. In some unusual circumstances the department may perscribe the IDF if the owner of an existing dam lacks the resources to define it themselves.

14 How are the guidelines applied?

Based on hazard classification only

Comments:

15 For PMP/PMF designs, is freeboard required?

No

Comments:

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

No

If "Yes", what are the specific analysis methodologies, procedures, or computer software that must be used?

Comments:

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

No

Comments:

18 Do the guidelines specify any criteria for storm duration?

No

Comments:

19 Do the guidelines specify any criteria for temporal storm distribution?

No

Comments:

20 Do the guidelines specify any criteria for spatial storm distribution?

No

Comments:

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

No

Comments: 100 year flood minimum IDF for all dams

22 Does the organization allow development of a site specific PMP?

Yes

If "Yes", are there any restrictions, requirements, or guidelines for performing a site specific PMP?

No

Comments:

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

Yes, a minor problem

Comments:

24 Do guidelines require consideration or analysis of future development?

Yes (Impacts of development on hazard classification or failure consequences)

Comments:

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

No

Comments:

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

Yes

If "Yes", do guidelines require analyses to include future downstream conditions within the dam failure inundation zone?

No

Comments:

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

Yes (Please specify)

Comments: 100 year flood is minimum IDF for all dams

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

No

If "Yes", complete as appropriate. If "No", describe below how spillway design capacity is determined.

New High Hazard Dam must pass		% of the	
Existing High Hazard Dam must pass		% of the	
New Significant Hazard Dam must pass		% of the	
Existing Significant Hazard Dam must pass		% of the	

Comments: Minimum Standard for any dam: 100 year flood
Maximum Standard for any dam: PMF

29 For low hazard dams, the spillway design requirement is:

100-year flood

Comments:

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

Yes

Comments: Yes for existing dam, No for new construction

31 Does your organization permit risk-based hydrologic designs?

Yes; although our regulations do not specifically address this topic, we review risk-based designs o

Comments:

32 Has your agency ever reviewed a risk-based hydrologic analysis?

No

Comments:

33 How difficult would it be to change your regulations? Please explain.

Difficult

Comments: Requires public comment and review

34 Are there any unique provisions in your regulations?

Yes (Please explain)

Comments: Protection of anadromous fish habitat included in hazard potential classification
Design criteria specifically excluded to allow engineers to develop reasonable designs

FEMA

HYDROLOGIC SAFETY OF DAMS QUESTIONNAIRE

Gannett Fleming
Your Trusted Advisor Since 1915

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	Arizona
Name of Representative	Nicole Spence-Gibson
Title of Representative	Engineering Section
Phone number(s)	602-771-8658
Email address	nsgibson@azwater.gov

2 Number of dams under Organization's jurisdiction by type:

Total Dams	
Total Regulated Dams	252
High Hazard Dams	100
Significant Hazard Dams	36
Low Hazard Dams	116
Unregulated Dams	
Other	

3 What year did your Agency adopt minimum Inflow Design Flood criteria? 1978

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Other (Please specify)

Comments: (a) any barrier that is or will be less than six feet in height, regardless of storage capacity
(b) any barrier between 6 and 25 ft in height with a storage capacity of less than 50 AF
(c) any barrier that has or will have a storage capacity of fifteen acre-feet or less, regardless of height
(d) any barrier for the purpose of controlling liquid-borne material
(e) any barrier that is a release-contained barrier (f) any barrier that is owned, controlled, operated, maintained or managed by the United States Government or its agencies or instrumentalities if a safety program that is as least as stringent as the state safety program applies and is enforced against the agent or instrumentality.

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

No

6 Does the Organization have published size classification criteria?

Yes

If "Yes", check and complete as appropriate:

Class A (Small)	=<	40	feet high and stores =<	1000	acre-feet
Class B (Medium)					
Class C (Large)	=>	100	feet high and stores =>	50000	acre-feet
Other (Specify)					

7 Does the Organization have published hazard classification criteria?

Yes (High, Significant, Low, Limited Hazard)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

No potential for loss of life with significant but not excessive economic loss

Comments: Significant hazard potential is defined as failure or improper operation of a dam would be unlikely to result in loss of human life but may cause significant or high economic loss, intangible damage requiring major mitigation, and disruption or impact on lifeline facilities. Property losses would occur in a predominantly rural or agricultural area with a transient population but significant infrastructure.

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Published guidelines/regulations for consideration by the engineer/designer

9 What is the origin of the guidelines?

Custom developed by Organization

10 When were the guidelines last revised (MM/DD/YYYY)? 03/01/2004

11 Are there any plans to update or revise the guidelines in the near future?

No

12 Are the guidelines different for new and existing dams?

Yes (Please elaborate)

Comments: Our rules related to the magnitude of idf do differ for new and existing dams.

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency reviews submitted designs

14 How are the guidelines applied?

Based on both size and hazard classification

15 For PMP/PMF designs, is freeboard required?

Other (Please specify)

Comments: Largest of the following: i.) The sum of the inflow design flood maximum water depth above the spillway crest plus wave run up. ii.) The sum of the inflow design flood

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

No

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

No

18 Do the guidelines specify any criteria for storm duration?

Other (Please specify)

Comments: Our rules do not specifiy criteria for storm duration; however, we developed general guidelines to assist with for the evaluation of spillway adequacy. For the evaluation, we require PMF studies include the 6-hour local and 72-hour. Site-specific PMP depths and distributions are accepted if independently reviewed by a qualified third-party meteorologist.

19 Do the guidelines specify any criteria for temporal storm distribution?

Yes (Other - please specify)

Comments: Time-distribution for the 6-hour local PMP follows the HMR 49 procedure. The 72-hour general storm PMP uses: A. 1st Day - Second Largest Day uniformly distributed. B. 2nd Day - Largest Day sequenced as follows: 1. 3rd largest 6-hr period uniformly distributed 2. 2nd largest 6hr period uniformly distributed 3. Largest 6-hour period uniformly distributed and 4. 4th largest 6-hr period uniformly distributed. c. 3rd Day - Smallest day uniformly distributed. Site-specific PMP depths and distributions may be accepted if independently reviewed by a qualified third party meteorologist.

20 Do the guidelines specify any criteria for spatial storm distribution?

Yes (Please specify)

Comments: See Comment 19.

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

No

22 Does the organization allow development of a site specific PMP?

Yes

If "Yes", are there any restrictions, requirements, or guidelines for performing a site specific PMP?

No

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

Yes, a minor problem

24 Do guidelines require consideration or analysis of future development?

Yes (Impacts of development on hazard classification or failure consequences)

Comments: The evaluation shall include land use zoning and development projected for the affected area over the 10 year period following classification of the dam.

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

No

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

Yes

If "Yes", do guidelines require analyses to include future downstream conditions within the dam failure inundation zone?

Yes

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

No

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

Yes

If "Yes", complete as appropriate. If "No", describe below how spillway design capacity is determined.

New High Hazard Dam must pass	50-100	% of the	PMF
Existing High Hazard Dam must pass	50-100	% of the	PMF
New Significant Hazard Dam must pass	25-50	% of the	PMF
Existing Significant Hazard Dam must pass	25-50	% of the	PMF

Comments: For significant hazard, design is determined by size classification. For high hazard, design is determined based on the number of persons at risk and the potential for downstream damage.

29 For low hazard dams, the spillway design requirement is:

Other (Please specify)

Comments: 25% of the PMF, Very low hazard potential dams it is the 100-year.

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

No

Comments: Our regulations do not specifically address this topic and it has never come up for consideration.

31 Does your organization permit risk-based hydrologic designs?

Our regulations do not specifically address this topic and it has never come up for consideration

32 Has your agency ever reviewed a risk-based hydrologic analysis?

No

33 How difficult would it be to change your regulations? Please explain.

Difficult

Comments: Any changes to our regulations would require stakeholder meetings and would go through the Governoring Regulatory Review Council.

34 Are there any unique provisions in your regulations?

Yes (Please explain)

1. Emergency Spillway Requirements. An applicant shall: a. Construct each spillway in a manner that avoids flooding in excess of the flooding that would have occurred in the same location under the same conditions before construction. The owner of a dam shall demonstrate that a spillway discharge would not result in incremental adverse consequences. In determining whether a spillway discharge of a dam would result in incremental adverse consequences, the Director shall evaluate whether the owner has taken any or all of the following actions: issuing public notice to downstream property owners, complying with flood insurance requirements, adopting emergency action plans, conducting mock flood drills, acquiring flow easements or other acquisitions of real property, or other actions appropriate to safeguard the dam site and flood channel. b. Include a control structure to avoid head cutting and lowering of the spillway crest for spillways excavated in soils or soft rock. In the alternative, the design may provide evidence acceptable to the Director that erosion during the inflow design flood will not result in a sudden release of the reservoir. c. Provide each spillway and channel with a minimum width of 10 feet and suitable armor to prevent erosion during the discharge resulting from the inflow design flood. d. Ensure that downstream spillway channel flows do not encroach on the dam unless suitable erosion protection is constructed.
e. Ensure that each spillway, in combination with outlets, is able to safely pass the peak discharge flow rate, as calculated on the basis of the inflow design flood. f. Not construct bridges or fences across a spillway unless the construction is approved in writing by the Director. The Director's approval may include conditions regarding the design and operation of the spillway and fencing, based on safety concerns. g. Not use a pipe or culvert as an emergency spillway unless the Director approves the use following review of the dam design and site characteristics.

Comments:

HYDROLOGIC SAFETY OF DAMS QUESTIONNAIRE

FEMA

Gannett Fleming
Your Trusted Advisor Since 1915

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	Arkansas
Name of Representative	Alvin Simmons, Jr., P.E.
Title of Representative	Engineer Supervisor
Phone number(s)	501-682-3981
Email address	alvin.simmons@arkansas.gov

2 Number of dams under Organization's jurisdiction by type:

Total Dams	
Total Regulated Dams	406
High Hazard Dams	103
Significant Hazard Dams	95
Low Hazard Dams	208
Unregulated Dams	
Other	

3 What year did your Agency adopt minimum Inflow Design Flood criteria?

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Other (Please specify)

Comments: Less than 25 feet dam height or less than 50 acre-feet of storage (top of dam)

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

No

6 Does the Organization have published size classification criteria?

Yes

If "Yes", check and complete as appropriate:

Class A (Small)	=<	40	feet high and stores =<	1000	acre-feet
Class B (Medium)					
Class C (Large)	=>	100	feet high and stores =>	50,000	acre-feet
Other (Specify)					

7 Does the Organization have published hazard classification criteria?

Yes (High, Significant, and Low)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

No potential for loss of life with significant but not excessive economic loss

Comments: Appreciable (Significant structures, industrial, or commercial development, or cropland); $100,000 to $500,000.

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Published within State Laws

9 What is the origin of the guidelines?

Combination of the above (Please specify)

10 When were the guidelines last revised (MM/DD/YYYY)? 10/01/1993

11 Are there any plans to update or revise the guidelines in the near future?

Yes (Please specify)

Comments: Within the next 2 years

12 Are the guidelines different for new and existing dams?

Yes (Please elaborate)

Comments: Existing dams will be evaluated periodically to determine if development of downstream areas warrants change in hazard classification and review of spillway design flood (SDF). Overtopping during the SDF may be allowed if properly prepared analyses demonstrate that: (1) overtopping will have a return interval greater than 25 years; and (2) the dam will withstand the projected overtopping without failure.

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency performs independent verification of submitted designs

14 How are the guidelines applied?

Based on both size and hazard classification

15 For PMP/PMF designs, is freeboard required?

No

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

No

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

No

18 Do the guidelines specify any criteria for storm duration?

No

19 Do the guidelines specify any criteria for temporal storm distribution?

No

20 Do the guidelines specify any criteria for spatial storm distribution?

No

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

No

22 Does the organization allow development of a site specific PMP?

Yes

If "Yes", are there any restrictions, requirements, or guidelines for performing a site specific PMP?

No

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

Yes, a minor problem

Comments: NRCS dams

24 Do guidelines require consideration or analysis of future development?

Yes (Impacts of development on hazard classification or failure consequences)

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

No

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

Yes

If "Yes", do guidelines require analyses to include future downstream conditions within the dam failure inundation zone?

Yes

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

No

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

Yes

If "Yes", complete as appropriate. If "No", describe below how spillway design capacity is determined.

New High Hazard Dam must pass	50-100	% of the	PMF
Existing High Hazard Dam must pass	50-100	% of the	PMF
New Significant Hazard Dam must pass	25-100	% of the	PMF
Existing Significant Hazard Dam must pass	25-100	% of the	PMF

Comments: Percentage ranges are given and are based upon effective height of dam or maximum storage, whichever computed SDF is greated.

29 For low hazard dams, the spillway design requirement is:

Other (Please specify)

Comments: 0.25PMF to 0.75PMF depending on size of dam (small, intermediate, or large).

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

No

31 Does your organization permit risk-based hydrologic designs?

Our regulations do not specifically address this topic and it has never come up for consideration

32 Has your agency ever reviewed a risk-based hydrologic analysis?

No

33 How difficult would it be to change your regulations? Please explain.

Moderate

34 Are there any unique provisions in your regulations?

No

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	California
Name of Representative	David A. Gutierrez
Title of Representative	Chief, Division of Safety of Dams
Phone number(s)	916-227-9800
Email address	daveg@water.ca.gov

2 Number of dams under Organization's jurisdiction by type:

Total Dams	
Total Regulated Dams	1247
High Hazard Dams	688
Significant Hazard Dams	274
Low Hazard Dams	285
Unregulated Dams	
Other	

3 What year did your Agency adopt minimum Inflow Design Flood criteria? 1930

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Both of the above

Comments: We also have other execptions to jurisdiction.

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

No

Comments: However, dams of different consequence class have varying design standards/requirements. For instance, a PMF is applied to very high hazard dams while a 1000 year level storm is for very low potential consequence. Same with earthquakes. Flood Control dams also have different requirements.

6 Does the Organization have published size classification criteria?

No

Comments: Damage potential classification based on capacity, height, estimated evacuation, and potential d/s damage

7 Does the Organization have published hazard classification criteria?

Yes (High, Significant, and Low)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

Other (Please specify)

Comments: Damage potential classification based on capacity, height, estimated evacuation, and potential d/s damage

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Published guidelines/regulations for consideration by the engineer/designer

Comments: The force of law is not specifically outlined but California gives dam safety program broad authority to enforce these requirements. These are not "guidelines" as defined by the State of California, but Technical Reference how it is done at DSOD.

9 What is the origin of the guidelines?

Custom developed by Organization

10 When were the guidelines last revised (MM/DD/YYYY)? 03/01/1981

11 Are there any plans to update or revise the guidelines in the near future?

Yes (Please specify)

Comments: There is no specific date yet determined

12 Are the guidelines different for new and existing dams?

Yes (Please elaborate)

Comments: The technical reference does not outline variations, but DSOD has different policy for new and existing dams.

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency performs independent verification of submitted designs

14 How are the guidelines applied?

Based on a combination of risk analysis and hazard/size classification

15 For PMP/PMF designs, is freeboard required?

1.5'

Comments: Additional freeboard is required for severe wave conditions from wind effects. In addtion 1.5 feet is required on new dams while existing dams may not be required to have more than zero residual freeboard depending on wave runup.

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

Yes

If "Yes", what are the specific analysis methodologies, procedures, or computer software that must be used?

Must use HMRs for developing PMP

Comments: Our inhouse evaluations use HEC. Statiscial requirements for dams is dependent on potential consequence.

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

No

18 Do the guidelines specify any criteria for storm duration?

Yes (72-hour)

Comments: In general, the total precipitation duration is taken to be 72 hours. If routing will not significantly affect the peak outflow, a shorter storm (e.g., 24 hours) can be considered since the peak inflow will be about the same in either case.

19 Do the guidelines specify any criteria for temporal storm distribution?

Yes (HMR)

20 Do the guidelines specify any criteria for spatial storm distribution?

No

Comments: The guidelines do not specify to this detail, but DSOD practice considers spatial storm distribution.

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

No

Comments: Spillway design criteria is based on frequency of flooding up to the PMP

22 Does the organization allow development of a site specific PMP?

Yes

If "Yes", are there any restrictions, requirements, or guidelines for performing a site specific PMP?

No

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

Yes, a minor problem

Comments: On occasion downstream development changes the hazard classification, but in most cases in California, most of the dams are already at the highest level.

24 Do guidelines require consideration or analysis of future development?

No

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

Yes (Please specify)

Comments: For non flood control dams, reservoir is taken at spillway level. Antecendent moisture conditions are considered in evaluating the runoff coefficient.

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

No

Comments: Guidelines don't specify, but DSOD has considered incremental damage in past and plans to develop guidelines for use.

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

No

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

No

Comments: It is prudent to a allow a continuous range of design floods corresponding to the developed Total Class Weights. The minimum allowable design event required is a 1000 year storm which corresponds with a TCW of 4. The maximum event is a storm derived from the Probable Maximum Precipitation and is equated with a TCW of 30. The design event is interpolated between these limits at the computed TCW. Typically, probable maximum precipitation storms are required only for dams that impound 1000 acre-feet or more, are at least 50 feet high, would require an estimated evacuation of at least 1000 people, and have a damage potential of $25,000,000 or greater. However, most dams require a design storm falling between the 1000 year event and the probable maximum event. Figure 2 presents a histogram of TCW (as determined by DSOD) for all jurisdictional dams within California. As can be seen, less than 8 percent of all dams require a PMF.

29 For low hazard dams, the spillway design requirement is:

Other (Please specify)

Comments: 1000-year

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

No

Comments: We have allowed the use of early warning systems as part of interim measures until dam is repaired.

31 Does your organization permit risk-based hydrologic designs?

Yes; although our regulations do not specifically address this topic, we review risk-based designs o

Comments: The definition of risk based hydrologic design is not defined in this question and means different things to different people. However based on the risk, DSOD applies statistical storms starting with a 1000 year level up to a PMP

32 Has your agency ever reviewed a risk-based hydrologic analysis?

Yes (Reviewed and approved)

33 How difficult would it be to change your regulations? Please explain.

Difficult

Comments: We usually apply policy and give direction based on that policy. Regulations are too stiff and do not seem the appropriate way to deal with technical issues. Statutes are even worse and should never be used to dictate technical issues.

34 Are there any unique provisions in your regulations?

No

HYDROLOGIC SAFETY OF DAMS QUESTIONNAIRE

FEMA

Gannett Fleming
Your Trusted Advisor Since 1915

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	Colorado
Name of Representative	Mark R. Haynes
Title of Representative	Chief Dam Safety Engineer
Phone number(s)	303-866-3581
Email address	mark.haynes@state.co.us

2 Number of dams under Organization's jurisdiction by type:

Total Dams	3000
Total Regulated Dams	1935
High Hazard Dams	352
Significant Hazard Dams	322
Low Hazard Dams	1261
Unregulated Dams	1065
Other	

3 What year did your Agency adopt minimum Inflow Design Flood criteria? 1967

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Other (Please specify)

Comments: Less than 100 acre-feet or creates a reservoir with a surface area less than 20 acres at the high-water line, or is less than 10 feet in height.

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

No

6 Does the Organization have published size classification criteria?

Yes

If "Yes", check and complete as appropriate:

Class A (Small)	=<	20	feet high and stores =<	100	acre-feet
Class B (Medium)					
Class C (Large)	=>	50	feet high and stores =>	4,000	acre-feet
Other (Specify)					

Comments: The three classes in increasing size are: Minor Dam, Small Dam, Large Dam.

7 Does the Organization have published hazard classification criteria?

Yes (High, Significant, Low, Limited Hazard)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

No potential for loss of life with significant but not excessive economic loss

Comments: The classfications are as follows: High, Significant, Low, and No Public Hazard (NPH).

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Published guidelines/regulations that are required

9 What is the origin of the guidelines?

USBR guidelines

10 When were the guidelines last revised (MM/DD/YYYY)? 01/01/2007

11 Are there any plans to update or revise the guidelines in the near future?

No

Comments: Next update in 10 years

12 Are the guidelines different for new and existing dams?

Yes (Please elaborate)

Comments: Grandfather clause for dams built prior to 1988. Minimum IDF criteria of the 100-year storm.

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency reviews submitted designs

Have final approval of IDF

14 How are the guidelines applied?

Based on both size and hazard classification

15 For PMP/PMF designs, is freeboard required?

Based on wave run up computations

Comments: The minimum freeboard requirements for new or enlarged dams shall be based upon the dam height required to prevent overtopping by wave action, or the sum of the inflow design flood maximum water surface level plus one foot of residual freeboard, but not less than five feet unless the State Engineer approves a lesser amount. Except for concrete dams where the design engineer has demonstrated that overtopping of the dam will not be detrimental to the safety of the dam, the inflow design flood can be accommodated with zero residual freeboard or the overtopping depth at which the dam still meets the stability and stress requirements of Rule 5.9.5.

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

No

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

No

18 Do the guidelines specify any criteria for storm duration?

Yes (24-hour)

Comments: For high frequency storms.

19 Do the guidelines specify any criteria for temporal storm distribution?

Yes (HMR)

20 Do the guidelines specify any criteria for spatial storm distribution?

No

Comments: Depends on procedures in HMRs and Hydrologic Software

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

No

22 Does the organization allow development of a site specific PMP?

Yes

If "Yes", are there any restrictions, requirements, or guidelines for performing a site specific PMP?

Yes (Please specify)

Comments: Site Specific Hydrometeorologic Analysis (SSHMA) may be used to determine the appropriate site specific extreme storm precipitation (SSESP) for the determination of the IDF. Site-specific evaluations are subject to approval by the State Engineer. Any procedures developed and approved by the State Engineer shall be used to determine the applicable Extreme Precipitation Event. Snowmelt conditions shall be considered as base flow when appropriate. The percentage reduction of the PMP as shown in Rule 5.9.1.5 are not applicable or allowed in the determination of site specific extreme storm precipitation or PMP values determined by the procedures and analysis provided for in this Rule for all High Hazard dams and Large Significant Hazard dams. Specific percentages of the Site-specific PMP are required based on size and hazard classification.

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

Yes, a moderate problem

Comments: Constant

24 Do guidelines require consideration or analysis of future development?

No

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

Yes (Please specify)

Comments: No for antecedent moisture conditions and yes for initial reservoir pool levels.

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

Yes

If "Yes", do guidelines require analyses to include future downstream conditions within the dam failure inundation zone?

No

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

Yes (Please specify)

Comments: Minimum IDF is the 100-year event

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

Yes

If "Yes", complete as appropriate. If "No", describe below how spillway design capacity is determined.

New High Hazard Dam must pass	0.45-0.90	% of the	PMP
Existing High Hazard Dam must pass		% of the	
New Significant Hazard Dam must pass	0.45-0.68	% of the	PMP
Existing Significant Hazard Dam must pass		% of the	

Comments: Based on size classification as well. There are also percentages of the PMP for special cases involving reductions due to elevation and site specific PMPs.

29 For low hazard dams, the spillway design requirement is:

Other (Please specify)

Comments: 50 to 100 year depending on size classification.

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

No

31 Does your organization permit risk-based hydrologic designs?

Our regulations do not specifically address this topic and it has never come up for consideration

32 Has your agency ever reviewed a risk-based hydrologic analysis?

No

33 How difficult would it be to change your regulations? Please explain.

Moderate

Comments: Could require Statutory changes and would require public review and hearings.

34 Are there any unique provisions in your regulations?

No

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	Connecticut
Name of Representative	Arthur P. Christian II, P.E.
Title of Representative	Supervising Civil Engineer
Phone number(s)	860-424-3880
Email address	art.christian@act.gov

2 Number of dams under Organization's jurisdiction by type:

Total Dams	
Total Regulated Dams	3024
High Hazard Dams	242
Significant Hazard Dams	267
Low Hazard Dams	2515
Unregulated Dams	1455
Other	

3 What year did your Agency adopt minimum Inflow Design Flood criteria?

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Both of the above

Comments: Or all other dams with an impoundment capacity of three (3) acre-feet or less.

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

No

6 Does the Organization have published size classification criteria?

No

7 Does the Organization have published hazard classification criteria?

Yes (Other)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

Loss of life potential is "few" with "appreciable" economic loss

Comments: Negligible (Class AA), Low (Class A), Moderate (Class BB), Significant (Class B), and High (Class C)

8 Does the Organization have guidelines for determining the spillway design flood?

No

If "Yes", what is the status of the guidelines; do they have the force of law?

Unpublished guidelines for consideration by the engineer/designer

9 What is the origin of the guidelines?

Combination of the above (Please specify)

Comments: Written by Philip Moreschi

10 When were the guidelines last revised (MM/DD/YYYY)? n/a

Comments: Continuous revision

11 Are there any plans to update or revise the guidelines in the near future?

Comments: Continuous revision

12 Are the guidelines different for new and existing dams?

No

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency reviews submitted designs

14 How are the guidelines applied?

Based on both size and hazard classification

15 For PMP/PMF designs, is freeboard required?

No

Comments: No specific requirements although wave runup may be considered by the design engineer based on the specific dam.

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

No

If "Yes", what are the specific analysis methodologies, procedures, or computer software that must be used?

Comments: The agency requires standard public domain software applications such as Hec-HMS or NRCS type modeling.

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

No

Comments: The agency requires that the engineer demonstrates that the methodolgy/analysis is both appropriate and an accepted engineering standard.

18 Do the guidelines specify any criteria for storm duration?

No

19 Do the guidelines specify any criteria for temporal storm distribution?

No

20 Do the guidelines specify any criteria for spatial storm distribution?

No

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

No

22 Does the organization allow development of a site specific PMP?

Yes

If "Yes", are there any restrictions, requirements, or guidelines for performing a site specific PMP?

No

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

Yes, a minor problem

Comments: Hazard classifications get changed routinely however most changes occur within the category of low hazard dams. Therefore spillway design requirements do not need to be modified.

24 Do guidelines require consideration or analysis of future development?

No

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

No

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

Yes

If "Yes", do guidelines require analyses to include future downstream conditions within the dam failure inundation zone?

No

Comments: Only if future development is known to be planned.

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

No

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

Yes

If "Yes", complete as appropriate. If "No", describe below how spillway design capacity is determined.

New High Hazard Dam must pass	100	% of the	PMF
Existing High Hazard Dam must pass	50-100	% of the	PMF
New Significant Hazard Dam must pass	50-100	% of the	PMF
Existing Significant Hazard Dam must pass	50	% of the	PMF

Comments: The above criteria assume that the impoundment sizes are large and intermediate as defined by the ACOE spillway design criteria.

29 For low hazard dams, the spillway design requirement is:

100-year flood

Comments: With one foot of freeboard or passing two times the 100 year without overtopping.

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

No

31 Does your organization permit risk-based hydrologic designs?

Our regulations do not specifically address this topic and it has never come up for consideration

Comments: The agency has not considered risk-based hydrologic designs at this time.

32 Has your agency ever reviewed a risk-based hydrologic analysis?

No

Comments: The agency has not considered risk-based hydrologic designs at this time.

33 How difficult would it be to change your regulations? Please explain.

Difficult

Comments: It is a lengthy formal process that can take up to two years. It is time intensive and sensitive to deadlines and subject to the will of a legislative committee.

34 Are there any unique provisions in your regulations?

No

Comments: The agency's regulations only pertain to the periodic inspection of dams.

FEMA

HYDROLOGIC SAFETY OF DAMS QUESTIONNAIRE

Gannett Fleming
Your Trusted Advisor Since 1915

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	Delaware
Name of Representative	David R. Twing
Title of Representative	State Dam Safety Engineer
Phone number(s)	302-834-5557
Email address	david.twing@state.de.us

2 Number of dams under Organization's jurisdiction by type:

Total Dams	49
Total Regulated Dams	49
High Hazard Dams	44
Significant Hazard Dams	5
Low Hazard Dams	0
Unregulated Dams	0
Other	0

3 What year did your Agency adopt minimum Inflow Design Flood criteria? 2009

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Other (Please specify)

Comments: any one of the following: privately owned; low hazard; less than 6 feet high; less than 15 acre-feet of storage

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

No

6 Does the Organization have published size classification criteria?

No

7 Does the Organization have published hazard classification criteria?

Yes (High, Significant, and Low)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

Loss of life potential is "few" with "appreciable" economic loss

Comments: High Hazard includes any dam whose failure or misoperation will cause probable loss of human life. Significant Hazard includes any dam whose failure or misoperation will cause possible loss of human life, economic loss, environmental damage, and disruption of lifeline facilities. Low Hazard is unlikely to cause loss of human life but may cause minor economic and/or environmental losses.

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Published guidelines/regulations that are required

9 What is the origin of the guidelines?

Custom developed by Organization

10 When were the guidelines last revised (MM/DD/YYYY)? 12/11/2009

11 Are there any plans to update or revise the guidelines in the near future?

No

12 Are the guidelines different for new and existing dams?

Yes (Please elaborate)

Comments: Incremental damage assessment may be used to reduce the spillway design flood of existing dams.

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency reviews submitted designs

14 How are the guidelines applied?

Based on hazard classification only

15 For PMP/PMF designs, is freeboard required?

Based on wave run up computations

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

No

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

No

18 Do the guidelines specify any criteria for storm duration?

No

19 Do the guidelines specify any criteria for temporal storm distribution?

No

20 Do the guidelines specify any criteria for spatial storm distribution?

No

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

Yes (Please specify)

Comments: Performance criteria specified for pipe conduit spillways, vegetated auxiliary spillways, etc. Activation criteria are also specified.

22 Does the organization allow development of a site specific PMP?

Yes

If "Yes", are there any restrictions, requirements, or guidelines for performing a site specific PMP?

No

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

No

Comments: Not a problem for us yet because we just started our dam safety program; the hazard classifications for all dams in the state were determined in 2008

24 Do guidelines require consideration or analysis of future development?

Yes (Impacts of development on hazard classification or failure consequences)

Comments: All Class II and III dams shall, where practicable, incorporate in the proposed design the ability to make modifications necessary to increase the spillway capacity of the facility or other alternative measures if the downstream hazard potential increases.

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

No

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

Yes

If "Yes", do guidelines require analyses to include future downstream conditions within the dam failure inundation zone?

No

Comments: For existing dams only.

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

Yes (Please specify)

Comments: Minimum design storm for the dam shall be the 100-year storm.

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

Yes

If "Yes", complete as appropriate. If "No", describe below how spillway design capacity is determined.

New High Hazard Dam must pass	100	% of the	PMF
Existing High Hazard Dam must pass	100	% of the	PMF
New Significant Hazard Dam must pass	50	% of the	PMF
Existing Significant Hazard Dam must pass	50	% of the	PMF

29 For low hazard dams, the spillway design requirement is:

100-year flood

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

No

31 Does your organization permit risk-based hydrologic designs?

Our regulations do not specifically address this topic and it has never come up for consideration

32 Has your agency ever reviewed a risk-based hydrologic analysis?

No

33 How difficult would it be to change your regulations? Please explain.

Moderate

Comments: Changes in the regulations that don't involve changing the enabling legislation still require public notice, so I would use "moderate" to describe that process.

34 Are there any unique provisions in your regulations?

No

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	Georgia
Name of Representative	Tom Woosley
Title of Representative	Program Manager
Phone number(s)	404-362-2678
Email address	tom_woosley@dnr.state.ga.us

2 Number of dams under Organization's jurisdiction by type:

Total Dams	
Total Regulated Dams	3926
High Hazard Dams	474
Significant Hazard Dams	0
Low Hazard Dams	3452
Unregulated Dams	
Other	

3 What year did your Agency adopt minimum Inflow Design Flood criteria? 1978

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Other (Please specify)

Comments: Less than 25 feet or stores less than 100 acre-feet. Also those less than 6 feet in height regardless of storage capacity or which have storage capacity of less than 15 acre-feet regardless of height.

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

No

6 Does the Organization have published size classification criteria?

Yes

If "Yes", check and complete as appropriate:

Class A (Small)	=<	25	feet high and stores =<	500	acre-feet
Class B (Medium)					
Class C (Large)	=>	35	feet high and stores =>	1000	acre-feet
Other (Specify)	Very Large Dams: > 100 feet and > 50,000 acre-feet				

7 Does the Organization have published hazard classification criteria?

Yes (Other)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

Other (Please specify)

Comments: Only two categories: Category I means the classification where improper operation or dam failure would result in probable loss of human life. Category II means the classification where improper operation or dam failure would not be expected to result in probable loss of human life.

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Published guidelines/regulations that are required

Comments: The law states the requirement, the guidelines detail out how we would determine the PMP

9 What is the origin of the guidelines?

Custom developed by Organization

Comments: Developed with help of consultants in 1998

10 When were the guidelines last revised (MM/DD/YYYY)? 06/01/2007

Comments: Version 3.1

11 Are there any plans to update or revise the guidelines in the near future?

Yes (Please specify)

Comments: Talking about it, but not in the works right now.

12 Are the guidelines different for new and existing dams?

Yes (Please elaborate)

Comments: Based on visual inspection and detailed hydrologic and hydraulic evaluation, including documentation of completed design and construction procedures, up to 10 percent lower requirement (22.5, 30, 45, 90) may be accepted on existing PL566 (including RC&D structures) and PL 534 Project Dams at the discretion of the Director, provided the project is in an acceptable state of maintenance. The design storm may be reduced on existing dams if the applicant's engineer can successfully demonstrate to the Director, by engineering analysis, that the dam is sufficient to protect against probable loss of human life downstream at a lesser design storm. Earth emergency spillways shall not function until the 50 year storm.

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency reviews submitted designs

14 How are the guidelines applied?

Based on size classification only

15 For PMP/PMF designs, is freeboard required?

Based on wave run up computations

Comments: 3-foot maximum

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

Yes

If "Yes", what are the specific analysis methodologies, procedures, or computer software that must be used?

Must use HEC-1

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

Yes (Please specify)

Comments: Models other than HEC-1 must be approved prior to design.

18 Do the guidelines specify any criteria for storm duration?

Yes (6-hr)

19 Do the guidelines specify any criteria for temporal storm distribution?

Yes (HMR)

20 Do the guidelines specify any criteria for spatial storm distribution?

No

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

Yes (Please specify)

Comments: Earth emergency spillways shall not function until the 50 year storm. SITES integrity analysis is required for earthen spillway.

22 Does the organization allow development of a site specific PMP?

Unknown (never requested)

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

Yes, a moderate problem

24 Do guidelines require consideration or analysis of future development?

Yes (Both of the above)

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

Yes (Please specify)

Comments: AMC-III is to be used on the 6-hr storm

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

Yes

If "Yes", do guidelines require analyses to include future downstream conditions within the dam failure inundation zone?

No

Comments: For existing dams only.

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

Yes (Please specify)

Comments: Requirement can be reduced by up to 10%.

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

Yes

Comments: Very large dam (100% of PMP), Large dam (50% of PMP), Medium dam (33.3% of PMP), and Small dam (25% of PMP)

29 For low hazard dams, the spillway design requirement is:

Not specified

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

No

31 Does your organization permit risk-based hydrologic designs?

No; our regulations forbid them

32 Has your agency ever reviewed a risk-based hydrologic analysis?

No

33 How difficult would it be to change your regulations? Please explain.

Difficult

Comments: Extremely, especially in the current political climate

34 Are there any unique provisions in your regulations?

No

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	Hawaii
Name of Representative	Edwin Matsuda
Title of Representative	Civil Engineer
Phone number(s)	808-587-0268
Email address	edwin.y.matsuda@hawaii.gov

2 Number of dams under Organization's jurisdiction by type:

Total Dams	
Total Regulated Dams	138
High Hazard Dams	123
Significant Hazard Dams	3
Low Hazard Dams	12
Unregulated Dams	
Other	

3 What year did your Agency adopt minimum Inflow Design Flood criteria? 1992

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Other (Please specify)

Comments: < 25ft height & < 50acft volume at max water surface elevation; or < 6 ft height; or < 15 acft volume at max water surface elevation

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

No

6 Does the Organization have published size classification criteria?

Yes

If "Yes", check and complete as appropriate:

Class A (Small)	=<	40	feet high and stores =<	1000	acre-feet
Class B (Medium)					
Class C (Large)	=>	100	feet high and stores =>	50,000	acre-feet
Other (Specify)					

7 Does the Organization have published hazard classification criteria?

Yes (High, Significant, and Low)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

No potential for loss of life with significant but not excessive economic loss

Comments: "Significant hazard" means a dam's or reservoir's failure will result in no probable loss of human life but can cause major economic loss, environmental damage, disruption of lifeline facilities, or impact other concerns. Significant hazard potential classification dams or reservoirs are often located in predominantly rural or agricultural areas but could be located in areas with population and significant infrastructure.

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Unpublished guidelines that are required

Comments: Design flows are specified in the draft administrative rules and pending approval will have the same authority as the law.

9 What is the origin of the guidelines?

Other (Please specify)

Comments: Originally specified in our guidelines and probably based on FEMA guidance material in the early 1990s. Current draft reflects previous guidelines with some minor

10 When were the guidelines last revised (MM/DD/YYYY)? 12/01/1992

Comments: Guidelines are currently being updated. Administrative rules have been drafted, passed through public hearings and is pending final approval.

11 Are there any plans to update or revise the guidelines in the near future?

Yes (Please specify)

Comments: Currently contracted out to consultant

12 Are the guidelines different for new and existing dams?

No

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency utilizes a combination of the above approaches, possibly on a case-by-case basis

14 How are the guidelines applied?

Based on both size and hazard classification

15 For PMP/PMF designs, is freeboard required?

Based on wave run up computations

Comments: Freeboard requirement determined on case by case requirement. Proposed Rules will specify "the greater of the following: (1) Two feet above the water level during the peak spillway flow associated with the inflow design flood; (2) Sum of the wave run-up and reservoir setup resulting from a 100 mph wind speed during the peak spillway flow associated with the inflow design flood."

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

Yes

If "Yes", what are the specific analysis methodologies, procedures, or computer software that must be used?

Must use HMRs for developing PMP

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

No

18 Do the guidelines specify any criteria for storm duration?

Yes (24-hour)

19 Do the guidelines specify any criteria for temporal storm distribution?

No

Comments: Existing guidelines specify SCS type I distribution however not defined in current draft HAR. May be addressed in guidelines update.

20 Do the guidelines specify any criteria for spatial storm distribution?

No

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

No

22 Does the organization allow development of a site specific PMP?

Unknown (never requested)

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

Yes, a major problem

24 Do guidelines require consideration or analysis of future development?

No

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

No

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

No

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

No

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

Yes

If "Yes", complete as appropriate. If "No", describe below how spillway design capacity is determined.

New High Hazard Dam must pass	100	% of the	PMF
Existing High Hazard Dam must pass	100	% of the	PMF
New Significant Hazard Dam must pass	50-100	% of the	PMF
Existing Significant Hazard Dam must pass	50-100	% of the	PMF

29 For low hazard dams, the spillway design requirement is:

Other (Please specify)

Comments: 100 year for small and intermediate low hazard dams and 0.5PMF for large low hazard dams.

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

Yes

Comments: There are provisions within our draft administrative rules for our approving board to grant variances to the requirements. Sufficient justification and assurances would likely be required for these to be approved.

31 Does your organization permit risk-based hydrologic designs?

Our regulations do not specifically address this topic and it has never come up for consideration

32 Has your agency ever reviewed a risk-based hydrologic analysis?

No

33 How difficult would it be to change your regulations? Please explain.

Difficult

Comments: Changes to our regulations can either be done through statute via our state legislature or through rules which require proceeding through the rule making process. Either change or revision will likely face a large amount of questions and possible resistance and require a lot of time and resources to address.

34 Are there any unique provisions in your regulations?

Yes (Please explain)

Comments: Our revisions do allow for our approving board to grant variances to the requirements stated. This was believed to be the best method of covering many of the specific issues in the regulations that we may not have addressed adequately. Also allows for owners of existing dams some other means of mitigating deficiencies which the dam may not have been required to meet when it was designed.

FEMA

HYDROLOGIC SAFETY OF DAMS QUESTIONNAIRE

Gannett Fleming
Your Trusted Advisor Since 1915

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	Idaho
Name of Representative	John Falk
Title of Representative	
Phone number(s)	208-287-4927 / 208-287-4800
Email address	John.Falk@idwr.idaho.gov

2 Number of dams under Organization's jurisdiction by type:

Total Dams	
Total Regulated Dams	569
High Hazard Dams	107
Significant Hazard Dams	149
Low Hazard Dams	313
Unregulated Dams	
Other	

3 What year did your Agency adopt minimum Inflow Design Flood criteria? Last revised 2006

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Other (Please specify)

Comments: Statute definition is for Regulated Dams; i.e. 10 feet or more in height or with an impounding capacity of 50 acre-feet or more. Conversely, non-regulated dams are those less than 10' high AND less than 50 ac-ft.

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

Yes (Please explain)

Comments: Mine tailings impoundment structures which are, or will be, more than 30 feet high are regulated by the state dam safety program.

6 Does the Organization have published size classification criteria?

Yes

If "Yes", check and complete as appropriate:

Class A (Small)	=<	20	feet high and stores =<	100	acre-feet
Class B (Medium)					
Class C (Large)	=>	40	feet high and stores =>	4,000	acre-feet
Other (Specify)					

Comments: Contained within Administrative Rules only

7 Does the Organization have published hazard classification criteria?

Yes (High, Significant, and Low)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

Other (Please specify)

Comments: In the Administrative Rules, the term "Risk" is substituted for "Hazard" inappropriately. In Rule, "Significant Risk" is based on flood depth, velocity, and consequence of significant damage to intrastructure; loss of life is not mentioned.

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Published within State Laws

Comments: Contained within Administrative Rules

9 What is the origin of the guidelines?

Unknown

10 When were the guidelines last revised (MM/DD/YYYY)? 01/01/2006

Comments: Administative Rules last revised in 2006

11 Are there any plans to update or revise the guidelines in the near future?

No

Comments: Lack of staff resources to pursue revisions

12 Are the guidelines different for new and existing dams?

Yes (Please elaborate)

Comments: Exemptions if approved by Director, exemptions based on existence prior to the state's dam safety laws.

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency reviews submitted designs

…with reference to existing Administrative Rule.

14 How are the guidelines applied?

Based on both size and hazard classification

15 For PMP/PMF designs, is freeboard required?

Based on wave run up computations

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

No

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

No

18 Do the guidelines specify any criteria for storm duration?

No

19 Do the guidelines specify any criteria for temporal storm distribution?

No

20 Do the guidelines specify any criteria for spatial storm distribution?

No

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

No

22 Does the organization allow development of a site specific PMP?

Unknown (never requested)

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

Yes, a moderate problem

Comments: Problem will intensify because cost for rehabilitation is increasingly costly, permitting may be Catch-22, and lack of dam safety resources likely will not allow periodic review and/or enforcement.

24 Do guidelines require consideration or analysis of future development?

No

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

No

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

No

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

No

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

Yes

If "Yes", complete as appropriate. If "No", describe below how spillway design capacity is determined.

New High Hazard Dam must pass	Q100-100	% of the	PMF
Existing High Hazard Dam must pass	Q100-100	% of the	PMF
New Significant Hazard Dam must pass	Q100-50	% of the	PMF
Existing Significant Hazard Dam must pass	Q100-50	% of the	PMF

Comments: High hazard dam: Q100-PMF, depending on size of dam; Significant hazard dam: Q100-0.5PMF, depending on size of dam.

29 For low hazard dams, the spillway design requirement is:

Other (Please specify)

Comments: Q50-Q500 depending on size of dam; these lower and upper boundaries are prescriptive and extreme, and badly in need of revision.

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

Comments: Cannot speculate as existing Statute and Rule do not address applicability. Organization would consider revising Rules to offer the opportunity, with conditions.

31 Does your organization permit risk-based hydrologic designs?

Our regulations do not specifically address this topic and it has never come up for consideration

32 Has your agency ever reviewed a risk-based hydrologic analysis?

No

Comments: The only review has been cursory for federal dams or federal regulated hydroelectric dams in which the State is a marginal participant.

33 How difficult would it be to change your regulations? Please explain.

Difficult

Comments: The procedure appears to be moderately involved (formation of committee, legislative committee recognition, hearings/testimony prior to acceptace by legislature). However, dam safety staff has been significantly reduced making any proposed revisions unlikely without neglecting primary safety mission of routine inspection and design review.

34 Are there any unique provisions in your regulations?

No

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	Illinois
Name of Representative	Jason Campbell
Title of Representative	Senior Permit Engineer
Phone number(s)	217-558-4532
Email address	jason.campbell@illinois.gov

2 Number of dams under Organization's jurisdiction by type:

Total Dams	
Total Regulated Dams	1485
High Hazard Dams	187
Significant Hazard Dams	299
Low Hazard Dams	999
Unregulated Dams	
Other	

3 What year did your Agency adopt minimum Inflow Design Flood criteria? 1980

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Both of the above

Comments: Also, if the drainage area of the dam is 6400 acres or less in a rural area, or 640 acres in an urban area

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

No

6 Does the Organization have published size classification criteria?

Yes

If "Yes", check and complete as appropriate:

Class A (Small)	=<	40	feet high and stores =<	1,000	acre-feet
Class B (Medium)					
Class C (Large)	=>	100	feet high and stores =>	50,000	acre-feet
Other (Specify)					

7 Does the Organization have published hazard classification criteria?

Yes (High, Significant, and Low)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

Loss of life potential is "few" with "appreciable" economic loss

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Published guidelines/regulations that are required

9 What is the origin of the guidelines?

Combination of the above (Please specify)

Comments: Technical publications other than the Corps Guidelines may be used to assure the use of current and applicable data for the hydrologic and hydraulic review of dam design.

10 When were the guidelines last revised (MM/DD/YYYY)? 01/01/2003

11 Are there any plans to update or revise the guidelines in the near future?

No

12 Are the guidelines different for new and existing dams?

Yes (Please elaborate)

Comments: Reduced spillway design requirements for dams built before September 2, 1980. Any submittal for variation from the reduced spillway design flood must include a detailed hydraulic risk assessment that shows that additional spillway capacity will not provide a decrease in potential loss of life or property damage or a detailed economic risk assessment that shows that the chosen spillway design alternative provides the minimum rehabilitation costs plus damage losses; a detailed early warning and emergency evacuation plan coordinated with the local ESDA; and a list (with mailing addresses) of all persons living within the dam breach wave inundation area.

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency utilizes a combination of the above approaches, possibly on a case-by-case basis

14 How are the guidelines applied?

Based on both size and hazard classification

15 For PMP/PMF designs, is freeboard required?

Other (Please specify)

Comments: Case-by-case basis considering many factors including duration of high water levels during the design flood, the effective wind fetch and reservoir depth available to support wave generation, the probability of high wind speed occurring from a critical direction, the potential wave runup on the dam based on roughness and slope, and the ability of the dam to resist erosion from overtopping waves.

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

No

If "Yes", what are the specific analysis methodologies, procedures, or computer software that must be used?

Must use HMRs for developing PMP

Comments: Procedures developed by US Army Corps of Engineers, US Dept of the Interior (Bureau of Reclamation), US Dept of Agriculture (Natural Resources Conservation Service), and the National Weather Service are recommended as acceptable. The programs typically used by OWR for review include: HEC-1, HEC-HMS, HEC-2, HEC-RAS and FLDWAV.

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

No

18 Do the guidelines specify any criteria for storm duration?

Other (Please specify)

Comments: At least a 24-hour duration.

19 Do the guidelines specify any criteria for temporal storm distribution?

Yes (HMR)

20 Do the guidelines specify any criteria for spatial storm distribution?

No

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

Yes (Please specify)

Comments: Regulations distinguish between principal spillway design flood and total spillway design flood.

22 Does the organization allow development of a site specific PMP?

Yes

If "Yes", are there any restrictions, requirements, or guidelines for performing a site specific PMP?

No

Comments: Never been done at this point.

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

No

Comments: Changing the classification / spillway design requirements is not difficult, occasionally there is some resistance to implementation of the new classification.

24 Do guidelines require consideration or analysis of future development?

Yes (Impacts of development on hazard classification or failure consequences)

Comments: For all proposed Class II or III dams, a determination of alternatives for increasing the total spillway capacity to accommodate the PMF shall also be submitted to OWR. The initial dam design shall provide for the capability of increasing the spillway capacity. future downstream land use, land use controls, and growth projections will be considered in the review of the spillway capacity design.

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

No

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

Yes

If "Yes", do guidelines require analyses to include future downstream conditions within the dam failure inundation zone?

No

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

Yes (Please specify)

Comments: No less than 100-year flood unless it is a small size, Class III structure with dam height multiplied by impounding capacity less than or equal to 300.

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

Yes

If "Yes", complete as appropriate. If "No", describe below how spillway design capacity is determined.

New High Hazard Dam must pass	50-100	% of the	PMF
Existing High Hazard Dam must pass	30-60	% of the	PMF
New Significant Hazard Dam must pass	100yr-100	% of the	PMF
Existing Significant Hazard Dam must pass	100yr-60	% of the	PMF

Comments: Class I: 0.5PMF-1.0PMF; Class II: 100-yr-PMF; Class III: 100-yr-0.5PMF; Ranges depend on the size of dam.

29 For low hazard dams, the spillway design requirement is:

Other (Please specify)

Comments: Ranges from 100-yr for a small dam to 0.5PMF for a large dam.

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

Yes

Comments: Any submittal for variation from the above-listed spillway design flood must include a detailed hydraulic risk assessment that shows that additional spillway capacity will not

31 Does your organization permit risk-based hydrologic designs?

Yes; although our regulations do not specifically address this topic, we review risk-based designs o

32 Has your agency ever reviewed a risk-based hydrologic analysis?

Unsure

33 How difficult would it be to change your regulations? Please explain.

Difficult

Comments: Theoretically, it should not be very difficult. However given the current state of State politics it would in all likelyhood be very difficult.

34 Are there any unique provisions in your regulations?

No

HYDROLOGIC SAFETY OF DAMS QUESTIONNAIRE

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	Indiana
Name of Representative	Kenneth E. Smith, P.E.
Title of Representative	Assistant Director
Phone number(s)	317-232-4224
Email address	kesmith@dnr.IN.gov

2 Number of dams under Organization's jurisdiction by type:

Total Dams	
Total Regulated Dams	1088
High Hazard Dams	240
Significant Hazard Dams	249
Low Hazard Dams	599
Unregulated Dams	
Other	

3 What year did your Agency adopt minimum Inflow Design Flood criteria? not formally adopted

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Other (Please specify)

Comments: The drainage area above the dam site is less than one square mile; the height of the dam above the natural stream bed or the lowest point on the valley floor is less than 20 feet; the volume of water impounded by the dam to the emergency spillway level is less than 100 acre-feet; or the rights of other property owners are affected.

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

Yes (Please explain)

Comments: coal mine related dams held to MSHA standards, by the Division of Reclamation

6 Does the Organization have published size classification criteria?

No

7 Does the Organization have published hazard classification criteria?

Yes (High, Significant, and Low)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

No potential for loss of life with significant but not excessive economic loss

Comments: Also includes a "Multiple Dams" classification. Where failure of a dam could contribute to failure of a downstream dam or dams, the minimum hazard class of the dam shall not be less than that of any such downstream structure.

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Published guidelines/regulations that are required

9 What is the origin of the guidelines?

Combination of the above (Please specify)

Comments: attempted to use typical national best management practices

10 When were the guidelines last revised (MM/DD/YYYY)? 01/01/2001

11 Are there any plans to update or revise the guidelines in the near future?

Yes (Please specify)

Comments: will revise if a new unified national practice is published

12 Are the guidelines different for new and existing dams?

Yes (Please elaborate)

Comments: The design storm for existing dams can be reduced using Incremental Damage Evaluation

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency reviews submitted designs

14 How are the guidelines applied?

Based on hazard classification only

15 For PMP/PMF designs, is freeboard required?

No

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

No

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

No

18 Do the guidelines specify any criteria for storm duration?

Yes (Based on Tc)

19 Do the guidelines specify any criteria for temporal storm distribution?

Yes (NRCS Standard)

20 Do the guidelines specify any criteria for spatial storm distribution?

No

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

No

22 Does the organization allow development of a site specific PMP?

Unknown (never requested)

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

Yes, a moderate problem

Comments: administrative legal processes, public notice and hearings required

24 Do guidelines require consideration or analysis of future development?

No

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

Yes (Please specify)

Comments: AMC II

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

Yes

If "Yes", do guidelines require analyses to include future downstream conditions within the dam failure inundation zone?

No

Comments: For existing dams only. The owner and engineer should recognize that dam construction typically results in higher risks. If an Incremental Hazard Evaluation procedure is utilized,

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

Yes (Please specify)

Comments: 50% PMP minimum for High Hazard dams, 100-Year minimum for Low Hazard dams

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

Yes

If "Yes", complete as appropriate. If "No", describe below how spillway design capacity is determined.

New High Hazard Dam must pass	100	% of the	PMP
Existing High Hazard Dam must pass	100	% of the	PMP
New Significant Hazard Dam must pass	50	% of the	PMP
Existing Significant Hazard Dam must pass	50	% of the	PMP

29 For low hazard dams, the spillway design requirement is:

Other (Please specify)

Comments: Ranges from 100-year to 50% PMP.

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

No

31 Does your organization permit risk-based hydrologic designs?

Our regulations do not specifically address this topic and it has never come up for consideration

32 Has your agency ever reviewed a risk-based hydrologic analysis?

No

33 How difficult would it be to change your regulations? Please explain.

Difficult

34 Are there any unique provisions in your regulations?

No

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	Iowa
Name of Representative	Mr. Jonathan Garton
Title of Representative	Senior Dam Safety Engineer
Phone number(s)	515-281-6940
Email address	jonathan.garton@dnr.iowa.gov

2 Number of dams under Organization's jurisdiction by type:

Total Dams	3568
Total Regulated Dams	3568
High Hazard Dams	99
Significant Hazard Dams	222
Low Hazard Dams	3247
Unregulated Dams	341
Other	

3 What year did your Agency adopt minimum Inflow Design Flood criteria? Pre 1990

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Other (Please specify)

Comments: Iowa Jurisdictional thresholds: a. Any dam designed to provide a sum of permanent and temporary storage exceeding 50 acre-feet at the top of dam elevation, or 25 acre-feet if the dam does not have an emergency spillway, and which has a height of 5 feet or more.
b. Any dam designed to provide permanent storage in excess of 18 acre-feet and which has a height of 5 feet or more.
c. Any dam across a stream draining more than 10 square miles.
d. Any dam located within 1 mile of an incorporated municipality, if the dam has a height of 10 feet or more, stores 10 acre-feet or more at the top of dam elevation, and is situated such that the discharge from the dam will flow through the incorporated area.

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

Yes (Please explain)

Comments: Major Dams have special requirements and are defined as: 1. Any high hazard dam.
2. Any moderate hazard dam with a permanent storage exceeding one hundred (100) acre-feet or a total of permanent and temporary storage exceeding two hundred fifty (250) acre-feet at the top of the dam elevation. 3. Any dam, including low hazard dams, where the height of the emergency spillway crest measured above the elevation of the channel bottom at the centerline of the dam (in feet) multiplied by the total storage volume (in acre-feet) to the emergency spillway crest elevation exceeds 30,000. For dams without emergency spillways, these measurements shall be taken to the top of dam elevation.

6 Does the Organization have published size classification criteria?

Yes

If "Yes", check and complete as appropriate:

Class A (Small)	=<		feet high and stores =<		acre-feet
Class B (Medium)					
Class C (Large)	=>		feet high and stores =>		acre-feet
Other (Specify)					

Comments: See comment above concerning major dam criteria.

7 Does the Organization have published hazard classification criteria?

Yes (High, Significant, and Low)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

No potential for loss of life with significant but not excessive economic loss

Comments: Structures located in areas where failure may damage isolated homes or cabins, industrial or commercial buildings, moderately traveled roads or railroads, interrupt major utility services, but without substantial risk of loss of human life.

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Published guidelines/regulations that are required

9 What is the origin of the guidelines?

NRCS guidelines

10 When were the guidelines last revised (MM/DD/YYYY)? 12/01/1990

11 Are there any plans to update or revise the guidelines in the near future?

Yes (Please specify)

Comments: Yes, we are beginning the process this year of updating our entire dam safety program rules.

12 Are the guidelines different for new and existing dams?

No

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency utilizes a combination of the above approaches, possibly on a case-by-case basis

14 How are the guidelines applied?

Based on both size and hazard classification

15 For PMP/PMF designs, is freeboard required?

Other (Please specify)

Comments: For dams with emergency spillways, the top of dam elevation after settlement shall not be less than the highest peak pool elevation reached during the freeboard design flood. For dams without an emergency spillway, the top of dam elevation shall be two feet higher than the peak flood elevation expected to occur during passage of the freeboard design flood, unless it is specifically designed to withstand the overflow.

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

No

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

No

18 Do the guidelines specify any criteria for storm duration?

Other (Please specify)

Comments: 6 hour, 24 hour, and 10-day storm durations are specified and recommendations are made for each.

19 Do the guidelines specify any criteria for temporal storm distribution?

Yes (Other - please specify)

Comments: Some acceptable methods of distributing the rainfall in Iowa are found in the U.S.D.A. Soil Conservation Service publication, TR-60, Earth Dams and Reservoirs; and the Illinois State Water Survey publication, Time Distribution of Rainfall In Heavy Storms by F. A. Huff.

20 Do the guidelines specify any criteria for spatial storm distribution?

No

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

Yes (Please specify)

Comments: Performance and activation criteria are given for both principal and emergency spillways.

22 Does the organization allow development of a site specific PMP?

Yes

If "Yes", are there any restrictions, requirements, or guidelines for performing a site specific PMP?

Yes (Please specify)

Comments: Follow guidelines in HMR 51 and 52.

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

Yes, a moderate problem

Comments: Dam owners are required to upgrade the dam if hazard classification changes.

24 Do guidelines require consideration or analysis of future development?

Yes (Impacts of development on hazard classification or failure consequences)

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

Yes (Please specify)

Comments: Conservative loss rates (interception, infiltration, etc.) and antecedent moisture conditions should be used in computing rainfall excess. Also, when applicable, snowmelt runoff rates should be estimated. The Soil Conservation Service (SCS) weighted curve number method is acceptable for determining rainfall losses and is explained in National Engineering Handbook Section 4 Hydrology, SCS, 1972.

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

No

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

No

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

Yes

If "Yes", complete as appropriate. If "No", describe below how spillway design capacity is determined.

New High Hazard Dam must pass	100	% of the	PMF
Existing High Hazard Dam must pass	100	% of the	PMF
New Significant Hazard Dam must pass	50	% of the	PMF
Existing Significant Hazard Dam must pass	50	% of the	PMF

29 For low hazard dams, the spillway design requirement is:

Other (Please specify)

Comments: Low hazard classified as major structures must also pass 50% of the PMF. Otherwise, a. Where the height of the emergency spillway crest* measured above the elevation of the channel bottom at the centerline of the dam (in feet) multiplied by the total storage volume (in acre-feet) to the emergency spillway crest elevation* is between 3,000 and 30,000, the flood shall correspond to the rainfall calculated from the following formula developed by the USDA Soil Conservation Service. Rainfall = P100 + 0.12 (PMP – P100) b. Where the height of the emergency spillway crest* measured above the elevation of the channel bottom at the centerline of the dam (in feet) multiplied by the total storage volume (in acre-feet) to the emergency spillway crest elevation* is less than 3,000, the flood shall be that resulting from the 50- year, 24-hour precipitation.

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

No

31 Does your organization permit risk-based hydrologic designs?

Our regulations do not specifically address this topic and it has never come up for consideration

32 Has your agency ever reviewed a risk-based hydrologic analysis?

No

33 How difficult would it be to change your regulations? Please explain.

Moderate

Comments: There is a formal rule making process for the DNR that involves public input. It is a lengthy process but can be initiated at any time.

34 Are there any unique provisions in your regulations?

No

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	Kansas
Name of Representative	Kimberly A. Feldkamp, P.E.
Title of Representative	Dam Safety Team Leader
Phone number(s)	785-296-4625
Email address	kimberly.feldkamp@kda.ks.gov

2 Number of dams under Organization's jurisdiction by type:

Total Dams	
Total Regulated Dams	6058
High Hazard Dams	202
Significant Hazard Dams	238
Low Hazard Dams	5618
Unregulated Dams	
Other	

3 What year did your Agency adopt minimum Inflow Design Flood criteria? 1984

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Other (Please specify)

Comments: A jurisdictional “dam” means any artificial barrier including appurtenant works with the ability to impound water, waste water or other liquids that has a height of 25 feet or more; or has a height of six feet or greater and also has the capacity to impound 50 or more acre feet. Anything that does not meet this definition is non-jurisdictional.

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

No

6 Does the Organization have published size classification criteria?

Yes

If "Yes", check and complete as appropriate:

Class A (Small)	=<		feet high and stores =<	3000	acre-feet
Class B (Medium)					
Class C (Large)	=>		feet high and stores =>	30000	acre-feet
Other (Specify)	Class 1 is less than 25 feet high and an effective storage of less				

Comments: Each dam with an effective height of less than 25 feet and an effective storage of less than 50 acre-feet shall be considered to be a class size 1 dam. The class size of all other dams shall be determined from the following table:

Class size	Size factor
2	less than 3,000
3	3,000 through 30,000
4	more than 30,000

"Effective height" means the difference in elevation between the crest of an auxiliary spillway or service spillway and the lowest point of the downstream toe of a dam. If the dam does not have an auxiliary or service spillway, the effective height means the difference in elevation between the top of the dam and the lowest point of the downstream toe of the dam.

7 Does the Organization have published hazard classification criteria?

Yes (High, Significant, and Low)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

Loss of life potential is "few" with "appreciable" economic loss

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Published guidelines/regulations that are required

9 What is the origin of the guidelines?

NRCS guidelines

Comments: The NRCS guidelines was used as guidance to develop our own criteria

10 When were the guidelines last revised (MM/DD/YYYY)? 05/18/2007

11 Are there any plans to update or revise the guidelines in the near future?

No

12 Are the guidelines different for new and existing dams?

Yes (Please elaborate)

Comments: There could be different guidelines on existing dams depending upon when they were permitted or constructed.

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency reviews submitted designs

14 How are the guidelines applied?

Based on both size and hazard classification

15 For PMP/PMF designs, is freeboard required?

Other (Please specify)

Comments: It varies do to size class and hazard classification.

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

Yes

If "Yes", what are the specific analysis methodologies, procedures, or computer software that must be used?

Must use SCS unit hydrograph

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

No

18 Do the guidelines specify any criteria for storm duration?

Yes (6-hr)

19 Do the guidelines specify any criteria for temporal storm distribution?

No

20 Do the guidelines specify any criteria for spatial storm distribution?

No

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

Yes (Please specify)

Comments: Auxiliary spillway failure criteria are provided. The auxiliary spillway shall not fail by breaching during the spillway stability design event indicated in the following: Hazard Class A, Size 1, 2, or 3: 0.3PMP; Hazard Class A, Size 4: 0.4 PMP; Hazard Class B, All Sizes: 0.5 PMP; Hazard Class C, All Sizes: PMP.

22 Does the organization allow development of a site specific PMP?

Unknown (never requested)

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

Yes, a major problem

24 Do guidelines require consideration or analysis of future development?

No

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

Yes (Please specify)

Comments: AMC II or III depending on location. The routing shall begin by assuming that the water surface elevation is at the elevation of the lowest uncontrolled spillway inlet, not including any low-flow augmentation works.

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

No

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

No

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

Yes

If "Yes", complete as appropriate. If "No", describe below how spillway design capacity is determined.

New High Hazard Dam must pass	40	% of the	PMP
Existing High Hazard Dam must pass	40	% of the	PMP
New Significant Hazard Dam must pass	25-30	% of the	PMP
Existing Significant Hazard Dam must pass	25-30	% of the	PMP

Comments: New and existing high hazard dams must pass 40% of PMP plus have 3 feet of freeboard. Significant hazard new and existing dam size class 1 and 2 must pass 25% of PMP plus have 2 feet of freeboard and significant hazard new and existing dams class 3 and 4 must pass 30% of PMP plus have 3 feet of freeboard.

29 For low hazard dams, the spillway design requirement is:

Other (Please specify)

Comments: Size class 1 50-year with 1 foot freeboard. Size class 2 100-yr plus 2 feet freeboard. Size Class 3 100-yr 3 feet of freeboard. Size class 4 25%PMP with 3 feet of freeboard.

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

No

31 Does your organization permit risk-based hydrologic designs?

Our regulations do not specifically address this topic and it has never come up for consideration

32 Has your agency ever reviewed a risk-based hydrologic analysis?

No

33 How difficult would it be to change your regulations? Please explain.

Difficult

Comments: The proposed regulations would have to be approved by the following Department of Agriculture Legal, Department of Administration, Attorney General's Office, and the Administrative Rules and Regulations Joint Committee

34 Are there any unique provisions in your regulations?

No

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	Kentucky
Name of Representative	Ms. Marilyn Thomas
Title of Representative	Environmental Engineer Consultant
Phone number(s)	502-564-3410
Email address	marilync.thomas@ky.gov

2 Number of dams under Organization's jurisdiction by type:

Total Dams	
Total Regulated Dams	1066
High Hazard Dams	178
Significant Hazard Dams	217
Low Hazard Dams	671
Unregulated Dams	
Other	

3 What year did your Agency adopt minimum Inflow Design Flood criteria? pre-1978

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Other (Please specify)

Comments: Less than 25 feet in height and an impounding capacity of less than 50 acre-feet or no downstream hazard to human life.

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

No

6 Does the Organization have published size classification criteria?

No

7 Does the Organization have published hazard classification criteria?

Yes (High, Significant, and Low)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

No potential for loss of life with significant but not excessive economic loss

Comments: Class A (High), Class B (Moderate), and Class C (High)

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Published guidelines/regulations that are required

9 What is the origin of the guidelines?

NRCS guidelines

10 When were the guidelines last revised (MM/DD/YYYY)? 06/01/1999

11 Are there any plans to update or revise the guidelines in the near future?

12 Are the guidelines different for new and existing dams?

No

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency utilizes a combination of the above approaches, possibly on a case-by-case basis

14 How are the guidelines applied?

Based on hazard classification only

15 For PMP/PMF designs, is freeboard required?

No

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

Yes

If "Yes", what are the specific analysis methodologies, procedures, or computer software that must be used?

Other (Please specify)

Comments: SITES, HMS, NWS DAMBRK, HEC-RAS are acceptable

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

No

18 Do the guidelines specify any criteria for storm duration?

Yes (6-hr)

19 Do the guidelines specify any criteria for temporal storm distribution?

No

20 Do the guidelines specify any criteria for spatial storm distribution?

No

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

Yes (Please specify)

Comments: Criteria are given for activation, performance, and capacity of earth emergency spillways.

22 Does the organization allow development of a site specific PMP?

Unknown (never requested)

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

Yes, a moderate problem

24 Do guidelines require consideration or analysis of future development?

Yes (Impacts of development on hazard classification or failure consequences)

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

Yes (Please specify)

Comments: AMCII or greater

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

No

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

No

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

Yes

If "Yes", complete as appropriate. If "No", describe below how spillway design capacity is determined.

New High Hazard Dam must pass	100	% of the	PMP
Existing High Hazard Dam must pass	100	% of the	PMP
New Significant Hazard Dam must pass		% of the	
Existing Significant Hazard Dam must pass		% of the	

Comments: P Design (Class B, Significant) = P100 + 0.40*(PMP-P100)

29 For low hazard dams, the spillway design requirement is:

Other (Please specify)

Comments: P Design (Class A) =P100 + 0.12*(PMP-P100)

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

No

Comments: Dam owners may not properly maintain or operate warning systems, rendering them ineffective.

31 Does your organization permit risk-based hydrologic designs?

Our regulations do not specifically address this topic and it has never come up for consideration

32 Has your agency ever reviewed a risk-based hydrologic analysis?

No

33 How difficult would it be to change your regulations? Please explain.

Difficult

Comments: Reg changes must be approved by the legislature. If the legislature perceives the change as more demanding or expensive to dam owners that change likely won't be approved. We've worked for 10 years to get approval for Emergency Action Plans with no success.

34 Are there any unique provisions in your regulations?

No

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	Louisiana
Name of Representative	Zahir "Bo" Bolourchi, P.E.
Title of Representative	Director, P.W. & Water Resources Programs
Phone number(s)	225-274-4170
Email address	Bo.Bolourchi@la.gov

2 Number of dams under Organization's jurisdiction by type:

Total Dams	599
Total Regulated Dams	555
High Hazard Dams	33
Significant Hazard Dams	72
Low Hazard Dams	450
Unregulated Dams	49
Other	

3 What year did your Agency adopt minimum Inflow Design Flood criteria? 1981

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Both of the above

Comments: LA R.S. 38:22

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

No

6 Does the Organization have published size classification criteria?

No

7 Does the Organization have published hazard classification criteria?

Yes (High, Significant, and Low)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

Loss of life potential is "few" with "appreciable" economic loss

Comments: Appreciable damage to property or possible loss of life.

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Published guidelines/regulations that are required

9 What is the origin of the guidelines?

Other (Please specify)

10 When were the guidelines last revised (MM/DD/YYYY)? 03/01/1997

11 Are there any plans to update or revise the guidelines in the near future?

No

12 Are the guidelines different for new and existing dams?

No

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency reviews submitted designs

Design storm is determined by down stream conditions

14 How are the guidelines applied?

Based on hazard classification only

15 For PMP/PMF designs, is freeboard required?

3.0' or more

Comments: Title 44, CRF 65.10 (B-1 Freeboard)

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

No

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

No

18 Do the guidelines specify any criteria for storm duration?

No

19 Do the guidelines specify any criteria for temporal storm distribution?

No

20 Do the guidelines specify any criteria for spatial storm distribution?

No

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

Yes (Please specify)

Comments: For the purpose of the Dam Safety Program, the Emergency Spillway shall be defined as being overtopped by the 100-year storm or greater and the Principal Spillway shall be defined as being overtopped by a storm less than the 100-year storm. Also, some damage to the emergency spillway is tolerable since they are activated only during major storm events.

22 Does the organization allow development of a site specific PMP?

No

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

No

Comments: Change in classification is based on down stream conditions

24 Do guidelines require consideration or analysis of future development?

Yes (Impacts of development on hazard classification or failure consequences)

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

No

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

Yes

If "Yes", do guidelines require analyses to include future downstream conditions within the dam failure inundation zone?

Yes

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

No

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

Yes

If "Yes", complete as appropriate. If "No", describe below how spillway design capacity is determined.

New High Hazard Dam must pass	50-100	% of the	PMF
Existing High Hazard Dam must pass	50-100	% of the	PMF
New Significant Hazard Dam must pass	100-yr-100	% of the	PMF
Existing Significant Hazard Dam must pass	100-yr-100	% of the	PMF

Comments: These are minimum IDFs. Regulations stipulate that an incremental assessment be performed for all High Hazard and some Significant Hazard dams. The full PMF is the maximum IDF for both of these hazard classes.

29 For low hazard dams, the spillway design requirement is:

50-year flood

Comments: Minimum IDF (no incremental assessment required)

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

No

31 Does your organization permit risk-based hydrologic designs?

No; our regulations forbid them

32 Has your agency ever reviewed a risk-based hydrologic analysis?

No

33 How difficult would it be to change your regulations? Please explain.

Difficult

Comments: Change in regulations could be challenging at this time.

34 Are there any unique provisions in your regulations?

No

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	Maine
Name of Representative	Tony Fletcher, P.E.
Title of Representative	State Dam Inspector
Phone number(s)	207-624-4465
Email address	Tony.Fletcher@maine.gov

2 Number of dams under Organization's jurisdiction by type:

Total Dams	
Total Regulated Dams	860
High Hazard Dams	29
Significant Hazard Dams	71
Low Hazard Dams	536
Unregulated Dams	191
Other	33

3 What year did your Agency adopt minimum Inflow Design Flood criteria? n/a

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Both of the above

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

No

6 Does the Organization have published size classification criteria?

No

7 Does the Organization have published hazard classification criteria?

Yes (High, Significant, and Low)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

No potential for loss of life with significant but not excessive economic loss

Comments: No probable loss of life but major economic loss, environmental damage or disruption of lifeline facilities.

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Other (Please specify)

Comments: The USACE are recommended when questions arise.

9 What is the origin of the guidelines?

USACE guidelines (including Phase I Study guidelines)

10 When were the guidelines last revised (MM/DD/YYYY)? n/a

Comments: Never revised

11 Are there any plans to update or revise the guidelines in the near future?

No

12 Are the guidelines different for new and existing dams?

No

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency reviews submitted designs

Makes recommedations

14 How are the guidelines applied?

Based on hazard classification only

15 For PMP/PMF designs, is freeboard required?

No

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

No

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

No

18 Do the guidelines specify any criteria for storm duration?

No

19 Do the guidelines specify any criteria for temporal storm distribution?

No

20 Do the guidelines specify any criteria for spatial storm distribution?

No

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

No

22 Does the organization allow development of a site specific PMP?

Unknown (never requested)

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

Yes, a minor problem

24 Do guidelines require consideration or analysis of future development?

No

Comments: A hazard inspection is required every 6 years when the hazard of a dam is reviewed.

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

No

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

Comments:

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

No

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

Yes

If "Yes", complete as appropriate. If "No", describe below how spillway design capacity is determined.

New High Hazard Dam must pass	100	% of the	PMF
Existing High Hazard Dam must pass	100	% of the	PMF
New Significant Hazard Dam must pass	50	% of the	PMF
Existing Significant Hazard Dam must pass	50	% of the	PMF

29 For low hazard dams, the spillway design requirement is:

Not specified

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

Yes

31 Does your organization permit risk-based hydrologic designs?

Our regulations do not specifically address this topic and it has never come up for consideration

32 Has your agency ever reviewed a risk-based hydrologic analysis?

No

33 How difficult would it be to change your regulations? Please explain.

Difficult

34 Are there any unique provisions in your regulations?

No

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	Maryland
Name of Representative	Harald W. Van Aller
Title of Representative	Geotechnical Engineer
Phone number(s)	410-901-4042
Email address	hvanaller@mde.state.md.us

2 Number of dams under Organization's jurisdiction by type:

Total Dams	406
Total Regulated Dams	382
High Hazard Dams	68
Significant Hazard Dams	87
Low Hazard Dams	227
Unregulated Dams	Unknown
Other	

3 What year did your Agency adopt minimum Inflow Design Flood criteria? About 1976

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Other (Please specify)

Comments: All dams in MD are juridictional regardless of size, although some low hazard dams less than 20 ft high can be approved by local soil conservation district in lieu of a state waterway construction permit.

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

No

6 Does the Organization have published size classification criteria?

Yes

If "Yes", check and complete as appropriate:

Class A (Small)	=<	25	feet high and stores =<	1,000	acre-feet
Class B (Medium)					
Class C (Large)	=>	50	feet high and stores =>	20,000	acre-feet
Other (Specify)	Class IV, see comments.				

Comments: Category IV is reserved for small dams which have a drainage area of less than 1 square mile (640 acres), and a normal depth of water less than 15 feet above the original stream bed, a normal pool storage of less than 100 acre-feet, and a normal surface area less than 12 acres.

7 Does the Organization have published hazard classification criteria?

Yes (High, Significant, and Low)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

Loss of life potential is "few" with "appreciable" economic loss

Comments: "small possibility" of loss of life. Located in predominately rural or agricultural areas where failure may cause damage to isolated residences or cause interruption of use or service of public utilities or roads. Damage is within the financial capability of owner to repair

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Published guidelines/regulations that are required

9 What is the origin of the guidelines?

USBR guidelines

10 When were the guidelines last revised (MM/DD/YYYY)? 07/01/1979

Comments: Some minor changes have been made since 1979, but no substantial changes have been made to hazard classification and design storm requirements

11 Are there any plans to update or revise the guidelines in the near future?

Yes (Please specify)

Comments: Current regs address only new dams. MD has been working on new regulations for about 15 years which would also include pre-existing dams.

12 Are the guidelines different for new and existing dams?

No

Comments: The new regulations would have different guidelines for pre-existing dams.

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency utilizes a combination of the above approaches, possibly on a case-by-case basis

14 How are the guidelines applied?

Based on both size and hazard classification

15 For PMP/PMF designs, is freeboard required?

Other (Please specify)

Comments: No specific freeboard is required. The design shall allow for certain freeboard as a minimum, not to be reduced under any circumstances during the operation of the dam and reservoir. The design freeboard is for that reservoir stage which will exist when the pool has reached maximum level during the inflow design flood with the outlet works and overflow spillway operating as planned. The freeboard is to be calculated to prevent overtopping and protect the dam against the destructive forces of waves, frost, settlement, and surface erosion.

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

Yes

If "Yes", what are the specific analysis methodologies, procedures, or computer software that must be used?

Other (Please specify)

Comments: For drainage areas less than or equal to 10 square miles, TR-20 or HEC-1 must be used. For drainage areas larger than 10 square miles, HMR-52 and HEC-1 is recommended.

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

Yes (Please specify)

Comments: software must be in the public domain (not proprietary) so the results can be duplicated by agency staff

18 Do the guidelines specify any criteria for storm duration?

Yes (6-hr)

Comments: For drainage areas less than or equal to 10 square miles, use a 24-hour duration for the 100-year and brim-up storm events, and a 6-hour duration for the 50%PMF and PMF.

19 Do the guidelines specify any criteria for temporal storm distribution?

Yes (HMR)

20 Do the guidelines specify any criteria for spatial storm distribution?

No

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

Yes (Please specify)

Comments: 100-year unless it is a small dam

22 Does the organization allow development of a site specific PMP?

Yes

If "Yes", are there any restrictions, requirements, or guidelines for performing a site specific PMP?

No

Comments: This has only been evaluated at one dam that I am aware of. use of FERC guidelines is suggested to other dam owners who ask about this issue.

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

Yes, a moderate problem

24 Do guidelines require consideration or analysis of future development?

Yes (Impacts of development on hazard classification or failure consequences)

Comments: Current regulations are based on ultimate development of land based on current zoning.

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

No

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

No

If "Yes", do guidelines require analyses to include future downstream conditions within the dam failure inundation zone?

Yes

Comments: Although current regulations do not allow for incremental analysis, MD has been allowing this on a case by case basis

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

No

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

Yes

If "Yes", complete as appropriate. If "No", describe below how spillway design capacity is determined.

New High Hazard Dam must pass	100	% of the	PMF
Existing High Hazard Dam must pass	100	% of the	PMF
New Significant Hazard Dam must pass	50	% of the	PMF
Existing Significant Hazard Dam must pass	50	% of the	PMF

Comments: Class II (Significant): Regulations state: The design storm shall be the "standard project flood" or the largest flood of record, whichever is greater.

29 For low hazard dams, the spillway design requirement is:

100-year flood

Comments: Plus 2 feet of freeboard, unless the design includes an open channel emergency spillway, in which case freeboard can be reduced to 1 foot.

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

No

Comments: At one time we allowed that, but not currently.

31 Does your organization permit risk-based hydrologic designs?

Our regulations do not specifically address this topic and it has never come up for consideration

32 Has your agency ever reviewed a risk-based hydrologic analysis?

No

Comments: However, the Corps of Engineers has recently cited a risk-based analyses for rejecting the need to upgrade a large dam designed in the 1960's and constructed in MD in 1980 to safely pass the full PMF

33 How difficult would it be to change your regulations? Please explain.

Moderate

Comments: We have been working on revised regulations for more than 15 years.

34 Are there any unique provisions in your regulations?

No

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	Massachusetts
Name of Representative	Michael D. Misslin
Title of Representative	Deputy Chief Engineer
Phone number(s)	617-626-4927
Email address	Mike.Misslin@state.ma.us

2 Number of dams under Organization's jurisdiction by type:

Total Dams	
Total Regulated Dams	1545
High Hazard Dams	304
Significant Hazard Dams	727
Low Hazard Dams	514
Unregulated Dams	
Other	

3 What year did your Agency adopt minimum Inflow Design Flood criteria?

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Other (Please specify)

Comments: All dams are inventoried. The following are non-jurisdictional:1) any barrier which is not in excess of six feet in height, regardless of storage capacity, or which has a storage capacity at max water storage elevation not in excess of 15 acre feet, regardless of height. 2) any barrier with low hazard potential classification in the use of agriculture.

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

Yes (Please explain)

Comments: FERC regulated dams are exempt from regulation

6 Does the Organization have published size classification criteria?

Yes

If "Yes", check and complete as appropriate:

Class A (Small)	=<	15	feet high and stores =<	50	acre-feet
Class B (Medium)					
Class C (Large)	=>	40	feet high and stores =>	1,000	acre-feet
Other (Specify)					

Comments: non-jurisdictional: not in excess of 15 ac ft regardless of ht & not in excess of 6 ft regardless of storage capacity; small: >= 15 ac ft and <50 ac ft storage & >= 6 ft and < 15

7 Does the Organization have published hazard classification criteria?

Yes (High, Significant, and Low)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

Loss of life potential is "few" with "appreciable" economic loss

Comments: Sig Haz Pot definition: Dams located where failure may cause loss of life and damge home(s), industrial or commercial facilities, secondary highway(s) or railroad(s) or cause interruption of use or service of relatively important facilities.

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Other (Please specify)

Comments: Regulatory requirements for new and existing dams.

9 What is the origin of the guidelines?

Other (Please specify)

Comments: federal guidelines

10 When were the guidelines last revised (MM/DD/YYYY)? 11/04/2005

11 Are there any plans to update or revise the guidelines in the near future?

No

12 Are the guidelines different for new and existing dams?

Yes (Please elaborate)

Comments: Existing dams are required to pass a smaller spillway design flood.

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency reviews submitted designs

14 How are the guidelines applied?

Based on both size and hazard classification

15 For PMP/PMF designs, is freeboard required?

Other (Please specify)

Comments: case by case

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

No

18 Do the guidelines specify any criteria for storm duration?

Other (Please specify)

Comments: regulations reference US Army Corps, US Bureau of Reclamation and USDA NRCS.

19 Do the guidelines specify any criteria for temporal storm distribution?

No

20 Do the guidelines specify any criteria for spatial storm distribution?

No

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

Yes (Please specify)

Comments: Emergency spillway frequency and performance guidelines are provided.

22 Does the organization allow development of a site specific PMP?

Yes

If "Yes", are there any restrictions, requirements, or guidelines for performing a site specific PMP?

No

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

Unsure

24 Do guidelines require consideration or analysis of future development?

No

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

No

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

Yes

If "Yes", do guidelines require analyses to include future downstream conditions within the dam failure inundation zone?

No

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

No

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

Yes

If "Yes", complete as appropriate. If "No", describe below how spillway design capacity is determined.

New High Hazard Dam must pass	100	% of the	PMF
Existing High Hazard Dam must pass	500-yr to 50	% of the	PMF
New Significant Hazard Dam must pass	500-yr to 50	% of the	PMF
Existing Significant Hazard Dam must pass	0-yr to 500	% of the	PMF

Comments: Varies depending on hazard classification, size, and whether it's a new or existing dam. Variations range from 100 year to full PMF.

29 For low hazard dams, the spillway design requirement is:

Other (Please specify)

Comments: Ranges from 50-year to 100-year for existing dams; 100-year for new dams. Change in requirement depends on the size of dam.

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

No

31 Does your organization permit risk-based hydrologic designs?

Yes; although our regulations do not specifically address this topic, we review risk-based designs o

32 Has your agency ever reviewed a risk-based hydrologic analysis?

Yes (Both approved and rejected)

33 How difficult would it be to change your regulations? Please explain.

Difficult

34 Are there any unique provisions in your regulations?

No

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	Michigan
Name of Representative	Byron Lane
Title of Representative	Chief, Hydrologic Studies and Dam Safety Unit
Phone number(s)	517-241-9862
Email address	LANEB@michigan.gov

2 Number of dams under Organization's jurisdiction by type:

Total Dams	
Total Regulated Dams	1034
High Hazard Dams	84
Significant Hazard Dams	138
Low Hazard Dams	812
Unregulated Dams	
Other	

3 What year did your Agency adopt minimum Inflow Design Flood criteria? 1990

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Other (Please specify)

Comments: Less than 6 feet in height or has an impounding capacity of 5 surface acres or less.

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

Yes (Please explain)

Comments: Inventory dams which have court ordered lake levels. There are 235 of them.

6 Does the Organization have published size classification criteria?

No

7 Does the Organization have published hazard classification criteria?

Yes (High, Significant, and Low)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

Loss of life potential is "few" with "appreciable" economic loss

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Published within State Laws

9 What is the origin of the guidelines?

Unknown

10 When were the guidelines last revised (MM/DD/YYYY)? 05/24/1995

11 Are there any plans to update or revise the guidelines in the near future?

No

12 Are the guidelines different for new and existing dams?

No

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency acts as designer/engineer

14 How are the guidelines applied?

Based on both size and hazard classification

15 For PMP/PMF designs, is freeboard required?

Other (Please specify)

Comments: Michigan does not require PMP/PMF designs.

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

No

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

No

18 Do the guidelines specify any criteria for storm duration?

No

19 Do the guidelines specify any criteria for temporal storm distribution?

No

20 Do the guidelines specify any criteria for spatial storm distribution?

No

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

No

22 Does the organization allow development of a site specific PMP?

Yes

If "Yes", are there any restrictions, requirements, or guidelines for performing a site specific PMP?

Yes (Please specify)

Comments: Agency must approve the design flood.

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

No

24 Do guidelines require consideration or analysis of future development?

No

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

No

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

Yes

If "Yes", do guidelines require analyses to include future downstream conditions within the dam failure inundation zone?

No

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

Yes (Please specify)

Comments: No less than the 200-year flood or the flood of record, whichever is greater.

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

Yes

If "Yes", complete as appropriate. If "No", describe below how spillway design capacity is determined.

New High Hazard Dam must pass	200 yr-50	% of the	PMF
Existing High Hazard Dam must pass	200 yr-50	% of the	PMF
New Significant Hazard Dam must pass	200-yr	% of the	
Existing Significant Hazard Dam must pass	200-yr	% of the	

Comments: High hazard dams < 40 feet shall pass the 200-year flood or the flood of record whichever is greater. High hazard dams > 40 feet shall pass 0.5PMF. Significant hazard dams shall pass the 200-year flood or the flood of record whichever is greater.

29 For low hazard dams, the spillway design requirement is:

100-year flood

Comments: Or the flood of record, whichever is greater.

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

No

31 Does your organization permit risk-based hydrologic designs?

Our regulations do not specifically address this topic and it has never come up for consideration

32 Has your agency ever reviewed a risk-based hydrologic analysis?

No

33 How difficult would it be to change your regulations? Please explain.

Difficult

34 Are there any unique provisions in your regulations?

No

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	Minnesota
Name of Representative	Jason Boyle, P.E.
Title of Representative	State Dam Safety Engineer
Phone number(s)	651-259-5715
Email address	Jason.Boyle@state.mn.us

2 Number of dams under Organization's jurisdiction by type:

Total Dams	
Total Regulated Dams	1161
High Hazard Dams	24
Significant Hazard Dams	126
Low Hazard Dams	1012
Unregulated Dams	
Other	

3 What year did your Agency adopt minimum Inflow Design Flood criteria? not formally adopted yet

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Other (Please specify)

Comments: Less than 6 feet high; or less than 15 acre-feet of storage; or less than 25 feet high and less than 50 acre-feet of storage with no potential for loss of life; or Federal dam

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

Yes (Please explain)

Comments: Yes, tailings and coal ash dams are held to a different standard.

6 Does the Organization have published size classification criteria?

No

7 Does the Organization have published hazard classification criteria?

Yes (High, Significant, and Low)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

No potential for loss of life with significant but not excessive economic loss

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Unpublished guidelines for consideration by the engineer/designer

Comments: Regulatory has final say.

9 What is the origin of the guidelines?

Other (Please specify)

Comments: Based on California or ICODS guidelines?

10 When were the guidelines last revised (MM/DD/YYYY)?

Comments: They have not been revised.

11 Are there any plans to update or revise the guidelines in the near future?

No

Comments: It would be a good idea to update these.

12 Are the guidelines different for new and existing dams?

Yes (Please elaborate)

Comments: There is some leeway for existing dams, depending on the situation.

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency reviews submitted designs

14 How are the guidelines applied?

Based on a combination of risk analysis and hazard/size classification

15 For PMP/PMF designs, is freeboard required?

Based on wave run up computations

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

No

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

No

18 Do the guidelines specify any criteria for storm duration?

No

Comments: We try to ensure the most critical storm duration is used. Based on dam type and time of concentration.

19 Do the guidelines specify any criteria for temporal storm distribution?

No

20 Do the guidelines specify any criteria for spatial storm distribution?

No

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

Yes (Please specify)

Comments: Spillway design floods based on frequency of flooding.

22 Does the organization allow development of a site specific PMP?

Yes

If "Yes", are there any restrictions, requirements, or guidelines for performing a site specific PMP?

Yes (Please specify)

Comments: Consistency with other methods.

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

No

Comments: It has not been a problem to date.

24 Do guidelines require consideration or analysis of future development?

Yes (Impacts of development on hazard classification or failure consequences)

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

No

Comments: We do check these assumptions.

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

Yes

If "Yes", do guidelines require analyses to include future downstream conditions within the dam failure inundation zone?

No

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

No

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

Yes

If "Yes", complete as appropriate. If "No", describe below how spillway design capacity is determined.

New High Hazard Dam must pass	100	% of the	PMF
Existing High Hazard Dam must pass	100	% of the	PMF
New Significant Hazard Dam must pass	100-yr-100	% of the	PMF
Existing Significant Hazard Dam must pass	100-yr-100	% of the	PMF

Comments: Class II (Significant): 100 year to PMF.

29 For low hazard dams, the spillway design requirement is:

Other (Please specify)

Comments: 50-yr to 50% PMF

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

No

Comments: May consider it for existing dams.

31 Does your organization permit risk-based hydrologic designs?

Yes; although our regulations do not specifically address this topic, we review risk-based designs o

32 Has your agency ever reviewed a risk-based hydrologic analysis?

Yes (Reviewed and approved)

33 How difficult would it be to change your regulations? Please explain.

Difficult

Comments: Changing regulations would be difficult, changing our internal guidelines would be fairly easy.

34 Are there any unique provisions in your regulations?

No

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	Mississippi
Name of Representative	James MacLellan
Title of Representative	Director of Dam Safety Division
Phone number(s)	601-961-5061
Email address	James_MacLellan@deq.state.ms.us

2 Number of dams under Organization's jurisdiction by type:

Total Dams	3755
Total Regulated Dams	3755
High Hazard Dams	257
Significant Hazard Dams	76
Low Hazard Dams	3422
Unregulated Dams	0
Other	0

3 What year did your Agency adopt minimum Inflow Design Flood criteria? 1982

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Other (Please specify)

Comments: Less than 8 feet in height, or impounds less than 25 acre-feet, or doesn't impound a stream and doesn't present a downstream threat

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

No

6 Does the Organization have published size classification criteria?

Yes

If "Yes", check and complete as appropriate:

Class A (Small)	=<	25	feet high and stores =<	150	acre-feet
Class B (Medium)					
Class C (Large)	=>	50	feet high and stores =>	1000	acre-feet
Other (Specify)					

Comments: The size criteria is in the guidance for the design of dams - general guidance

7 Does the Organization have published hazard classification criteria?

Yes (High, Significant, and Low)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

No potential for loss of life with significant but not excessive economic loss

Comments: Significant Hazard is a class of dam in which failure poses no threat to life but may cause significant damage to public infrastructure - roads, railroads, utilities

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Published guidelines/regulations that are required

9 What is the origin of the guidelines?

Combination of the above (Please specify)

Comments: The portion of the regulations that determine the spillway design flood come from NWS HMR and NRCS design hydrograph as well as the hazard classification

10 When were the guidelines last revised (MM/DD/YYYY)? 08/25/2005

11 Are there any plans to update or revise the guidelines in the near future?

No

12 Are the guidelines different for new and existing dams?

Yes (Please elaborate)

Comments: High hazard dams that were constructed prior to 1982 are allowed to remain in operation if they pass 50% of PMP and are structurally sound.

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency utilizes a combination of the above approaches, possibly on a case-by-case basis

Agency reviews submitted designs and performs independent verification if needed. Agency does independent analysis for state lakes.

14 How are the guidelines applied?

Based on hazard classification only

15 For PMP/PMF designs, is freeboard required?

No

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

Yes

If "Yes", what are the specific analysis methodologies, procedures, or computer software that must be used?

Other (Please specify)

Comments: Must use HMR and SCS unit hydrograph

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

Yes (Please specify)

Comments: Rational equation is not accepted in any case.

18 Do the guidelines specify any criteria for storm duration?

Yes (24-hour)

19 Do the guidelines specify any criteria for temporal storm distribution?

Yes (NRCS Standard)

20 Do the guidelines specify any criteria for spatial storm distribution?

Yes (Please specify)

Comments: Only if drainage area is greater than 10 square miles.

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

Yes (Please specify)

Comments: Principal spillway must pass 100 year 24 hour design storm without activating emergency spillway for High hazard dams.

22 Does the organization allow development of a site specific PMP?

Yes

If "Yes", are there any restrictions, requirements, or guidelines for performing a site specific PMP?

Yes (Please specify)

Comments: Will only consider a site specific PMP if drainage area is greater than 10 square miles.

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

No

24 Do guidelines require consideration or analysis of future development?

Yes (Impacts of development on hazard classification or failure consequences)

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

No

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

No

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

No

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

Yes

If "Yes", complete as appropriate. If "No", describe below how spillway design capacity is determined.

New High Hazard Dam must pass	100	% of the	PMP
Existing High Hazard Dam must pass	100	% of the	PMP
New Significant Hazard Dam must pass	50	% of the	PMP
Existing Significant Hazard Dam must pass	50	% of the	PMP

29 For low hazard dams, the spillway design requirement is:

Other (Please specify)

Comments: 35% of the PMP.

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

No

31 Does your organization permit risk-based hydrologic designs?

Our regulations do not specifically address this topic and it has never come up for consideration

32 Has your agency ever reviewed a risk-based hydrologic analysis?

No

33 How difficult would it be to change your regulations? Please explain.

Moderate

Comments: It involves a lot of work on mine and our legal department's part. The difficulty to accepting the change would depend on public opposition and justifying to our Commission.

34 Are there any unique provisions in your regulations?

No

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	Missouri
Name of Representative	Paul Simon
Title of Representative	Civil Engineer - Dam Safety
Phone number(s)	573-368-2179
Email address	paul.simon@dnr.mo.gov

2 Number of dams under Organization's jurisdiction by type:

Total Dams	5240
Total Regulated Dams	677
High Hazard Dams	457
Significant Hazard Dams	147
Low Hazard Dams	73
Unregulated Dams	4563
Other	

3 What year did your Agency adopt minimum Inflow Design Flood criteria? 1981

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Other (Please specify)

Comments: Any artificial or man-made barrier which does or may impound water and is less than 35 feet in height.

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

No

Comments: Design requirements are based on downstream hazard classification for all regulated dams.

6 Does the Organization have published size classification criteria?

No

7 Does the Organization have published hazard classification criteria?

Yes (High, Significant, and Low)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

Loss of life potential is "few" with "appreciable" economic loss

Comments: They are: class I, which contains ten (10) or more permanent dwellings or any public building; class II, which contains one to nine (1–9) permanent dwellings, or one (1) or more campgrounds with permanent water, sewer and electrical services or one (1) or more industrial buildings; and class III, which is everything else.

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Published guidelines/regulations that are required

Comments: class 1 = 75% pmp, class 2 = 50% pmp, class 3 = 100 year event

9 What is the origin of the guidelines?

Custom developed by Organization

Comments: NWS HMR 51 is used to define the pmp.

10 When were the guidelines last revised (MM/DD/YYYY)? 06/09/1994

11 Are there any plans to update or revise the guidelines in the near future?

No

12 Are the guidelines different for new and existing dams?

No

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency performs independent verification of submitted designs

14 How are the guidelines applied?

Based on hazard classification only

Comments: Also determined by dam type (conventional or industrial), stage of construction, and environmental class

15 For PMP/PMF designs, is freeboard required?

No

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

No

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

No

18 Do the guidelines specify any criteria for storm duration?

Other (Please specify)

Comments: The critical duration is used, normally 6, 12, or 24hr storm.

19 Do the guidelines specify any criteria for temporal storm distribution?

No

Comments: Bulletin 71, Rainfall Frequency Atlas of the Midwest is recommended in the Engineering Analysis of Dams manual for Missouri, dated August 1989. Huff distribution is used.

20 Do the guidelines specify any criteria for spatial storm distribution?

No

Comments: hmr 51 is recommended in the Engineering Analysis of Dams manual for Missouri, dated August 1989.

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

No

Comments: 50-100 yr event is the minimum recommended to activate grass lined emergency spillway in the Engineering Analysis of Dams manual for Missouri, dated August 1989.

22 Does the organization allow development of a site specific PMP?

No

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

Yes, a moderate problem

Comments: All cost is on the dam owner.

24 Do guidelines require consideration or analysis of future development?

No

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

No

Comments: AMC 2 is recommended in the Engineering Analysis of Dams manual for missouri, dated August 1989.

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

No

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

No

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

Yes

If "Yes", complete as appropriate. If "No", describe below how spillway design capacity is determined.

New High Hazard Dam must pass	75-50	% of the	PMP
Existing High Hazard Dam must pass	75-50	% of the	PMP
New Significant Hazard Dam must pass	50-20	% of the	PMP
Existing Significant Hazard Dam must pass	50-20	% of the	PMP

Comments: Ranges depending on the stage of construction

29 For low hazard dams, the spillway design requirement is:

Other (Please specify)

Comments: Ranges from 0.10PMP to 100 year depending on the stage of construction

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

No

31 Does your organization permit risk-based hydrologic designs?

Our regulations do not specifically address this topic and it has never come up for consideration

32 Has your agency ever reviewed a risk-based hydrologic analysis?

No

33 How difficult would it be to change your regulations? Please explain.

Difficult

Comments: We would have to go through a public hearing process.

34 Are there any unique provisions in your regulations?

No

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	Montana
Name of Representative	Laurence Siroky
Title of Representative	Chief, Water Operations
Phone number(s)	(406) 444-6816
Email address	lsiroky@mt.gov

2 Number of dams under Organization's jurisdiction by type:

Total Dams	
Total Regulated Dams	2893
High Hazard Dams	105
Significant Hazard Dams	152
Low Hazard Dams	2636
Unregulated Dams	
Other	

3 When did your Organization adopt minimum Inflow Design Flood criteria? 1999

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Less than 50 acre-feet of storage (top of dam)

Comments: All dams regardless of size are jurisdictional dams. Only High Hazard dams and 50 acre-feet or larger are required to be permitted.

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

Yes (Please explain)

Comments: State minimum design standards apply only to HH dams.

6 Does the Organization have published size classification criteria?

Yes

Comments: We have regulations that specify the criteria for a HH dam and applies to dams 50 acre-feet or larger.

7 Does the Organization have published hazard classification criteria?

Yes (Other)

Comments: High Hazard if loss of human life is likely to occur within the breach flooded area as a result of failure of the dam. All other dams are classified separately. Significant and Low Hazard dams are not regulated or inspected by the state.

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Published guidelines/regulations for consideration by the engineer/designer

Comments: We have agency regulations as well as guidelines.

9 What is the origin of the guidelines?

Custom developed by Organization

Comments: Washington State's approach was consulted in the development of these guidelines.

10 When were the guidelines last revised (MM/DD/YYYY)? 10/01/2008

11 Are there any plans to update or revise the guidelines in the near future?

No

Comments: We are in the process of adding siesmic standards.

12 Are the guidelines different for new and existing dams?

No

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency reviews submitted designs

14 How are the guidelines applied?

Based on a combination of risk analysis and hazard/size classification

Comments: IDF is determined based on estimated loss of life downstream from the dam caused by spillway failure.

15 For PMP/PMF designs, is freeboard required?

No

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

Yes

If "Yes", what are the specific analysis methodologies, procedures, or computer software that must be used?

Comments: Tech notes(guidelines are being developed)

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

No

18 Do the guidelines specify any criteria for storm duration?

No

19 Do the guidelines specify any criteria for temporal storm distribution?

Yes (Regional)

20 Do the guidelines specify any criteria for spatial storm distribution?

No

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

No

22 Does the organization allow development of a site specific PMP?

Yes

If "Yes", are there any restrictions, requirements, or guidelines for performing a site specific PMP?

Yes (Please specify)

Comments: HMR

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

Yes, a minor problem

24 Do guidelines require consideration or analysis of future development?

No

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

Yes (Please specify)

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

Yes

If "Yes", do guidelines require analyses to include future downstream conditions within the dam failure inundation zone?

No

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

No

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

No

Comments: Minimum inflow design flood for estimated loss of life of 0.5 or less shall be the 500-year recurrence interval flood. Minimum inflow design flood for estimated loss of life greater

29 For low hazard dams, the spillway design requirement is:

Not specified

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

No

31 Does your organization permit risk-based hydrologic designs?

Yes; our regulations permit them

32 Has your agency ever reviewed a risk-based hydrologic analysis?

Yes (Reviewed and approved)

33 How difficult would it be to change your regulations? Please explain.

Moderate

34 Are there any unique provisions in your regulations?

Yes (Please explain)

Comments: Design standards apply to HH dams only.

FEMA

HYDROLOGIC SAFETY OF DAMS QUESTIONNAIRE

Gannett Fleming Your Trusted Advisor Since 1915

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	Nebraska
Name of Representative	Mr. Patrick Diederich
Title of Representative	Chief of Dam Safety
Phone number(s)	402-471-1222
Email address	

2 Number of dams under Organization's jurisdiction by type:

Total Dams	
Total Regulated Dams	2386
High Hazard Dams	134
Significant Hazard Dams	192
Low Hazard Dams	2061
Unregulated Dams	0
Other	0

3 What year did your Agency adopt minimum Inflow Design Flood criteria? unknown

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Both of the above

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

No

6 Does the Organization have published size classification criteria?

No

7 Does the Organization have published hazard classification criteria?

Yes (High, Significant, Low, Limited Hazard)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

No potential for loss of life with significant but not excessive economic loss

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Unpublished guidelines that are required

9 What is the origin of the guidelines?

USACE guidelines (including Phase I Study guidelines)

10 When were the guidelines last revised (MM/DD/YYYY)?

11 Are there any plans to update or revise the guidelines in the near future?

Yes (Please specify)

Comments: Currently underway

12 Are the guidelines different for new and existing dams?

Yes (Please elaborate)

Comments: Reduced spillway design flood for existing dams as outlined in Question 28

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency performs independent verification of submitted designs

14 How are the guidelines applied?

Based on both size and hazard classification

15 For PMP/PMF designs, is freeboard required?

No

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

Yes

If "Yes", what are the specific analysis methodologies, procedures, or computer software that must be used?

Must use SITES

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

No

18 Do the guidelines specify any criteria for storm duration?

Yes (Based on Tc)

19 Do the guidelines specify any criteria for temporal storm distribution?

Yes (Regional)

Comments: Site-Specific PMP Study for Nebraska by Applied Weather Associates, LLC (Ed Tomlinson)

20 Do the guidelines specify any criteria for spatial storm distribution?

No

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

Yes (Please specify)

22 Does the organization allow development of a site specific PMP?

Yes

If "Yes", are there any restrictions, requirements, or guidelines for performing a site specific PMP?

Yes (Please specify)

Comments: Follow industry standards

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

Yes, a moderate problem

24 Do guidelines require consideration or analysis of future development?

Yes (Both of the above)

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

Yes (Please specify)

Comments: Use normal pool with a TR-60 10-day drawdown requirement; AMC II

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

Yes

If "Yes", do guidelines require analyses to include future downstream conditions within the dam failure inundation zone?

Yes

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

No

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

Yes

If "Yes", complete as appropriate. If "No", describe below how spillway design capacity is determined.

New High Hazard Dam must pass	100	% of the	PMP
Existing High Hazard Dam must pass	50	% of the	PMP
New Significant Hazard Dam must pass		% of the	
Existing Significant Hazard Dam must pass		% of the	

Comments: NRCS guidelines on SH dams

29 For low hazard dams, the spillway design requirement is:

Other (Please specify)

Comments: NRCS TR-60

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

No

31 Does your organization permit risk-based hydrologic designs?

Yes; although our regulations do not specifically address this topic, we review risk-based designs o

32 Has your agency ever reviewed a risk-based hydrologic analysis?

No

33 How difficult would it be to change your regulations? Please explain.

Moderate

34 Are there any unique provisions in your regulations?

No

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	Nevada
Name of Representative	Robert K. Martinez, P.E.
Title of Representative	Chief, Engineering & Dam Safety
Phone number(s)	775-684-2844
Email address	robertm@water.nv.gov

2 Number of dams under Organization's jurisdiction by type:

Total Dams	962
Total Regulated Dams	792
High Hazard Dams	171
Significant Hazard Dams	145
Low Hazard Dams	476
Unregulated Dams	0
Other	170

3 What year did your Agency adopt minimum Inflow Design Flood criteria? 1951 separate statutes; 2003 codified regulations

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Other (Please specify)

Comments: All dams are "jurisdictional" so non-inventory are: Less than 20 feet in height or less than 20 feet in height and impounds less than 20 acre-feet of water. Dams permitted under an older standard (10' high and 10AF of water) are also still inventoried.

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

Yes (Please explain)

Comments: Most effluent, process fluid, and tailing impoundments are exempt from having a spillway, but must be "ring dikes" or divert run-on water. Storm Water Detention dams may have reduced freeboard requirement for PMF.

6 Does the Organization have published size classification criteria?

Yes

If "Yes", check and complete as appropriate:

Class A (Small)	=<	20	feet high and stores =<	100	acre-feet
Class B (Medium)					
Class C (Large)	=>	50	feet high and stores =>	10000	acre-feet
Other (Specify)					

Comments: "Class C" (Large) is "=>50 feet in height OR >= 10,000 acre feet of storage.

7 Does the Organization have published hazard classification criteria?

Yes (High, Significant, and Low)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

Loss of life potential is "few" with "appreciable" economic loss

Comments: Reasonably low probability of loss of human life or high probability of extensive economic loss or disruption of a lifeline.

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Published guidelines/regulations that are required

9 What is the origin of the guidelines?

Combination of the above (Please specify)

Comments: Office policy was incorporated into the regulations in 2003. Guidelines are expanded upon Chapter 535 of the Nevada Revised Statutes (NRS) and Chapter 535 of the Nevada Administrative Code (NAC). Policy was developed in association with COE, USBR, FERC, FEMA, and public input.

10 When were the guidelines last revised (MM/DD/YYYY)? 01/01/2011

Comments: Minor revisions to reflect inventory numbers and changes to forms.

11 Are there any plans to update or revise the guidelines in the near future?

Yes (Please specify)

Comments: We anticipate an update commencing in SFY2012.

12 Are the guidelines different for new and existing dams?

No

Comments: However; owners of existing dams are not expected to "instantly" cure any deficiencies due to regulatory thresholds, but be working towards a solution.

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency reviews submitted designs

Models are not re-run but the asumptions/parameters and model type/suitability are reviewed.

14 How are the guidelines applied?

Based on both size and hazard classification

15 For PMP/PMF designs, is freeboard required?

Other (Please specify)

Comments: "Rule of thumb" is 3'. Wave runup calculations are preferred and required if the owner is requesting a smaller freeboard. Exceptions are tailings facilities for deposition (beach) side embankments and Storm Water detention facilities, as requested and supported by calculations then approval by this office.

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

No

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

No

Comments: However we are discouraging use of TR-55 under most conditions.

18 Do the guidelines specify any criteria for storm duration?

NO

Comments: Loosely based on Tc. The consultant is expected to use reasonable and prudent criteria which are reviewed. The storm duration is more closely tied to the storage regime. 6hr and 24hr local storms are most common but regional storm may control in some circumstances.

19 Do the guidelines specify any criteria for temporal storm distribution?

No

Comments: NRCS type II and type III most commonly used but HMR approach also utilized.

20 Do the guidelines specify any criteria for spatial storm distribution?

No

Comments: Areal reduction for large watersheds is allowed/expected. Generally under HMR 49 guidelines.

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

No

Comments: Individual operating criteria are developed by the owner and local jurisdictions regarding allowed flow rates/spillway activation and reviewed for adequacy. Operating criteria drives storm selection for design aspects of an individual structure. In all regards the facility must "accomodate" the IDF and the means by which that is accomplished is largely up to the owner and designer.

22 Does the organization allow development of a site specific PMP?

Yes

If "Yes", are there any restrictions, requirements, or guidelines for performing a site specific PMP?

No

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

Yes, a major problem

Comments: As urbanization occurs, previously compliant or what may be called "safe" structures become noncompliant or "unsafe" due to hydrologic or other inadequacy.

24 Do guidelines require consideration or analysis of future development?

Yes (Impacts of development on hazard classification or failure consequences)

Comments: Likely downstream land use is considered in determining hazard classification and IDF selection.

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

No

Comments: Again, individual operating regime drives antecedent conditions. Response to a specific recurrence interval storm and antecedent moisture are handled on a case-by-case basis. For the intermountain west, the most common antecedent moisture condition is "dry" for convection-type storms but "rain on snow" events often are most severe.

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

Yes

If "Yes", do guidelines require analyses to include future downstream conditions within the dam failure inundation zone?

No

Comments: However, if in the review it is determined that the downstream area is likely to see development in the near future (10-20 years) potential impacts are expected to be discussed. It is largely a local government land-use planning issue. Again, it is on a case-by-case basis. Future anticipated conditions often are the driving force in new dam design.

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

Yes (Please specify)

Comments: Never less than a 1% chance of exceedence storm.

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

Yes

If "Yes", complete as appropriate. If "No", describe below how spillway design capacity is determined.

New High Hazard Dam must pass	100	% of the	PMF
Existing High Hazard Dam must pass	100	% of the	PMF
New Significant Hazard Dam must pass	500yr-100	% of the	PMF
Existing Significant Hazard Dam must pass	500yr-100	% of the	PMF

Comments: Significant Hazard: 100% PMF if no provision for a spillway is incorporated into the design or it is classified as a "large" dam. The greater of 0.5PMF or a 500 year flood for "medium" and "small" dams.

29 For low hazard dams, the spillway design requirement is:

100-year flood

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

No

Comments: But we may allow one to help mitigate for certain unsafe conditions (such as an increased hazard situation at an existing dam) depending on the specific need and situation if it is proposed and is reasonable.

31 Does your organization permit risk-based hydrologic designs?

Our regulations do not specifically address this topic and it has never come up for consideration

32 Has your agency ever reviewed a risk-based hydrologic analysis?

No

33 How difficult would it be to change your regulations? Please explain.

Moderate

Comments: Although exempt from the "normal" statutory process to adopt or modify regulations, we do follow them. That requires workshops and public comment. Not impossible but time consuming and somewhat costly.

34 Are there any unique provisions in your regulations?

Yes (Please explain)

Comments: Nevada specifically prohibits use of CMP within a dam embankment unless it is the interior "form" for a CIP concrete pipe. Dam owners are prohibited from abandoning a dam. All dams are jurisdictional and notice of construction must be made for "below permitting threshold" dams. Owners of a dam are defined as any person who has a water right impounded by the dam, owns land on which the dam lies or owns land on which the reservoir lies.

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	New Hampshire Dam Bureau
Name of Representative	Jim Gallagher
Title of Representative	Chief Engineer
Phone number(s)	(603) 271-1961
Email address	James.Gallagher@des.nh.gov

2 Number of dams under Organization's jurisdiction by type:

Total Dams	
Total Regulated Dams	2615
High Hazard Dams	134
Significant Hazard Dams	164
Low Hazard Dams	554
Unregulated Dams	
Other	1773

3 When did your Organization adopt minimum Inflow Design Flood criteria? 1981

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Other (Please specify)

Comments: Less than 6 feet high.

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

No

6 Does the Organization have published size classification criteria?

No

7 Does the Organization have published hazard classification criteria?

Yes (High, Significant, Low, Limited Hazard)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

No potential for loss of life with significant but not excessive economic loss

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Published guidelines/regulations that are required

9 What is the origin of the guidelines?

Combination of the above (Please specify)

Comments: FEMA guidelines customized by program

10 When were the guidelines last revised (MM/DD/YYYY)? 08/20/2005

11 Are there any plans to update or revise the guidelines in the near future?

Yes (Please specify)

Comments: Reviewed and updated or readopted every 5 to 7 years. Currently in the review process.

12 Are the guidelines different for new and existing dams?

Yes (Please elaborate)

Comments: Dams constructed prior to 2/19/1981 are required to pass the following flows with 1 foot of freeboard and without manual operations: Class A (50-year flood or site specific), Class B (100-year flood or site specific), Class C (250% of 100-year flood or site specific)

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency utilizes a combination of the above approaches, possibly on a case-by-case basis

Comments: A combination of the 2nd, 3rd, and 4th options. Our agency also designs and performs the repair and reconstruction of 274 state-owned dams

14 How are the guidelines applied?

Based on hazard classification only

15 For PMP/PMF designs, is freeboard required?

Based on wave run up computations

Comments: For existing dams and new Low Hazard and Non-Menace dams, owners have option of one foot of freeboard rather than maximum wave run up.

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

Yes

If "Yes", what are the specific analysis methodologies, procedures, or computer software that must be used?

Must use HMRs for developing PMP

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

No

18 Do the guidelines specify any criteria for storm duration?

Yes (Based on Tc)

19 Do the guidelines specify any criteria for temporal storm distribution?

No

20 Do the guidelines specify any criteria for spatial storm distribution?

No

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

No

22 Does the organization allow development of a site specific PMP?

Yes

If "Yes", are there any restrictions, requirements, or guidelines for performing a site specific PMP?

No

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

Yes, a moderate problem

Comments: Hazard Creep has caused an increase in hazard classification for some dams in the state requiring an increase in spillway discharge capacity,

24 Do guidelines require consideration or analysis of future development?

No

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

Yes (Please specify)

Comments: 50-year and 100-year storms shall incorporate antecedent moisture condition 2 as defined in the USDA NRCS NEH, 210-VI-NEH-630.10, August 1, 1969

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

Yes

If "Yes", do guidelines require analyses to include future downstream conditions within the dam failure inundation zone?

No

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

No

Comments: Not currently, but we are currently evaluating whether or not tot require minimum spillway discharge standards regardless of downstream consequences.

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

Yes

If "Yes", complete as appropriate. If "No", describe below how spillway design capacity is determined.

New High Hazard Dam must pass	100	% of the	PMF
Existing High Hazard Dam must pass		% of the	
New Significant Hazard Dam must pass	50	% of the	PMF
Existing Significant Hazard Dam must pass		% of the	

29 For low hazard dams, the spillway design requirement is:

100-year flood

Comments: 100-year for Low Hazard, 50-year for Non-Menace

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

No

31 Does your organization permit risk-based hydrologic designs?

Yes; our regulations permit them

32 Has your agency ever reviewed a risk-based hydrologic analysis?

Yes (Reviewed and approved)

33 How difficult would it be to change your regulations? Please explain.

Moderate

Comments: Regulations are reviewed and updated if necessary every 5 to 7 years. Rulemaking process includes assembling an Advisory Committee of dam owners, consultants, and other interested parties; review and approval by the Agency Legal Unit; and review and approval by Legislative Committee on Administrative Rules.

34 Are there any unique provisions in your regulations?

Yes (Please explain)

Comments: waiver provisions

FEMA

HYDROLOGIC SAFETY OF DAMS QUESTIONNAIRE

Gannett Fleming
Your Trusted Advisor Since 1915

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	New Jersey Office of Engineering and Construction
Name of Representative	John Moyle
Title of Representative	Manager, Dam Safety and Flood Control
Phone number(s)	609-984-0859
Email address	john.moyle@dep.state.nj.us

2 Number of dams under Organization's jurisdiction by type:

Total Dams	
Total Regulated Dams	1721
High Hazard Dams	215
Significant Hazard Dams	338
Low Hazard Dams	1168
Unregulated Dams	
Other	

3 When did your Organization adopt minimum Inflow Design Flood criteria? 1981

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Other (Please specify)

Comments: Any dam which raises the waters of a stream five feet or more above its usual, mean, low water height

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

No

6 Does the Organization have published size classification criteria?

No

7 Does the Organization have published hazard classification criteria?

Yes (High, Significant, Low, Limited Hazard)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

No potential for loss of life with significant but not excessive economic loss

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Published within State Laws

9 What is the origin of the guidelines?

USACE guidelines (including Phase I Study guidelines)

10 When were the guidelines last revised (MM/DD/YYYY)? 06/16/2008

11 Are there any plans to update or revise the guidelines in the near future?

Yes (Please specify)

Comments: Every 5 years the state must readopt the standards.

12 Are the guidelines different for new and existing dams?

No

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency utilizes a combination of the above approaches, possibly on a case-by-case basis

14 How are the guidelines applied?

Based on hazard classification only

15 For PMP/PMF designs, is freeboard required?

1.0'

Comments: Greater than 1' is required if special conditions of severe frost damage, ice damage or wave action may occur

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

No

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

No

18 Do the guidelines specify any criteria for storm duration?

Yes (24-hour)

Comments: For Classes III and IV only

19 Do the guidelines specify any criteria for temporal storm distribution?

Yes (NRCS Standard)

Comments: Type III storm or later

20 Do the guidelines specify any criteria for spatial storm distribution?

No

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

Yes (Please specify)

Comments: Pipe conduits used as principal spillways must meet different criteria than auxiliary spillways. For example, all pipe conduits shall convey water at the maximum design velocity without damage to the interior surface. On the other hand, vegetated or unlined auxiliary spillways must be able to pass the design storm without jeopardizing the safety of the structure. Frequency of use criteria are also specified for auxiliary spillways.

22 Does the organization allow development of a site specific PMP?

Yes

If "Yes", are there any restrictions, requirements, or guidelines for performing a site specific PMP?

Yes (Please specify)

Comments: Only for existing dams

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

No

24 Do guidelines require consideration or analysis of future development?

Yes (Impacts of development on hazard classification or failure consequences)

Comments: All Class II and III dams shall, where practicable incorporate in the proposed design, the ability to make modifications necessary to increase the spillway capacity of the facility or other alternative measures if the downstream hazard potential increases.

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

No

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

Yes

If "Yes", do guidelines require analyses to include future downstream conditions within the dam failure inundation zone?

No

Comments: Not specified - used for existing dams only.

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

Yes (Please specify)

Comments: Minimum design storm shall be the 100 year storm.

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

Yes

If "Yes", complete as appropriate. If "No", describe below how spillway design capacity is determined.

New High Hazard Dam must pass	100	% of the	PMP
Existing High Hazard Dam must pass	100	% of the	PMP
New Significant Hazard Dam must pass	50	% of the	PMP
Existing Significant Hazard Dam must pass	50	% of the	PMP

29 For low hazard dams, the spillway design requirement is:

100-year flood

Comments: 24-hour, Type III storm

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

No

31 Does your organization permit risk-based hydrologic designs?

Our regulations do not specifically address this topic and it has never come up for consideration

32 Has your agency ever reviewed a risk-based hydrologic analysis?

No

33 How difficult would it be to change your regulations? Please explain.

Difficult

Comments: There is a public notification process that takes approximately a year to change a rule.

34 Are there any unique provisions in your regulations?

No

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	New Mexico
Name of Representative	Elaine C. Pacheco, P.E.
Title of Representative	Dam Safety Bureau Chief
Phone number(s)	505-827-6111
Email address	elaine.pacheco@state.nm.us

2 Number of dams under Organization's jurisdiction by type:

Total Dams	
Total Regulated Dams	297
High Hazard Dams	149
Significant Hazard Dams	62
Low Hazard Dams	86
Unregulated Dams	101
Other	

3 What year did your Agency adopt minimum Inflow Design Flood criteria? 1985

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Both of the above

Comments: NM Law was changed in 2009 to mirror the National Inventory Criteria for the size of a jurisdictional dam.

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

No

Comments: With the change in NM Law the exemptions for Stock and erosion control dams were no longer needed.

6 Does the Organization have published size classification criteria?

Yes

If "Yes", check and complete as appropriate:

Class A (Small)	=<	40	feet high and stores =<	1,000	acre-feet
Class B (Medium)					
Class C (Large)	=>	100	feet high and stores =>	50,000	acre-feet
Other (Specify)					

Comments: NM Classes are small, intermediate and large.

7 Does the Organization have published hazard classification criteria?

Yes (High, Significant, and Low)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

No potential for loss of life with significant but not excessive economic loss

Comments: No probable loss of life but can cause economic loss, environmental damage, disruption of lifeline facilities.

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Published guidelines/regulations that are required

9 What is the origin of the guidelines?

Other (Please specify)

Comments: Combination of federal and other western states.

10 When were the guidelines last revised (MM/DD/YYYY)? 12/31/2010

Comments: Changes to the Incremental Damage Assessment language to try and clarify the process.

11 Are there any plans to update or revise the guidelines in the near future?

Yes (Please specify)

Comments: Hope to develop guidelines for evaluating incremental damage. It would be great if FEMA's proposed guidelines provided details rather than a general approach.

12 Are the guidelines different for new and existing dams?

No

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency reviews submitted designs

Agency will perform independent verification on a case by case basis.

14 How are the guidelines applied?

Based on both size and hazard classification

15 For PMP/PMF designs, is freeboard required?

Based on wave run up computations

Comments: Anticipated wave runup resulting from a 100 mph wind with reservoir level at the spillway crest will not overtop the dam; Anticipated wave runup resulting from a 50 mph wind with maximum reservoir level from routed SDF will not overtop the dam; Clay core cover and capillary rise requirements are satisfied; A minimum of 3 feet of freeboard remains after seismic deformation; In any case, at least 4 feet of freeboard shall be provided.

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

No

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

Yes (Please specify)

Comments: AHYMO a black box program customized from HYMO for hydrology in the Albuquerque area. Program is a black box hard wired and is no longer allowed because intermediate results could not be verified.

18 Do the guidelines specify any criteria for storm duration?

Other (Please specify)

Comments: NM requires that both the Local Storm (6 hours) and General Storm (72 hours) be considered and the more critical storm (results in highest routed water level in the reservoir) be used.

19 Do the guidelines specify any criteria for temporal storm distribution?

Yes (HMR)

Comments: Local Storm: HMR 55A and HMR 49 recommend the distribution in HMR5 or USACE EM 1110-2-1411. The more critical distribution is selected. General Storm: The HMRs do not specify a distribution. Center peaking or USBR 2/3 peak is acceptable.

20 Do the guidelines specify any criteria for spatial storm distribution?

No

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

Yes (Please specify)

Comments: No damage to the spillway during normal operation. Damage to the spillway during the SDF is acceptable as long as the damage does not result in an uncontrolled release of the reservoir.

22 Does the organization allow development of a site specific PMP?

Yes

If "Yes", are there any restrictions, requirements, or guidelines for performing a site specific PMP?

No

Comments: However, analysis will be evaulated for appropriateness. NM is also developing a tool for site specific Extreme Precipitation for areas west of the continental divide to the eastern plains.

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

Yes, a major problem

Comments: Hazard creep is a major problem for dams designed and constructed by the NRCS and for other entities

24 Do guidelines require consideration or analysis of future development?

Yes (Both of the above)

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

Yes (Please specify)

Comments: Initial reservoir pool must be at normal operation or at the crest of the spillway for permanent water storage reservoirs.

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

Yes

If "Yes", do guidelines require analyses to include future downstream conditions within the dam failure inundation zone?

Yes

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

Yes (Please specify)

Comments: Lower limit is the 100-year event.

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

Yes

If "Yes", complete as appropriate. If "No", describe below how spillway design capacity is determined.

New High Hazard Dam must pass	100	% of the	PMP
Existing High Hazard Dam must pass	100	% of the	PMP
New Significant Hazard Dam must pass	50-75	% of the	PMP
Existing Significant Hazard Dam must pass	50-75	% of the	PMP

Comments: Significant varies with size classification

29 For low hazard dams, the spillway design requirement is:

100-year flood

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

No

Comments: Our regulations state no, but waivers could be requested and we might consider the request if adequate justification is provided and the owner has a history of reliability

31 Does your organization permit risk-based hydrologic designs?

Our regulations do not specifically address this topic and it has never come up for consideration

Comments: We would be open to consider this option.

32 Has your agency ever reviewed a risk-based hydrologic analysis?

No

33 How difficult would it be to change your regulations? Please explain.

Moderate

Comments: Process is defined in statute. Funds would need to be identified and the change presented to stakeholders to get support (or at least no opposition) during the hearing process.

34 Are there any unique provisions in your regulations?

No

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	New York
Name of Representative	Alon Dominitz
Title of Representative	
Phone number(s)	518-402-8130
Email address	axdomini@gw.dec.state.ny.us

2 Number of dams under Organization's jurisdiction by type:

Total Dams	
Total Regulated Dams	5624
High Hazard Dams	390
Significant Hazard Dams	750
Low Hazard Dams	4484
Unregulated Dams	
Other	

3 What year did your Agency adopt minimum Inflow Design Flood criteria? 1970's or earlier

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Other (Please specify)

Comments: A construction permit is required unless the dam is 6 ft high or may impound less than 1 million gallons, or is less than 15 ft high AND may impound less than 3 million gallons.

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

No

Comments: Inventory contains structures not considered dams - dams that were never built, failed, or removed.

6 Does the Organization have published size classification criteria?

Yes

If "Yes", check and complete as appropriate:

Class A (Small)	=<	40	feet high and stores =<	1,000	acre-feet
Class B (Medium)					
Class C (Large)	=>	40	feet high and stores =>	1,000	acre-feet
Other (Specify)					

Comments: No Medium Size Classification. Storage refers to normal storage

7 Does the Organization have published hazard classification criteria?

Yes (High, Significant, and Low)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

No potential for loss of life with significant but not excessive economic loss

Comments: A dam failure may result in damage to isolated homes, main highways, and minor railroads; may result in the interruption of important utilities, including water supply, sewage treatment, fuel, power, cable or telephone infrastructure; and/or is otherwise likely to pose the threat of personal injury and/or substantial economic loss or substantial environmental damage. Loss of human life is not expected.

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Published guidelines/regulations that are required

9 What is the origin of the guidelines?

Combination of the above (Please specify)

Comments: Appear to be mostly NRCS criteria, plus for gravity dams USBR Design of Small Dams and USACE

10 When were the guidelines last revised (MM/DD/YYYY)? 01/01/1989

11 Are there any plans to update or revise the guidelines in the near future?

Yes (Please specify)

Comments: In early stages of internal development now

12 Are the guidelines different for new and existing dams?

Yes (Please elaborate)

Comments: Low (100-year), Significant (150% of 100-year), High (50% PMF)

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency utilizes a combination of the above approaches, possibly on a case-by-case basis

May do independent verification for certain projects

14 How are the guidelines applied?

Based on both size and hazard classification

15 For PMP/PMF designs, is freeboard required?

Other (Please specify)

Comments: 1 ft minimum for small dam, 2 ft minimum for large dam

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

No

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

Yes (Please specify)

Comments: Do not allow Rational Method

18 Do the guidelines specify any criteria for storm duration?

No

19 Do the guidelines specify any criteria for temporal storm distribution?

No

20 Do the guidelines specify any criteria for spatial storm distribution?

No

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

Yes (Please specify)

Comments: Service Spillway Design Flood vs. Spillway Design Flood

22 Does the organization allow development of a site specific PMP?

Yes

If "Yes", are there any restrictions, requirements, or guidelines for performing a site specific PMP?

Yes (Please specify)

Comments: Have allowed a couple, combined with Incremental Hazard Assessment.

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

Yes, a moderate problem

Comments: 2009 revised regulations give hazard class much more importance, so change hazard classes is a growing problem.

24 Do guidelines require consideration or analysis of future development?

Yes (Both of the above)

Comments: New guidance on Engineering Assesment Reports mentions this - DOW TOGS 3.1.4

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

No

Comments: Typically assume normal initial pool

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

No

Comments: When site-specific PMP is combined with 1/2 PMF Existing Dam spillway capacity standard, we have asked for an incremental damage assessment. In other cases, dam owners have conducted incremental damage assessment on own initiatiative, to reduce spillway design flood or hazard classification

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

No

Comments: Nothing in guidelines but have never accepted less than 100-year storm

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

Yes

If "Yes", complete as appropriate. If "No", describe below how spillway design capacity is determined.

New High Hazard Dam must pass	50-100	% of the	PMF
Existing High Hazard Dam must pass	50	% of the	PMF
New Significant Hazard Dam must pass	225% of 100yr-40	% of the	PMF
Existing Significant Hazard Dam must pass	150% of 100yr	% of the	

Comments: Depending on size and hazard classification

29 For low hazard dams, the spillway design requirement is:

100-year flood

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

No

Comments: Not for new dam. Maybe for existing, if all other options were exhausted. Have never approved this.

31 Does your organization permit risk-based hydrologic designs?

Our regulations do not specifically address this topic and it has never come up for consideration

32 Has your agency ever reviewed a risk-based hydrologic analysis?

No

33 How difficult would it be to change your regulations? Please explain.

Difficult

34 Are there any unique provisions in your regulations?

Yes (Please explain)

Comments: Authority for state to regulate any dam whose failure could cause significant damage, regardless of size

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	North Carolina
Name of Representative	Steve McEvoy
Title of Representative	State Dam Safety Engineer
Phone number(s)	919-733-4574
Email address	Steve.McEvoy@ncdenr.gov

2 Number of dams under Organization's jurisdiction by type:

Total Dams	
Total Regulated Dams	4640
High Hazard Dams	1125
Significant Hazard Dams	655
Low Hazard Dams	2860
Unregulated Dams	
Other	

3 What year did your Agency adopt minimum Inflow Design Flood criteria? 1980

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Other (Please specify)

Comments: Less than 15 feet in structural height or less than 10 acre-feet of storage at top of dam elevation unless high hazard. All high hazard dams are jurisdictional.

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

Yes (Please explain)

Comments: Dams designed in accordance with NRCS Engineering Standard 378 are allowed to deviate from frequency of use criteria for unlined emergency spillways

6 Does the Organization have published size classification criteria?

Yes

If "Yes", check and complete as appropriate:

Class A (Small)	=<	35	feet high and stores =<	750	acre-feet
Class B (Medium)					
Class C (Large)	=>	50	feet high and stores =>	7500	acre-feet
Other (Specify)	Very Large: > 100 feet high and stores > 50000 acre-feet				

7 Does the Organization have published hazard classification criteria?

Yes (High, Significant, Low, Limited Hazard)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

No potential for loss of life with significant but not excessive economic loss

Comments: Includes interruption to public utilities and minor damage to isolated homes or commercial and industrial buildings

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Published guidelines/regulations that are required

9 What is the origin of the guidelines?

Custom developed by Organization

Comments: Developed by state dam safety staff and codified through appropriate legal procedure

10 When were the guidelines last revised (MM/DD/YYYY)? 12/01/1994

11 Are there any plans to update or revise the guidelines in the near future?

No

12 Are the guidelines different for new and existing dams?

No

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency utilizes a combination of the above approaches, possibly on a case-by-case basis

14 How are the guidelines applied?

Based on both size and hazard classification

15 For PMP/PMF designs, is freeboard required?

No

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

No

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

No

18 Do the guidelines specify any criteria for storm duration?

No

19 Do the guidelines specify any criteria for temporal storm distribution?

No

20 Do the guidelines specify any criteria for spatial storm distribution?

No

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

Yes (Please specify)

Comments: The guidelines specify activation and performance criteria for vegetated earth or unlined emergency spillways.

22 Does the organization allow development of a site specific PMP?

Yes

If "Yes", are there any restrictions, requirements, or guidelines for performing a site specific PMP?

Yes (Please specify)

Comments: Utilize Hyrdometeorological Report (HMR) Numbers 51, 52, 56

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

Yes, a moderate problem

24 Do guidelines require consideration or analysis of future development?

Yes (Impacts of development on hazard classification or failure consequences)

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

No

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

Yes

If "Yes", do guidelines require analyses to include future downstream conditions within the dam failure inundation zone?

Yes

Comments: The spillway should be sized so that the increased downstream damage resulting from overtopping failure of the dam would not be significant as compared with the damage caused by the flood in the absence of dam overtopping failure. SDF for high hazard dams cannot be more frequent than the 100-year return frequency.

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

Yes (Please specify)

Comments: A design storm more frequent than once in 100 years will not be acceptable for any Class C dam.

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

Yes

If "Yes", complete as appropriate. If "No", describe below how spillway design capacity is determined.

New High Hazard Dam must pass	33-100	% of the	PMP
Existing High Hazard Dam must pass	33-100	% of the	PMP
New Significant Hazard Dam must pass	100yr - 75	% of the	PMP
Existing Significant Hazard Dam must pass	100yr - 75	% of the	PMP

29 For low hazard dams, the spillway design requirement is:

Other (Please specify)

Comments: Ranges from 50 year to 1/2PMP, depending on size of dam.

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

Yes

Comments: Dams will be subject to reclassification if the Director determines that the hazard potential has changed. Non-structural provisions of adequately demonstrated effectiveness and reliability such as flood plain zoning, and early warning systems may be considered by the Director in making this determination.

31 Does your organization permit risk-based hydrologic designs?

Our regulations do not specifically address this topic and it has never come up for consideration

Comments: Our agency will review incremental damage analysis for SDF selection which could be considered as somewhat related to risk analysis

32 Has your agency ever reviewed a risk-based hydrologic analysis?

No

Comments: Nothing other than incremental damage analysis

33 How difficult would it be to change your regulations? Please explain.

Difficult

Comments:

Change requires public comment process and legislative scrutiny. Process takes approximately two years.

34 Are there any unique provisions in your regulations?

No

FEMA

HYDROLOGIC SAFETY OF DAMS QUESTIONNAIRE

Gannett Fleming
Your Trusted Advisor Since 1915

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	North Dakota
Name of Representative	Mr. Jonathan Kelsch
Title of Representative	Engineer / Manager
Phone number(s)	701-328-4948
Email address	jkelsch@nd.gov

2 Number of dams under Organization's jurisdiction by type:

Total Dams	
Total Regulated Dams	1165
High Hazard Dams	30
Significant Hazard Dams	94
Low Hazard Dams	1041
Unregulated Dams	
Other	

3 What year did your Agency adopt minimum Inflow Design Flood criteria? unknown

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Other (Please specify)

Comments: under 12.5 acre-feet of storage

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

Yes (Please explain)

Comments: Existing dams that are functioning correctly and built to a different standard.

6 Does the Organization have published size classification criteria?

Yes

If "Yes", check and complete as appropriate:

Class A (Small)	=<	10	feet high and stores =<	12.5	acre-feet
Class B (Medium)					
Class C (Large)	=>		feet high and stores =>		acre-feet
Other (Specify)	Five categories: Less than 10 ft, 10-24 ft, 25-39 ft, 40-55 ft, and Over 55 ft				

7 Does the Organization have published hazard classification criteria?

Yes (High, Significant, and Low)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

Loss of life potential is "few" with "appreciable" economic loss

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Published guidelines/regulations for consideration by the engineer/designer

9 What is the origin of the guidelines?

Custom developed by Organization

10 When were the guidelines last revised (MM/DD/YYYY)? 06/01/1985

11 Are there any plans to update or revise the guidelines in the near future?

No

12 Are the guidelines different for new and existing dams?

No

Comments: Exceptions can be made for existing dams to be repaired.

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency reviews submitted designs

14 How are the guidelines applied?

Based on both size and hazard classification

15 For PMP/PMF designs, is freeboard required?

Based on wave run up computations

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

No

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

No

18 Do the guidelines specify any criteria for storm duration?

Yes (Based on Tc)

19 Do the guidelines specify any criteria for temporal storm distribution?

Yes (HMR)

20 Do the guidelines specify any criteria for spatial storm distribution?

No

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

Yes (Please specify)

Comments: Activation and damage criteria for principal vs. emergency spillways.

22 Does the organization allow development of a site specific PMP?

Yes

If "Yes", are there any restrictions, requirements, or guidelines for performing a site specific PMP?

Yes (Please specify)

Comments: Recommended guidelines have been published (not required)

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

Yes, a major problem

24 Do guidelines require consideration or analysis of future development?

Yes (Both of the above)

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

Yes (Please specify)

Comments: AMC II or III

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

Yes

If "Yes", do guidelines require analyses to include future downstream conditions within the dam failure inundation zone?

No

Comments: Probably location dependent, not usually required for rural areas

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

No

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

Yes

If "Yes", complete as appropriate. If "No", describe below how spillway design capacity is determined.

New High Hazard Dam must pass		% of the	PMP
Existing High Hazard Dam must pass		% of the	PMP
New Significant Hazard Dam must pass		% of the	PMP
Existing Significant Hazard Dam must pass		% of the	PMP

Comments: Dam Design Classification I: 25-yr, II: 50-yr, III: 30% PMP, IV: 50% PMP, V: 100% PMP

29 For low hazard dams, the spillway design requirement is:

Not specified

Comments: See above criteria for five classifications.

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

No

31 Does your organization permit risk-based hydrologic designs?

Yes; although our regulations do not specifically address this topic, we review risk-based designs

32 Has your agency ever reviewed a risk-based hydrologic analysis?

Yes (Both approved and rejected)

33 How difficult would it be to change your regulations? Please explain.

Difficult

34 Are there any unique provisions in your regulations?

No

FEMA

HYDROLOGIC SAFETY OF DAMS QUESTIONNAIRE

Gannett Fleming
Your Trusted Advisor Since 1915

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	Ohio
Name of Representative	Dena Barnhouse
Title of Representative	Project Manager
Phone number(s)	614-265-6723
Email address	Dena.Barnhouse@dnr.state.oh.us

2 Number of dams under Organization's jurisdiction by type:

Total Dams	3572
Total Regulated Dams	1564
High Hazard Dams	368
Significant Hazard Dams	554
Low Hazard Dams	642
Unregulated Dams	991
Other	

3 What year did your Agency adopt minimum Inflow Design Flood criteria? 1967

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Other (Please specify)

Comments: Dam less than 6 feet in height OR less than 15 acre-feet in storage OR greater than 6 feet and less than 10 feet in height and less than 50 acre-feet in storage are exempt from Ohio's dam safety laws.

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

Yes (Please explain)

Comments: Ohio has jurisdiction over dams less than 25 feet in height and less than 50 acre-feet in storage with downstream hazard limited to the dam itself and agricultural land (Class IV). There is no minimum inflow design flood for Class IV dams specified in Ohio's dam safety laws.

6 Does the Organization have published size classification criteria?

Yes

If "Yes", check and complete as appropriate:

Class A (Small)	=<	40	feet high and stores =<	500	acre-feet
Class B (Medium)					
Class C (Large)	=>	60	feet high and stores =>	5000	acre-feet
Other (Specify)	Small > 25 feet high and stores > 50 acre-feet				

Comments: The "other" category above is a Class IV dam as described in question 5 above.

7 Does the Organization have published hazard classification criteria?

Yes (High, Significant, Low, Limited Hazard)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

No potential for loss of life with significant but not excessive economic loss

Comments: Class I (High), Class II (Significant), Class III (Low), and Class IV (limited).

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Published within State Laws

9 What is the origin of the guidelines?

Combination of the above (Please specify)

10 When were the guidelines last revised (MM/DD/YYYY)?

Comments: Critical flood guidelines added in the 1990's.

11 Are there any plans to update or revise the guidelines in the near future?

No

12 Are the guidelines different for new and existing dams?

No

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency utilizes a combination of the above approaches, possibly on a case-by-case basis

For existing dams, this agency performs rough calculations to determine whether the dam owner must hire an engineer to do further calculations. For dams being permitted, the dam owner's engineer submits an analysis which we review and sometimes perform our own calculations to verify the results.

14 How are the guidelines applied?

Based on both size and hazard classification

15 For PMP/PMF designs, is freeboard required?

No

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

No

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

No

18 Do the guidelines specify any criteria for storm duration?

Other (Please specify)

Comments: All methodologies must follow current publications from ODNR, USCOE, USGS, NOAA, or others acceptable to ODNR.

19 Do the guidelines specify any criteria for temporal storm distribution?

No

Comments: All methodologies must follow current publications from ODNR, USCOE, USGS, NOAA, or others acceptable to ODNR.

20 Do the guidelines specify any criteria for spatial storm distribution?

No

Comments: All methodologies must follow current publications from ODNR, USCOE, USGS, NOAA, or others acceptable to ODNR.

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

Yes (Please specify)

Comments: Emergency spillway channels must flow less than once in 50 years for Class I dams, once in 25 years for Class II dams, and less than once in 10 years for Class III dams.

22 Does the organization allow development of a site specific PMP?

Yes

If "Yes", are there any restrictions, requirements, or guidelines for performing a site specific PMP?

Yes (Please specify)

Comments: ODNR has currently hired a consultant to provide site specific PMP study for 2 department-owned dams. The results will be used to provide revised PMP values for roughly 2/3 of the state. The study will be indepdently reviewed before adopted.

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

Yes, a moderate problem

24 Do guidelines require consideration or analysis of future development?

Yes (Impacts of development on hazard classification or failure consequences)

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

No

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

Yes

If "Yes", do guidelines require analyses to include future downstream conditions within the dam failure inundation zone?

Yes

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

Yes (Please specify)

Comments: Class I (40% PMF minimum), Class II (20% PMF minimum), Class III (100-year minimum)

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

Yes

If "Yes", complete as appropriate. If "No", describe below how spillway design capacity is determined.

New High Hazard Dam must pass	100	% of the	PMF
Existing High Hazard Dam must pass	100	% of the	PMF
New Significant Hazard Dam must pass	50	% of the	PMF
Existing Significant Hazard Dam must pass	50	% of the	PMF

Comments: Can be reduced to the critical flood through an incremental damage assessment.

29 For low hazard dams, the spillway design requirement is:

Other (Please specify)

Comments: 25% PMF down to no less than 100 year based on incremental damage assessment.

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

No

31 Does your organization permit risk-based hydrologic designs?

No; our regulations forbid them

Comments: This type of analysis is not addressed in regulations. By omission, the regulations forbid them.

32 Has your agency ever reviewed a risk-based hydrologic analysis?

No

33 How difficult would it be to change your regulations? Please explain.

Moderate

34 Are there any unique provisions in your regulations?

No

FEMA

HYDROLOGIC SAFETY OF DAMS QUESTIONNAIRE

Gannett Fleming
Your Trusted Advisor Since 1915

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	Oklahoma
Name of Representative	Robert S. Fabian
Title of Representative	Technical Section Program Manager
Phone number(s)	405-530-8800
Email address	rsfabian@owrb.ok.gov

2 Number of dams under Organization's jurisdiction by type:

Total Dams	4672
Total Regulated Dams	4543
High Hazard Dams	320
Significant Hazard Dams	202
Low Hazard Dams	4021
Unregulated Dams	
Other	

3 What year did your Agency adopt minimum Inflow Design Flood criteria? 26828

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Both of the above

Comments: 15 af or less of impounding capacity irregardless of height of dam and 6 feet to 25 feet in height and with an impounding capacity of less than 50 acre-feet.

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

No

6 Does the Organization have published size classification criteria?

Yes

If "Yes", check and complete as appropriate:

Class A (Small)	=<	50	feet high and stores =<	10,000	acre-feet
Class B (Medium)					
Class C (Large)	=>	100	feet high and stores =>	50,000	acre-feet
Other (Specify)					

7 Does the Organization have published hazard classification criteria?

Yes (High, Significant, and Low)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

No potential for loss of life with significant but not excessive economic loss

Comments: A written guidance document is under development describing criteria to be used for determination of a dam's hazard potential.

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Published guidelines/regulations that are required

9 What is the origin of the guidelines?

Unknown

10 When were the guidelines last revised (MM/DD/YYYY)? 07/01/1995

11 Are there any plans to update or revise the guidelines in the near future?

No

12 Are the guidelines different for new and existing dams?

Yes (Please elaborate)

Comments: Any dam constructed prior to June 13, 1973 and which is classified as intermediate size and high hazard potential according to 785:25-3-3 shall be required to pass a minimum design of 50% of the PMF. Any dam constructed prior to June 13, 1973 and which is classified as large size and high hazard potential according to 785:25-3-3 shall be required to pass a minimum design flood of 75% of the PMF.

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency reviews submitted designs

14 How are the guidelines applied?

Based on both size and hazard classification

15 For PMP/PMF designs, is freeboard required?

Other (Please specify)

Comments: Minimum freeboard varies from 1 to 3 feet based on both hazard and size classification

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

Yes

If "Yes", what are the specific analysis methodologies, procedures, or computer software that must be used?

Must use HMRs for developing PMP

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

No

18 Do the guidelines specify any criteria for storm duration?

Yes (24-hour)

Comments: This is in a guidance document being develop and is not part of dam safety rules and regulations at this time.

19 Do the guidelines specify any criteria for temporal storm distribution?

No

20 Do the guidelines specify any criteria for spatial storm distribution?

Yes (Please specify)

Comments: If watershed above dam is greater than 10 sq. mi. then use concentric elipse pattern. This is in a guidance document being develop and is not part of dam safety rules and regulations at this time.

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

Yes (Please specify)

Comments: Dam safety rules specify a PMF and freeboard requirement based on size and hazard classification of the dam.

22 Does the organization allow development of a site specific PMP?

Yes

If "Yes", are there any restrictions, requirements, or guidelines for performing a site specific PMP?

No

Comments: This is in a guidance document being develop and is not part of dam safety rules and regulations at this time.

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

Yes, a major problem

24 Do guidelines require consideration or analysis of future development?

Yes (Impacts of development on hazard classification or failure consequences)

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

Yes (Please specify)

Comments: Specify saturated antecedent moisture condition and initial reservoir pool at normal levels.

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

No

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

No

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

Yes

If "Yes", complete as appropriate. If "No", describe below how spillway design capacity is determined.

New High Hazard Dam must pass	50-100	% of the	PMF
Existing High Hazard Dam must pass	50-75	% of the	PMF
New Significant Hazard Dam must pass	40-75	% of the	PMF
Existing Significant Hazard Dam must pass		% of the	

29 For low hazard dams, the spillway design requirement is:

Other (Please specify)

Comments: 25-50% of PMF depending on size classification

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

Yes

Comments: A non-structural alternative will only be considered as a temporay solution until such time as structural changes could be made.

31 Does your organization permit risk-based hydrologic designs?

Yes; although our regulations do not specifically address this topic, we review risk-based designs o

32 Has your agency ever reviewed a risk-based hydrologic analysis?

Yes (Reviewed and approved)

Comments: We rarely have a request for a risk-based hydrologic analysis.

33 How difficult would it be to change your regulations? Please explain.

Moderate

Comments: This is a time consuming process that includes an analysis of impacts, including financial impacts, on the regulated community.

34 Are there any unique provisions in your regulations?

No

FEMA

HYDROLOGIC SAFETY OF DAMS QUESTIONNAIRE

Gannett Fleming
Your Trusted Advisor Since 1915

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	Oregon
Name of Representative	Keith Mills
Title of Representative	Dam Safety Engineer
Phone number(s)	503-986-0840
Email address	millska@wrd.state.or.us

2 Number of dams under Organization's jurisdiction by type:

Total Dams	
Total Regulated Dams	1318
High Hazard Dams	126
Significant Hazard Dams	197
Low Hazard Dams	995
Unregulated Dams	
Other	

3 What year did your Agency adopt minimum Inflow Design Flood criteria? N/A

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Other (Please specify)

Comments: Less than 10 feet in height or that impounds less than 9.2 acre-feet.

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

No

6 Does the Organization have published size classification criteria?

No

If "Yes", check and complete as appropriate:

Class A (Small)	=<		feet high and stores =<	acre-feet
Class B (Medium)				
Class C (Large)	=>		feet high and stores =>	acre-feet
Other (Specify)	Oregon classifies dams into two categories: large and small.			

Comments: Small dams are those less than 9.2 acre-feet and 10 feet in height. They are not subject to state dam safety oversight. All large dams must be designed by an engineer licensed in Oregon.

7 Does the Organization have published hazard classification criteria?

Yes (High, Significant, and Low)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

No potential for loss of life with significant but not excessive economic loss

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Unpublished guidelines for consideration by the engineer/designer

9 What is the origin of the guidelines?

Combination of the above (Please specify)

Comments: Some custom as well

10 When were the guidelines last revised (MM/DD/YYYY)? N/A

11 Are there any plans to update or revise the guidelines in the near future?

No

12 Are the guidelines different for new and existing dams?

No

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency reviews submitted designs

We ask for PMF - High Hazard; 1/2 PMF Significant Hazard; 100 year flood with 2 feet of spillway freeboard for low hazard. All are minimum design criteria.

14 How are the guidelines applied?

Based on hazard classification only

15 For PMP/PMF designs, is freeboard required?

2.0'

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

No

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

No

18 Do the guidelines specify any criteria for storm duration?

No

19 Do the guidelines specify any criteria for temporal storm distribution?

No

20 Do the guidelines specify any criteria for spatial storm distribution?

No

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

No

22 Does the organization allow development of a site specific PMP?

Yes

If "Yes", are there any restrictions, requirements, or guidelines for performing a site specific PMP?

No

Comments: We need compelling evidence the analysis is appropriate.

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

Yes, a minor problem

Comments: Likely to become more of a problem with new development.

24 Do guidelines require consideration or analysis of future development?

No

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

No

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

No

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

No

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

Yes

If "Yes", complete as appropriate. If "No", describe below how spillway design capacity is determined.

New High Hazard Dam must pass	100	% of the	PMF
Existing High Hazard Dam must pass		% of the	
New Significant Hazard Dam must pass	50	% of the	PMF
Existing Significant Hazard Dam must pass		% of the	

Comments: We ask owners to upgrade spillway capacity when the hazard rating is upgraded. If it is necessary, would use a legal process to compel an owner to upgrade.

29 For low hazard dams, the spillway design requirement is:

100-year flood

Comments: 100 year with 2 feet of freeboard in the emergency spillway.

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

No

31 Does your organization permit risk-based hydrologic designs?

Our regulations do not specifically address this topic and it has never come up for consideration

32 Has your agency ever reviewed a risk-based hydrologic analysis?

No

33 How difficult would it be to change your regulations? Please explain.

Difficult

34 Are there any unique provisions in your regulations?

No

FEMA

HYDROLOGIC SAFETY OF DAMS QUESTIONNAIRE

Gannett Fleming
Your Trusted Advisor Since 1915

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	Pennsylvania
Name of Representative	Roger P. Adams, P.E.
Title of Representative	Chief, Division of Dam Safety
Phone number(s)	717-772-5951
Email address	roadams@state.pa.us

2 Number of dams under Organization's jurisdiction by type:

Total Dams	Unknown
Total Regulated Dams	3213
High Hazard Dams	782
Significant Hazard Dams	277
Low Hazard Dams	2154
Unregulated Dams	Unknown
Other	

3 What year did your Agency adopt minimum Inflow Design Flood criteria? 1913

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Other (Please specify)

Comments: Less than or equal to 15 feet and the impounding capacity at maximum storage elevation is less than or equal to 50 acre-feet and the drainage area is less than or equal to 100

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

Yes (Please explain)

Comments: Under PA mining laws, coal waste slurry dams have added regulations on time to dewater.

6 Does the Organization have published size classification criteria?

Yes

If "Yes", check and complete as appropriate:

Class A (Small)	=<	40	feet high and stores =<	1,000	acre-feet
Class B (Medium)					
Class C (Large)	=>	100	feet high and stores =>	50,000	acre-feet
Other (Specify)					

Comments: Note: In PA, Class A is large and Class C is small.

7 Does the Organization have published hazard classification criteria?

Yes (High, Significant, Low, Limited Hazard)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

Loss of life potential is "few" with "appreciable" economic loss

Comments: Category 1 = substantial population at risk (PAR) and/or excessive economic loss (EL); Category 2 = few PAR and/or appreciable EL; Category 3 = no PAR and or significant EL; and Category 4 = no PAR and minimal EL.

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Published guidelines/regulations that are required

Comments: By regulation

9 What is the origin of the guidelines?

Custom developed by Organization

10 When were the guidelines last revised (MM/DD/YYYY)? 01/08/2011

Comments: Regulations revised.

11 Are there any plans to update or revise the guidelines in the near future?

Yes (Please specify)

Comments: Developing a process to conduct an incremental dam break analysis.

12 Are the guidelines different for new and existing dams?

No

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency utilizes a combination of the above approaches, possibly on a case-by-case basis

14 How are the guidelines applied?

Based on both size and hazard classification

15 For PMP/PMF designs, is freeboard required?

No

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

No

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

Yes (Please specify)

Comments: Rational Method

18 Do the guidelines specify any criteria for storm duration?

Yes (24-hour)

Comments: By regulations.

19 Do the guidelines specify any criteria for temporal storm distribution?

No

20 Do the guidelines specify any criteria for spatial storm distribution?

No

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

Yes (Please specify)

Comments: For projects increasing spillway capacity, we may require no increase in outflows up to the 100-year frequency flood.

22 Does the organization allow development of a site specific PMP?

Yes

If "Yes", are there any restrictions, requirements, or guidelines for performing a site specific PMP?

Yes (Please specify)

Comments: Must be approved by NOAA.

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

Yes, a minor problem

24 Do guidelines require consideration or analysis of future development?

Yes (Impacts of development on hazard classification or failure consequences)

Comments: By Regulation

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

No

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

Yes

If "Yes", do guidelines require analyses to include future downstream conditions within the dam failure inundation zone?

Yes

Comments: Incremental dam break analysis is required for high hazard dams. SDF is based on no additional impact to homes.

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

Yes (Please specify)

Comments: 100-year frequency flood is considered a minimum SDF for high hazard dam.

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

Yes

If "Yes", complete as appropriate. If "No", describe below how spillway design capacity is determined.

New High Hazard Dam must pass	IDBA	% of the	PMF
Existing High Hazard Dam must pass	IDBA	% of the	PMF
New Significant Hazard Dam must pass	50-100	% of the	PMF
Existing Significant Hazard Dam must pass	50-100	% of the	PMF

Comments: New regulations require Incremental Dam Break Analysis (IDBA) to determine spillway design flood.

29 For low hazard dams, the spillway design requirement is:

Other (Please specify)

Comments: Medium (100-year to 1/2 PMF); Small (50-year to 100-year)

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

No

31 Does your organization permit risk-based hydrologic designs?

Other (Please explain)

Comments: Regulations do not address this issue; however, our procedures do not allow for this type of analysis

32 Has your agency ever reviewed a risk-based hydrologic analysis?

No

33 How difficult would it be to change your regulations? Please explain.

Moderate

Comments: We just went through a change so we are familiar with the procedure.

34 Are there any unique provisions in your regulations?

Yes (Please explain)

Comments: Requiring an incremental dam break analysis for the spillway design flood for high hazard dams.

ON THE RECORD

State/Federal Dam Safety Organization	Puerto Rico
Name of Representative	Luis A. Suarez Sanchez
Title of Representative	Administrator, Dams & Reservoirs Safety Program
Phone number(s)	787-521-3256
Email address	l-suarez@prepa.com

2 Number of dams under Organization's jurisdiction by type:

Total Dams	36
Total Regulated Dams	36
High Hazard Dams	35
Significant Hazard Dams	0
Low Hazard Dams	1
Unregulated Dams	0
Other	0

3 What year did your Agency adopt minimum Inflow Design Flood criteria? 1979

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Other (Please specify)

Comments: Is 25 feet or less in height or has an impounding capacity at the maximum water storage elevation of 50 acre-feet or less.

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

No

6 Does the Organization have published size classification criteria?

Yes

If "Yes", check and complete as appropriate:

Class A (Small)	=<	25	feet high and stores =<	50	acre-feet
Class B (Medium)					
Class C (Large)	=>	25	feet high and stores =>	50	acre-feet
Other (Specify)					

7 Does the Organization have published hazard classification criteria?

Yes (High, Significant, and Low)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

No potential for loss of life with significant but not excessive economic loss

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Published guidelines/regulations that are required

9 What is the origin of the guidelines?

FEMA/FERC federal guidelines

10 When were the guidelines last revised (MM/DD/YYYY)? 01/01/1998

Comments: In 1998 the Guidelines Development Subcommittee update the FEMA Guidelines.

11 Are there any plans to update or revise the guidelines in the near future?

No

12 Are the guidelines different for new and existing dams?

No

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency utilizes a combination of the above approaches, possibly on a case-by-case basis

14 How are the guidelines applied?

Based on a combination of risk analysis and hazard/size classification

15 For PMP/PMF designs, is freeboard required?

1.0'

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

Yes

If "Yes", what are the specific analysis methodologies, procedures, or computer software that must be used?

Other (Please specify)

Comments: Can use the computer software of the Corp of Engineer and analysis methodologies developed by USBR to Puerto Rico.

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

No

18 Do the guidelines specify any criteria for storm duration?

Yes (6-hr)

Comments: We use 24-hr too.

19 Do the guidelines specify any criteria for temporal storm distribution?

Yes (HMR)

20 Do the guidelines specify any criteria for spatial storm distribution?

No

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

No

22 Does the organization allow development of a site specific PMP?

No

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

No

24 Do guidelines require consideration or analysis of future development?

No

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

Yes (Please specify)

Comments: Antecedent moisture condition III and normal pool level.

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

No

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

No

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

Yes

If "Yes", complete as appropriate. If "No", describe below how spillway design capacity is determined.

New High Hazard Dam must pass	100	% of the	PMF
Existing High Hazard Dam must pass		% of the	
New Significant Hazard Dam must pass	100	% of the	PMF
Existing Significant Hazard Dam must pass		% of the	

29 For low hazard dams, the spillway design requirement is:

Not specified

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

Yes

31 Does your organization permit risk-based hydrologic designs?

Our regulations do not specifically address this topic and it has never come up for consideration

32 Has your agency ever reviewed a risk-based hydrologic analysis?

No

33 How difficult would it be to change your regulations? Please explain.

Difficult

34 Are there any unique provisions in your regulations?

No

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	Rhode Island
Name of Representative	Paul Guglielmino
Title of Representative	Senior Sanitary Engineer
Phone number(s)	401-222-1360 xt. 7122
Email address	paul.guglielmino@dem.ri.gov

2 Number of dams under Organization's jurisdiction by type:

Total Dams	671
Total Regulated Dams	538
High Hazard Dams	97
Significant Hazard Dams	83
Low Hazard Dams	492
Unregulated Dams	94
Other	

3 What year did your Agency adopt minimum Inflow Design Flood criteria? N/A

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Other (Please specify)

Comments: RI defines a 'regulated' dam as a low hazard dam that is six (6) feet or more in height or has fifteen (15) acre-feet or more of storage capacity; or a high hazard dam; or a significant hazard dam. 'Not regulated' doesn't meet the criteria. 'Non-jurisdictional' dams are FERC (for example), not RI, regulated. 'Non-inventory' are dams that we don't have in our database (typically small dams that wouldn't be regulated.

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

No

Comments: RI doesn't have specific design standards.

6 Does the Organization have published size classification criteria?

No

7 Does the Organization have published hazard classification criteria?

Yes (High, Significant, and Low)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

No potential for loss of life with significant but not excessive economic loss

Comments: A dam where failure or misoperation results in no probable loss of human life but can cause major economic loss, disruption of lifeline facilities or impact other concerns detrimental to the public's health, safety or welfare.

8 Does the Organization have guidelines for determining the spillway design flood?

No

9 What is the origin of the guidelines?

Unknown

10 When were the guidelines last revised (MM/DD/YYYY)? n/a

11 Are there any plans to update or revise the guidelines in the near future?

No

12 Are the guidelines different for new and existing dams?

No

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency reviews submitted designs

14 How are the guidelines applied?

15 For PMP/PMF designs, is freeboard required?

No

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

No

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

No

18 Do the guidelines specify any criteria for storm duration?

No

19 Do the guidelines specify any criteria for temporal storm distribution?

No

20 Do the guidelines specify any criteria for spatial storm distribution?

No

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

No

22 Does the organization allow development of a site specific PMP?

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

No

Comments: No to changing the hazard classification. N/a to design requirements.

24 Do guidelines require consideration or analysis of future development?

No

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

No

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

No

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

No

Comments: None.

29 For low hazard dams, the spillway design requirement is:

Not specified

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

31 Does your organization permit risk-based hydrologic designs?

Our regulations do not specifically address this topic and it has never come up for consideration

32 Has your agency ever reviewed a risk-based hydrologic analysis?

No

33 How difficult would it be to change your regulations? Please explain.

Moderate

Comments: It would be more difficult if the regulation change required a change in the law.

34 Are there any unique provisions in your regulations?

Yes (Please explain)

Comments: Although dam safety law has been in place since 1800's, our first set of regulations were promulgated in 2007. We're just entering puberty.

FEMA

HYDROLOGIC SAFETY OF DAMS QUESTIONNAIRE

Gannett Fleming
Your Trusted Advisor Since 1915

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	South Carolina
Name of Representative	Steven M. Bradley, P.E.
Title of Representative	Dam Safety Hydrologist
Phone number(s)	803-898-4027
Email address	

2 Number of dams under Organization's jurisdiction by type:

Total Dams	
Total Regulated Dams	2317
High Hazard Dams	153
Significant Hazard Dams	481
Low Hazard Dams	1683
Unregulated Dams	
Other	

3 What year did your Agency adopt minimum Inflow Design Flood criteria? 1980

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Other (Please specify)

Comments: Less than 25 feet in height or shall have an impounding capacity at maximum water storage elevation of less than 50 acre-feet.

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

No

6 Does the Organization have published size classification criteria?

Yes

If "Yes", check and complete as appropriate:

Class A (Small)	=<	40	feet high and stores =<	1,000	acre-feet
Class B (Medium)					
Class C (Large)	=>	100	feet high and stores =>	50,000	acre-feet
Other (Specify)	Very Small < 25 feet high and stores < 50 acre-feet				

7 Does the Organization have published hazard classification criteria?

Yes (High, Significant, and Low)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

No potential for loss of life with significant but not excessive economic loss

Comments: Published guidelines, but still subject to a lot of engineering judgment.

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Published guidelines/regulations that are required

9 What is the origin of the guidelines?

FEMA/FERC federal guidelines

10 When were the guidelines last revised (MM/DD/YYYY)? n/a

11 Are there any plans to update or revise the guidelines in the near future?

No

12 Are the guidelines different for new and existing dams?

Yes (Please elaborate)

Comments: New dams are conservatively classified.

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency reviews submitted designs

14 How are the guidelines applied?

Based on both size and hazard classification

15 For PMP/PMF designs, is freeboard required?

Based on wave run up computations

Comments: For 50 mph wind. For small dams, we usually use 1 ft.

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

No

Comments: Usually check it using HEC-1 (transitioning to HEC-HMS)

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

No

Comments: Has to pass review

18 Do the guidelines specify any criteria for storm duration?

Yes (24-hour)

Comments: Great majority of drainage areas are very small (<10 square miles). For these we use 24-hour duration.

19 Do the guidelines specify any criteria for temporal storm distribution?

No

Comments: Use of SCS Type II is common.

20 Do the guidelines specify any criteria for spatial storm distribution?

No

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

Yes (Please specify)

Comments: Activation criteria for earth spillways: Low hazard (1 year), Significant Hazard (10 year), High (25 year)

22 Does the organization allow development of a site specific PMP?

Yes

If "Yes", are there any restrictions, requirements, or guidelines for performing a site specific PMP?

Yes (Please specify)

Comments: Depends on credentials on person performing analysis

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

No

24 Do guidelines require consideration or analysis of future development?

No

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

Yes (Please specify)

Comments: AMC-II, Normal pool

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

Yes

If "Yes", do guidelines require analyses to include future downstream conditions within the dam failure inundation zone?

No

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

No

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

Yes

If "Yes", complete as appropriate. If "No", describe below how spillway design capacity is determined.

New High Hazard Dam must pass	50-100	% of the	PMF
Existing High Hazard Dam must pass	500yr-100	% of the	PMF
New Significant Hazard Dam must pass	100yr-50	% of the	PMF
Existing Significant Hazard Dam must pass	100yr-50	% of the	PMF

Comments: High Hazard: Very Small (100yr to 1/2PMF), Small (1/2PMF to PMF, Intermediate and Large (PMF). Significant Hazard: Small (100yr to 1/2PMF), Intermediate (1/2PMF to PMF), Large (PMF).

29 For low hazard dams, the spillway design requirement is:

Other (Please specify)

Comments: Small (50-yr to 100-yr), Intermediate (100-yr to 1/2 PMF), Large (1/2 PMF to PMF)

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

Yes

31 Does your organization permit risk-based hydrologic designs?

Our regulations do not specifically address this topic and it has never come up for consideration

32 Has your agency ever reviewed a risk-based hydrologic analysis?

No

33 How difficult would it be to change your regulations? Please explain.

Moderate

Comments: Current political climate makes it very difficult

34 Are there any unique provisions in your regulations?

Yes (Please explain)

Comments: We supply forms for EAPs to dam owners. All high hazard dams are being updated to meet FEMA rules

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	South Dakota
Name of Representative	Timothy G. Schaal
Title of Representative	Natural Resources Engineer
Phone number(s)	605-773-3352
Email address	tim.schaal@state.sd.us

2 Number of dams under Organization's jurisdiction by type:

Total Dams	
Total Regulated Dams	2349
High Hazard Dams	47
Significant Hazard Dams	144
Low Hazard Dams	2158
Unregulated Dams	
Other	

3 What year did your Agency adopt minimum Inflow Design Flood criteria? 1986

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Other (Please specify)

Comments: A barrier is not considered a dam if height does not exceed 6 feet regardless of storage capacity of if storage capacity does not exceed 15 acre-feet.

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

Yes (Please explain)

Comments: Design requirements for category 1 tailings dams. Dams constructed to store, without discharge, tailings as defined by 45-6B-3 (14) shall be sized to retain the PMF plus at least a 100-year flood

6 Does the Organization have published size classification criteria?

Yes

If "Yes", check and complete as appropriate:

Class A (Small)	=<	40	feet high and stores =<	1,000	acre-feet
Class B (Medium)					
Class C (Large)	=>	100	feet high and stores =>	50,000	acre-feet
Other (Specify)					

7 Does the Organization have published hazard classification criteria?

Yes (High, Significant, and Low)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

No potential for loss of life with significant but not excessive economic loss

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Published within State Laws

Comments: SDCL 46-2-5 & 46-7-3

9 What is the origin of the guidelines?

USACE guidelines (including Phase I Study guidelines)

Comments: Corps of Engineers Phase I Inspections Recommemded Guidelines

10 When were the guidelines last revised (MM/DD/YYYY)? 4/23/1989

11 Are there any plans to update or revise the guidelines in the near future?

No

Comments: not in the "Near Future"

12 Are the guidelines different for new and existing dams?

Yes (Please elaborate)

Comments: Category 3 dams constructed before October 27, 1986 are exempt from minimum spillway requirements unless the dam fails and is rebuilt.

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency reviews submitted designs

14 How are the guidelines applied?

Based on both size and hazard classification

15 For PMP/PMF designs, is freeboard required?

No

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

Yes

If "Yes", what are the specific analysis methodologies, procedures, or computer software that must be used?

Must use HMRs for developing PMP

Comments: we are open to other suggestions/methods

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

No

18 Do the guidelines specify any criteria for storm duration?

Yes (24-hour)

Comments: For 25-year, 50-year, and 100-year frequency floods.

19 Do the guidelines specify any criteria for temporal storm distribution?

Yes (HMR)

20 Do the guidelines specify any criteria for spatial storm distribution?

No

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

No

22 Does the organization allow development of a site specific PMP?

Unknown (never requested)

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

No

24 Do guidelines require consideration or analysis of future development?

Yes (Impacts of development on hazard classification or failure consequences)

Comments: 74:02:08:02 states that if the classification of a dam changes, the dam must comply with spillway requirements of the higher catergory

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

No

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

Yes

If "Yes", do guidelines require analyses to include future downstream conditions within the dam failure inundation zone?

No

Comments: SDCL 46-7-5.3

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

Yes (Please specify)

Comments: SDCL -46-7-5.3

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

Yes

If "Yes", complete as appropriate. If "No", describe below how spillway design capacity is determined.

New High Hazard Dam must pass	50-100	% of the	PMF
Existing High Hazard Dam must pass	50-100	% of the	PMF
New Significant Hazard Dam must pass	100yr-100	% of the	PMF
Existing Significant Hazard Dam must pass	100yr-100	% of the	PMF

Comments: High Hazard: Small (0.5PMF), Intermediate (0.5PMF), Large (PMF). Significant Hazard: Small (100-year), Intermediate (0.5PMF), Large (PMF).

29 For low hazard dams, the spillway design requirement is:

Other (Please specify)

Comments: Small (50-year), Intermediate (100-year), Large (0.5 PMF)

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

Comments: That would be a Water Management Board decision

31 Does your organization permit risk-based hydrologic designs?

Yes; our regulations permit them

Comments: SDCL 46-7-5.3

32 Has your agency ever reviewed a risk-based hydrologic analysis?

Yes (Reviewed and approved)

33 How difficult would it be to change your regulations? Please explain.

Difficult

Comments: Legislative Research Council review and approval, public notice and Water Management Board approval, Legislative Oversite Committee review and approval

34 Are there any unique provisions in your regulations?

No

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	Tennessee
Name of Representative	Lyle Bentley
Title of Representative	Chief, Dam Safety Program
Phone number(s)	615-532-0154
Email address	Lyle.Bentley@tn.gov

2 Number of dams under Organization's jurisdiction by type:

Total Dams	1227
Total Regulated Dams	662
High Hazard Dams	150
Significant Hazard Dams	210
Low Hazard Dams	302
Unregulated Dams	565
Other	

3 What year did your Agency adopt minimum Inflow Design Flood criteria? 1987

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Other (Please specify)

Comments: Dam means any artificial barrier, together with appurtenant works, which does or may impound or divert water, and which either (1) is or will be twenty (20) feet or more in height from the natural bed of the stream or watercourse at the downstream toe of the barrier, as determined by the Commissioner, or (2) has or will have an impounding capacity at maximum water storage elevation of thirty (30) acre-feet or more. Provided, however, that any such barrier which is or will be less than six (6) feet in height, regardless of storage capacity, or which has or will have a maximum storage capacity not in excess of fifteen (15) acre-feet, regardless of height, shall not be considered a dam, nor shall any barrier, regardless of size, be considered a dam, if, in the judgment of the Commissioner, such barrier creates an impoundment used only as a farm pond.

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

Yes (Please explain)

Comments: Dams designed and mostly paid for by the federal government, such as watershed district dams, cannot be required to have changes made in the design.

6 Does the Organization have published size classification criteria?

Yes

If "Yes", check and complete as appropriate:

Class A (Small)	=<	49	feet high and stores =<	999	acre-feet
Class B (Medium)					
Class C (Large)	=>	100	feet high and stores =>	50,000	acre-feet

7 Does the Organization have published hazard classification criteria?

Yes (High, Significant, and Low)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

No potential for loss of life with significant but not excessive economic loss

Comments: Category 1 (High), Category 2 (Significant), and Category 3 (Low).

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Published guidelines/regulations that are required

9 What is the origin of the guidelines?

USACE guidelines (including Phase I Study guidelines)

Comments: The Corps standards used in the Phase 1 investigations I the late 1970's and early 1980's.

10 When were the guidelines last revised (MM/DD/YYYY)? 02/19/2001

11 Are there any plans to update or revise the guidelines in the near future?

No

12 Are the guidelines different for new and existing dams?

Yes (Please elaborate)

Comments: Different Freeboard Design Storms for new and existing dams.

13 Which of the following best describes your agency's role in determining the spillway design flood:

It's specified in the regualtions.

14 How are the guidelines applied?

Based on both size and hazard classification

15 For PMP/PMF designs, is freeboard required?

Other (Please specify)

Comments: Sufficient freeboard shall be provided to prevent overtopping with the passage of the freeboard hydrograph plus the additional freeboard required by the site for wave action.

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

No

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

No

18 Do the guidelines specify any criteria for storm duration?

Yes (6-hr)

19 Do the guidelines specify any criteria for temporal storm distribution?

Yes (HMR)

20 Do the guidelines specify any criteria for spatial storm distribution?

No

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

Yes (Please specify)

Comments: Activation and performance guidelines are provided for vegetated earth or unlined emergency spillways

22 Does the organization allow development of a site specific PMP?

Yes

If "Yes", are there any restrictions, requirements, or guidelines for performing a site specific PMP?

No

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

No

Comments: No, although it has been a source on contention at times.

24 Do guidelines require consideration or analysis of future development?

Yes (Impacts of development on hazard classification or failure consequences)

Comments: This only applies if development is actually planned - not if development could occur "one day."

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

No

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

Yes

If "Yes", do guidelines require analyses to include future downstream conditions within the dam failure inundation zone?

No

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

No

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

Yes

If "Yes", complete as appropriate. If "No", describe below how spillway design capacity is determined.

New High Hazard Dam must pass	50-100	% of the	PMP
Existing High Hazard Dam must pass	50-100	% of the	PMP
New Significant Hazard Dam must pass	50-100	% of the	PMP
Existing Significant Hazard Dam must pass	33-100	% of the	PMP

Comments: Existing, High Hazard: Large and Intermediate (PMP), Small (1/2 PMP). Significant Hazard: Large (PMP), Intermediate (1/2 PMP), Small (1/3 PMP). New (regardless of hazard class): Large and Intermediate (PMP), Small (1/2 PMP)

29 For low hazard dams, the spillway design requirement is:

Other (Please specify)

Comments: Existing: Large (1/2 PMP), Intermediate (1/3PMP), Small (100-year).
New (regardless of hazard class): Large and Intermediate (PMP), Small (1/2 PMP)

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

No

31 Does your organization permit risk-based hydrologic designs?

No; our regulations address this topic and we have made an administrative decision not to conside

32 Has your agency ever reviewed a risk-based hydrologic analysis?

No

33 How difficult would it be to change your regulations? Please explain.

Moderate

Comments: It can be done through our rulemaking process.

34 Are there any unique provisions in your regulations?

No

FEMA

HYDROLOGIC SAFETY OF DAMS QUESTIONNAIRE

Gannett Fleming
Your Trusted Advisor Since 1915

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	Texas
Name of Representative	Warren D. Samuelson, P.E.
Title of Representative	Dam Safety Program Coordinator
Phone number(s)	512-239-5195
Email address	warren.samuelson@tceq.texas.gov

2 Number of dams under Organization's jurisdiction by type:

Total Dams	
Total Regulated Dams	7212
High Hazard Dams	1002
Significant Hazard Dams	735
Low Hazard Dams	5485
Unregulated Dams	
Other	

3 What year did your Agency adopt minimum Inflow Design Flood criteria? 1986

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Both of the above

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

No

6 Does the Organization have published size classification criteria?

Yes

If "Yes", check and complete as appropriate:

Class A (Small)	=<	40	feet high and stores =<	1,000	acre-feet
Class B (Medium)					
Class C (Large)	=>	100	feet high and stores =>	50,000	acre-feet
Other (Specify)	Intermediate = Equal to or Greater than 1,000 AF & Less than 50,000 AF or Equal to or Greater than 40 ft & Less than 100 ft				

Comments: Small = Equal to or Greater than 15 AF & Less than 1,000 AF; Equal to or Greater than 50 AF & Less than 1,000 AF; Equal to or Greater than 25 ft & Less than 40 ft; or Greater than 6 ft & Less than 40 ft

7 Does the Organization have published hazard classification criteria?

Yes (High, Significant, and Low)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

Loss of life potential is "few" with "appreciable" economic loss

Comments: Loss of one to six lives or one or two habitable structures in the breach inundation area downstream of the dam

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Published within State Laws

Comments: Guidelines entitled "Hydrologic and Hydraulic Guidelines for Dams in Texas"

9 What is the origin of the guidelines?

Custom developed by Organization

10 When were the guidelines last revised (MM/DD/YYYY)? 01/01/2007

11 Are there any plans to update or revise the guidelines in the near future?

No

12 Are the guidelines different for new and existing dams?

Yes (Please elaborate)

Comments: An owner of a large- or high-hazard existing dam that was required to meet 100% of the probable maximum flood (PMF) before the effective date of these rules and that is shown by an evaluation by a professional engineer to meet 75% or more of the PMF will not be required to upgrade the dam to meet minimum hydrologic criteria in paragraph (1)(A) of this subsection.

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency performs independent verification of submitted designs

14 How are the guidelines applied?

Based on both size and hazard classification

15 For PMP/PMF designs, is freeboard required?

Based on wave run up computations

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

Yes

If "Yes", what are the specific analysis methodologies, procedures, or computer software that must be used?

Other (Please specify)

Comments: HEC-HMS, HEC-1, SITES, WIN TR20, WIN TR55, HEC-RAS, and NWS Dynamic Wave Models. Other models may be acceptable upon written approval.

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

No

18 Do the guidelines specify any criteria for storm duration?

Other (Please specify)

Comments: Minimum storm duration is specified based on drainage area. All durations from the minimum up to the 72-hour duration shall be used to determine the most critical duration or the duration that produces the maximum reservoir level.

19 Do the guidelines specify any criteria for temporal storm distribution?

Yes (Other - please specify)

Comments: PMP distributions are provided for 1-hr to 72-hr duration events. More conservative distributions (such as the HMR-51 or NRCS distributions) can be used.

20 Do the guidelines specify any criteria for spatial storm distribution?

Yes (Please specify)

Comments: Based upon drainage area

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

Yes (Please specify)

Comments: It is often accepted that erosion damage will occur should the emergency spillway operate, but that the effective cost of the very infrequent repairs is much lower than the upfront capital costs of the means to prevent the erosion. Most emergency spillways are built to prevent passage of flows for less than about the 50- or 100-year flood.

22 Does the organization allow development of a site specific PMP?

Yes

If "Yes", are there any restrictions, requirements, or guidelines for performing a site specific PMP?

No

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

Yes, a moderate problem

Comments: We get comments from Legislative staff due to changing hazard classification. Owners also have a problem understanding floods that have "never occurred".

24 Do guidelines require consideration or analysis of future development?

No

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

Yes (Please specify)

Comments: Superimpose the PMP upon watershed soils assumed to be saturated. This will equate to losses at the beginning of the design storm equal to zero or Natural Resources Conservation Service Antecedent Runoff Conditions III (ARC III), or some other equivalent and approved assumptions. In Texas, there is no need to analyze snowmelt contributions to runoff or frozen ground conditions for infiltration for design-flood calculations.

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

Yes

If "Yes", do guidelines require analyses to include future downstream conditions within the dam failure inundation zone?

No

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

No

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

Yes

If "Yes", complete as appropriate. If "No", describe below how spillway design capacity is determined.

New High Hazard Dam must pass	75-100	% of the	PMF
Existing High Hazard Dam must pass	75-100	% of the	PMF
New Significant Hazard Dam must pass	50-75	% of the	PMF
Existing Significant Hazard Dam must pass	50-75	% of the	PMF

Comments: Significant: Small (50% PMF), Intermediate (50-75% PMF), Large (75% PMF)
High: Small (75% PMF), Intermediate (75-100% PMF), Large (100% PMF)

29 For low hazard dams, the spillway design requirement is:

Other (Please specify)

Comments: Small (25% PMF), Intermediate (25-50% PMF), Large (50-75% PMF)

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

Yes

Comments: It happened one time a number of years ago. The owners would have to provide much more justification for it to be approved today.

31 Does your organization permit risk-based hydrologic designs?

Yes; our regulations permit them

32 Has your agency ever reviewed a risk-based hydrologic analysis?

No

33 How difficult would it be to change your regulations? Please explain.

Difficult

Comments: The last change to the rules took four years and four different stakeholder meetings. The process is done internal to the agency, but takes a long time. Today, there would be considerable input from the Legislature. It would be difficult to get some of the changes we got in 2009 today.

34 Are there any unique provisions in your regulations?

No

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	Utah
Name of Representative	Everett Taylor
Title of Representative	Dam Safety
Phone number(s)	801-538-7372
Email address	everetttaylor@utah.gov

2 Number of dams under Organization's jurisdiction by type:

Total Dams	5031
Total Regulated Dams	5031
High Hazard Dams	196
Significant Hazard Dams	301
Low Hazard Dams	4534
Unregulated Dams	0
Other	0

3 What year did your Agency adopt minimum Inflow Design Flood criteria? 1990

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Other (Please specify)

Comments: Owned by Bureau of Reclamation

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

Yes (Please explain)

Comments: Low Hazard, Flood control, less than 20 ac-ft & not high hazard

6 Does the Organization have published size classification criteria?

No

7 Does the Organization have published hazard classification criteria?

Yes (Other)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

Other (Please specify)

Comments: Those dams which, if they fail, have a low probablility of causing loss of human life, but would cause appreciable property damage, including damage to public utilities.

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Published within State Laws

Comments: Found within State Administrative Rules

9 What is the origin of the guidelines?

Other (Please specify)

Comments: HMR 49 with state approved adjustments based on commissioned studies.

10 When were the guidelines last revised (MM/DD/YYYY)? 12/31/2003

11 Are there any plans to update or revise the guidelines in the near future?

No

12 Are the guidelines different for new and existing dams?

No

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency performs independent verification of submitted designs

14 How are the guidelines applied?

Based on hazard classification only

15 For PMP/PMF designs, is freeboard required?

No

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

Yes

If "Yes", what are the specific analysis methodologies, procedures, or computer software that must be used?

Must use HMRs for developing PMP

Comments: The 72 hour SEF using HMR49/ USUL as well as the 6 hour SEF using HMR49/ USUS.

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

No

Comments: Reserve the right to question methodologies

18 Do the guidelines specify any criteria for storm duration?

Other (Please specify)

Comments: Route the 72 hour SEF using HMR49/ USUL as well as the 6 hour SEF using HMR49/ USUS to determine the more extreme event.

19 Do the guidelines specify any criteria for temporal storm distribution?

Yes (HMR)

20 Do the guidelines specify any criteria for spatial storm distribution?

No

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

Yes (Please specify)

Comments: In designing the spillway for a dam to pass the IDF, the State Engineer will consider the use of a principal spillway in conjunction with emergency spillways. The principal spillway must be designed so that no structural damage will occur during passage of the IDF. Emergency spillways, including Fuse Plug Spillways, may be designed so that some damage may be expected during use provided the anticipated damage does not represent a threat to the dam. Sunny day failure modeling of Fuse Plug Spillways may be required to determine if they are creating an additional unacceptable risk. Overtopping of the dam will not be considered as an emergency spillway on earthfill dams, unless it can be demonstrated that the dam is protected from erosion, and the duration of overtopping will not saturate the dam and reduce its stability.

22 Does the organization allow development of a site specific PMP?

No

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

Yes, a moderate problem

24 Do guidelines require consideration or analysis of future development?

No

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

Yes (Please specify)

Comments: Reservoir pool at spillway crest (except flood control) AMC III for 100 year flood criteria

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

Yes

If "Yes", do guidelines require analyses to include future downstream conditions within the dam failure inundation zone?

No

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

Yes (Please specify)

Comments: 100-year flood

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

No

Comments: The IDF for all High and Moderate Hazard Dams will be the SEF. It will be necessary to calculate both the 72 hour SEF using HMR49/ USUL as well as the 6 hour SEF using HMR49/ USUS. Both of these hydrographs must be routed through the reservoir to determine which one represents the most extreme event. Once the critical SEF has been determined, it must be compared to a flood generated by the 100 year, 6 hour (for local storms), or 100 yr, 24 hour (for general storms) precipitation applied on a saturated watershed. If the routed 100 year event, including appropriate allowances for freeboard, is more critical than the SEF it must be used as the minimum IDF.

29 For low hazard dams, the spillway design requirement is:

100-year flood

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

Yes

Comments: Possibly on upgrading existing structure to meet minimum standards. Not for new construction.

31 Does your organization permit risk-based hydrologic designs?

No; our regulations forbid them

32 Has your agency ever reviewed a risk-based hydrologic analysis?

No

33 How difficult would it be to change your regulations? Please explain.

Moderate

Comments: Changed through administrative rule process

34 Are there any unique provisions in your regulations?

No

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	Vermont
Name of Representative	Stephen Bushman
Title of Representative	Environmental Engineer IV
Phone number(s)	802-241-3450
Email address	steve.bushman@state.vt.us

2 Number of dams under Organization's jurisdiction by type:

Total Dams	
Total Regulated Dams	572
High Hazard Dams	55
Significant Hazard Dams	136
Low Hazard Dams	379
Unregulated Dams	
Other	

3 What year did your Agency adopt minimum Inflow Design Flood criteria?

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Other (Please specify)

Comments: Non jurisdictional: Capable of impounding 500,000 cubic feet or less of water. No non-inventory dam in VT, all dams we know of are included in inventory.

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

No

6 Does the Organization have published size classification criteria?

No

7 Does the Organization have published hazard classification criteria?

Yes (High, Significant, and Low)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

Loss of life potential is "few" with "appreciable" economic loss

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Published guidelines/regulations for consideration by the engineer/designer

9 What is the origin of the guidelines?

Combination of the above (Please specify)

Comments: Primarily USACE and NRCS.

10 When were the guidelines last revised (MM/DD/YYYY)?

11 Are there any plans to update or revise the guidelines in the near future?

No

12 Are the guidelines different for new and existing dams?

Yes (Please elaborate)

Comments: New dams must meet appropriate SDF. We have allowed reconstruction of existing dams to meet less than SDF required for a new dam, but at least Q100, and usually improvement over existing.

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency reviews submitted designs

14 How are the guidelines applied?

Based on hazard classification only

15 For PMP/PMF designs, is freeboard required?

Other (Please specify)

Comments: Freeboard, as appropriate, but not less than 1.5 feet with a routed Q100 inflows, and not less than 3.0 feet from principal spillway crest.

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

No

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

No

18 Do the guidelines specify any criteria for storm duration?

No

Comments: No, but typically 24-hr is used.

19 Do the guidelines specify any criteria for temporal storm distribution?

No

Comments: No, but typically HMR is used.

20 Do the guidelines specify any criteria for spatial storm distribution?

No

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

Yes (Please specify)

Comments: As appropriate (USCOE, NRCS)

22 Does the organization allow development of a site specific PMP?

Unknown (never requested)

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

No

24 Do guidelines require consideration or analysis of future development?

No

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

No

Comments: Typically use normal pool level

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

No

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

No

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

No

Comments: SDF and outlet works capacities should be consistent with guidelines or service criteria established by Federal agencies such as the Corps of Engineers, Soil Conservation Service and the Bureau of Reclamation for a given size and hazard classification, with the following additional requirements: 1) SDF, as appropriate, but in no case less than a routed Q100 (one hundred-year frequency) inflow (Ref: FERC Engineering Guidelines . . . , October 1993, Paragraph 2-3.3.). 2) Freeboard, as appropriate, but not less than 1.5 feet with a routed Q100 inflows, and not less than 3.0 feet from principal spillway crest (usually NWL). Applies to all embankment dams and other dams where appropriate.

29 For low hazard dams, the spillway design requirement is:

100-year flood

Comments: SDF

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

No

31 Does your organization permit risk-based hydrologic designs?

Our regulations do not specifically address this topic and it has never come up for consideration

32 Has your agency ever reviewed a risk-based hydrologic analysis?

Unsure

33 How difficult would it be to change your regulations? Please explain.

Moderate

Comments: Statute change required. Would require amendment to individual sections of the law or addition of new sections. Difficulty increases with complexity of change.

34 Are there any unique provisions in your regulations?

No

FEMA

HYDROLOGIC SAFETY OF DAMS QUESTIONNAIRE

Gannett Fleming
Your Trusted Advisor Since 1915

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	Virginia
Name of Representative	Robert T. Bennett, P.E., R.A., C.F.M.
Title of Representative	Director, Div. of Dam Safety & Floodplain Man.
Phone number(s)	804-786-3914
Email address	Robert.Bennett@dcr.virginia.gov

2 Number of dams under Organization's jurisdiction by type:

Total Dams	11,568
Total Regulated Dams	1,568
High Hazard Dams	162
Significant Hazard Dams	382
Low Hazard Dams	1024
Unregulated Dams	10,000 +/-
Other	

3 What year did your Agency adopt minimum Inflow Design Flood criteria? 1982

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Other (Please specify)

Comments: Owned or regulated by the Federal Government, or Permitted Mining Dam, or size exempt. Size exempt: <6', or <50 ac-ft for dams 6' - 25', or <15 ac-ft for dams >25'

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

Yes (Please explain)

Comments: Pemitted Dams by VA Dept. Mines, Minerals, & Energy, and Agricultural Use Dams that are <25' high and Agricultural Use Dams < 100ac-ft.

6 Does the Organization have published size classification criteria?

Yes

If "Yes", check and complete as appropriate:

Class A (Small)	=<	40	feet high and stores =<	1,000	acre-feet
Class B (Medium)					
Class C (Large)	=>	100	feet high and stores =>	50,000	acre-feet
Other (Specify)					

Comments: Medium is between Large and Small. Small is further defined as >=6'

7 Does the Organization have published hazard classification criteria?

Yes (Other)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

No potential for loss of life with significant but not excessive economic loss

Comments: From 4VAC50-20-40: Significant Hazard Potential is defined where an impounding structure failure may cause the loss of life or appreciable economic damage. "May cause loss of life" means that impacts will occur that could cause a loss of human life, including but not limited to impacts to facilities that are frequently utilized by humans other than residences, businesses, or other occupied structures, or to secondary roadways. Economic damage may occur to, but not be limited to, building(s), industrial or commercial facilities, public utilities, secondary roadways, railroads, personal property, and agricultural interests. "Secondary roadways" include, but are not limited to, secondary highways, low-volume urban streets, service roads, or other low-volume roadways.

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Published guidelines/regulations that are required

9 What is the origin of the guidelines?

USACE guidelines (including Phase I Study guidelines)

10 When were the guidelines last revised (MM/DD/YYYY)? 12/22/2010

11 Are there any plans to update or revise the guidelines in the near future?

Yes (Please specify)

Comments: Will be forming a Technical Advisory Committee (TAC) to revise regulations in 2011, may or may not change guidelines on determining SDF.

12 Are the guidelines different for new and existing dams?

Yes (Please elaborate)

Comments: Existing high hazard dams maximum SDF required = Flood resulting from the 90%PMP, new high hazard dams maximum required SDF = PMF.

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency reviews submitted designs

Agency advises dam owners through the required certificate to operate renewal process that upgrades are needed if applicable.

14 How are the guidelines applied?

Based on hazard classification only

15 For PMP/PMF designs, is freeboard required?

Other (Please specify)

Comments: Yes, in conformance with Fed. Guidelines (See USBR Design of Small Dams) Freeboard determination and justification must be addressed by the owner's engr.

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

Yes

If "Yes", what are the specific analysis methodologies, procedures, or computer software that must be used?

Other (Please specify)

Comments: Federal guidelines unless alternate method pre-approved by Dam Safety.

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

Yes (Please specify)

Comments: Any software not approved by Fed. or non Fed. Approved and not pre-approved by Dam Safety

18 Do the guidelines specify any criteria for storm duration?

Other (Please specify)

Comments: PMF hydrographs for 6-, 12-, and 24-hr. The hydrograph that creates the largest peak outflow used to determine capacity for nonfailure and failure analysis.

19 Do the guidelines specify any criteria for temporal storm distribution?

Yes (Other - please specify)

Comments: Must comply with federal standard being used for calculations.

20 Do the guidelines specify any criteria for spatial storm distribution?

Yes (Please specify)

Comments: Must comply with federal standard being used for calculations.

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

Yes (Please specify)

Comments: Freeboard Design Flood may be used for NRCS Flood Control Struct. Only. All others must use spillway design flood and applicable Fed. Guidelines.

22 Does the organization allow development of a site specific PMP?

No

Comments: Not yet.

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

Yes, a moderate problem

24 Do guidelines require consideration or analysis of future development?

Yes (Both of the above)

Comments: Both is for impacts on watershed hydrology and impacts on downstream hazards.

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

Yes (Please specify)

Comments: Regs. 4VAC50-20-50 …."C. PMF: Probable Maximum Flood is the flood that might be expected from the most severe combination of critical meteorologic and hydrologic conditions that are reasonably possible in the region."

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

Yes

If "Yes", do guidelines require analyses to include future downstream conditions within the dam failure inundation zone?

Yes

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

Yes (Please specify)

Comments: Minimum threshold for IDA: High (100-yr), Significant (100-yr), Low (50-yr)

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

Yes

If "Yes", complete as appropriate. If "No", describe below how spillway design capacity is determined.

New High Hazard Dam must pass	100	% of the	PMF
Existing High Hazard Dam must pass	90	% of the	PMP
New Significant Hazard Dam must pass	50	% of the	PMF
Existing Significant Hazard Dam must pass	50	% of the	PMF

Comments: The above numbers are without guidelines for incremental damage analysis reduction of spillway capacity requirements.

29 For low hazard dams, the spillway design requirement is:

100-year flood

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

No

31 Does your organization permit risk-based hydrologic designs?

Other (Please explain)

Comments: No

32 Has your agency ever reviewed a risk-based hydrologic analysis?

Other (Please explain)

Comments: Proposed by dam owner, but concept rejected without consideration.

33 How difficult would it be to change your regulations? Please explain.

Difficult

34 Are there any unique provisions in your regulations?

Yes (Please explain)

Comments: See: http://www.dcr.virginia.gov/dam_safety_and_floodplains/documents/dsregs.pdf

FEMA

HYDROLOGIC SAFETY OF DAMS QUESTIONNAIRE

Gannett Fleming
Your Trusted Advisor Since 1915

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	Washington State
Name of Representative	Jerald LaVassar, P.E.
Title of Representative	Unit Lead, Dam Safety Office
Phone number(s)	360-407-6625
Email address	jlsd461@ecy.wa.gov

2 Number of dams under Organization's jurisdiction by type:

Total Dams	1381
Total Regulated Dams	1217
High Hazard Dams	137
Significant Hazard Dams	224
Low Hazard Dams	856
Unregulated Dams	164
Other	

3 What year did your Agency adopt minimum Inflow Design Flood criteria? 1989

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Other (Please specify)

Comments: Non-jurisdictional - Less than 10 acre-feet of storage (top of dam); USACE or USBR ownership; or FERC regulation. Of the unregulated dams, 106 are high hazard USACE, USBR or FERC dams.

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

No

6 Does the Organization have published size classification criteria?

Yes

If "Yes", check and complete as appropriate:

Class A (Small)	=<	15	feet high and stores =<		acre-feet
Class B (Medium)					
Class C (Large)	=>	50	feet high and stores =>		acre-feet

7 Does the Organization have published hazard classification criteria?

Yes (High, Significant, and Low)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

Loss of life potential is "few" with "appreciable" economic loss

Comments: Population at Risk = 1 to 6 people. 1 or 2 inhabited structures. Other criteria include notable agriculture or work sites, secondary highway and/or rail lines, limited water quality degradation and only short term environmental impacts.

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Published guidelines/regulations that are required

Comments: Guidelines establish design minimums as a function of the downstream hazard setting.

9 What is the origin of the guidelines?

Custom developed by Organization

Comments: Dam Safety Guidelines, Technical Note 3: Design Storm Construction. Washington State Department of Ecology Publication No. 99-55G.

10 When were the guidelines last revised (MM/DD/YYYY)? 10/30/2009

11 Are there any plans to update or revise the guidelines in the near future?

No

12 Are the guidelines different for new and existing dams?

Yes (Please elaborate)

Comments: New dams typically have the rainfall depth increased by 15%.

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency performs independent verification of submitted designs

14 How are the guidelines applied?

Based on a combination of risk analysis and hazard/size classification

15 For PMP/PMF designs, is freeboard required?

Other (Please specify)

Comments: Usually based on wave run up computations; if computed freeboard is too low, may be superseded by minimum requirements; minimums depend on size of dam, range from 0.5 feet to 1.0 feet. Ref: Dam Safety Guidelines, Part IV: Dam Design and Construction. Washington State Department of Ecology Publication No. 99-55D. See Section 4.6, Reservoir Freeboard.

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

Yes

If "Yes", what are the specific analysis methodologies, procedures, or computer software that must be used?

Other (Please specify)

Comments: WSDSO's basic requirement is to use good engineering practice. Usually means using HEC-HMS with our Tech Note 3 dam safety storms. On occasion, we have accepted HSPF with our Tech Note 3 dam safety storms inserted into the rainfall record. We have also accepted NRCS storms that captured the same (or greater) total rainfall volume and peak rainfall intensity as our Tech Note 3 dam safety storms. As noted in item 13, we often do our own calculations to verify the designer's calculations.

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

No

18 Do the guidelines specify any criteria for storm duration?

Other (Please specify)

Comments: Three storm scenarios must be considered: a short 4- to 6-hour storm, an intermediate 18-hour storm, and a long 72-hour storm. The IDF is the scenario that yields the highest peak water level in the reservoir.

19 Do the guidelines specify any criteria for temporal storm distribution?

Yes (Regional)

Comments: Design storm hyetographs are provided in Technical Note 3, at 5-minute intervals for the short storms and at 15-minute intervals for the intermediate and long storms.

20 Do the guidelines specify any criteria for spatial storm distribution?

Yes (Please specify)

Comments: Again, WSDSO's basic requirement is to use good engineering practice. One method is to use Areal Adjustments to Account for Storm Spatial Distributions as a Percent of At-Site Precipitation Amount - see Dam Safety Gudelines Tech Note 3: Design Storm Construction, Section 1.2.3

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

Yes (Please specify)

Comments: Because of infrequent operation, economy in design and construction can sometimes be accomplished for small and intermediate size dams by utilizing the concept of survivability. That is, erosional damage can often be tolerated provided the damage does not jeopardize the structural integrity of the impounding barrier or allow an uncontrolled release of the reservoir waters.

22 Does the organization allow development of a site specific PMP?

Yes

If "Yes", are there any restrictions, requirements, or guidelines for performing a site specific PMP?

Yes (Please specify)

Comments: Must be more conservative than Washington State DSO Design Storm Criteria as described in Tech Note 3. The 2009 update to Tech Note 3 is more recent than HMR-57 (NWS, Oct. 1994),and is based on a larger database of storms.

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

Yes, a moderate problem

Comments: There are several dimensions to this issue: (a) Downstream development may require simply a reclassification based on the existing flood analysis and inundation mapping, or may require us to do a new dam breach flood study. (b) The new hazard rating will require us to do a new hydrology study to determine the spillway dimensions required to pass the new (larger) inflow design flood. (c) The dam owner must modify or reconstruct the spillway(s) to the new dimensions. The inundation and IDF studies (a, b) may be a problem for us (Dam Safety Office) depending on our other inspection and plan review workload. The physical work on the spillway (c) may be a problem for the dam owner, depending on their ability to fund the reconstruction. If we (Dam Safety) perform the engineering analyses, we have found that this fosters something of a partnership attitude with the dam owner so that they may be more willing to devote their funds to the physical construction (a more tangible product). A few dam owners may require specific enforcement action to nudge them into making the spillway modifications, which creates additional workload for the Dam Safety Office.

24 Do guidelines require consideration or analysis of future development?

No

Comments: Our Design Step Worksheet asks the engineer of record to consider the potential for future development and his/her assessment then is reflected in the minimum design level. If the engineer's assessment is grossly at odds with what we judge the potential for future development to be, we will raise the concern with the owner. Our position is that the owner is then making an informed judgment of whether to pay some more now or much more later if they ignore growth potential.

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

Yes (Please specify)

Comments: Should be representative of typical conditions during the season when the storm might occur. This usually means normal pool elevation, typical snowpack, and AMC-II soil moisture conditions.

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

Yes

If "Yes", do guidelines require analyses to include future downstream conditions within the dam failure inundation zone?

Yes

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

Yes (Please specify)

Comments: Must select a Inflow Design Flood with reservoir routing through the embankment's spillways, determine the flood levels and areal extent of dam failure inundation vs stream flood inundation, proceed to the next design step if it exceeds 2 ft and assess against the US Bureau of Reclamation Hazard Assessment Curves (Ref: Dam Safety Guidelines, Part IV, Section 2.4). If any population at risk, minimum Design Step is Step 3, recurrence interval 1 in 3,000 years. (Ref: Dam Safety Guidelines Technical Note 2, Selection of Design/Performance Goals for Critical Project Elements. Washington State Department of Ecology Publication No. 99-55F. See Section 5.1.5 on page 22.)

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

No

Comments: Consquence rating points determine the design flood based on a sliding scale. The scale ranges from the 500-year flood to the PMF or theoretical maximum event.

29 For low hazard dams, the spillway design requirement is:

500-year flood

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

No

Comments: Generally, safety design must be passive.

31 Does your organization permit risk-based hydrologic designs?

Yes; our regulations permit them

32 Has your agency ever reviewed a risk-based hydrologic analysis?

Yes (Reviewed and approved)

33 How difficult would it be to change your regulations? Please explain.

Difficult

Comments: Administrative procedures are quite detailed and time-consuming, with considerable public involvement, at a time when we have no extra staff to devote to that effort.

34 Are there any unique provisions in your regulations?

Yes (Please explain)

Comments: Risk-based design storm levels; design storm hyetographs based on Washington State historical storms; numerical rating scheme for design/performance goals. Also, the level of detail in our guidance documents is more detailed typically than other states.

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	West Virginia Dam Safety Section
Name of Representative	Brian Long
Title of Representative	Section Manager
Phone number(s)	(304) 926-0499 ext1005
Email address	brian.r.long@wv.gov

2 Number of dams under Organization's jurisdiction by type:

Total Dams	524
Total Regulated Dams	355
High Hazard Dams	253
Significant Hazard Dams	80
Low Hazard Dams	22
Unregulated Dams	44
Other	125

3 When did your Organization adopt minimum Inflow Design Flood criteria? 1982

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Both of the above

Comments: Exemptions for federal owned dam, farm pond dams, and road fills that do not normally impound water

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

Yes (Please explain)

Comments: Coal refuse dams vary in freeboard requirements

6 Does the Organization have published size classification criteria?

No

Comments: An impoundment exceeding forty (40) feet in height or four hundred (400) acre-feet storage volume shall not be classified as a Class 3 (low hazard) dam.

7 Does the Organization have published hazard classification criteria?

Yes (High, Significant, Low, Limited Hazard)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

No potential for loss of life with significant but not excessive economic loss

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Published guidelines/regulations that are required

Comments: Rule guidelines are passed by Legislature, signed by Gov with force of law

9 What is the origin of the guidelines?

Other (Please specify)

Comments: NRCS & MSHA

10 When were the guidelines last revised (MM/DD/YYYY)? 06/01/2009

Comments: Revision to create a revolving loan fund

11 Are there any plans to update or revise the guidelines in the near future?

No

12 Are the guidelines different for new and existing dams?

No

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency performs independent verification of submitted designs

14 How are the guidelines applied?

Based on hazard classification only

Comments: Risk assessment is allowed with justification

15 For PMP/PMF designs, is freeboard required?

No

Comments: Coal refuse dams are required to include additional freeboard.

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

No

Comments: Applicant may use any procedure. WVDEP advises procedures used to review applications.

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

No

Comments: Applicant may use any software. WVDEP advises software used to review applications.

18 Do the guidelines specify any criteria for storm duration?

Yes (6-hr)

19 Do the guidelines specify any criteria for temporal storm distribution?

No

Comments: Type II storm distribution used in review

20 Do the guidelines specify any criteria for spatial storm distribution?

No

Comments: Point rainfall reduction assumed in review for watersheds exceeding 10 square miles

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

No

22 Does the organization allow development of a site specific PMP?

Unknown (never requested)

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

Yes, a moderate problem

24 Do guidelines require consideration or analysis of future development?

Yes (Impacts of development on hazard classification or failure consequences)

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

Yes (Please specify)

Comments: AMC II unless a different condition is required by the Secretary

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

Yes

If "Yes", do guidelines require analyses to include future downstream conditions within the dam failure inundation zone?

Yes

Comments: Future downstream conditions are required as part of the dam break analysis

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

Yes (Please specify)

Comments: Class I - no less than 70% of the PMP; Class II - no less than 25% of the PMP; Class III - no less than P100

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

Yes

If "Yes", complete as appropriate. If "No", describe below how spillway design capacity is determined.

New High Hazard Dam must pass	100	% of the	PMP
Existing High Hazard Dam must pass	100	% of the	PMP
New Significant Hazard Dam must pass	50	% of the	PMP
Existing Significant Hazard Dam must pass	50	% of the	PMP

29 For low hazard dams, the spillway design requirement is:

Other (Please specify)

Comments: 25% of the PMP; Class IV required to pass P100

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

No

31 Does your organization permit risk-based hydrologic designs?

Yes; our regulations permit them

Comments: Rule permits reduction of hazard potential or design storm (see #27) based upon risk assessment analysis subject to agency approval

32 Has your agency ever reviewed a risk-based hydrologic analysis?

Yes (Both approved and rejected)

33 How difficult would it be to change your regulations? Please explain.

Difficult

34 Are there any unique provisions in your regulations?

Yes (Please explain)

Comments: Statute require additional "Criteria" to govern design, construction, repair, inspection & maintenance of proposed dams with annual review to consider improved technology.

HYDROLOGIC SAFETY OF DAMS QUESTIONNAIRE

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	Wisconsin
Name of Representative	Meg Galloway
Title of Representative	State Dam Safety Engineer
Phone number(s)	608-266-7014
Email address	Meg.galloway@dnr.state.wi.us

2 Number of dams under Organization's jurisdiction by type:

Total Dams	
Total Regulated Dams	3653
High Hazard Dams	189
Significant Hazard Dams	170
Low Hazard Dams	3294
Unregulated Dams	
Other	

3 What year did your Agency adopt minimum Inflow Design Flood criteria? 1985

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Both of the above

Comments: The state definition of Large Dam matches the NID criteria.

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

Yes (Please explain)

Comments: We do not have jurisdictional authority under our dam statutes over dams associated with cranberry operations, manure storage facilities, tailings facilities and dams not on watercourses.

6 Does the Organization have published size classification criteria?

Yes

Comments: Large: >6 feet and =>50 acre feet or =>25 feet and >15 acre-feet.

7 Does the Organization have published hazard classification criteria?

Yes (High, Significant, and Low)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

No potential for loss of life with significant but not excessive economic loss

Comments: We may also call a dam signifcant if failure would cause significant environmental harm.

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Published within State Laws

Comments: Rules are in Administrative Code NR 333

9 What is the origin of the guidelines?

Unknown

10 When were the guidelines last revised (MM/DD/YYYY)? 7/1/2001

11 Are there any plans to update or revise the guidelines in the near future?

No

12 Are the guidelines different for new and existing dams?

No

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency utilizes a combination of the above approaches, possibly on a case-by-case basis

In most cases we do a review of submitted design. In some cases we may do independent analysis. Agency engineers may do analysis on department-owned dams; however, the analysis will receive an independent review by another agency engineer.

14 How are the guidelines applied?

Based on hazard classification only

15 For PMP/PMF designs, is freeboard required?

Other (Please specify)

Comments: Do not use PMP/PMF. We do not have written freeboard criteria but we will push for freeboard to be included in design on a case-by-case basis

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

Yes

If "Yes", what are the specific analysis methodologies, procedures, or computer software that must be used?

Other (Please specify)

Comments: Must use methods identified as acceptable in our Floodplain regulations (NR 116)

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

Yes (Please specify)

Comments: If it is not acceptable by the floodplain regulations the decision would be made on a case-by-case basis

18 Do the guidelines specify any criteria for storm duration?

No

Comments: We have occasionally commented on and requested a change in storm duration during the review process

19 Do the guidelines specify any criteria for temporal storm distribution?

No

20 Do the guidelines specify any criteria for spatial storm distribution?

No

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

No

22 Does the organization allow development of a site specific PMP?

No

Comments: Do not use PMP criteria

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

Yes, a minor problem

Comments: It should never be a problem as the design criteria are tied into existing land use and future land use controls. It is occasionally an issue for an existing dam if land use controls do not get put in place in a timely manner to prevent hazard creep.

24 Do guidelines require consideration or analysis of future development?

Yes (Impacts of development on hazard classification or failure consequences)

Comments: NR 333 and NR 116 tie dam safety and floodplain regulations together to try and minimize development potential in the hazard area downstream of dams.

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

No

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

Yes

If "Yes", do guidelines require analyses to include future downstream conditions within the dam failure inundation zone?

No

Comments: Any owner may provide documentation to justify a different spillway capacity from that specified in Table I. The department shall review such documentation and may approve the spillway capacity proposed by the owner if it determines that such capacity will not result in an additional hazard to life, health or property when compared to the capacity specified in Table I.

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

No

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

No

Comments: High (Q1000), Significant (Q500)

29 For low hazard dams, the spillway design requirement is:

100-year flood

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

No

31 Does your organization permit risk-based hydrologic designs?

Our regulations do not specifically address this topic and it has never come up for consideration

32 Has your agency ever reviewed a risk-based hydrologic analysis?

No

33 How difficult would it be to change your regulations? Please explain.

Moderate

Comments: Unless done for emergency purposes the rule making process typically takes at least 18 months.

34 Are there any unique provisions in your regulations?

Yes (Please explain)

Comments: Linking the hazard potential to both existing land use and land use controls downstream of the dam.

ON THE RECORD

1 Respondent information:

State/Federal Dam Safety Organization	Wyoming
Name of Representative	Mr. Larry L. Stockdale
Title of Representative	Safety of Dams Engineer
Phone number(s)	307-777-3500
Email address	lstock@seo.wy.gov

2 Number of dams under Organization's jurisdiction by type:

Total Dams	
Total Regulated Dams	1512
High Hazard Dams	79
Significant Hazard Dams	112
Low Hazard Dams	1321
Unregulated Dams	
Other	

3 What year did your Agency adopt minimum Inflow Design Flood criteria? n/a

4 How does the Organization define a non-inventory or non-jurisdictional dam? Minimum criteria:

Other (Please specify)

Comments: Anything less than 15 acre-feet regardless of height, less than or equal to 6 feet in height regarless of capacity, or less than 20 feet in height and less than 50 acre-feet.

5 Are there types/categories of dams(other than federally-owned or non-jurisdictional dams) that are held to different design standards than the majority of dams under your jurisdiction? (e.g. tailings dams)

No

6 Does the Organization have published size classification criteria?

No

7 Does the Organization have published hazard classification criteria?

Yes (High, Significant, and Low)

If "Yes", and Significant Hazard is defined, how is Significant Hazard defined?

No potential for loss of life with significant but not excessive economic loss

8 Does the Organization have guidelines for determining the spillway design flood?

Yes

If "Yes", what is the status of the guidelines; do they have the force of law?

Published guidelines/regulations for consideration by the engineer/designer

Comments: Regulations in draft form.

9 What is the origin of the guidelines?

Combination of the above (Please specify)

10 When were the guidelines last revised (MM/DD/YYYY)? n/a

Comments: Still in draft form.

11 Are there any plans to update or revise the guidelines in the near future?

Yes (Please specify)

Comments: Will be revised when review comments are received

12 Are the guidelines different for new and existing dams?

No

13 Which of the following best describes your agency's role in determining the spillway design flood:

Agency reviews submitted designs

14 How are the guidelines applied?

Based on hazard classification only

15 For PMP/PMF designs, is freeboard required?

No

16 Do the guidelines or Organization stipulate specific analysis methodologies, procedures or computer software that must be used?

No

17 Do the guidelines or Organization stipulate specific analysis methodologies, procedures, or computer software that cannot be used?

No

18 Do the guidelines specify any criteria for storm duration?

No

19 Do the guidelines specify any criteria for temporal storm distribution?

No

20 Do the guidelines specify any criteria for spatial storm distribution?

No

21 Do the guidelines specify spillway performance/design criteria based on the frequency of flooding (e.g. spillway design flood vs. freeboard design flood)?

Yes (Please specify)

Comments: High and Significant hazard are a performance design. Frequency is based on the 100-year.

22 Does the organization allow development of a site specific PMP?

Yes

If "Yes", are there any restrictions, requirements, or guidelines for performing a site specific PMP?

No

23 Is changing dam classifications/spillway design requirements because of downstream development a regulatory problem?

No

24 Do guidelines require consideration or analysis of future development?

No

25 Do guidelines specify antecedent moisture conditions or initial reservoir pool levels?

No

26 Do guidelines allow the use of incremental damage assessments to establish the spillway design flood?

No

27 Are there any restrictions or guidelines on the use of incremental damage assessments or risk analyses such as a minimum percent of the PMP, regardless of downstream consequences?

No

28 Do any of the guidelines specify the spillway design capacity for any dam classification as a percentage of the PMP or PMF?

Yes

If "Yes", complete as appropriate. If "No", describe below how spillway design capacity is determined.

New High Hazard Dam must pass	100	% of the	PMF
Existing High Hazard Dam must pass	100	% of the	PMF
New Significant Hazard Dam must pass	50	% of the	PMF
Existing Significant Hazard Dam must pass	50	% of the	PMF

29 For low hazard dams, the spillway design requirement is:

100-year flood

30 Would your organization accept the use of an early warning system as an alternative to designing a high hazard dam for the regulatory spillway design flood?

No

31 Does your organization permit risk-based hydrologic designs?

Yes; our regulations permit them

32 Has your agency ever reviewed a risk-based hydrologic analysis?

Yes (Reviewed and approved)

33 How difficult would it be to change your regulations? Please explain.

Moderate

Comments: Moderately difficult due to public comment, etc.

34 Are there any unique provisions in your regulations?

No

Appendix D. Federal Guidelines

D.1 Bureau of Indian Affairs
D.2 Federal Emergency Management Agency
D.3 Mine Safety and Health Administration
D.4 National Park Service
D.5 Natural Resources Conservation Service
D.6 Nuclear Regulatory Commission
D.7 Tennessee Valley Authority
D.8 U.S. Army Corps of Engineers
D.9 U.S. Bureau of Reclamation
D.10 U.S. Fish and Wildlife Service
D.11 U.S. Forest Service

FEMA

D.1. Bureau of Indian Affairs

1.1 Purpose. This Chapter establishes the basic policy, authorities, and responsibilities for the Bureau of Indian Affairs (BIA) Safety of Dams (SOD) Program.

1.2 Policy. It is the BIA SOD Program policy to:

A. Reduce the potential loss of human life and property damage due to a catastrophic dam failure by making BIA dams as safe as practically possible; and

B. Encourage flood plain management below dams and on reservoir shorelines.

1.3 Authorities.

A. Presidential Memorandum issued April 23, 1977, to the Heads of Federal Agencies that have dam safety responsibilities, requiring each agency to conduct a thorough review of practices affecting the safety and integrity of dams;

B. Executive Memorandum dated October 9, 1979, implementing Federal Guidelines for Dam Safety for each agency;

C. 25 U.S.C. § 3801, Public Law 103-302**,** Indian Dams Safety Act of 1994. This law directs the Secretary to establish a dam safety maintenance and repair program within the BIA to monitor the condition of all dams on Indian lands and maintain them in a satisfactory condition on a long-term basis;

D. 33 U.S.C. § 467, Public Law 92-367**,** National Dam Inspection Act of 1972; and

E. 33 U.S.C. § 2201 et seq., Public Law 99-662, Water Resources Development Act of 1986.

1.4 Guidance. Government-wide, Department of the Interior, and BIA guidance documents are available from the BIA SOD Officer, MS 4515-MIB, 1849 C Street NW, Washington, DC 20240.

A. Government-Wide. Federal Guidelines for Dam Safety, June 25, 1979.

B. Department of the Interior.

(1) Departmental Manual Part 753, Dam Safety Program;

(2) Secretarial Order No. 3048, February 28, 1980;

(3) Interagency Agreement between the BIA and the Bureau of Reclamation, dated May 16, 1996;

(4) Value Engineering Guidance Handbook, No. VE-1; and

(5) Departmental Manual Part 369, Value Engineering.

C. Bureau of Indian Affairs. Bureau of Indian Affairs Safety of Dams Handbook (BIA SOD Handbook).

D. Other Federal Agencies. Bureau of Reclamation and Federal Emergency Management Administration technical guidance documents referenced in the BIA SOD Handbook are available from the Bureau of Reclamation, Technical Service Center, Client Liaison, BIA and Tribal Projects, P.O. Box 25007, D-8010, Denver, CO 80225-0007.

1.5 Responsibilities.

A. Director, Office of Trust Responsibilities, designates the BIA SOD Officer.

B. BIA SOD Officer.

(1) Plans, manages, directs, and provides program oversight and guidance to Regional SOD Officers;

(2) Provides staff assistance and advice to the Commissioner/Deputy Commissioner of Indian Affairs;

(3) Develops and manages programs relating to the BIA responsibilities to Indian tribes as they relate to the SOD Program;

(4) Monitors compliance and makes recommendations for changes to Federal, Departmental, and BIA SOD guidelines;

(5) Drafts legislation and regulations as required, and reviews proposed legislation and regulations initiated elsewhere that may affect the SOD Program;

(6) Formulates policy recommendations and provides direction and guidance on implementation to Regional Directors or their designated representatives;

(7) Serves as liaison and promotes working agreements with tribes, states, and other Federal agencies concerning SOD Program activities;

(8) Represents the BIA on the Department of the Interior Dam Safety Working Group;

(9) Coordinates with other program offices of the BIA and other agencies on SOD issues, including emergency preparedness; and

(10) Reviews and provides updates on BIA data for the National Inventory of Dams.

C. Regional Directors.

(1) Provide program oversight for the operation of the SOD Program within their jurisdiction in accordance with established policy, procedures, directives, and this manual part;

(2) Submit an Annual Status Report to the BIA SOD Officer by December 31 of each year for all SOD Program dams under the jurisdiction of the Regional Office; and

(3) Designate a Regional SOD Officer.

D. Regional SOD Officers.

(1) Plan, manage, and direct Regional SOD Program activities;

(2) Prepare the Regional Director's Annual Status Report on each SOD Program dam as described in the BIA SOD Program Handbook;

(3) Maintain the Regional Office record-keeping and reporting system for the SOD Program, including the National Inventory of Dams;

(4) Provide technical assistance to other Regional staff and tribes;

(5) Coordinate SOD activities with the BIA SOD Officer and provide liaison with other organizations and government agencies;

(6) Serve as the Contracting Officer's Representative (COR) or Contracting Officer's Technical Representative (COTR) on Regional SOD Program contracts when designated by the Regional Contracting Officer;

(7) Coordinate all SOD Program activities with Agency Superintendents and Agency and tribal SOD personnel, and expedite all matters relating to dam safety for any new dam project, on or off a reservation, which could affect trust lands, including those planned, designed, and/or constructed by others;

(8) Review all roadway embankments which cross waterways with the potential to affect BIA dams or trust lands to determine possible hazards from impoundment of water and to ensure adequate design of such embankments;

(9) Immediately report to the Regional Director any dam failure, incident, or any abnormal operations which adversely affect public safety or dam operations;

(10) Maintain a set of the documents referenced in the Record Keeping section of the BIA SOD Handbook;

(11) Develop and implement emergency management procedures as described in Chapter 2, Section 2.5 of this Part for each SOD Program dam;

(12) Provide oversight for, and conduct a final inspection of, all completed modifications to existing dams or new dam construction, prepare a Final Project Report for each project, and determine the need for any post construction activities; and

(13) Arrange and facilitate training for Regional and tribal SOD Program personnel.

E. Agency Superintendents.

.

(1) Coordinate SOD Program activities with the Regional SOD Officer, including training for Agency personnel involved in the SOD Program; and

(2) Ensure that Agency responsibilities in Emergency Action Plans for dams under their jurisdiction are implemented.

2.1 Scope. BIA SOD Program dams include all dams that meet the criteria in the National Dam Inspection Act. This includes all dams which impound or divert water and are 25 feet or more in height from the natural bed of the watercourse, measured from the downstream toe (or lowest elevation) of the dam to the top (crest) of the dam, or which have an impounding capacity at maximum water storage elevation of 50 acre-feet or more. This does not include dams which are less than six feet in height, regardless of storage capacity, nor dams having a storage capacity at maximum water elevation of less than 15 acre-feet, unless downstream hazards to life or property exist.

2.2 Downstream Hazard Classification. A Downstream Hazard Classification (High, Significant, or Low) will be determined for each BIA SOD Program dam in accordance with the Bureau of Reclamation's Assistant Commissioner-Engineering Research Technical Memorandum No. 11, Downstream Hazard Classification Guidelines.

2.3 Applicability.

A. SOD Program requirements in this Chapter apply to all BIA dams with a High or Significant Downstream Hazard Classification.

B. BIA SOD Program funding is available only for dams with a High or Significant Downstream Hazard Classification.

C. For BIA dams with a Low Downstream Hazard Classification, further application of any SOD Program technical requirements in this Chapter and the SOD Program Handbook to activities conducted with non-SOD Program funding is at the discretion of the Regional SOD Officer based on the specific conditions at each Low Hazard dam.

2.4 Operation and Maintenance for Existing Dams includes the operation and maintenance activities for the dams and appurtenant structures and the emergency management activities undertaken to safely operate and maintain dams.

A. Standing Operating Procedures. Standing Operating Procedures must be established for each High or Significant Hazard dam. The procedures permit responsible persons, knowledgeable in reservoir operations, but who are unfamiliar with the conditions at a particular dam, to operate the dam and reservoir during emergency situations and at times when the regular operator is not available to perform normal duties. Additional details on Standing Operating Procedures are contained in the BIA SOD Handbook. Copies of the Standing Operating Procedures are maintained at the Agency Office and the dam site, if an on-site facility exists.

B. Documentation. A documented history of the field exploration programs, design, construction, operation, maintenance, instrumentation data monitoring, periodic examinations, corrective actions, repairs, and remedial work will be established and maintained by the Regional SOD Officers so that data relating to the dam are preserved and readily available for reference. This documentation will commence with the initial site investigation for the dam and continue through the life of the structure.

C. Training. Personnel involved in the operation and maintenance of BIA dams will be

trained to detect, evaluate, and appropriately respond to emergency and non-emergency situations. Regional SOD Officers and Agency Superintendents are to identify training needs for the personnel under their supervision and request such training from appropriate sources.

2.5 Emergency Management.

A. Emergency Action Plan. This plan will be developed for all High or Significant Hazard dams as required by 753DM1.5. An Emergency Action Plan (EAP) is prepared to aid the facility manager and operations and maintenance personnel during an emergency situation or unusual occurrence. It provides information on detection of problems, immediate steps to take, whom to notify, what decisions to make, steps to take in the event of loss of communications, and other appropriate measures.

B. Inundation Maps. Inundation maps will be developed for each High or Significant Hazard dam. The inundation maps include, as a minimum, delineation of flooded areas to the point where the subject flood no longer poses a risk. The inundation maps will be included in the EAP.

C. Warning and Evacuation Plans. The Regional SOD Officer is responsible for identifying all entities, including local, state, tribal, and federal, who would be impacted during a dam failure or large operational releases. These entities should be encouraged to develop their own Warning and Evacuation Plans for each dam. The EAP must be coordinated with these Warning and Evacuation Plans.

D. Incident Response. Following an incident or emergency event, an incident report will be prepared by the Regional SOD Officer and submitted to the Regional Director and the BIA SOD Officer.

E. Early Warning Systems (EWS). EWS instrumentation will be installed, operated, and maintained at High or Significant Hazard dams and in the upstream basin when early detection of hydrologic events would provide additional time needed for emergency management activities.

2.6 Monitoring of Non-Bureau of Indian Affairs Dams. The Regional SOD Officer will be aware of the safety status of dams which are not under the jurisdiction of the BIA, but pose a potential hazard to persons or property on trust lands. The Regional SOD Officer will ensure that the EAP for these dams provides adequate notification to the BIA in the event of a dam failure or other emergency event.

2.7 Evaluation of Existing Dams.

A. Safety Evaluation of Existing Dams (SEED) Examination Program. The BIA SEED Examination Program is an onsite examination to document the structural integrity of High or Significant Hazard dams and appurtenant structures. SEED examinations will be conducted according to the BIA SOD Handbook.

B. Deficiency Verification Analysis (DVA) Report. A Deficiency Verification Analysis will

be performed on each High or Significant Hazard dam to determine if the dam has deficiencies which could lead to the failure of the dam. The results of this analysis will be included in the DVA Report and will serve as the technical documentation of any deficiencies that must be resolved or mitigated.

2.8 Short-term Remediation Actions. Examination and evaluation activities could reveal deficiencies or potential deficiencies which, if uncorrected, could eventually lead to failure or misoperation of a dam. The following actions may be taken under the direction of the Regional SOD Officer when conditions warrant. Some actions may involve NEPA compliance.

A. Emergency Corrective Action. Emergency corrective action is required for deficiencies which could result in failure of the dam within a short period of time. The BIA SOD Officer and Regional Director will be notified immediately by the Regional SOD Officer of any dams that are in this condition, and informed as to what action is being taken to remove the threat;

B. Interim Actions. Measures considered necessary to protect the public during the time between a safety examination and the safety modifications will be implemented at the earliest possible time after completion of the onsite examination. Interim actions could include implementing reservoir level restrictions, temporary breach, operational changes, installation of early warning systems, or specific monitoring of instrumentation at the dam site; or

C. Non-emergency Corrective Action. Non-emergency corrective action is taken when there is no immediate threat to the safety or operation of the dam, or any threat to life or property downstream. The corrective action should be scheduled in advance of the fiscal year in which the work is to be done to allow time for planning, funding through the normal budgeting process, and arrangements for special reservoir operations when required.

2.9 Design Process for New Dams and for Modifications to Existing Dams. The design of new dams and modifications to existing dams contain the same elements, which include:

A. Conceptual Designs. The initial phase of the design process, which leads to the selection of a preferred design alternative, must include the following:

(1) National Environmental Policy Act compliance will be initiated and substantially completed during this phase of the design process in accordance with 40 CFR 1500-1508;

(2) National Historic Preservation Act compliance will be conducted in accordance with 36 CFR 60 and 36 CFR 80;

(3) Native American Graves Protection and Repatriation Act and Archaeological Resources Protection Act compliance will be conducted as required;

(4) A Conceptual Design Report will be prepared to document all viable alternatives for a new dam or for resolving or mitigating verified deficiencies at an existing dam; and

(5) A Value Engineering study, if required, will be completed during this phase of the design process in accordance with the Department of the Interior Value Engineering Guidance

Handbook, No. VE-1.

B. Final Design. Final design, including assumptions, calculations, drawings and specifications will be completed for the selected alternative.

(1) Appropriate and practical state-of-the-art design methods and procedures will be incorporated into the final design;

(2) A Design Summary Report will be prepared which includes complete written documentation of all data, computations, and the decision making process, including the rationale supporting the design decisions;

(3) Construction specifications, including all bidding, award, and contract documents, will be in accordance with current Federal Acquisition Regulations and other applicable laws and regulations; and

(4) An environmental compliance review will be conducted by Regional environmental and archeological personnel.

C. Independent Technical Review. An independent technical review is required for every modification or construction project. The review will be:

(1) Arranged by the Regional SOD Officer;

(2) Performed early in the final design process, preferably not later than at the 30 percent completion milestone of the final design; and

(3) Conducted by qualified engineers and other experts not otherwise involved in the project, including Regional environmental and archeological personnel.

2.10 Construction of New Dams and Modifications to Existing Dams. BIA personnel play a key role in several elements of the construction process, including:

A. Construction Management. During the construction phase, close coordination between the BIA, design personnel, construction personnel, and Regional safety and environmental officers is required to assure that the project design intent is carried out, that new field information is incorporated into the construction, and that the cost and time schedules are being met. This includes site inspections.

B. Documentation, Records, and Drawings. Complete written and photographic documentation of the construction will be developed and maintained by the project construction engineer and the Regional SOD Officer. This includes, but is not limited to, records of the foundation excavation and treatment, revised drawings to show "as built" conditions, and complete records of all construction inspections.

C. First and Subsequent Fillings. All aspects of the dam and reservoir performance must

be monitored and evaluated by the project construction engineer and the Regional SOD Officer from visual observation and instrumentation data during first filling. First filling must be conducted according to the first fill plan developed during the design phase.

D. Completion Report and Project Acceptance.

(1) Upon completion of construction, the project construction engineer will prepare a completion report in consultation with design and environmental personnel that documents compliance with specifications and drawings;

(2) A detailed inspection of the constructed project will be conducted or arranged by the Regional SOD Officer, and upon approval and acceptance of the project, the facility will be transferred from a construction to an operation and maintenance status; and

E. Final Project Report.

(1) After construction and the first and subsequent successful fillings and monitoring, all identified deficiencies in the DVA Report from pre-construction will be examined to determine if the deficiencies are corrected. A Final Project Report will be prepared by the Regional SOD Officer that documents the status of these deficiencies; and

(2) After the Final Project Report is submitted, the dam will transfer to an operation and maintenance status. The periodic SEED examination and analysis process will resume once the dam is in this status.

F. Post-Construction Activities. The Regional SOD Officer will critique and evaluate design, construction, and administrative activities to assist in improving future designs and construction methods for dams. The Regional SOD Officer will determine which post-construction activities are appropriate for each project and whether a written report is warranted.

D.2. Federal Emergency Management Agency

Federal Guidelines for Dam Safety

April 2004

FEMA

FEDERAL GUIDELINES FOR DAM SAFETY

prepared by the
INTERAGENCY COMMITTEE ON DAM SAFETY

U. S. DEPARTMENT OF HOMELAND SECURITY
FEDERAL EMERGENCY MANAGEMENT AGENCY
JUNE 1979

Reprinted April 2004

PREFACE

These guidelines represent the culmination of efforts, initiated by President Carter in April 1977, to review procedures and criteria used by Federal Agencies involved in the design, construction, operation, and regulation of dams and to prepare guidelines for management procedures to ensure dam safety. The guidelines are based on an intensive review of Agency practices conducted by the Departments and Agencies themselves, by an *ad hoc* interagency committee of the Federal Coordinating Council for Science, Engineering and Technology (FCCSET), and by an Independent Review Panel of recognized experts from the academic and private sectors. These reviews are summarized in two earlier reports: *Improving Federal Dam Safety,* a report of the FCCSET, November 1977, and *Federal Dam Safety Report of the OSTP Independent Review Panel,* December 1978.

Publication of the guidelines marks the final step in the review process. However, the Departments and Agencies recognize that there must be a continuing Federal effort to improve dam safety. Federal dam safety remains a fundamental responsibility of each Federal employee in every Department and Agency involved and it is on their technical expertise and dedication that the safety of Federal dams rests. These guidelines recognize that underlying fact and support management efforts to discharge that responsibility effectively and efficiently.

These guidelines apply to Federal practices for dams with a direct Federal interest and are not intended to supplant or otherwise conflict with State or local government responsibilities for safety of dams under their jurisdiction. Current Federal initiatives to assist States and others with non-Federal dam safety programs are being pursued under other authorities. The objective of both programs, however, is the same: to allow the people of this country to enjoy the benefits of water resource development with the best assurance of dam safety possible.

The members of the FCCSET *Ad Hoc* Committee are to be commended for their diligent and highly professional efforts. Gratitude and appreciation are also due the several Departments and Agencies involved for their whole-hearted interest and support.

Frank Press, Chairman
Federal Coordinating Council
for Science, Engineering and
Technology

I. INTRODUCTION

These guidelines apply to management practices for dam safety of all Federal agencies responsible for the planning, design, construction, operation, or regulation of dams. They are not intended as guidelines or standards for the technology of dams. The basic principles of the guidelines apply to all dams. However, reasonable judgments need to be made in their application commensurate with each dam's size, complexity, and hazard.

The Federal agencies have a good record and generally sound practices on dam safety. These guidelines are intended to promote management control of dam safety and a common approach to dam safety practices by all the agencies. Although the guidelines are intended for and applicable to all agencies, it is recognized that the methods of the degree of application will vary depending on the agency mission and functions.

A. BACKGROUND

Throughout history, in all parts of the world, dams built to store water have occasionally failed and discharged the stored waters to inflict sometimes incalculable damage in the loss of lives and great damage to property. Failures have involved dams built without application of engineering principles, but have also involved dams built to, at the time, accepted engineering standards of design and construction. The technology of dams has improved with the increased knowledge of design principles and of the characteristics of foundation and dam materials, and it is generally agreed that safe dams can be built and existing dams can be safely maintained with proper application of current technology. It is the intent of these guidelines to outline management practices that will help to ensure the use of the best current technology in the design, construction, and operation of new dams and in the safety evaluation of existing dams.

As early as 1929, following the failure of the St. Francis Dam, the State of California enacted a dam safety program. Subsequently, other dam failures causing loss of life and property have prompted additional legislation on state and national levels.

The Congress in 1972 enacted Public Law 92-367, known as the "National Dam Inspection Act." The Secretary of the Army was authorized to inspect non-Federal dams in the nation meeting the size and storage limitations of the Act to evaluate their safety; report inspection results to the States and advise the States on actions needed to ensure dam safety; report to the Congress the information given to the States; prepare a national inventory of dams; and make recommendations to the Congress "for a comprehensive national program for the inspection and regulation for safety purposes of dams of the nation." Responsibilities under the law were delegated to the Corps of Engineers. The activities performed under the program consisted of an inventory of dams; a survey of each State and Federal agency's capabilities, practices, and regulations regarding the design, construction, operation, and maintenance of dams; development of guidelines for inspection and evaluation of dam safety; and formulation of recommendations for a comprehensive national program. A report on these activities and proposed legislation to implement a Federal dam safety program were transmitted to Congress in November 1976, but lack of funding prevented the execution of the detailed dam inspections.

The failure during initial filling in 1976 of the Teton Dam in Idaho, a Federal earth embankment dam over 300 feet high, reactivated intense public and governmental concern for dam safety. Congressional and Federal agency investigations were made into this disaster and the entire question of dam safety, and new Federal legislation for dam safety was initiated in the Congress.

An April 23, 1977, Presidential memorandum (reproduced in Section I.B) directed federal agencies to review their dam safety practices, addressing many elements of dam safety. Major elements included internal and external review, qualifications of personnel, integration of new technology, emergency preparedness plans, and review of existing dams. The agencies' reviews and the assessment of the reviews by a Federal *ad hoc* interagency committee and by an Independent Review Panel showed that sound practices are generally being used, but concluded that improvement is needed in some management practices for dam safety.

B. AUTHORITY AND IMPLEMENTATION

The authority for preparation of these guidelines is contained in a memorandum from President Carter dated April 23, 1977, which read as follows:

"MEMORANDUM FOR:

The Secretary of the Interior
The Secretary of Agriculture
The Secretary of the Army
The Director, Office of Management and Budget
The President's Adviser on Science and Technology
The Chairman, Federal Power Commission
The Chairman, Tennessee Valley Authority
The Commissioner, U.S. Section, International Boundary and Water Commission

The safety of dams has been a principal concern of Federal agencies that are involved with the various aspects of their planning, construction, operation and ultimate disposal. Events of the past several years have highlighted the need to review procedures and criteria that are being employed by these agencies with the objective of ensuring that the most effective mechanisms are established to give the best assurance of dam safety possible within the limitations of the current state of knowledge available to the scientific and engineering communities. The safety of such projects should continue to be accorded highest consideration, and it is the responsibility of the head of each agency concerned to ensure the adequacy of his agency's dam safety program.

I. Agency Dam Safety Reviews

The head of each Federal agency responsible for, or involved with site selection, design, construction, certification or regulation, inspection, maintenance and operation, repair and ultimate disposition of dams shall immediately undertake a thorough review of practices which could affect the safety and integrity of these structures. This review will encompass all activities which can be controlled or regulated by the agency.

Several aspects of the problem require special attention. In particular, the following items should be investigated: the means of inclusion of new technological methods into existing structures and

procedures; the degree to which probabilistic or risk-based analysis is incorporated into the process of site selection, design, construction, and operation; the degree of reliance on in-house, interagency, and outside expert interpretation of geologic data in site selection and design development; the effect on dam safety of earthquake or other earth movement hazards; the effects of cost-saving incentives on decisions both prior to and during construction; the procedures by which dam safety problems are identified, analyzed, and solved; the involvement of local communities in identifying, analyzing, and solving dam safety questions; and the major outstanding dam safety problems of the agency.

II. Interagency Report and Proposed Guidelines

The Chairman of the Federal Coordinating Council for Science, Engineering and Technology (FCCSET) shall convene an *ad hoc* interagency committee to coordinate dam safety programs, seeking consistency and commonality as appropriate, and providing recommendations as to the means of improving the effectiveness of the Government-wide dam safety effort. The agency reviews described above should be provided to the FCCSET as a basis for the interagency analysis on a timetable established by the FCCSET group as reasonable and consistent with the October 1, 1977 deadline for a final report. Representation on the FCCSET for this activity should be expanded to include other appropriate Federal agencies or departments including, but not limited to, the Tennessee Valley Authority, the United States Section-International Boundary and Water Commission and the Federal Power Commission. The FCCSET effort will include preparation of proposed Federal dam safety guidelines for management procedures to ensure dam safety. FCCSET should report on all these items.

III. Independent Review Panel

In addition, the Director of the Office of Science and Technology Policy will arrange for review of agency regulations, procedures and practices, and of the proposed federal dam safety guidelines, by a panel of recognized experts to be established immediately. The panel will obtain the views and advice of established organizations, professional societies, and others concerned with the safety of dams which are in any way affected by a Federal role.

The review report thereon should be completed no later than October 1, 1978."

(signed) Jimmy Carter

The *ad hoc* interagency committee called for in paragraph II of the memorandum was established by FCCSET, under the direction of the Office of Science and Technology Policy. The committee was represented by:

Office of Science and Technology Policy (Chairman)
Department of the Army
Department of Agriculture
Department of the Interior
Nuclear Regulatory Commission (NRC)
U.S. Section, International Boundary and Water Commission (IBWC)
Federal Energy Regulatory Commission (FERC) (Formerly Federal Power Commission)
Tennessee Valley Authority (TVA)

The Nuclear Regulatory Commission was added to the dam agencies addressed in the memorandum. Members of the *ad hoc* committee are listed in Appendix A.

Also established were subcommittees for the preparation of the proposed Federal dam safety guidelines called for in paragraph II of the memorandum. These subcommittees and their task groups had representatives from all the agencies with responsibilities for dams. Appendix B lists the members of the subcommittees and task groups and their agencies.

In accordance with the Presidential memorandum, the participating agencies submitted their reports on review of agency management practices involving dam safety; the subcommittees submitted the proposed Federal dam safety guidelines; and the *ad hoc* committee prepared the FCCSET report, *Improving Federal Dam Safety*, dated November 15, 1977. The report contains summaries of the agency reports, and the subcommittee proposed guidelines and summary thereof; assesses the agency reports; and makes recommendations for improvement of management practices for dam safety.

Pursuant to paragraph III of the President's memorandum, the Independent Review Panel was formed with specialists from the academic and private sectors concerned with dams. Members of the panel are listed in Appendix C. The panel reviewed the FCCSET and associated reports and proposed guidelines, and submitted a report, *Federal Dam Safety, Report of the OSTP Independent Review Panel,* December 6, 1978.

These guidelines were developed from the FCCSET report and its proposed guidelines, from Independent Review Panel recommendations, and with the cooperation of the panel.

C. DEFINITIONS

The following definitions apply in these guidelines.

Dam or Project. Any artificial barrier, including appurtenant works, which impounds or diverts water, and which (1) is twenty-five feet or more in height from the natural bed of the stream or watercourse measured at the downstream toe of the barrier or from the lowest elevation of the outside limit of the barrier if it is not across a stream channel or watercourse, to the maximum water storage elevation or (2) has an impounding capacity at maximum water storage elevation of fifty acre-feet or more. These guidelines do not apply to any such barrier which is not in excess of six feet in height regardless of storage capacity, or which has a storage capacity at maximum water storage elevation not in excess of fifteen acre-feet regardless of height. This lower size limitation should be waived if there is a potentially significant downstream hazard.

The guidelines apply with equal force whether the dam has a permanent reservoir or is a detention dam for temporary storage of floodwaters. The impounding capacity at maximum water storage elevation includes storage of floodwaters above the normal full storage elevation.

In addition to conventional structures, this definition of "dam" specifically includes "tailings dams," embankments built by waste products disposal and retaining a disposal pond.

Dam Failure. Catastrophic type of failure characterized by the sudden, rapid, and uncontrolled release of impounded water. It is recognized that there are lesser degrees of failure and that any malfunction or abnormality outside the design assumptions and parameters which adversely affect a dam's primary function of impounding water is properly considered a failure. Such lesser degrees of failure can progressively lead to or heighten the risk of a catastrophic failure. They are, however, normally amenable to corrective action.

Contract. Contracts relating to project design, construction equipment, operation, or regulation, as applicable to the project and the agency function. Where work is described using the terms contract or contractor, it is meant to include also similar work by the agency's own personnel

Maintenance. Maintaining structures and equipment in intended operating condition; equipment repair and minor structure repair.

Rehabilitation or Improvement. Repair of structure deterioration to restore original condition; alteration of structures to improve dam stability, enlarge reservoir capacity, or increase spillway and outlet works capacity; replacement of equipment.

Hazard. Potential loss of life or property damage downstream of a dam from floodwaters released at the dam or waters released by partial or complete failure of the dam, and upstream of the dam from effects of rim slides. A hazard is considered significant if there is a potential to cause loss of life or major damage to permanent structures, utilities, or transportation facilities.

Emergency Preparedness Plan. Formal plan of procedures to alleviate hazards during construction of or after completion of a dam or to reduce damages if conditions develop in which dam failure is likely or unpreventable. These emergency plans related to dam safety do not include flood plain management for the controlled release of floodwater for which the project is designed.

II. OBJECTIVES AND SCOPE

The overall purpose of these guidelines is to enhance national dam safety. The immediate objective is to encourage high safety standards in the practices and procedures Federal agencies use or require of those they regulate for dam site investigation, design, construction, operation and maintenance, and emergency preparedness. As these guidelines are directly applied to make Federal dams as safe as practical, it is hoped that they will also influence state dam safety agencies and public and private dam owners to be more safety conscious where programs are now weak.

The guidelines are intended to outline Federal agency management procedures that will continually stimulate technical methods in dam planning, design, construction, and operation for minimizing risk of failure. The objective of dam safety would be achieved as management and technical decisions during all project stages give proper recognition to safety considerations, and the strategy of these guidelines toward that end is to describe definite management practices to reinforce decision-maker awareness of safety needs. Those charged with administering these guidelines must recognize that the achievement of dam safety is through a continuous, dynamic process in which guidelines, practices, and procedures are examined periodically and updated. Technical procedures need to change with technological advancement, and management should ensure that observed deficient practices are corrected and that successful practices are duplicated.

The goal of making dams as safe as practical implies a limit to maximum reasonable effort. Those charged with implementing these guidelines need to recognize that no dam can ever be completely "fail-safe" because of incomplete understanding of or uncertainties associated with natural (earthquakes and floods) and manmade (sabotage) destructive forces; with materials behavior and response to these forces; and in control of the construction process. Management must ensure that uncertainties are properly balanced with competent technical judgment.

Although dams have been built for thousands of years, dam engineering is not an exact science and is more accurately described as an "art." It is true that this branch of engineering, like any other, draws heavily upon mathematical principles and physical laws, but every stage of the planning and execution of a dam project also requires the exercise of experienced judgment. This is true in designing and constructing new dams, and especially true in evaluating and/or improving existing dams. For many of these "older dams," there is little information available to document original site exploration, design, construction, and past operation. These dams must be carefully inspected and observed for indicators of distress.

To illustrate a principle from just one aspect of dam design, there are practical limitations on the amount of physical data that can be obtained during planning and design. Judgment and extrapolation are necessary to assess foundation conditions and to design an appropriate structure. Experience is essential in applying these judgments.

Construction is a critical phase in achieving a safe dam. Any project must be continuously evaluated, and "re-engineered" as required, during construction to assure that the final design is compatible with conditions encountered during construction. Quality of construction is also critical to safety. Deficiencies in materials or construction practices can occur during all stages of

the construction, and constant vigilance is necessary to prevent them. Sampling and testing at a completed project cannot be relied on as an effective substitute for inspection and quality control during construction.

Monitoring existing dams and reacting quickly to inadequate performance or to danger signals is a continuing critical aspect for dam safety. Careful monitoring and quick response can prevent failures, including those caused by poor construction.

The guidelines are intended to make as small as possible the failure risk inherent in constructing new dams, and to prioritize needs to improve existing dams according to hazard potential as estimated by technical analysis and as constrained by financial and personnel resources.

In the development of these guidelines, consideration was given to the broad diversity of agency missions. The guidelines were designed to be free of specific agency policies and unnecessary details. The resultant level of detail in the guidelines represents an attempt to achieve a balance between general management goals for assuring dam safety and meaningful principles which can survive technological changes and be useful to the non-Federal community.

A special situation exists regarding the application of these guidelines to dams of international nature. Several dams of concern to the United States are located partially in the United States and partially in Mexico or Canada. Those dams located at the U.S.-Mexican border are only partly subject to the jurisdiction of a U.S. Federal agency, the U.S. Section of the International Boundary and Water Commission. In this case, the U.S. should seek agreement with the Mexican Section of the Commission for adoption of applicable sections of these guidelines for ensuring dam safety. For dams located on the U.S.-Canadian border, the guidelines should be referred to the U.S. Section of the International Joint Commission (IJC) to seek agreement with the Canadian Section of the Commission on means by which the guidelines could be implemented through the entities that are responsible for construction, operation, and maintenance of the projects.

Section III.A., *Organization Management,* outlines the elements of agency management responsibilities for dam safety. Sections III.B, III.C, and III.D, *Management of Technical Activities,* contain additional guidance on technical activities for *Site Investigation and Design, Construction, and Operation and Maintenance* (includes Periodic Inspection Program and Emergency Action Planning). *Appendix E* is a bibliography of references to related guidelines and practices developed by Federal dam building agencies and other scientific and technical organizations. The body of knowledge represented by the bibliography is intended to be representative of dam technology, but not inclusive of all available literature that may be helpful.

III. GUIDELINES

A. ORGANIZATION MANAGEMENT

1. General

Heads of Federal agencies are responsible for the development and implementation of policy, resources and procedures for safe design, construction, operation, and inspection of each dam under their jurisdiction, as applicable to the agency mission. The agency management structure assists the head of the agency in discharging this responsibility and shares in it. The management structure is ultimately responsible for obtaining compliance with the intent of these management and technical activities guidelines, and for assuring that procedures are evaluated and updated periodically.

a. Administration

The head of each Federal agency having responsibility for design, construction, operation, or regulation of dams should establish a dam safety office (officer) which reports directly to the head of the agency or his designated representative. The office should be responsible for ensuring that the agency, as a matter of policy and in actual practice, makes every reasonable and prudent effort to enhance the safety of the dams under its jurisdiction. Duties of the office should include surveillance and evaluation of the agency's administrative and technical or regulatory practices related to dam safety concerning design and construction of new dams, and operation, maintenance and rehabilitation of existing dams; recommending improvements in the practices when evaluation reveals safety-related deficiencies; and maintaining an inventory of agency dams.

The functions of the office should be advisory to the agency head, and through the agency head to the agency administrative and technical units. The staffing and detailed duties of the office should be commensurate with the agency mission.

If a Federal dam safety office is established within the recently proposed Federal Emergency Management Agency (FEMA), the heads of the dam safety offices in the respective agencies should be advisory in FEMA's interagency coordinating functions.

The agency organization for the design, construction, operation, or regulation of a dam project should be structured so that a single identifiable, technically qualified administrative head has the responsibility for assuring that all management and technical safety aspects of dam engineering are adequately considered throughout the development and operation of the project. The position must have continuity of guidance and direction, and the authority and resources to ensure these responsibilities can be carried out.

Management should ensure that organization staffing is sufficient and qualified for the projected workload, and that all programs necessary for the safety of dams are established, continued, and realistically funded. Allocation of manpower and funds should give high priority to safety-related functions. Safety-related functions and features must not be sacrificed to reduce costs, improve project justification, or expedite time schedules.

b. Design Responsibility

The design function can never be considered finished as long as the dam remains in place; design involvement should continue throughout construction and operation of the project. The design office should establish specific programs for onsite construction and operational inspection for review by appropriate design personnel and technical specialists. The programs should include frequent and mandatory inspections during construction to confirm that site conditions conform to those assumed for design or to determine if design changes may be required to suit the actual conditions. A major requirement is inspection and approval of the dam foundation and foundation treatment before placing of dam materials. Final design inspection of the construction should include complete project surveillance and testing of operating equipment. Operational design inspections should continue throughout the life of the project, in accordance with a formal inspection program covering all project features. Management must program adequate funds to assure dam safety is not compromised by failure to conduct regular and thorough inspections and reviews.

The design function includes responsibility for planning any dam instrumentation to be installed during construction and/or operation to monitor conditions that could potentially threaten dam safety. The design should identify the purpose of the instrumentation, and include the plans for timely reading, collecting, reducing, and interpreting the data. It should include an advance determination of critical instrument observations or rates of data change, and a plan of action if observations indicate a critical condition may occur.

c. Construction Responsibility

The responsibility for administering construction and supply contracts, for understanding the design and contract intent, for maintaining technical coordination between design and construction engineers, and for managing the construction staff to assure compliance with specifications should be vested in an identified engineer at the construction project. He should have the administrative and technical control of all resources necessary to accomplish safe construction of the dam. Construction personnel should understand the conditions upon which the design is based and the relationship between these conditions and the design features. When unanticipated conditions are encountered, design personnel should be involved in determining their effect.

d. Operation Responsibility

The responsibility for project operation should be assigned to a single staff member of the operating organization. He should also handle the operating organization requirements for coordination with the design organization, including reporting changed conditions discovered by operators and participation of the operating organization personnel with design personnel in the periodic inspection program.

e. Technical Coordination

All technical specialties required to plan, design, construct, and operate dams to achieve dam safety should be staffed and their efforts coordinated to ensure technical adequacy. A project design engineer should be assigned technical coordination responsibility for each dam. He should handle necessary technical coordination within the agency and with private and public organizations.

Continuing liaison should be maintained among the personnel concerned with the various stages of project development and operation so that each concerned discipline and organizational unit knows and understands the relevant activities of the others. This coordination must be given constant attention to be sure proper action is taken.

f. Emergency Planning

An emergency plan should be formulated for each dam. The plan should be in the detail warranted by the size and location of the dam and reservoir. It should evaluate downstream inundation hazards resulting from floods or dam failure, and upstream conditions that might result from major land displacements or increased flood flows, including the effects from failure of upstream dams.

Where applicable, the plan should include inundation maps for the flows resulting from design floods and from possible failure of the dam. The complete emergency plan should be transmitted to appropriate local, state, and Federal governmental bodies. The plan should be periodically reviewed and kept up to date, and periodically publicized to maintain awareness of its existence.

In addition to the emergency plan for the completed dam, a similar plan should be prepared for the construction period, including area facilities that may remain during the period and floods that may be anticipated.

g. Risk-Based Analysis

Risk-based analytical techniques and methodologies are a relatively recent addition to the tools available for assessing dam safety. With further refinement and improvement, risk-based analyses will probably gain wider acceptance in the engineering profession and realize potential as a major aid to decision-making in the interest of public safety. However, even when fully developed, risk analyses cannot be used as a substitute for sound professional judgment of engineers, contractors, or review boards. In view of the dual problems of uncertainty in analysis and possibility of misinterpretation by the public, but in recognition of the high potential these techniques have, agencies should be encouraged to conduct research to refine and improve the techniques and to develop the methodologies and base of expertise necessary to apply them to dam safety evaluations. Specifically, agencies should strive to perfect techniques for evaluating the probability of possible deficiencies causing dam failure and estimating the potential losses due to such a failure. Meanwhile, the agencies should evaluate the potential consequences of failure of the dams under their jurisdiction. Although the value of potential property losses can be estimated, it is recognized that potential loss of lives can only be quantified, but not evaluated. On new dams, potential losses can be used in study of project alternatives and in assessment of additional safety incorporated into the dam facilities. On existing dams, a risk-based analysis should be considered in establishing priorities for examining and rehabilitating the dams, or for improving their safety.

2. Staffing

a. Technical Support

Management should assure adequate and competent technical staffing to perform the essential functions in planning design, construction, and operation and maintenance of dams. Technical

staff should be well supported by administrative, clerical, and other elements to ensure that the technical staff is not diverted from technical work. In the planning and design function, particular emphasis should be given to adequate staffing in hydrology, hydraulics, geology, engineering seismology, field investigation, and geotechnical and structural design. Sufficient expertise should be available on the construction staff and on the operation staff to maintain an understanding of design decisions related to the various design specialties.

Construction inspection staffing should assure quality as well as quantity inspection coverage. Staffing should be reviewed by higher authority than the local construction office. Field personnel should be well trained and experienced if the design is to be implemented and a safe structure is to be constructed. They must not only recognize the need for adherence to the design, but must be able to recognize when the design is at odds with conditions being encountered. The responsibility and importance of the construction staff to dam safety must be given appropriate consideration in organizational and position classification decisions.

The operating personnel must be qualified to perform the many functions required in the operation, including the recognition of conditions possibly detrimental to dam safety. Operation and maintenance staffing requires careful attention to personnel responsible for operating inspections, and to personnel who participate in the periodic inspection program. It is essential that support personnel and equipment are provided to accomplish needed maintenance activities.

b. Competence

Job-related experience, professional aptitudes, and educational background should be major factors in evaluating the competence of individuals for the requirements of each responsible position concerned with the safe design, construction, and operation of dams. All positions should be staffed by competent engineers or specialists in the related disciplines.

c. Continuity

Staffing policies should recognize that continuity of technical positions is essential to maintain consistent high standards of practice. This applies in all elements of project development from design to operation, and is especially critical in those positions having supervisory responsibility related to dam safety.

d. Professional Advancement

The agencies should maintain a positive program for advancement of technical personnel in recognition of acquired experience, training and education, and increased competence. It is essential that agencies maintain the technical as well as the managerial expertise required for safe, effective dam design, construction, and operating programs. Organizational structure, position classification, and career incentives must recognize both technical and managerial responsibility and compensate both equitably.

3. Training

a. Internal

To supplement technical staffing, agency management should provide internal personnel training. A rotational training program should be established to familiarize new personnel with

all major aspects of the agency functions and the interrelationships of its organizational units. Provisions should be made for technical personnel to observe and participate in decision-making meetings and to make site visits with more experienced staff. Staff members should be allowed to attend consultant meetings in order to gain valuable experience.

Technical personnel concerned with all phases of project development should be given broad exposure to a variety of field conditions. For example, geologists and geotechnical personnel should gain experience with soil and rock drill crews and in the laboratory testing facilities; design personnel should be familiar with concrete and soil placing and testing techniques; operating personnel should be familiar with equipment installation and testing procedures.

A rotational training program should be considered that would place construction engineers in the design organization during design and design engineers in the field during construction on temporary assignments. Preconstruction training should be provided for inspection personnel, covering the design engineering considerations and the requirements and importance of thorough field inspection. The training should be given by embankment or structural engineers and geologists assigned from design or by the construction engineer who had received preconstruction orientation by the designers, geologists, and embankment and structural engineers (section III.A.4.a). This training should make sure that all inspectors know the expected requirements in detail. Onsite instruction sessions for inspection of new features of construction should be developed and given by supervisors or lead inspectors before initiation of the work.

Operation and maintenance personnel should be trained by personnel experienced in operation of similar projects, covering all features of facilities operation and inspection. Thorough training should be provided for the personnel who will take observations on and monitor any installed dam instrumentation. The training should be conducted by experienced observers and by the engineers responsible for analyzing the structure effects revealed by the instrumentation data.

Technically qualified operating personnel should be trained in problem detection and evaluation, and application of appropriate remedial (emergency and non-emergency) measures. This is essential for proper evaluation of developing situations at all levels of responsibility which, initially, must be based on observations made by trained operating personnel at the project. The training should cover the problems that experience has shown are most likely to occur with the type of dam and facilities, and include the kinds of monitoring best suited to early detection of those problems. Such training will permit prompt action when time is a critical factor. A sufficient number of personnel should be trained to ensure adequate coverage of all tasks at all times. If a dam is operated by remote control, training must include procedures for dispatching trained personnel to the site at any reported indication of distress.

Personnel involved in inspections should be trained for the requirements of these duties. The training should cover the types of information needed to prepare for the inspections, critical features that should be observed, inspection techniques, and preparation of inspection reports.

b. Academic
Agency management should establish and maintain a program for continuing formal education and training aimed at increasing and broadening the agency's base of professional expertise in areas related to safe design and construction of dams. Such training should provide for part and/or full time attendance at universities and at special courses prepared by technical and professional organizations. Programs should be designed to further the development of younger personnel and to provide refresher training or sabbaticals for senior personnel.

Supervisory construction, inspection, and operation and maintenance staff should keep current on modern methods and techniques by attending technical courses. Pertinent courses are available from private sources and educational institutions. Also, agencies that develop internal educational programs for this purpose should make them available to other agencies, permitting the agencies to gain mutual benefit in the exchange of information on new methods and practices.

c. Professional
Professional growth of personnel should be encouraged by policies which ensure adequate training, support participation in technical and professional societies, and establish attractive career and promotional ladders for technical specialists. Professional registration and active membership in professional and technical societies should be given due consideration in assessing qualifications for higher technical positions.

d. New Technology
Provision should be made for the establishment of procedures to screen and disseminate information on technical advances relating to dam design, construction, and operation. Programs for continuing professional training should be oriented toward keeping the technical staff abreast of improved technology. Interagency coordination on training in new technology should be established in areas of mutual interest.

4. Communication
Effective methods of communication, coordination, and review should be established and functioning properly at all times, and be periodically reviewed and updated. Procedures for communications among Federal, State, and local agencies on safety-related matters should be established. Specific areas of suggested communication are discussed below.

a. Interdisciplinary
Direct and easily accessible means of communication should be established between personnel in planning, design, construction, and operations. Coordination is necessary for preparation of the site investigation plan and for a common understanding of information needed for design. Prior to the site investigation the design staff should arrange for meetings between geologists, geotechnical engineers, and designers to review known site conditions, project functional requirements, and preliminary design concepts. A visit to the site should be included in the review of existing information.

A document, referred to by some agencies as "Design Considerations," should be prepared by the design staff to transmit site-specific design considerations to the construction staff. This

document should cover, but not be limited to, hydrologic and hydraulic considerations, geologic and geotechnical data, foundation conditions, foundation treatment details, and anticipated foundation problems. It should specify points at which inspection and approval are required by the design staff. Copies of the document should be furnished to those responsible for dam operation and inspection.

Additionally, the design staff should arrange preconstruction orientation for the construction engineers by the designers, geologists, and embankment and structural engineers so that the construction engineer and his staff fully understand the design concepts and the significance of the results of the exploratory work. The construction engineers need to provide the designers, prior to advertising the construction contract, comments on the constructability and the ease of contract administration for the plans and specifications.

During construction, the construction engineers should be alert for conditions that need to be reported to the design engineers. Field personnel should notify design personnel of any critical construction sequence or of a suspected change in conditions that could affect the design of the structure. Design engineers with relevant expertise must be available to make regular visits to the construction site, and additional visits as needed when varying conditions arc encountered. Changes in construction or materials should be made only after plans for changes are approved by design personnel.

The design staff should furnish to the operation staff documents, referred to by some agencies as "Operation and Maintenance Manuals," containing pertinent design and construction information on structures and equipment required for effective and safe operation of the dam. A conference of design and operating personnel should be held to ensure that the operators understand the operating and inspection procedures required for safe and reliable operation. Both the operators and the designers should have copies of equipment operating and testing manuals and procedures. The operators should notify the designers of any safety-related operating malfunctions and the actions taken to correct them. There should be continuing communication between operating and design staffs regarding plans and schedules for periodic safety inspections of the dam. Copies of operation and maintenance manuals should be furnished to the dam inspection staff.

b. Interagency

Interagency communications should be maintained on safety matters related to design, construction, and operation of dams, and related research. This should include exchange of materials such as design standards, construction specifications, significant research reports, and final design and construction reports on major structures. The agencies should establish communications to periodically review investigation methods, construction materials testing standards, analytical methods, design philosophies, and management procedures.

5. Documentation

Throughout project development (planning, site investigation, design, construction, initial reservoir filling, and operation), all data, computations, and engineering and management decisions should be documented. Documentation should cover investigation and design, construction plans and construction history, operation and maintenance instructions and history,

damage and repairs and improvements, and periodic inspections during construction and operation. It should include, but not be limited to, memoranda, engineering reports, criteria, computations, drawings, and records of all major decisions pertaining to the safety of the dam.

a. Design Record

Written documentation should be maintained in standardized format on all design-related information for the project. Planning design documentation should cover the project objectives and the studies made to locate, size, classify as to potential hazard, and select the type of dam and auxiliary facilities. Site investigation documentation should cover geologic mapping and studies made of the geologic and geotechnical explorations and conditions for the various dam sites considered and the detailed investigations for the chosen site. Geological, seismological, and geotechnical features and considerations, whether specifically identified during the investigation, interpretations from the data and experience at other sites, or suspected by experienced personnel, should be fully documented. Design documentation should include all design criteria, data and qualitative information, assumptions, analyses and computations, studies on discarded alternatives, and derived judgments and decisions.

As-built drawings should be prepared as facilities are completed, and should be made available to operation and maintenance personnel and to the dam inspection staff.

b. Construction Record

All phases of the construction should be documented, including reporting of routine and special activities. Changes in construction plans and departures from expected site conditions should be documented, with any consequent design changes. The record should include information on materials and construction processes, field exploration and test results, geologic mapping of foundations and excavations, inspection records, as-built drawings, and decisions to adapt the design to actual field conditions.

A formal plan for a construction inspection system should be developed, including inspection procedures and types and forms of reports. The system should identify and record the status of inspection of approved and rejected materials. Survey notes, sketches, and records of all materials tests made for the control of construction quality should be maintained for the life of the project. A job diary should be maintained for each construction contract to provide a complete history of the work, listing in chronological order the events having a bearing on performance of the work, and analysis of cause and effects of special events. Photographic documentation of significant events, findings, and safety problems should be provided. The inspection program and record should give special attention to factors that may have a future influence on dam safety.

Documentation must also be provided, as required, by applicable procurement, safety and health personnel, and financial regulations.

c. Initial Reservoir Filling and Surveillance Record

An initial reservoir filling and surveillance plan should be prepared by the design staff. Initial filling should be well documented, including a record of reservoir elevations and controlled water releases during the filling. The record should include complete written justification and

design approval of any deviations from the planned filling. The surveillance record should include all information obtained from inspection of the dam, appurtenant structures, abutments, and reservoir rim during the initial filling.

d. Operation and Maintenance Record
Operation and maintenance should be fully documented, including the routine activities and systematic inspection processes, and complete information on project maintenance, rehabilitation, and improvements. In addition to records on the actual operations, the operating record should include data on reservoir levels, inflow and outflow, drainage system discharge and structural behavior.

If there are maintenance problems that require continuing remedial work, a thorough record of the work should be maintained, and a final report made after complete remedy of the problem.

e. Permanent Files
One copy of all documents concerning the project should be assembled in a single project file. The file should be kept up to date and should be maintained as a permanent archival reference. A second file of the materials should always be easily accessible to responsible personnel for reference in future reviews and inspections, and in dealing with problems, repairs, etc. Both files should be continuously updated with records on problems, repairs, operation, instrumentation, and inspection for the life of the project. Information such as foundation reports and as-built drawings and maps should be permanently retained at the project and also at the agency's engineering design office.

6. Reviews

a. Extent
All factors affecting the safety of a dam during design, construction, and operation should be reviewed on a systematic basis at appropriate levels of authority. Reviews include those internal to the agency, and those external to the agency, by individuals or boards (consultants) with recognized expertise in dam planning, design, and construction.

b. Internal
Provision should be made for automatic internal review of all design decisions, methods, and procedures related to dam safety. Review should be at levels of authority above the design section or designer-supervisor relation. Uniformity of criteria and design technique should be maintained, as well as methods to ensure that specific experience is exchanged and used to advance the agency's ability to design, construct, and operate safe dams.

Management technical personnel should review the construction periodically. Reviewing personnel should include geologists, geotechnical engineers, and embankment and/or structural engineers who have had experience in responsible positions relating to similar structures. When appropriate, the reviews should include mechanical and/or electrical equipment engineers. Preconstruction inspection should be made after geologic mapping is done and prior to ground surface disturbance. On large projects, construction reviews would normally be at critical construction periods such as start and completion of foundation preparation and grouting, dam

construction at several stages, and completion of the dam. Visits by appropriate personnel are recommended every six months, and to accompany the consultants during scheduled reviews. The final construction inspection should cover inspection of completed structures and equipment, the adjacent valley floor and abutments, and the reservoir rim.

On smaller projects, the frequency of construction review and the disciplines represented in the review would vary with the size and complexity of the project. However, management should make certain that construction reviews arc sufficient to cover the requirements for dam safety.

Reviews should be made of the agency's procedures for post-construction operation and periodic inspections. These would include the responsibilities for collection and evaluation of data from any dam instrumentation.

Reviews should be made to ensure that the project emergency preparedness plan is periodically updated.

Formal documentation should be made of all significant findings from reviews and inspections.

c. External

The need for review of a dam by independent experts (consultant board or firm) from outside the agency should be determined on a case-by-case basis, depending on the degree of hazard, size of the dam, complexity of the site geology and geotechnology, complexity of the design, or a specific need perceived by the public. Consultant reviews should provide appropriate overview evaluations of site investigation, design, and construction.

Consultant reviews of operation and maintenance practices, and of alterations and improvements, should be conducted when the agency considers such reviews advisable.

The following text deals first with design and construction reviews. Applicable portions apply also to post-construction reviews; specifics for post-construction reviews are in the last paragraph of the section.

The agency should be represented at each consultant meeting by appropriate design and construction staff. When appropriate, meetings should include a site visit. At each meeting the agency should formally document all aspects of the continued development of the project for presentation in a meeting-opening briefing to the consultants. The consultants should formally document findings and recommendations and present them at a closing conference with the agency staff.

The consultant board members should be chosen to assure coverage of all areas of expertise needed to assess the dam design, construction, and safety. The board should contain at least three, but normally not more than five, permanent members. The board should always contain a general civil engineer, a geologist and/or geotechnical engineer, as appropriate, a concrete and/or embankment dam engineer, and usually a member for the electrical and mechanical features, especially necessary if a power plant is part of the project. Additional specialists covering specific aspects such as structural integrity, earthquake response, or three-dimensional analysis

should be assigned for short intervals as recommended by the board. The board should be formed during the design stage and consulted (if possible) on site selection, on type of structure, and for input to the feasibility study. The board should be kept active throughout design and construction, in order to keep the board completely familiar with all aspects of the project so they are in a position to respond rapidly if problems arise.

During design and construction of large projects, the board should meet every 6 to 12 months, depending upon activities and duration of the work. Meetings should be scheduled to review at specific phases of construction. These phases might include, but not be limited to, review during the early stages of foundation cleanup and treatment, on completion of foundation cleanup, and during the early stages of embankment and/or concrete placement. All board members should attend every meeting even though some meetings may not apply to all members. This would ensure that the entire board is fully aware of the complete work status before being asked for their input on specific points.

The briefing to the board by agency personnel at the start of a meeting should include exploration data, structural adequacy and seepage characteristics of the foundation, proposed foundation treatment, grouting programs, quarry test data, test fill data, embankment requirements for zones and material for those zones, sources of materials, compaction requirements, inspection requirements, instrumentation program, type of spillway (gated or ungated), proposed water release control systems, diversion requirements and care and diversion of water, power generation anticipated, and surge tank design. For concrete dams, the review would include concrete design and placement requirements in lieu of the embankment information.

On a smaller project, the use of consultants should be commensurate with the dam size and complexity, and with the degree of associated hazard. If there is significant hazard, the agency should obtain consultant reviews adequate to assure independent assessment of the dam safety.

Consultants should be engaged during agency evaluations of existing dams if considered necessary to provide independent support for agency assessment of dam safety. This might be in connection with studies for alterations or improvements for potential criticality of dam stability resulting from structure deterioration, or from increased reservoir levels due to possible flood inflows larger than design floods and consequent inadequate spillway capacity. It might involve consultation on seismic design; and in the case of old dams, especially embankment dams with inadequate records of materials properties, it might include consultation on the advisability and procedures for new materials investigations. Consultants on features of existing dams may be individuals rather than formal boards.

7. Research and Development

A strong research and development effort is a necessary element in reducing the uncertainties still present in dam design, hydrology and hydraulics, materials behavior, and construction techniques, equipment and practices. As part of their dam safety programs, agency management should identify opportunities and needs for research and programs to meet those needs both internally and through other agencies such as the National Science Foundation and the U.S. Geological Survey.

a. Methods and Materials
Management should ensure that a continuing review is made of state-of-the-art methods, experience, research, etc., and that improvements are incorporated into agency criteria and methods of analysis, exploration, construction, testing, and instrumentation. The process should build from experience on past projects relating to constructability, observed behavior, problems encountered, and problem solutions tried and their results. Experience histories should be reviewed, summarized, and disseminated to evaluate current practice in order to advance agency practices. Research and development needed on materials and their use as revealed by dam observation and monitoring and new developments should be conducted on a continuing basis. Establishing a schedule of research priorities is necessary for overall research and development goals and for orderly and consistent progress in advancing dam technology.

b. Risk-Based Analysis
The agencies should individually and cooperatively support research and development of risk-based analysis and methodologies as related to the safety of dams. This research should be directed especially to the fields of hydrology, earthquake hazard, and potential for dam failure. Existing agency work in these fields should be continued and expanded more specifically into developing risk concepts useful in evaluating safety issues. Existing work is exemplified by (1) the interagency research conference cited in paragraph c below, (2) its adjunct meetings on hydraulics and earthquakes, and (3) the NRC methods of risk evaluation for nuclear plants as applicable to radiological safety-related dams.

c. Interagency Coordination
Existing interagency research coordination activities should be continued, with attention to minimizing unnecessary duplication. The biennial research coordination conference on water resources among the Corps of Engineers, Bureau of Reclamation, Tennessee Valley Authority, and Bonneville Power Administration is an example of beneficial exchange needed on issues relating to dam safety.

8. Contracts

a. Documents
Agency procedures should ensure that all contracts for dam design, construction, and operation are written to accomplish the design intent and to require that contractors provide complete documentation of their work.

b. Modifications
During the construction period, any modifications in the design or construction which result from significant departures from expected field conditions, design reviews, or other studies should be promptly included in revisions to appropriate contracts. Such modifications, and any discovered later, that affect operation should be included in operation contracts (and in agency operation, monitoring, and maintenance policy). The basis and justification for any change should be documented.

9. Constraints
Many constraints which are outside agency authority can directly or indirectly affect dam safety. Managers at all levels must be continually aware of their fundamental responsibilities for dam

safety and exercise vigilance in identifying constraints on fulfilling those responsibilities. Every manager has a duty to seek resolution or mitigation of such constraints through his own agency channels or through interagency or intergovernmental channels as appropriate and available to him.

a. Funding for Organizational Management

Continuity and adequacy of funding are essential to carry out the various programs which ensure safe dams. The Zero Based Budget system offers an opportunity to managers to identify for high funding priority those activities, programs, staff levels, and other operating requirements of a sound dam safety program. Managers should avail themselves of this opportunity. Agencies should cooperatively develop common budgetary terms and consistent processes to provide the necessary visibility of dam safety funding essentials at all levels and within all branches of the government. Long-term programming objectives should be established and adhered to, to meet the requirements of organization management, personnel staffing and training, research and development, quality construction and operation, a complete program of inspection and evaluation of the safety of existing dams, and a planned program for the rehabilitation and/or improvement of existing dams.

b. Public Concerns

Public individuals and groups should have the opportunity to voice their concerns in the development of public works projects and during their operation. These concerns often represent constraints in the form of local or regional political interests, legislation, perceptions of risk and hazard, environmental factors, social conflicts, etc., which can influence technical decisions. Agencies should develop and organize their procedures for early assimilation of those public views which affect possible design, construction, or operating parameters and, in turn, influence dam safety. Resolution of public issues conflicts and problems, including use of executive and legislative government decisions, should be made prior to the start of construction so that dam safety is not compromised.

B. MANAGEMENT OF TECHNICAL ACTIVITIES — SITE INVESTIGATION AND DESIGN (SID)

This section of the guidelines outlines the site investigation and design technical activities that agency management should ensure are undertaken to obtain safe design of dams. It is recognized that the extent of application of these guidelines will vary depending on the size and function of the dam.

1. Hydrology

a. Hazard Evaluation

Areas impacted by dam construction and existing dams should be examined for potential hazards to present and future developments in the event of major flooding by controlled flood discharges or flooding induced by dam failure or misoperation. This hazard evaluation is the basis for selection of the performance standards to be used in dam design or in evaluation of existing dams.

b. Flood Development

Hypothetical floods, generally of severe magnitude, should be developed for use in design or evaluation of major dam and reservoir features, including development of appropriate floods for the construction period.

c. Flood Selection for Design (or Evaluation)

The selection of the design flood should be based on an evaluation of the relative risks and consequences of flooding, under both present and future conditions. Higher risks may have to be accepted for some existing structures because of irreconcilable conditions.

When flooding could cause significant hazards to life or major property damage, the flood selected for design should have virtually no chance of being exceeded. If lesser hazards are involved, a smaller flood may be selected for design. However, all dams should be designed to withstand a relatively large flood without failure even when there is apparently no downstream hazard involved under present conditions of development.

d. Hydrologic Design of Reservoir

In addition to selection of a design flood, the hydrologic design of a new reservoir or the evaluation of an existing project involves consideration of discharge and storage capacities, reservoir regulation plans including constraints, land requirements, and wind/wave effects. The evaluation of existing projects also should include observed performance capabilities and whether improvements are necessary to ensure safety.

Reservoir regulation plans should be developed in the planning of projects so that realistic release rates will be used in routing the design flood. Regulation plans should include the construction period. When gate operations are involved, a water control management plan should be established to direct reservoir regulation in an effective and efficient manner. An emergency regulation plan is also required for use by the dam tender in the event of loss of communication with the water control management staff during a flood. A data information system should be designed to collect and process pertinent hydro meteorological data in a timely and reliable manner.

The reservoir regulation plans, water control management plan, and data information systems should be periodically reviewed for safely deficiencies and potential for misoperation during both severe flood events and normal conditions. Necessary corrections should be made as soon as practicable.

e. Downstream Effects

Safety design includes studies to ascertain areas that would be flooded during occurrence of the design flood and in the event of dam failure. The areas downstream from the project should be evaluated to determine the need for land acquisition, flood plain management, or other methods to prevent major damage. Information should be developed and documented suitable for releasing to downstream interests regarding remaining risks of flooding.

f. Warning Systems

Safety design should include an emergency flood warning system and action plan that would effectively notify all concerned in ample time for appropriate action.

2. Earthquake Investigation and Design

a. Investigation Factors

The following factors should be considered in selection of design earthquakes.

(1) Geologic and tectonic setting of the site area by analysis of the lithology, stratigraphy, structural geology, and tectonic history.

(2) Historical earthquake record to include the size, location, and other seismological characteristics as available, and the relationship, if possible, with the tectonic siting of the area in which the earthquakes have occurred.

(3) Influence of the properties of the surficial materials on the determination of the size of historical earthquakes.

(4) Influence of faulting or other tectonic features on the estimate of the occurrence, size, and location of possible future earthquakes.

b. Selection of Design Earthquakes

From the above factors, earthquakes should be selected that have sufficient potential of occurring to require consideration in the dam design. Earthquake description should include estimates to the extent practical of the size, location, depth, focal mechanism, and frequency of occurrence.

c. Engineering Seismology

Determination should be made of the characteristics of ground motion that would be expected from the design earthquakes, to the extent possible, to include amplitude (displacement, velocity and acceleration), frequency content, and duration.

d. Need for Earthquake Analysis

The probable effects of earthquakes on the dam and its appurtenant structures should be evaluated to determine the need for inclusion of earthquake forces in the structures analyses. Evaluation includes consideration of factors such as the project stage, hazard and risk factors, the size of the dam and reservoir, the potential ground motion at the site, site geology, and type of structure. Where determination is made that no earthquake forces are required in analysis, the determination should be justified.

e. Seismic and Geologic Studies

(1) Earthquake Sources. The essential first step is determination of the design seismic events (usually the maximum credible earthquakes) and an estimate of the ground motion at the site due

to these events. From a study of the regional tectonics and seismicity, and both regional and local geology, potential sources for seismic events are identified, and the maximum credible earthquake magnitudes postulated.

(2) Design Events. A maximum credible earthquake (MCE) is defined herein as the hypothetical earthquake from a given source that could produce the severest vibratory ground motion at the dam. Time histories of the estimated rock motion (accelerograms) at the dam for the various seismic events are selected to characterize the severity of the strong motions by their peak accelerations, frequency content, and duration.

f. Design for Earthquake Forces

(1) Safety Concerns. All earthquake-related safety concerns should be identified. Potential safety concerns include but should not be limited to dam foundation integrity, stability, unacceptable stress levels, fault displacements; abutments stability; effects of dam overtopping; dam stability; susceptibility of embankment dams to embankment or foundation liquefaction, cracking or excessive deformation.

A survey of component and accessory structures and equipment should be made to identify those which have functions that are essential for earthquake-related safety.

(2) Analysis Method. Determination of appropriate earthquake analysis methods for evaluation of safety concerns may be, as appropriate, by qualitative evaluations, pseudostatic analysis, and dynamic analysis. The methods selected should be appropriate to the identified safety concerns, in accordance with good engineering practice and with currently available technology.

(3) Structural Adequacy. Structural adequacy assessments should be made of all safety-related components and concerns identified. These assessments should incorporate all applicable data and analysis.

3. Geotechnics

a. General

(1) Site Specifics. After a site is selected, a program for the geotechnical exploration, design, and analysis of that specific site is required. No checklist can be made which would cover all eventualities at all sites, or at any one site, and attempts to formulate such a list would be counterproductive to the intent to ensure dam safety. The best insurance for adequate geotechnical work is a well-trained and experienced staff actively involved in field inspections throughout all phases of the development of the site.

(2) Documentation. Because many evaluations are possible for a given set of geotechnical conditions, it is important that full documentation be made of the reasoning process involved in geotechnical decisions. General guidelines for documentation are given in section III.A.5.

(3) Management of Diverse Technical Expertise. Geotechnical work encompasses the expertise of geologists, geophysicists, and engineers—all with diverse experience, training, interest, and technical terminology. The administrative and technical supervision of these experts should be structured to optimize coordination and cooperation. Management should encourage intellectual curiosity and an inquisitive approach to all geotechnical work. Since the field of geotechniques is rapidly expanding, management should assure that those associated with site exploration and development maintain currency with the state of the art.

b. Exploration and Identification of Geotechnical Problems

The exploration program needs to be site specific, flexible, and executed so as to obtain the maximum data from each part of the program. Agency management should ensure sufficient funding for an orderly development of the exploration program in order to reduce uncertainties and to make adequate provisions for required corrective measures.

The initial onsite exploration should be preceded by a review of all available information pertinent to the development of the site (literature, maps, photographs, well and spring information, seismic data, area construction records, etc.). This should lead to the preparation of a detailed geological map of the site using all available data. Geotechnical explorations generally proceed from wide-spaced borings and geophysical surveys to determine the general geological conditions, to additional explorations assigned in an ongoing sequence to develop the geologic correlations and to determine the type of dams suitable for the site. The extent, depth, and type of exploration depend on the complexity of the geology and size and type of dam.

Generally, explorations are not complete at the end of the planning phase but continue during the preparation of plans and specifications and into the construction phase. Conditions encountered during construction often require additional explorations to evaluate the need for changes in the design.

All potential geological problems, inferred from onsite data and from experience at similar sites, should be fully explored and described. This information should cover the types of adverse features and geologic processes generally associated with a geological environment similar to that at the site. It should also cover the expected short- and long-term behavior of foundation and reservoir rim materials at the site when subjected to the changed geological environment associated with the construction and operation of the dam and to geologic processes operating during the life of the project.

During the course of the design and continued exploration of the project, all potential problems should be investigated and corrected with appropriate treatment, or where uncertainty remains, design defenses should be provided to control or monitor the problems. Types of problems which might require consideration include reservoir-induced seismicity, solubility, pipability and liquefaction potential of materials, foundation heave or deterioration during excavation, reservoir rim leakage and stability, past and future mining, and differential consolidation associated with petroleum or water extraction.

c. Geotechnical Design

Geotechnical design considerations for the dam foundation and reservoir area are essentially defined after the geologic conditions of the site, the type of dam, and the magnitude of the stresses imposed on the foundation by the dam and reservoir have been determined.

Foundation design typically consists of four distinct elements. These are (1) definition of the geometry of the foundations and areas of potential instability in the foundations, abutments, and slopes; (2) determination of the properties of foundation materials using judgment, past experience, laboratory testing, and in situ testing; (3) an analytical procedure that predicts the behavior of the foundation in terms of stability, permeability, and deformation; and (4) a reevaluation of parts (1) through (3) as construction progresses so that a comparison can be made of preconstruction assumptions and conditions with the actual conditions revealed by the foundation excavation and treatment. Additional exploratory work may be required.

d. Foundation Treatment

(1) General. The preparation of the foundation, including the abutments, is one of the most important phases of construction. The primary purposes of foundation treatment are to provide stability, obtain positive control of seepage, and minimum adverse deformation. The geology, foundation conditions, foundation treatment, and proposed structure should be considered together.

(2) Stability. Surfaces should be prepared to provide a satisfactory contact between the foundation and the overlying structure by removal of unsuitable materials. Deficiencies in the foundation which are not removed should either be treated by modification of the structure or by appropriate foundation treatment tailored to handle the conditions encountered.

(3) Positive Control of Seepage. Highly permeable foundations should be treated by such measures as cutting off the pervious material, grouting, increasing the seepage path by upstream blankets, or controlling the seepage with drainage systems. Where appropriate, surficial cavities should be traced, cleaned out, and backfilled with material satisfying the design requirements. When cavities exist at depth, measures should be taken to ensure against the migration of cavity filling material.

(4) Control of Piping. Silts and fine sands in the foundation, which are susceptible to piping, should be removed if practical, cut off near the downstream limits of the dam, covered with impervious material, or provided with filtered drainage systems. If pipable material is used in the dam, the foundation surface treatment should prevent migration of dam material into the foundation.

(5) Deformation. Foundations subject to differential settlement or foundations having highly compressible anomalies can cause stress concentrations or cracking in dams. The foundation excavation should be shaped to remove abrupt changes in elevation to preclude excessive differential settlement or stress concentrations. Low shear strength material in a foundation can

cause shear failure. Excavation and replacement of low strength material is a positive method for treating a foundation that has either or both of these unfavorable conditions.

e. Instrumentation

Although a well conceived foundation instrumentation program serves to monitor the foundation and gives an indication of distress, it cannot of itself certify the safety of the foundation. The expertise of the engineer/geologist to analyze and design and prepare a foundation that will safely carry the loads and water pressure imposed by the dam and the reservoir is fundamental to the design adequacy of the foundation. The purposes of foundation instrumentation are fourfold: to (1) provide data to validate design assumptions; (2) provide information on the continuing behavior of the foundation; (3) observe the performance of critical known features; and (4) advance the state of the art of foundation engineering.

The general requirements for foundation instrumentation should be determined early in the design of the project, and the rationale for the instrumentation should be thoroughly documented. Factors that will influence the need for and the type of instrumentation include the geology of the foundation, size and type of the dam and reservoir, and the location of the project. Flexibility must be provided in the program to allow for changes from anticipated foundation conditions that are encountered during construction and/or operations.

Intrinsic to an instrumentation program is the schedule for reading the instruments before and during construction, during initial reservoir filling, and through the service life of the project. No less important is the need for clear instructions for the prompt evaluation of data and prompt notification to responsible personnel when observations are atypical or diverge markedly from the design assumptions.

f. Inspection and Continuing Evaluation during Construction

Those responsible for the investigation and design of the foundation should make onsite evaluations to confirm that actual conditions conform to those assumed in the design and to review documentation of site conditions.

A qualified project geologist should examine and map geologic details of the foundation as it is being exposed during construction. Investigation and testing at this point provide details useful in controlling grouting and other improvements and in confirming the competency of the foundation. Even though extensive exploration and testing may have been conducted prior to construction, most foundations can be expected to reveal unanticipated conditions which may require redesign or changes in the type or extent of foundation treatment.

Approval should be obtained from the geotechnical and design staffs before placement of dam materials on the foundation. This approval should be documented and should indicate that all unanticipated conditions encountered were dealt with and that the foundation and its treatment meet the design requirements.

g. Reevaluation at Existing Structures

Older Federal dams may not have been designed to standards equal to current criteria. Also, a substantial portion of safety-related dam incidents are associated with foundation problems which develop in a time-dependent fashion after construction. For these reasons, systematic reevaluation of existing Federal dams should be made.

These reevaluation should go beyond analysis of problems which are observed visually or from instrumentation data. A review should be made of all existing exploratory information, design information, construction records, and operation records, to determine the adequacy of the foundation with respect to the present site of the dam. Where available information is insufficient or where deficiencies are found or suspected, modern criteria for analysis, instrumentation, exploration, and testing should be used as appropriate to gather the necessary data to show that no problem exists or to furnish information to modify the structure or foundation.

4. Hydraulic Appurtenances

a. General

(1) Protective Measures**.** All hydraulic appurtenances used for releasing water should be designed to preclude jeopardy to the damming provisions.

(2) Blockage. Allowances for or preclusion of blockage of hydraulic facilities should be incorporated in the design.

(3) Reliability. When operational failure of a gated passage would jeopardize the damming provisions, alternate capacity should be provided. When operation of a gated passage is essential to safety, reliable manpower, communications and accessibility should be assured.

(4) Hydraulics and Hydrology. Hydraulic and hydrologic design considerations should be correlated with section III.B.1.

b. Design Flood Releases

(1) Spillway and Outlets. Gated spillways are the usual hydraulic appurtenances for control of all or the major portion of the design flood and major emergency releases. Outlets (sluiceways, conduits and tunnels) may be used alone or in conjunction with spillways to control flood discharges.

(a) Selection of type. Spillways and outlets should be selected to meet the site specific purposes of the project. For a drainage area with short concentration time combined with reservoir storage capacity that is small relative to the flood volume, especially for embankment dams, (1) the spillway should usually be uncontrolled, and (2) outlets should not normally be used for sole or part control of the design flood except in special cases where the outlets can be uncontrolled.

(b) Capacity. Spillway and outlet capacity should be sufficient to satisfy the discharge

requirements of the reservoir regulation plan and other design considerations.

(2) Power Facilities. A portion of installed turbine flow capacity may be considered to assist in control of the design flood if it is demonstrated that possible power load interruptions during the design flood would not preclude operation of the power facilities.

c. Other Water Releases

Other water release hydraulic appurtenances such as navigation facilities, locks, fish facilities, ice sluices**,** trash sluices, and water quality facilities should conform to the requirements of section 4.a.

d. Reservoir Evacuation

Where practicable, reservoir release facilities should be provided to lower the pool to a safe level adequate to correct conditions that might threaten the integrity of the dam.

e. Control of Flows during Construction

The provisions of section 4.a also apply generally to the design of hydraulic appurtenances used during construction. The capacity of these appurtenances should be sufficient to satisfy the discharge requirements of the regulation plan for control of water during construction.

f. Design Criteria and Guidance

(1) General. If existing design criteria and guidance from past projects and experience are used for design of the hydraulic appurtenances, their sufficiency should be documented.

(2) Hydraulic Model Tests. When sufficient criteria and guidance are not available for analytical design of the hydraulic appurtenances, physical hydraulic model studies should be performed.

(3) Prototype Testing. Features of safety-related hydraulic appurtenances that are beyond the state of the art, or for which model to prototype relationships have not been verified, should be tested in the prototype.

g. Reanalysis Because of Changes

Changes in project purpose, new purposes, operational requirements, limitations of constraints, design criteria, or legal requirements may require that a reanalysis be made of the hydraulic appurtenances.

h. Hydraulic Design Involvement during Life of Structure

Hydraulic design engineers should participate in the project periodic inspection program to evaluate the operational adequacy of all hydraulic appurtenances essential to dam safety throughout the life of the structure including final disposition.

5. Concrete Dams and Concrete Elements of Embankment Dams

a. Site Specific Design

Because all dam sites are unique, the type of dam and its appurtenances should be specifically matched to site conditions and project requirements. It is essential when reviewing the safety of existing dams to consider conditions which may have changed physically and new concepts resulting from new technology, or because of additional project information since construction, such as foundation deterioration, increased flood hydrographs, or larger design earthquakes.

b. Materials

Concrete for the structures requires competent investigation of materials sources and adequacy of supply testing of materials properties in accordance with accepted standards, and proper proportioning of concrete mixes (including additives) for strength, durability, control of thermal properties, and economy.

c. Design of Structures

There are three components of a dam which must be considered for safety: the foundation, the dam, and its appurtenant structures.

(1) Foundation. Proper design of a concrete dam requires information on the foundation geological conditions and materials properties to assure its capability to support the loads of the dam and reservoir, in its natural state or as improved by foundation treatment.

(2) Dam. Concrete dams should be designed to be safe against overturning and sliding without exceeding allowable stresses of the foundation and the concrete for all loading conditions imposed on the dam. The shape and/or curvature of a dam and its contact with the foundation are extremely important in providing stability and favorable stress conditions. Proper consideration should be given to ensure the dam's safety in the event of overtopping.

Joints in the dam should be properly designed to control cracking due to thermal, shrinkage, and structural effects. Temperature control measures such as proper concrete mix design, pre-cooling of the concrete mix, and post-cooling of the concrete blocks can also be used to control cracking. Openings in the dam such as waterways, galleries, chambers, and shafts should be designed with consideration for their effects on the behavior of the structure.

(3) Appurtenances. Safety-related appurtenances, such as outlet works structures, spillways, and navigation locks, should be designed with the same degree of safety as the main dam. If the project has a powerhouse as an integral part of the dam, it should be designed for the same safety requirements as the dam.

d. Definition of Loads

The dam and appurtenances should be designed for all static and dynamic loads to which they will be subjected. Dynamic loadings to be considered should include inertial, hydrodynamic, and earth pressures from earthquake ground motions and structural response; and dynamic loads resulting from flowing water.

e. Design Methods
The methods required for design of the several types of concrete dams and their appurtenances vary from simple to complex, depending on the type and size of the structure, the hazard potential of the site, the kinds of loading, and foundation conditions. The design process involves judgment and analytical expertise to select appropriate methods to analyze a structure whether it requires a simple or complex analysis, and to determine design input data that is representative of the range and variation of foundation and structural material properties. The selection of input parameters is just as important as the mechanics of the analysis used.

f. Design Evaluation
Technically qualified supervisory personnel should assure that structures are designed to meet the requirements for safety. This includes confirmation of design input parameters, design methods, and utilization of allowable factors of safety against overturning, sliding, and stressing appropriate to the probability of the loading conditions.

g. Instrumentation
Knowledge of the behavior of structures and their foundations may be gained by studying the service action of the structures using observations on embedded and other internal instrumentation and external measurements. Information from which a continuing assurance of the structural safety of the dam can be assessed is of primary importance, but information on structure behavior and the properties of dam and foundation materials serve to verify the design and to provide information for improvement of design. Observations may be made in the dam and foundation in terms of strain, deflection, pressure, temperature, stress, deformation, and drainage flows. External measurements for deflection and settlements may be made by precise surveys on targets set on the dam, in galleries, in vertical wells in the dam, in tunnels, and on the foundation. Status reports on the condition of structures should be issued regularly. Examinations of existing structures should include assessments of whether additional instrumentation is required.

h. Construction and Operational Follow-up
It is necessary that the designers should be involved in the construction and operation processes to confirm that the design intent is carried out, and to allow changes and modifications resulting from redesign necessitated by differences between design assumptions and actual field or operating conditions.

6. Embankment Dams
Section 5 contains general dam considerations; the following additional considerations are applicable to embankment dams.

a. Site Specific Design
Embankment design should be developed for specific site conditions and based on adequate exploration and testing to determine all pertinent geologic and material factors with particular emphasis on shear strength and stability, permeability and control of seepage, and consolidation and settlement.

Embankment dams are particularly vulnerable to damage and possible failure from internal erosion when founded on rock having large cavities, open joints, discontinuities, or other geologic defects. The sites should be carefully explored and special attention given to design of cutoffs, foundation treatment, and other defensive measures. Special problems related to embankment integrity may include soft rock such as clay shales, areal subsidence, old mining activity, solution-susceptible rock, and collapsing soils.

b. Materials

Embankments can generally be designed to utilize locally available construction material; investigation of materials characteristics is required and problem materials should be either discarded or protected by defensive design. There is often a need for importing special materials for slope protection, filters, and drainage systems**.** Any embankment zoning should consider the properties and quantities of available materials and the effect of their characteristics on the construction process.

c. Design Constructability

Embankment designs should be constructible with regard to such items as location of borrow areas with respect to flooding, in-situ moisture conditions, climatic effects on construction schedules, width of zoning, and needs for special material processing. Design should include protection of critical features from overtopping by floods during construction.

d. Embankment Design

The safety of an embankment is dependent on its continued stability without excessive deformation under all conditions of environment and operation, and on control of seepage to preclude adverse effects on stability and prevent migration of soil materials. Design considerations given below are specific to embankment dams.

(1) Seismic. Where earthquake design is necessary, consideration should be given to earthquake-related concerns of soil liquefaction and cracking potential, stability and excessive deformation, abutment stability, overtopping effects, and required defensive measures.

(2) Stability. Embankment stability should be analyzed for all pertinent static and dynamic loading conditions without exceeding allowable shearing stresses in the embankment or foundation. Factors of safety should be appropriate to the probability of the loading conditions, and should consider the effects of loading and time on shear strength, particularly if limited placement volume can result in rapid construction. In most cases**,** embankments should be designed for unrestricted rates of reservoir filling and drawdown.

(3) Settlement and Cracking. The potential for transverse cracking of the embankment caused by differential settlement, tension zones, and possible hydraulic fracturing should be minimized by careful consideration of abutments, foundation and cutoff trenches, and their geometry and treatment. Filter zones of adequate size should be positioned upstream and downstream of the impervious zone at all locations where there is a possibility of transverse cracking regardless of cause. Potential problems of differential settlement should be considered in establishing the construction sequence.

(4) Seepage. The design should attempt to prevent or minimize seepage through the embankment and its foundation and abutments; however, the designer should recognize that seepage usually occurs and that protective control measures must be provided. Filtering transition zones and foundation and abutment treatment to seal openings should be provided wherever necessary to preclude migration of soil materials into or out of all embankment element contacts both upstream and downstream. Filters, drainage blankets, and transitions should be of a quality and size to conservatively control and safely discharge seepage for all conditions for the life of the project. Particular attention should be given to contacts with foundation, abutments, embedded structures, and the end slope of closure sections to ensure adequate compaction and bonding to control seepage.

(5) Zoning. Embankment zoning when used should ensure adequate stability for all pertinent conditions, and should control seepage through the embankment and provide filter action to prevent migration of material.

(6) Erosion. Upstream and downstream slopes and foundation and abutment contacts should be protected against erosion from surface runoff, wave action, and impinging currents. Spillways and outlet works should be located and designed so that discharges do not erode the embankment or its foundation.

e. Instrumentation

Embankment design and prediction of embankment performance are based on an imprecise combination of theory and empirical procedure; consequently, performance during construction and operation should be monitored by a designed system of external measurements and/or installed instrumentation. A well planned system of instruments, when appropriate, should be installed to provide data on internal and external movements and on water pressures at critical locations in the embankment and foundation during both construction and operation.

f. Construction and Operational Follow-up

In addition to the need for designers to be involved in construction and operation of dams in general to confirm the design intent and assess the need for possible design changes, certain other requirements should be observed at embankment dams. Stability should be evaluated during and after construction using strength parameters from as-placed materials and observations of pore pressure and seepage if and when conditions warrant. Designers should inspect and review performance of embankments during and after reservoir impoundment to detect and provide prompt remedial treatment for problems. While major emphasis is placed on initial impoundment, the surveillance should continue for the life of the project. As the state of the art advances in analysis, material behavior, and methods of observation, deficiencies in embankments may be suspected or become obvious and should be investigated and corrected. Collected experience information should be summarized and used to further advance the state of the art.

C. MANAGEMENT OF TECHNICAL ACTIVITIES — CONSTRUCTION (CON)

1. Introduction

This section of the guidelines outlines the construction technical activities that agency management should ensure are undertaken to obtain safe construction of dams. The principles and guidelines arc prepared in a broad sense to ensure that construction of a safe structure is the prime requisite.

a. Construction Contracts

Construction contracts should be based on site conditions as interpreted at the time of contract award. All anticipated work on foundation cleanup, preparation, and treatment should be included as specified items of the work. Contract provisions should require the contractor to submit to the construction engineer advance notice of significant shift change, to enable adequate inspection coverage of multishift operations.

b. Construction/Design Interface

Many aspects of construction directly overlap in design considerations. Reference is made below to numbered paragraphs in Section III.B. Management of Technical Activities-Site Investigation and Design, which concern such common interests:

3. Geotechnics
a. General
(1) Site Specifics
b. Exploration and Identification of Geotechnical Problems
c. Geotechnical Design
d. Foundation Treatment
e. Instrumentation
f. Inspection and Continuing Evaluation during Construction

4. Hydraulic Appurtenances
e. Control of Flows during Construction

5. Concrete Dams and Concrete Elements of Embankment Dams
a. Site Specific Design
b. Materials
c. Design of Structures
(1) Foundation
g. instrumentation
h. Construction and Operational Follow-up

6. Embankment Dams
a. Site Specific Design
b. Materials
c. Design Constructability
d. Embankment Design
(3) Settlement and Cracking
(4) Seepage

e. Instrumentation
f. Construction and Operational Follow-up

2. Evaluation during Construction
Field personnel must be highly trained and experienced if the design principles and site conditions are to be understood and a safe structure is to be constructed.

When differing site conditions (different from those anticipated) are encountered, construction supervisory forces must have authority to suspend any or all portions of the work affected until the design engineers, with assistance as needed, can evaluate the condition and determine if design modification is required.

Construction milestones should be identified when the design engineers will inspect the work and concur with the progress of construction.

3. Orientation of Construction Engineers and Field Inspectors
Construction engineers need to be aware of design philosophies and assumptions as to site conditions and function of project structures, and must understand the designers' intent concerning special technical provisions in the specifications. Identified preconstruction activities should include the orientation of construction engineers to the site specificity of the design and to the close communication requirements with all concerned engineering disciplines during the construction process. For major projects, there should be periodic meetings between design and construction engineers to discuss upcoming construction activities. Also, during the initial stages of important construction activities, the construction engineers should request site inspection by the design engineers to assure construction procedures are in accordance with design requirements.

Construction specifications, supplemental reports, and conferences to orient field personnel to the particular site, the features of the dam, and the designers' intent for construction should, as applicable, include the following:

a. Design Related
(1) Design concepts. Explanation of philosophies and assumptions and the reasons for special requirements in the specifications to assure accomplishment of design intent.

(2) Construction sequence. Identification and explanation of the dates to which construction progress must conform to satisfy project requirements, and the special sequences for construction activities that are required by design.

(3) Instrumentation systems. Description of the instrument types, their purpose, the procedures for installation of each instrument type, the method and time interval for reading each instrument, and the importance of prompt data transmission for analysis and feedback.

(4) Care and diversion of water. Description of the design features included to prevent and/or control flooding and turbidity and accomplish diversion and closure of the dam. This should also contain the design requirements for controlling normal flows through the work area to assure that construction is always accomplished under dry conditions. Critical aspects of the construction schedule related to flood problems should be emphasized.

b. Foundation

(1) Description. Discussion of the type of foundation conditions expected to exist, i.e., over-burden, general rock description, formation weaknesses such as joints, shears and faults, and acceptable foundation conditions.

(2) Excavation. Discussion of the depth and nature of materials expected to be encountered, the controls for dewatering and blasting, identification of critical areas, quantity estimates, and an acceptable foundation.

(3) Preparation. Review of the methods of rock foundation preparations such as: cleaning; the use of wire mesh, mortar, shotcrete, or rock bolts; grouting, and treatment of faults, shears and joints; as well as subsequent exploration to assure desired results. Review of methods of earth foundation preparation.

c. Materials

(1) Materials from required excavation. Definition of acceptable and unacceptable properties of materials, the usage and the processing requirements if used, and identification of waste area locations.

(2) Other excavated materials. Identification of the location and amount of usable material, "based on current test data," available from all designated areas, including borrow pits. Review of the blasting methods that are expected to produce the desired rock quality and sizes. Discussion of the expected amounts of waste and the areas where borderline material may be used in lieu of wasting, such as in berms or certain zones of the downstream shell of an earthfill dam.

(3) Embankment. Description of both acceptable and unacceptable material properties, place-ment, and compaction procedures for each zone. Review of required procedures for areas adjacent to abutments, around instruments, and at interfaces between zones and/or structures.

(4) Concrete and concrete materials. Identification of acceptable aggregate sources and review of mix designs, joint and surface treatment, finish requirements, form tolerances, and placement procedures. Cooling as well as hot and cold weather protection requirements should be defined.

d. Construction General

(1) Field control. Discussion of the quality assurance procedures required to control all phases of construction. Acceptable placement standards should be established for concrete, earth and rock materials, and embankments.

(2) Structural. Discussion of structural steel installation, reinforcing steel placement, and anticipated problem areas and specified treatment for such areas.

(3) Mechanical-electrical. Description of equipment installation requirements, special procedures, performance tests, protective coatings, and protection devices such as ground fault indicators.

(4) Environmental-Identification of those construction controls required to minimize environmental damage, comply with environmental regulations, and assure public involvement.

4. Construction Assurance

a. Construction Procedures
Agency criteria must assure that acceptable methods and procedures are specified and utilized to accomplish design requirements. At the same time, the design and construction organizations must maintain the flexibility necessary to modify design, material requirements, and construction specifications as conditions dictate without altering the basic design intent.

b. Construction Materials Testing
A materials laboratory must be established at the field construction office that is adequately staffed and equipped to accomplish the on-site testing requirements set forth in the engineering considerations and instructions to field inspection personnel. Provisions should be made for a thorough and periodic review "above project level" of the construction materials testing procedures to assure their continued suitability. Periodic companion test samples of embankment material should be checked by higher echelon for uniform test assurance.

c. Quality Assurance
It is mandatory that adequate construction quality assurance systems and procedures be established to assure safe dam construction. The quality assurance system must guarantee, by direct inspection and testing, that construction is accomplished in compliance with the contract plans and specifications. The quality assurance system must identify when site conditions require modification of the design to ensure construction of a safe dam and must document the construction activities and test results. Daily inspector’s reports, laboratory test data records, and photographs are the minimum mandatory methods of documentation. General guidelines for documentation are given in section III.A.5.

As a part of the quality assurance program the contractor should normally be required to submit various plans for approval not limited to, but including, the following:

Construction Schedule Safety Program
Care and Diversion of Water (including pollution control)
Fire Protection
Plant Layout (including haulroads)
Environmental Measures
Equipment Inventory
Dewatering Foundations and Borrow Areas

Excavation Sequence of Foundations and Borrow Areas
Drilling and Blasting Procedures
Concrete Placement
Restoration of Construction Area

D. MANAGEMENT OF TECHNICAL ACTIVITIES-OPERATION AND MAINTENANCE (O&M)

This section of the guidelines outlines the technical activities for operation and maintenance, periodic inspection program, and emergency action planning that agency management should ensure are undertaken to obtain safe operation of dams.

1. Operation and Maintenance

a. General

The intent is to define practices which will ensure safe operation of dams and reservoirs and to require a maintenance program that will provide timely repair of facilities. It is assumed that each Federal agency is responsible for proper operation and maintenance of dams that are owned by the agency or that are under its jurisdiction.

Operation and maintenance personnel should be selected on the basis of their capability to acquire the knowledge needed to perform the many functions of operation and maintenance, and should be trained for the associated duties at each specific project.

All operation and maintenance manuals should be kept current, and records should be maintained of instructions, inspections and equipment testing, with copies to those responsible for design and dam safety inspections. General guidelines for documentation are given in section III.A.5.

In the following sections, outlets or outlet gates refer to gates or valves on any outlets such as sluices, conduits or tunnels, pumps, generating units, and infrequently operated plant intake and discharge gates. If the project has a navigation lock, emergency closure and other infrequently operated equipment are also included.

b. Operating Procedures

Written operating instructions should be prepared for the dam and its associated structures and equipment. The instructions should cover the functions of the dam and reservoir and describe procedures to follow during flood conditions to ensure dam safety.

Reservoir operating rule curves should be available for each normal mode of operation and for emergency conditions.

An auxiliary power system, such as a gasoline or diesel-operated generator, is essential if the outlet and spillway gates and other dam facilities are electrically operated.

All spillway and outlet gates should be tested on a regular schedule. The tests should include use of both the primary and the auxiliary power systems.

Project security is a matter of concern at all major dams. This includes preventing structural damage by vandals or saboteurs and unauthorized operation of outlet or spillway gates. In most cases, restricting public access is essential, and in some instances armed guards may be necessary.

Public safety is of paramount importance at all dams and reservoirs. Specifically, public safety on the reservoir, in areas adjacent to the reservoir, and below the dam should be considered, particularly in recreational areas. Safety measures should include identification of high watermarks to indicate past or probable reservoir levels and streamflows, posting of safety instructions at highly visible and key locations, and providing audible safety warnings upstream of and below outlets as appropriate.

Communication should be maintained among affected governmental bodies and with the public to enhance the safety aspects of the operation of the dam. Communication alternatives include written communications, radio, telephone, television, and newspapers.

c. Maintenance Procedures

Written instructions should provide information needed for proper maintenance of all water control facilities.

Specialists should prepare maintenance checklists indicating the maintenance procedures and protective measures for each structure and for each piece of operating, communications, and power equipment, including existing monitoring systems. Special attention should be given to known problem areas.

Special instructions should be provided for checking operating facilities following floods, earthquakes, tornados, and other natural phenomena.

Maintenance procedures include preventive measures such as painting and lubrication as well as repairs to keep equipment in intended operating condition, and minor structural repairs such as maintaining drainage systems and correcting minor deterioration of concrete and embankment surfaces. The design staff should be apprised of any significant maintenance work.

2. Periodic Inspection Program

a. General

The purpose of a periodic inspection program is to verify throughout the operating life of the project the structural integrity of the dam and appurtenant structures, assuring protection of human life and property. Periodic inspections disclose conditions which might disrupt operation or threaten dam safety, in time for them to be corrected. When such conditions are encountered, it is necessary to determine the adequacy of structures and facilities to continue

serving the purposes for which they were designed, and to identify the extent of deterioration as a basis for planning maintenance, repair or rehabilitation.

The following general principles and guidelines for a periodic inspection program should be used by Federal agencies responsible for operation or regulation of dams.

All existing dams with a significant hazard potential should have a safety evaluation based on current technical guidelines and criteria. New dams added to the inspection program should be planned, designed, and constructed in accordance with current technical criteria. Improvements in dam technology require that dams and appurtenant structures be reassessed to assure dam safety for more stringent design and materials criteria.

Periodic inspection of dams, reservoirs, and appurtenant structures involves important aspects other than dam safety; however, these guidelines encompass only dam safety issues. Each agency is responsible for assuring that the existing dams for which it is responsible are periodically inspected, and that new dams are re-inspected initially upon completion of construction and periodically thereafter.

b. Types and Frequencies of Inspections

The inspection types and intervals herein recommended are for general guidance in developing inspection programs for all Federal dams. These guidelines do not preclude other inspections or more frequent inspections if deemed necessary depending on project history and importance of the facility. For some projects less frequent inspections may be permissible where hazard potential and structural integrity warrant such relaxation.

To maintain control of the inspection program, a formal inspection schedule should be maintained which lists each feature to be inspected, frequency of inspection, date last inspected, date of last inspection report, maintenance record, description of repairs made, and date of next inspection. The schedule should also have a note on major alterations that are made.

Inspection personnel should be selected carefully, have qualifications commensurate with their assigned levels of responsibility, and receive training in the inspection procedures. Qualifications and training required for inspection personnel may vary with the complexity of the facility and with the level of inspection.

(1) Informal Inspections. The purpose of informal inspections is to have as far as practicable a continuous surveillance of the dam. Employees at the project are to make frequent observations of the dam and appurtenances and of operation and maintenance. They are to identify and report abnormal conditions in accordance with adequate instructions and guidance. A detailed checklist of items to be inspected may be provided. The instructions or checklists should be prepared specifically for the project by engineering and operating specialists. The personnel performing these inspections should be properly trained and made aware of the heavy reliance placed upon them, and the great importance and absolute necessity of their careful inspection and reporting. Any unusual conditions that seem critical or dangerous should be reported

immediately to the agency's inspection organization or to those assigned inspection responsibility.

Particular attention should be given to detecting evidence of (or changes in) leakage, erosion, sinkholes, boils, seepage, slope instability, undue settlement, displacement, tilting, cracking, deterioration, and improper functioning of drains and relief wells.

(a) Frequency of informal inspections. Informal inspections should be scheduled by experienced, trained engineers as needed according to the dam's size, importance, and potential for loss of life and damage to property. The schedule for inspection should be changed by the engineers as required to be responsive to observed changing conditions.

Operating personnel should make an inspection immediately after any unusual event such as large floods, earthquakes, suspected sabotage, or vandalism.

(b) Qualifications of personnel for informal inspections. Informal inspections in most instances can be performed satisfactorily by dam tenders or operation and maintenance personnel not formally educated in the field of engineering or geology. Persons selected to make informal inspections, however, must have sufficient training and experience to allow them to recognize abnormal conditions, must have demonstrated their ability to perform operation and maintenance functions, and must have an appreciation for the importance of their responsibilities. They must be provided adequate written instructions on performance of responsibilities and must be evaluated periodically to assure that they understand the requirements and are capable of performing them. In addition, procedures for monitoring structural performance, observing the structure, its foundation, abutments, and appurtenances, and reporting abnormal conditions must be clearly defined and understood by these personnel.

(2) Intermediate Inspections. Intermediate inspections should include a thorough field inspection of the dam and appurtenant structures, and a review of the records of inspections made at and following the last formal inspection. If unusual conditions are observed that are outside the expertise of these inspectors, arrangements should be made for inspections to be conducted by specialists.

(a) Frequency of intermediate inspections. Intermediate inspections should be performed preferably on an annual basis, but at least biennially, where there is a high probability that dam failure could result in loss of life. For other dams, intermediate inspections should be scheduled by responsible engineers on the basis of the dam's size, importance, and potential for damage to property.

(b) Qualifications of personnel for intermediate inspections. Intermediate inspections should be performed by technically qualified engineers, experienced in the operation and maintenance of dams and trained to recognize abnormal conditions. The inspectors should have access to and be familiar with all permanent documentation, especially the operation and maintenance histories for the dam and should be directly responsible for and intimately familiar with the operating characteristics of the dam. The dam tender or operator should be a participant in these inspections.

(3) Formal and Special Inspections. A formal inspection is required periodically to verify the safety and integrity of the dam and appurtenant structures. Formal inspections should include a review to determine if the structures meet current accepted design criteria and practices. The inspection should include a review of all pertinent documents including instrumentation, operation, and maintenance and, to the degree necessary, documentation on investigation, design, and construction. In making the detailed inspection of the dam appurtenant structures and equipment, diving inspections of underwater structures affecting the integrity of the dam should be included. All formal inspections should be conducted by a team of highly trained specialists. To assure that a dam and its appurtenant facilities are thoroughly inspected, checklists should be prepared to cover the condition of structural, electrical, and mechanical features. This inspection should also verify that operating instructions are available and understood, instrumentation is adequate and data is assessed to assure structures are performing as designed, and there are emergency provisions for access to and communication with all project operating facilities.

(a) Frequency of formal inspections. Formal inspections should be made periodically at intervals not to exceed 5 years. Depending on past experience or the project history, some dams may require more frequent formal inspections.

(b) Frequency of special inspections. Special inspections should be performed immediately after the dam has passed unusually large floods and after the occurrence of significant earthquakes, sabotage, or other unusual events reported by operating personnel.

(c) Qualifications of personnel for formal and special inspections. Formal and special inspections should be conducted under the direction of licensed professional engineers experienced in the investigation, design, construction, and operation of dams. The inspection team should be chosen on a site-specific basis considering the nature and type of the dam. The inspection team should comprise individuals having appropriate specialized knowledge in structural, mechanical, electrical, hydraulic, and embankment design; geology; concrete materials; and construction procedures. They must be capable of interpreting structural performance and relating conditions found to current criteria and safety aspects. It is imperative that the inspection team adequately prepare for the inspections by reviewing and discussing all documents relative to the safety of the dam.

c. Instrumentation

Instrumentation or performance observation devices are used to supplement visual inspections in evaluating the performance and safety of dams. Careful examination of instrumentation data on a continuing basis may reveal a possible critical condition. Conversely, instrumentation may be a means of assuring that an observed condition is not serious and does not require immediate remedial measures.

(1) Adequacy of Instrumentation. Instrumentation to monitor structural and functional performance should be installed in dams where complex or unusual site conditions have been encountered or where there is a high probability that failure could result in loss of life or extensive property damage. Instruments should be examined periodically for proper functioning. The adequacy of the installed instrumentation should be assessed from time to

time by specialists to determine if it is sufficient to help evaluate the performance of the dam. When required, additional instrumentation should be installed to confirm suspicious trends or to explore an indicated potential adverse trend.

(2) Observation of Monitoring Devices. The instrumentation data should be collected by personnel trained specifically for the purpose, including training to recognize and immediately report to those responsible for inspections any anomalies in the readings or measurements. Performance observation data should be properly tabulated for record purposes.

(a) Frequency of observations. The frequency of instrument readings should be established at the time the instrumentation system is designed in order to give a timely warning of possible adverse conditions. Whenever necessary, more frequent readings, sometimes as often as hourly, should be taken to monitor a suspected rapidly changing adverse condition. The frequency or number of readings may be reduced after the project has been in operation for an extended time and performance observation data indicates that readings have stabilized.

(3) Data Analysis. It is essential that instrumentation data be processed, reviewed and assessed in a timely manner by specialists familiar with the design, construction, and operation of the project. Operation manuals and design information should be referred to in the evaluation of possible adverse trends. The performance observation data should be periodically analyzed to determine whether project structures are reacting as assumed in the design, and to detect behavior conditions that may indicate the need for corrective action.

d. Correction of Deficiencies

The inspection program could reveal those deficiencies or potential deficiencies which, if uncorrected, could eventually lead to failure of the dam. Deficiencies may vary from emergency type items where immediate action is required, to non-emergency type items which must be corrected in a timely manner but do not present an immediate danger to the safety of the structure. In all cases corrective action should be made under the supervision of qualified personnel. Emergency action plans to be implemented when failure has already occurred or is imminent are discussed in Section III.D.3, Emergency Action Planning.

(1) High Priority Corrective Action. High priority corrective action is required for deficiencies which could result in failure of the dam within a short period of time. Heads of agencies should have authorities, procedures and levels of delegation for transfer of funds and other emergency funding provisions to ensure they are adequate for accomplishing corrective actions in cases where time constraints will not permit allocation through the normal budget process. Procedures for seeking transfer authority beyond that delegated to the agency and/or requests for supplemental appropriations should also be reviewed to ensure such requests can be forwarded quickly and with all necessary supporting documentation to enable expeditious action by the President and/or the Congress.

(2) Non-emergency Corrective Action. Non-emergency corrective action is action taken when there is no immediate threat to the safety or operation of the dam, nor any threat to life or property downstream. The corrective action should be scheduled in advance of the fiscal year in which the work is to be done to allow time for planning, funding through the normal

budgeting process, and arranging for special reservoir operations when required. Some of these deficiencies may be corrected through the regular operation and maintenance program discussed in Section III.D.1, Operation and Maintenance.

(3) Follow-up Action. Periodic inspection reports should continue to list previously identified deficiencies along with any newly discovered deficiencies and show the status of corrective action. Appropriate inspection personnel should make frequent field examinations as long as the problem exists to see all corrective measures are being completed. When deficiencies are not corrected in a reasonable length of time, an investigation should be made to determine the reason for delay and appropriate management personnel should be notified of the findings.

e. Documentation

Proper documentation of the dam's current condition and past performance is necessary to assess the adequacy of operation, maintenance, surveillance, and proposed corrective actions. A complete record or history of the investigation, design, construction, operation, maintenance, surveillance, periodic inspections, modifications, repair, and remedial work should be established and maintained so that relevant data relating to the dam is preserved and readily available for reference. This documentation should commence with the initial site investigation for the dam and continue through the life of the structure.

(1) Instrumentation. All instrumentation observation data and evaluations thereof should be properly tabulated and documented for record purposes. Maintenance of instrumentation systems requires that details of the installation be available for a clear understanding of its functioning. A complete history of past repairs, testing, readings, and analyses should be available as pertinent reference data in the evaluation of current instrumentation data.

(2) Inspections. All inspection observations, especially as related to the safety of the dam, should be documented. The extent and nature of inspection reports required for the informal, intermediate formal, and special inspections will vary in proportion to the intensity of the inspection and the nature of the findings. Informal inspection reports may range from memoranda to supervisors which describe conditions and corrective actions, to detailed accounts of an event or occurrence. Intermediate inspection reports may vary from similar memoranda or trip reports to more formal reports containing substantial records, detail, and recommendations. Formal and special inspections require complete formal technical reports of all findings, corrective actions and recommendations, for permanent record and reference purposes in order to form a basis for major remedial work when required.

All reports should be in a self-explanatory form that permits their retention as permanent records and should carefully document times of inspections, inspection personnel, and findings of the inspection.

(3) Correction of Deficiencies. All deficiencies corrected as a result of the recommendations contained in periodic inspection reports should be fully documented in report form and made a part of the permanent project record. Alterations made to the facility as a result of changes in criteria to meet current practices or changes in dam technology should be fully documented, including as-constructed drawings.

3. Emergency Action Planning

a. General

It is intended that the guidelines for the design, construction, operation and maintenance, and inspection of dams will minimize the risk of future dam failures. Nevertheless, it is recognized that despite the adequacy of those guidelines and their implementation, the possibility of dam failures still exists**.** Even though the probability of such failures is small, preplanning is required to identify conditions which could lead to failure, in order to initiate emergency measures to prevent such failures as a first priority, and, if this is not possible, to minimize the extent and effects of such failure. These guidelines provide operating and mobilization procedures to be followed upon indication of an impending or possible dam failure or a major flood.

Each Federal agency which owns or is responsible for dams and each public or private owner of a Federally regulated dam (hereinafter, dam agency or owner) should evaluate the possible modes of failure of each dam, indicators or precursors of failure for each mode, possible emergency actions appropriate for each mode, and the effects on downstream areas of failure by each mode. In every case the evaluation should recognize the possibility of sudden failure, and should provide a basis for such "worst case" emergency planning actions in terms of notification and evacuation procedures where failure would pose a significant danger to human life and property. Plans should then be prepared in a degree of detail commensurate with the hazard, and instructions provided to operators and attendants regarding the actions to be taken in an emergency. Planning should be coordinated with local officials, as necessary, to enable those officials to draw up a workable plan for notifying and evacuating local communities when conditions affecting dam safety arise.

b. Evaluation of Emergency Potential

Prior to development of an emergency action plan, consideration must be given to the extent of land areas, and types of development with the areas, that would be inundated as a result of dam failure or flood, and the time available for emergency response.

(1) Determination of Mode of Dam Failure. There are many potential causes and modes of dam failure, depending upon the type of structure and its foundation characteristics. Similarly, there are degrees of "failure" and, often progressive stages of failure. Many dam failures can be prevented from reaching a final catastrophic stage by recognition of early indicators or precursor conditions, and by prompt, effective emergency actions. While emergency planning should emphasize preventive actions, recognition must be given to the catastrophic condition and hazard potential. Analysis should be made to determine the most likely mode of dam failure under the most adverse condition and the resulting peak water outflow following the failure. Where there is a series of dams on the stream, analyses should include consideration of

the potential for progressive "domino" failure of the dams.

(2) Inundation Maps. To evaluate the effects of dam failure, maps should be prepared delineating the area which would be inundated in the event of failure. Land uses and significant development or improvements within the area of inundation should be indicated. The maps should be equivalent to or more detailed than the United States Geological Survey (USGS) quadrangle maps, 7-1/2 minute series, or of sufficient scale and detail to identify clearly the area that should be evacuated if there is evident danger of failure of the dam. Copies of the maps should be distributed to local government officials for use in the development of an evacuation plan.

(3) Classification of Inundation Areas. To assist in the evaluation of hazard potential, areas delineated on inundation maps should be classified in accordance with the degree of occupancy and hazard potential. The potential for loss of life is affected by many factors, including but not limited to the capacity and number of exit roads to higher ground and available transportation. Hazard potential is greatest in urban areas. Since the extent of inundation is usually difficult to delineate precisely because of topographic map limitations, the evaluation of hazard potential should be conservative.

The hazard potential for affected recreation areas varies greatly, depending on the type of recreation offered, intensity of use, communication facilities, and available transportation. The potential for loss of life may be increased where recreationists are widely scattered over the area of potential inundation since they would be difficult to locate on short notice.

Many industries and utilities requiring substantial quantities of water for one or more stages in the manufacture of products or generation of power are located on or near rivers or streams. Flooding of these areas and industries can, in addition to causing the potential for loss of life, damage to machinery, manufactured products, raw materials and materials in process of manufacture, interrupt essential community services.

Rural areas usually have the least hazard potential. However, the potential for loss of life exists, and damage to large areas of intensely cultivated agricultural land can cause high economic loss.

(4) Time Available for Response. Analyses should be made to evaluate the structural, foundation, and other characteristics of the dam and determine those conditions which could be expected to result in slow, rapid or practically instantaneous dam failure.

c. Actions to Prevent Failure or Minimize Effects of Failure

(1) Development of Emergency Action Plan. An emergency action plan should be developed for each dam that constitutes a hazard to life and property, incorporating preplanned emergency measures to be taken prior to and following assumed dam failure. The plan should be coordinated with local governmental and other authorities involved in public safety and be approved by appropriate top level agency or owner management. To the extent possible, the emergency action plan should define emergency situations that require immediate notification of local officials. The emergency action plan should include notification plans, which are

discussed in section (2) below.

Emergency scenarios should be prepared for possible modes of failure for each dam. Periodically these scenarios should be used to test the readiness capabilities of project staff and logistics.

A procedure should be established for review and revision, as necessary, of the emergency action plan, including notification plans and evacuation plans, at least once every 2 years. Such reviews should be coordinated among all organizations responsible for preparation and execution of the plans.

(2) Notification Plans. Plans for notification of key personnel and the public are an integral part of the emergency action plan and should be prepared for slowly developing, rapidly developing, and instantaneous dam failure conditions. Notification plans should include a list of names and position titles, addresses, office and home telephone numbers, and radio communication frequencies and call signals, if available, for agency or owner personnel, public officials, and other personnel and alternates who should be notified as soon as emergency situations develop. A procedure should be developed to keep the list current.

Each type of notification plan should contain the order in which key agency or owner supervisory personnel or alternates should be notified. At least one key supervisory level or job position should be designated to be manned or the responsible person should be immediately available by telephone or radio 24 hours a day. A copy of each notification plan must be posted in a prominent place at the project site near a telephone and/or radio transmitter. All project personnel should be familiar with the plans and the procedures each is to follow in the event of an emergency. Copies of the notification plans should be readily available at the home and the office of each person involved.

Where dams located upstream from the dam for which the plan is being prepared could be operated to reduce inflow or where the operation of downstream dams would be affected by failure of the dam, operators of those dams should be kept informed of the current and expected conditions of the dam as the information becomes available.

Civil defense officials having jurisdiction over all or part of the area subject to inundation should receive early notification. Local law enforcement officials and, when possible, local government officials and public safety officials should receive early notification.

The capabilities of the Defense Civil Preparedness Agency's National Warning System (NAWAS) should be determined for the project and utilized as appropriate. Information can be obtained from State or local civil defense organizations.

Potentially affected industries downstream should be kept informed so that actions to reduce risk of life and economic loss can be taken. Coordination with local government and civil defense officials would determine responsibility for the notification. Normally, this would be a local government responsibility.

When it is determined that a dam may be in danger of failing, the public officials responsible for the decision to implement the evacuation plan should be kept informed of the developing emergency conditions.

The news media, including radio, television, and newspapers, should be utilized to the extent available and appropriate. Notification plans should define emergency situations for which each medium will be utilized and should include an example of a news release that would be the most effective for each possible emergency. Use of news media should be preplanned insofar as is possible by agency and owner personnel and the State and/or local government. Information should be written in clear, concise language. Releases to news media should not be relied upon as the primary means of notification.

Notification of recreation users is frequently difficult because the individuals are often alone and away from any means of ready communication. Consideration should be given to the use of standard emergency warning devices such as sirens at the dam site. Consideration should be given to the use of helicopters with bullhorns for areas further downstream. Vehicles equipped with public address systems and helicopters with bullhorns are capable of covering large areas effectively.

Telephonic communication should not be solely relied on in critical situations. A backup radio communication system should be provided and tested at least once every 3 months. Consideration should be given to the establishment of a radio communication system prior to the beginning of construction and to the maintenance of the system throughout the life of the project.

(3) Evacuation Plans. Evacuation plans should be prepared and implemented by the local jurisdiction controlling inundation areas. This would normally not be the dam agency or owner. Evacuation plans should conform to local needs and vary in complexity in accordance with the type and degree of occupancy of the potentially affected area. The plans may include delineation of area to be evacuated; routes to be used; traffic control measures; shelter, methods of providing emergency transportation; special procedures for the evacuation and care of people from institutions such as hospitals, nursing homes, and prisons; procedures for securing the perimeter and for interior security of the area; procedures for the lifting of the evacuation order and reentry to the area; and details indicating which organizations are responsible for specific functions and for furnishing the materials, equipment, and personnel resources required.

The assistance of local civil defense personnel, if available, should be requested in preparation of the evacuation plan. State and local law enforcement agencies usually will be responsible for the execution of much of the plan and should be represented in the planning effort. State and local laws and ordinances may require that other State, county, and local government agencies have a role in the preparation, review, approval, or execution of the plan. Before finalization, a copy of the plan should be furnished to the dam agency or owner for information and comment.

(4) Stockpiling Repair Materials. Suitable construction materials should be stockpiled for

emergency use. The amounts and types of construction materials needed for emergency repairs should be determined based on the structural, foundation, and other characteristics of the dam; design and construction history; and history of prior problems.

(5) Locating Local Repair Forces. Arrangements should be made with, and a current list maintained of, local entities, including contractors, and Federal, State and local construction departments, for possible emergency use of equipment and labor.

(6) Training Operating Personnel. Technically qualified project personnel should be trained in problem detection, evaluation, and appropriate remedial (emergency and non-emergency) measures. This is essential for proper evaluation of developing situations at all levels of responsibility which, initially, must be based on at-site observations. A sufficient number of personnel should be trained to assure adequate coverage at all times. If a dam is operated by remote control, arrangements must be made for dispatching trained personnel to the project at any indication of distress.

(7) Increasing Inspection Frequency. Frequency of appropriate surveillance activities should be increased when the reservoir level exceeds a predetermined elevation. Piezometers, water level gauges, and other instruments should be read frequently and on schedule. The project structures should be inspected as often as necessary to monitor conditions related to known problems and to detect indications of change or new problems that could arise. Hourly or continuous surveillance may be mandated in some instances. Any change in conditions should be reported promptly to the supervisor for further evaluation.

The supervisor should issue additional instructions, as necessary, and alert repair crews and contractors for necessary repair work if developing conditions indicate that emergency repairs or other remedial measures may be required.

d. Actions Upon Discovery of a Potentially Unsafe Condition

Action to be taken will depend on the nature of the problem and the time estimated to be available for remedial or mitigation measures. As time permits, one or more of the following actions will be required.

(1) Notification of Supervisory Personnel. This is essential, if time permits, since development of failure could vary in some or many respects from previous forecasts or assumptions, and advice may be needed.

(2) Initiation of Predetermined Remedial Action. It is imperative that at least one technically qualified individual, previously trained in problem detection, evaluation, and remedial action, be at the project or on call at all times. Depending on the nature and seriousness of the problem and the time available, emergency actions can be initiated, such as lowering the reservoir and holding water in upstream reservoirs. Other actions to be taken include notifying appropriate highway and traffic control officials promptly of any rim slides or other reservoir embankment failures which may endanger public highways.

(3) Determination of Need for Public Notification. To the extent possible, emergency situations

that will require immediate notification of public officials in time to allow evacuation of the potentially affected area should be predefined for the use of management and project personnel. If sufficient time is available, the decision to notify public officials that the dam can be expected to fail will be made at a predetermined supervisory level within the agency or owner organization. If failure is imminent or has already occurred, project personnel at the dam site would be responsible for direct notification of the public official. The urgency of the situation should be made clear so that public officials will take positive action immediately.

APPENDIX A
FCCSET *AD HOC* INTERAGENCY COMMITTEE MEMBERS

Members

Phillip M. Smith (Chairman)
Assistant Director for Natural Resources and Commercial Services
Office of Science and Technology Policy
Washington, D.C.

William S. Bivins
Hydrology and Meteorology Branch
Director of Site Safety and Environmental Analysis
Nuclear Regulatory Commission
Washington, D.C.

Neil F. Bogner
Director, Engineering Division
Soil Conservation Service
Department of Agriculture
Washington, D.C.

George L. Buchanan
Chief, Civil Engineering and Design Branch
Division of Engineering Design
Office of Engineering Design and Construction
Tennessee Valley Authority
Knoxville, Tennessee

Donald Dillon
Deputy for Policy Planning and Legislative Analysis
Department of the Army
Washington, D.C.

Joseph Friedkin
Commissioner, U.S. Section
International Boundary and Water Commission
Washington, D.C.

Gary Wicks
Deputy Assistant Secretary for Land and Water Resources
Department of the Interior
Washington, D.C.

Gerald R. Wilson, Jr.
Chief, Project Analysis Branch
Licensed Projects Division
Federal Energy Regulatory Commission
Washington, D.C.

APPENDIX D
ACKNOWLEDGMENTS

The authority for preparation of the guidelines is given in section I.B. They were prepared by an interagency guidelines task group composed of the Chairmen of the subcommittees identified in Appendix B. Specific sections preparation assignments were:

Section I. SID Chairman, George L. Buchanan, TVA

Section II, CON Chairman, Donald A. Giampaoli, BoR, and O&M Chairman, Gerald R. Wilson, FERC, with the cooperation of L. Douglas James, representative of the Independent Review Panel (Appendix C) to the guidelines task group, and Bruce A. Tschantz, consultant to OSTP and advisor to the task group.

Section III A. and III.B. SID Chairman

Section III.C. CON Chairman

Section III.D. O&M Chairman

The Chairmen were assisted by their subcommittee and task groups members (listed in Appendix B).

Reviews were made by subcommittee members and by representatives of the agencies other than the preparing agency and by L. Douglas James of the Independent Review Panel. Major contributory reviews were made by representatives of the major dam building agencies, BoR, Corps, SCS, and TVA, and the Independent Review Panel member.

Editing and assembly of the final working draft for submittal to FCCSET were handled by the SID Chairman (TVA). Oliver H. Raine of the SID Chairman's engineering staff assisted in the preparation and review of various portions of the guidelines and in the editing and assembly of the working draft.

FEMA

FEDERAL GUIDELINES FOR DAM SAFETY: SELECTING AND ACCOMMODATING INFLOW DESIGN FLOODS FOR DAMS

prepared by the
INTERAGENCY COMMITTEE ON DAM SAFETY

U.S. DEPARTMENT OF HOMELAND SECURITY
FEDERAL EMERGENCY MANAGEMENT AGENCY
OCTOBER 1998

Reprinted April 2004

PREFACE

In April 1977, President Carter issued a memorandum directing the review of federal dam safety activities by an *ad hoc* panel of recognized experts. In June 1979, the *ad hoc* interagency committee on dam safety (ICODS) issued its report, which contained the first guidelines for federal agency dam owners. The Federal Guidelines for Dam Safety (Guidelines) encourage strict safety standards in the practices and procedures employed by federal agencies or required of dam owners regulated by the federal agencies. The Guidelines address management practices and procedures but do not attempt to establish technical standards. They provide the most complete and authoritative statement available of the desired management practices for promoting dam safety and the welfare of the public.

To supplement the Guidelines, ICODS prepared and approved federal guidelines in the areas of emergency action planning; earthquake analysis and design of dams; and selecting and accommodating inflow design floods for dams. These publications, based on the most current knowledge and experience available, provided authoritative statements on the state of the art for three important technical areas involving dam safety. In 1994, the ICODS Subcommittee to Review/Update the Federal Guidelines began an update to these guidelines to meet new dam safety challenges and to ensure consistency across agencies and users. In addition, the ICODS Subcommittee on Federal/Non-Federal Dam Safety Coordination developed a new guideline, Hazard Potential Classification System for Dams.

With the passage of the National Dam Safety Program Act of 1996, Public Law 104-303, ICODS and its Subcommittees were reorganized to reflect the objectives and requirements of Public Law 104-303. In 1998, the newly convened Guidelines Development Subcommittee completed work on the update of all of the following guidelines:

- Federal Guidelines for Dam Safety: Emergency Action Planning for Dam Owners
- Federal Guidelines for Dam Safety: Hazard Potential Classification System for Dams
- Federal Guidelines for Dam Safety: Earthquake Analyses and Design of Dams
- Federal Guidelines for Dam Safety: Selecting and Accommodating Inflow Design Floods for Dams
- Federal Guidelines for Dam Safety: Glossary of Terms

The publication of these guidelines marks the final step in the review and update process. In recognition of the continuing need to enhance dam safety through coordination and information exchange among federal and state agencies, the Guidelines Development Subcommittee will be responsible for maintaining these documents and establishing additional guidelines that will help achieve the objectives of the National Dam Safety Program.

The members of all of the Task Groups responsible for the update of the guidelines are to be commended for their diligent and highly professional efforts:

Harold W. Andress, Jr.
Chairman, Interagency Committee on Dam Safety

I. INTRODUCTION

A. Purpose

The purpose of these Guidelines is to provide thorough and consistent procedures for selecting and accommodating Inflow Design Floods (IDFs). The IDF is the flood flow above which the incremental increase in water surface elevation downstream due to failure of a dam or other water retaining structure is no longer considered to present an unacceptable additional downstream threat.

B. Background

Current practice in the design of dams is to use the IDF that is deemed appropriate for the hazard potential of the dam and reservoir, and to design spillways and outlet works that are capable of safely accommodating the floodflow without risking the loss of the dam or endangering areas downstream from the dam to flows greater than the inflow. However, there are many dams whose discharge capabilities were designed using methods that are now considered unconservative and potentially unsafe.

Inflow design flood selection began primarily as a practical concern for protection of a dam and the benefits it provides. The early 1900's saw an increase in the Nation's social awareness that was demonstrated by various legislative acts designed to protect the public from certain high risk activities. The same era witnessed an increase in the number and size of dams built. When the "big dam" era began in the 1930's, safety clearly became a more dominant factor. It was recognized that dams needed to be designed to accommodate water flows that might be greater than the anticipated "normal" flow.

1. Early Periods. Before 1900, designers of dams had relatively little hydrologic data or tools to indicate flood potential at a proposed dam site. Estimates of flood potential were selected by empirical techniques and engineering judgment based on high water marks or floods of record on streams being studied.

Later, engineers began examining all past flood peaks in a region to obtain what was hoped to be a more reliable estimate of maximum flood-producing potentials than a limited record on a single stream. Designers would base their spillway design on these estimates, sometimes providing additional capacity as a safety factor. Some spillways were designed for a multiple of the maximum known flood, for example, twice the maximum known flood. The multiples and safety factors were based on engineering judgment; the degree of conservatism in the design was unknown.

By the 1930's, it became apparent that this approach was inadequate. As longer hydrologic records were obtained, new floods exceeded previously recorded maximum floods. With the introduction of the unit hydrograph concept by Sherman in 1933, it became possible to estimate floodflows from storm rainfall. The design of dams began to be based upon the transposition of major storms that had occurred within a region, *i.e.*,

transfer and centering of relevant storm rainfall patterns over the basin above the dam site being evaluated. It was recognized that flood peaks are dependent on topography, size of individual watersheds, and chance placement of the storm's center over the watershed. In addition, within meteorologically similar areas, observed maximum rainfall values could provide a better indication of maximum flood potentials than data on flood discharges from individual watersheds. If, in the judgment of the designer, the storm was not representative of what might occur, rainfall amounts were increased to represent a more severe event, and the dam was designed accordingly.

2. Transition. Engineers next turned to hydrometeorologists to determine if upper limits for rates of precipitation could be established on a rational basis. Careful consideration was given to the meteorology of storms that produced major floods in various parts of the country. The large scale features of the storm and measures of atmospheric moisture, such as dewpoint temperatures, were considered as well as the rainfall depth-area-duration values produced by these storms. It was then possible to increase the storm dewpoint temperature and other factors affecting rainfall to the maximum appropriate values. This increase resulted in estimates of probable maximum precipitation (PMP), and thus introduced the concept of a physical upper limit to precipitation. When translated to runoff, the estimated floodflow is known as the probable maximum flood (PMF).

At first, the terms maximum possible precipitation and maximum possible flood were used. However, the terminology was changed to probable maximum to recognize the uncertainties in the estimates of the amount of precipitation, and the most severe combination of critical meteorological and hydrologic conditions that are reasonably possible in the region. Today, the PMF is generally accepted as the standard for the safety design of dams where the incremental consequences of failure have been determined to be unacceptable.

In the late 1940's, the ability to estimate the consequences of dam failure, including the loss of life, was still quite limited. The height of the downstream flood wave and the extent of wave propagation were known to be a function of dam height and reservoir volume. Thus, early standards for dam design were based upon the size of the dam in terms of its height, the reservoir storage volume, and the downstream development.

The practice of setting inflow design flood standards based upon the size of a dam, its reservoir volume, and current downstream development resulted in an inconsistent level of design throughout the country. The determination of the consequences of a dam failure is more complex than can be evaluated by these simple relationships.

3. Current Practices. In 1985, the National Academy of Sciences (NAS) published a study of flood and earthquake criteria which contained an inventory of current practices in providing dam safety during extreme floods. The inventory showed considerable diversity in approach by various federal, state, and local government agencies,

professional societies, and private firms. While the inventory shows a fair consensus on spillway requirements for dams having a high-hazard potential, there is a wide range of criteria being applied to dams with lower hazard classifications.

Several observations about the evaluation of hydrologic conditions were made in the NAS study. Use of PMP for evaluating spillway capacity requirements for large, high-hazard dams predominates, although some state agencies have standards that do not require such dams to pass the full estimated PMF based on the PMP. The influence of the principal federal dam-building and dam safety agencies is evident in the majority of the standards for large, high-hazard dams, but the practices of those agencies have had less effect on current state standards for small dams in less hazardous situations.

As a result of inspections authorized by Public Law 92-367, the National Dam Inspection Act, and carried out by the U.S. Army Corps of Engineers from 1977 to 1981, several states have adopted the spillway capacity criteria used in those inspections. Several other states have adopted the standards used by the Natural Resources Conservation Service (formerly the Soil Conservation Service) for the design of smaller dams constructed under that agency's programs.

Most agencies draw a distinction between design criteria that are applied to existing dams and those that are applied to new dams. However, because dam failures present the same consequences to life and property, it is desirable that existing dams meet the criteria established for new dams.

Today, hydrologically safe designs should be based on current state-of-the-art criteria. Now that engineers can estimate downstream flood levels resulting from dam failure, safety design standards can be tied specifically to a detailed evaluation of the impacts of a flood if a dam were to fail. Although debate continues over the proper criteria and degree of conservatism warranted when evaluating and designing modifications to existing dams, and when designing new dams, criteria used by dam designers, regulators, and owners now focus on ensuring public safety.

C. Scope

1. General. These Guidelines are not intended to provide a complete manual of all procedures used for estimating inflow design floods; the selection of procedures is dependent upon available hydrologic data and individual watershed characteristics. All studies should be performed by an engineer experienced in hydrology and hydraulics, directed and reviewed by engineers experienced in dam safety, and should contain a summary of the design.

2. Philosophy and Principles. The basic philosophy and principles are described in sufficient detail to achieve a reasonable degree of uniformity in application, and to achieve a consistent and uniform nationwide treatment among federal agencies in the design of dams from the standpoint of hydrologic safety.

3. Content. The following topics are discussed in these Guidelines:

- Selecting the IDF - The selection of the appropriate IDF for a dam is related to the hazard potential classification and is the result of the incremental hazard evaluation.

- Accommodating the IDF - Site-specific considerations are necessary to establish hydrologic flood routing criteria for each dam and reservoir. The criteria for routing the IDF or any other flood should be consistent with the reservoir regulation procedure that is to be followed in actual operation.

II. DEFINITION OF TERMS

This chapter contains definitions of technical terms used in these Guidelines.

Breach: An opening through a dam which drains the reservoir. A controlled breach is a constructed opening. An uncontrolled breach is an unintentional discharge from the reservoir.

Concurrent Inflows: Flows expected on tributaries to the river system downstream of the dam at the same time a flood inflow occurs.

Concurrent Floods: Flows expected on the river to which the river system with a dam is a tributary at the same time a flood inflow occurs at the reservoir.

Dam Failure: The catastrophic breakdown of a dam, characterized by the uncontrolled release of impounded water. There are varying degrees of failure.

Deterministic Methodology: A method in which the chance of occurrence of the variable involved is ignored and the method or model used is considered to follow a definite law of certainty, and not probability.

Dewpoint Temperature: The temperature at which dew begins to form or vapor begins to condense into a liquid.

Dynamic Routing: Hydraulic flow routing based on the solution of the St.-Venant Equation(s) to compute the changes of discharge and stage with respect to time at various locations along a stream.

Embankment Dam: Any dam constructed of excavated natural materials (includes both earthfill and rockfill dams).

Erosion: The wearing away of a surface (bank, streambed, embankment) by floods, waves, wind, or any other natural process.

Flashboards: Structural members of timber, concrete, or steel placed in channels or on the crest of a spillway to raise the reservoir water level but are intended to be quickly removed, tripped or fail, in the event of a flood.

Flood: A temporary rise in water surface elevation resulting in inundation of areas not normally covered by water. Hypothetical floods may be expressed in terms of average probability of exceedance per year such as one-percent-chance flood, or expressed as a fraction of the probable maximum flood or other reference flood.

Flood Plain: The downstream area that would be inundated or otherwise affected by the failure of a dam or by large flood flows.

Flood Routing: A process of determining progressively the amplitude of a flood wave as it moves past a dam and continues downstream.

Flood Storage: The retention of water or delay of runoff either by planned operation, as in a reservoir, or by temporary filling of overflow areas, as in the progression of a flood wave through a natural stream channel.

Freeboard: Vertical distance between a specified stillwater reservoir surface elevation and the top of the dam, without camber.

Foundation: The portion of the valley floor that underlies and supports the dam structure.

Gate: A movable water barrier for the control of water.

Hazard: A situation which creates the potential for adverse consequences such as loss of life, property damage, or other adverse impacts. Impacts in the area downstream of a dam are defined by the flood waters released through spillways and outlet works of the dam or waters released by partial or complete failure of the dam. There may also be impacts upstream of the dam due to backwater flooding or landslides around the reservoir perimeter.

Hazard Potential Classification: A system that categorizes dams according to the degree of adverse incremental consequences of a failure or misoperation of a dam. The Hazard Potential Classification does not reflect in any way on the current condition of the dam (*i.e.*, safety, structural integrity, flood routing capacity).

Hydrograph, Flood: A graphical representation of the flood discharge with respect to time for a particular point on a stream or river.

Hydrology: One of the earth sciences that encompasses the natural occurrence, distribution, movement, and properties of the waters of the earth and their environmental relationships.

Hydrometeorology: The study of the atmospheric and land-surface phases of the hydrologic cycle with emphasis on the interrelationships involved.

Inflow Design Flood (IDF): The flood flow above which the incremental increase in downstream water surface elevation due to failure of a dam or other water impounding structure is no longer considered to present an unacceptable additional downstream threat. The IDF of a dam or other water impounding structures is the flood hydrograph

used in the design or evaluation of a dam, its appurtenant works, particularly for sizing the spillway and outlet works, for determining maximum height of a dam, freeboard, and flood storage requirements. The upper limit of the IDF is the probable maximum flood.

Intake: Placed at the beginning of an outlet-works waterway (power conduit, water supply conduit), the intake establishes the ultimate drawdown level of the reservoir by the position and size of its opening(s) to the outlet works. The intake may be vertical or inclined towers, drop inlets, or submerged, box-shaped structures. Intake elevations are determined by the head needed for discharge capacity, storage reservation to allow for siltation, the required amount and rate of withdrawal, and the desired extreme drawdown level.

Inundate: To overflow, to flood.

Inundation Map: A map showing areas that would be affected by flooding from an uncontrolled release of a dam's reservoir.

Landslide: The unplanned descent (movement) of a mass of earth or rock down a slope.

Maximum Wind: The most severe wind for generating waves that is reasonably possible at a particular reservoir. The determination will generally include results of meteorologic studies which combine wind velocity, duration, direction, fetch, and seasonal distribution characteristics in a realistic manner.

Meteorological Homogeneity: Climates and orographic influences that are alike or similar.

Meteorology: The science that deals with the atmosphere and atmospheric phenomena, the study of weather, particularly storms and the rainfall they produce.

One-Percent-Chance Flood: A flood that has 1 chance in 100 of being equaled or exceeded during any year.

Orographic: Physical geography that pertains to mountains and to features directly connected with mountains and their general effect on storm path and generation of rainfall.

Outlet Works: A dam appurtenance that provides release of water (generally controlled) from a reservoir.

Probable Maximum Flood (PMF): The flood that may be expected from the most severe combination of critical meteorologic and hydrologic conditions that are reasonably possible in the drainage basin under study.

Probable Maximum Precipitation (PMP): Theoretically, the greatest depth of precipitation for a given duration that is physically possible over a given size storm area at a particular geographical location during a certain time of the year. Reservoir Regulation Procedure (Rule Curve): Refers to a compilation of operating criteria, guidelines, and specifications that govern the storage and release function of a reservoir. It may also be referred to as operating rules, flood control diagram, or water control schedule. These are usually expressed in the form of graphs and tabulations, supplemented by concise specifications and are often incorporated in computer programs. In general, they indicate limiting rates of reservoir releases required or allowed during various seasons of the year to meet all functional objectives of the project.

Reservoir Rim: The boundary of the reservoir including all areas along the valley sides above and below the water surface elevation associated with the routing of the IDF.

Risk: The relationship between the consequences resulting from an adverse event and its probability of occurrence.

Risk-based Analysis: A procedure in which the consequences and risks of adverse events and alternatives for mitigation are evaluated and arranged in a manner that facilitates a decision on the action to be taken. A risk-based analysis may be the basis for the selection of the IDF for a particular dam.

Seiche: An oscillating wave in a reservoir caused by a landslide into the reservoir or earthquake-induced ground accelerations or fault offset.

Sensitivity Analysis: An analysis in which the relative importance of one or more of the variables thought to have an influence on the phenomenon under consideration is determined.

Settlement: The vertical downward movement of a structure or its foundation.

Significant Wave Height: Average height of the one-third highest individual waves. May be estimated from wind speed, fetch length, and wind duration.

Spillway: A structure over or through which flow is discharged from a reservoir. If the rate of flow can be controlled by mechanical means, such as gates, it is considered a controlled spillway. If the geometry of the spillway is the only control, it is considered an uncontrolled spillway. Definitions of specific types of spillways follow:

> **Service Spillway:** A spillway that is designed to provide continuous or frequent regulated or unregulated releases from a reservoir without significant damage to either the dam or its appurtenant structures. This is also referred to as principal spillway.

Auxiliary Spillway: Any secondary spillway which is designed to be operated infrequently, possibly in anticipation of some degree of structural damage or erosion to the spillway that would occur during operation.

Emergency Spillway: A spillway that is designed to provide additional protection against overtopping of dams, and is intended for use under extreme flood conditions or misoperation or malfunction of the service spillway and/or the auxiliary spillway.

Spillway Capacity: The maximum spillway outflow which a dam can safely pass with the reservoir at its maximum level.

Stillwater Level: The elevation that a water surface would assume if all wave actions were absent.

Storm: The depth, area, and duration distributions of precipitation.

Storm Center: Location of the storm pattern such that the precipitation falls on a specific drainage basin to create the runoff at the site under consideration.

Storm Transposition: The application of a storm from its actual location of occurrence to some other area within the same region of meteorological homogeneity. Storm transposition requires the determination of whether the particular storm could occur over the area to which it is to be transposed.

Surcharge: The volume or space in a reservoir between the controlled retention water level and the maximum water level. Flood surcharge cannot be retained in the reservoir but will flow out of the reservoir until the controlled retention water level is reached.

Toe of the Dam: The junction of the downstream slope or face of a dam with the ground surface; also referred to as the **downstream toe**. The junction of the upstream slope with the ground surface is called the heel or the **upstream toe**.

Topographic Map: A detailed graphic delineation (representation) of natural and man-made features of a region with particular emphasis on relative position and elevation.

Tributary: A stream that flows into a larger stream or body of water.

Unit Hydrograph: A hydrograph with a volume of one inch of direct runoff resulting from a storm of a specified duration and areal distribution. Hydrographs from **other storms** of the same duration and distribution are assumed to have the same time base but with ordinates of flow in proportion to the runoff volumes.

Watershed: The area drained by a river or river system.

Wave Runup: Vertical height above the stillwater level to which water from a specific wave will run up the face of a structure or embankment.

Wind Setup: The vertical rise of the stillwater level at the face of a structure or embankment caused by wind stresses on the surface of the water.

III. SELECTING INFLOW DESIGN FLOODS

A. Introduction

Many thousands of dams have been constructed in the United States, and new dams continue to add to this total. The proper operation of dams to withstand natural forces, including extreme hydrologic events, is an important matter of public safety and concern.

In today's technical world, extreme hydrologic events resulting in dam failures are classified as "low-probability, high-consequence" events. In addition, the potential for losses due to increased downstream development may increase the consequences of a dam failure.

There has been a growing concern and increased attention to dam safety over the past two decades, primarily as a result of a number of catastrophic dam failures. As a result, the inspection of non-federal dams authorized by Public Law 92-367, the National Dam Inspection Act, identified some 2,900 unsafe dams of which 2,350 had inadequate spillway capacities. Since there are approximately 23,772 high and significant-hazard dams in the present National Inventory of Dams, the number of dams which have inadequate spillways could be significantly higher.

The adequacy of a spillway must be evaluated by considering the hazard potential, which would result from failure of the project works during flood flows. (See Chapter II for a definition of hazard potential.) If failure of the project works would present an unacceptable downstream threat, the project works must be designed to either withstand overtopping for the loading condition that would occur during a flood up to the probable maximum flood, or to the point where a failure would no longer cause an unacceptable additional downstream threat.

The procedures used to determine whether or not the failure of a project would cause an unacceptable downstream threat vary with the physical characteristics and location of the project, including the degree and extent of development downstream.

Analyses of dam failures are complex, with many historical dam failures not completely understood. The principal uncertainties in determining the outflow from a dam failure involve the mode and degree of failure. These uncertainties can be circumvented in situations where it can be shown that the complete and sudden removal of the dam would not result in unacceptable consequences. Otherwise, reasonable failure postulations and sensitivity analyses should be used. Suggested references regarding dam failure studies are listed in Appendix A. If it is judged that a more extensive mode of failure than that normally recommended for the type of structure under investigation is possible, then analyses should be done to determine whether remedial action is required. Sensitivity studies on the specific mode of failure should be performed when failure is due to overtopping.

B. Hazard Potential Evaluation

A properly designed, constructed, and operated dam can be expected to improve the safety of downstream developments during floods. However, the impoundment of water by a dam can

create a potential hazard to downstream developments greater than that which would exist without the dam because of the potential for dam failure. There are several potential causes of dam failure, including hydrologic, geologic, seismic, and structural.

These Guidelines are limited to the selection of the inflow design flood (IDF) for the hydrologic design of a dam.

1. General. Once a dam is constructed, the downstream hydrologic regime may change, particularly during floods. The change in hydrologic regime could alter land use patterns to encroach on a flood plain that would otherwise not be developed without the dam. **Consequently, evaluation of the consequences of dam failure must be based on the dam being in place, and must compare the impacts of with-failure and without-failure conditions on existing development and known and prospective future development when evaluating the downstream hazard potential.**

2. Hydrologic Modes of Failure. Many dam failures have resulted because of an inability to safely pass flood flows. Failures caused by hydrologic conditions can range from sudden, with complete breaching or collapse, to gradual, with progressive erosion and partial breaching.

The most common modes of failure associated with hydrologic conditions include overtop-ping, erosion of earth spillways, and overstressing the dam or its structural components. The following paragraphs describe briefly each of the modes of failure caused by hydrologic conditions.

a. Overtopping. Overtopping of a dam occurs when the water level in the reservoir exceeds the height of the dam and flows over the crest. Overtopping will not necessarily result in a failure. Failure depends on the type, composition, and condition of the dam and the depth and duration of flow over the dam.

Embankment dams are very susceptible to failure when overtopped because of potential erosion. If the erosion is severe, it can lead to a breach and failure of the dam. During overtopping, the foundation and abutments of concrete dams also can be eroded, leading to a loss of support and failure from sliding or overturning. In addition, when a concrete dam is subjected to overtopping, the loads can be substantially higher than those for which the dam was designed. If the increased loading on the dam itself due to overtopping is too great, a concrete dam can fail by overturning or sliding.

b. Erosion in Earth Spillways. High or large flows through earthen spillways adjacent to dams can result in erosion that progresses to the dam and threatens it. Erosion can also cause headcutting that progresses toward the spillway crest and eventually leads to a breach. Discontinuities in slope, nonuniform vegetation or bed materials, and concentrated flow areas can start headcuts and accelerate the erosion process. Flood depths that exceed the safe design parameters can produce erosive forces that may cause serious erosion in the spillway.

Erosion that occurs due to flow concentrations can start where roads or trails are devoid of vegetation or have ruts that run parallel to the spillway flow. A varied mix of earth materials, unlevel cross sections, uneven stands of vegetation, and obstructions such as trash accumulations can cause turbulent, concentrated flow conditions that start gullies that can widen and migrate upstream to breach the spillway crest.

Runoff brought into a spillway channel by a side inlet may also disrupt the desirable uniform flow pattern and increase the erosion in the channel.

The probability of failure of an earthen auxiliary spillway due to erosion is increased when the capacity of the service spillway inlets (outlet works) or gates are reduced due to trash accumulations. These accumulations reduce the available capacity through these appurtenances and increase the volume, depth, frequency, and duration of flow in the auxiliary spillway.

c. Overstressing of Structural Components. As flood flows enter the reservoir, the reservoir will normally rise to a higher elevation. Even though a dam (both concrete and earth embankment dams) may not be overtopped, the reservoir surcharge will result in a higher loading condition. If the dam is not properly designed for this flood surcharge condition, either the entire dam or the structural components may become overstressed, resulting in an overturning failure, a sliding failure, or a failure of specific structural components (such as the upstream face of a slab and buttress dam). Embankment dams may be at risk if increased water surfaces result in increased pore pressures and seepage rates, which exceed the seepage control measures for the dam.

3. Defining the Hazard Potential. The hazard potential is the possible adverse incremental consequences that result from the release of water or stored contents due to failure of the dam or misoperation of the dam or appurtenances. Hazard potential does not indicate the structural integrity of the dam itself, but rather the effects if a failure should occur. The hazard potential assigned to a dam is based on consideration of the effects of a failure during both normal and flood flow conditions.

Dams assigned the low hazard potential classification are those where failure or misoperation results in no probable loss of human life and low economic and/or environ-mental losses. Losses are principally limited to the owner's property.

Dams assigned the significant hazard potential classification are those dams where failure or misoperation results in no probable loss of human life but can cause economic loss, environmental damage, disruption of lifeline facilities, or can impact other concerns. Significant hazard potential classification dams are often located in predominantly rural or agricultural areas but could be located in areas with population and significant infrastructure.

Dams assigned the high hazard potential classification are those where failure or misoperation will probably cause loss of human life.

The hazard potential classification assigned to a dam should be based on the worst-case failure condition, *i.e.*, the classification is based on failure consequences resulting from the failure condition that will result in the greatest potential for loss of life and property damage. For example, a failure during normal operating conditions may result in the released water being confined to the river channel, indicating a low-hazard potential. However, if the dam were to fail during a floodflow condition, and the resultant incremental flood flow would be a potential loss of life or serious damage to property, the dam would have high-hazard potential classification.

In many cases, the hazard potential classification can be determined by field investigations and a review of available data, including topographic maps. However, when the hazard potential classification is not apparent from field reconnaissance, detailed studies, including dambreak analyses, are required. These detailed studies are required to identify the floodflow condition above which the additional incremental increase in elevation, due to failure of a dam, is no longer considered to present an unacceptable threat to downstream life and property.

The hazard potential classification of a project determines the level of engineering review and the criteria that are applicable. Therefore, it is critical to determine the appropriate hazard potential of a dam because it sets the stage for the analyses that must be completed to properly evaluate the integrity of any dam.

4. Evaluating the Consequences of Dam Failure.
There have been about 200 notable dam failures resulting in more than 8,000 deaths in the Twentieth Century. Dam failure is not a problem confined to developing countries or to a compilation of past mistakes that are unlikely to occur again.

Many dam owners have a difficult time believing that their dams could experience a rainfall many times greater than any they have witnessed over their lifetimes. Unfortunately, this attitude leads to a false sense of security because floods much greater than those experienced during any one person's lifetime can and do occur.

Estimates of the potential for loss of human life and the economic impacts of damage resulting from dam failure are the usual bases for defining hazard potential. Social and environmental impacts, damage to national security installations, and political and legal ramifications are not easily evaluated, and are more susceptible to subjective or qualitative evaluation. Because their actual impacts cannot be clearly defined, particularly in economic terms, their consideration as factors for determining the hazard potential must be on a case-by-case basis.

In most situations, the investigation of the impacts of failure on downstream life and property is sufficient to determine the appropriate hazard potential rating and to select the appropriate IDF for a project. However, in determining the appropriate IDF for a project, there could be

circumstances beyond loss of life and property damage, particularly when a failure would have minimal or no impact on downstream life and property, which would dictate using a more conservative hazard potential and IDF. For example, the reservoir of a dam that would normally be considered to have a low-hazard potential classification based on insignificant incremental increases (in elevation) due to a failure may be known to contain extensive toxic sediments. If released, those toxic sediments would be detrimental to the ecosystem. Therefore, a low-hazard potential classification would not be appropriate. Instead, a higher standard should be used for classifying the hazard potential and selecting the IDF.

5. Studies To Define the Consequences of Dam Failure.
The degree of study required to sufficiently define the impacts of dam failure for selecting an appropriate IDF will vary with the extent of existing and potential downstream development, the size of the reservoir (depth and storage volume), and type of dam. Evaluation of the river reach and areas impacted by a dam failure should proceed only until sufficient information is generated to reach a sound decision, or until there is a good understanding of the consequences of failure. In some cases, it may be apparent from a field inspection or a review of aerial photographs, Flood Insurance Rate Maps, and recent topographic maps, that consequences attrib-utable to dam failure would occur and be unacceptable. In other cases, detailed studies, including dambreak analyses, will be required. It may also be necessary to perform field surveys to determine the basement and first floor elevations of potentially affected habitable structures (such as residential and commercial).

When conducting dambreak studies, the consequences of the incremental increase due to failure under both normal (full reservoir with normal streamflow conditions prevailing) and floodflow conditions up to the point where a dam failure would no longer significantly increase the threat to life or property should be considered. For each flood condition, water surface elevations with and without dam failure, flood wave travel times, and rates of rise should be determined. This evaluation is known as an incremental hazard evaluation (See Appendix B, Flowchart 2). Since dambreak analyses and flood routing studies do not provide precise results, evaluation of the consequences of failure should be conservative.

The type of dam and the mechanism that could cause failure require careful consideration if a realistic breach is to be assumed. Special consideration should be given to the following factors:

- Size and shape of the breach
- Time of breach formation
- Hydraulic head
- Storage in the reservoir
- Reservoir inflow

In addition, special cases where a dam failure could cause *domino-like* failure of downstream dams resulting in a cumulative flood wave large enough to cause a threat should be considered.

The area affected by dam failure during a given flow condition on a river is the additional area inundated by the incremental increase in flood elevation due to failure over that which would occur normally by flooding without dam failure. The area affected by a flood wave resulting from a theoretical dam breach is a function of the height of the flood wave and the downstream distance and width of the river at a particular location. An associated and important factor is the flood wave travel time. These elements are primarily a function of the rate and extent of dam failure, but also are functions of channel and floodplain geometry and roughness and channel slope.

The flood wave should be routed downstream to the point where the incremental effect of a failure will no longer result in unacceptable additional consequences. When routing a dambreak flood through the downstream reaches, appropriate concurrent inflows should be considered in the computations. Downstream concurrent inflows can be determined using one of the following approaches:

- Concurrent inflows can be based on historical records if these records indicate that the tributaries contributing to the flood volume are characteristically in a flood stage at the same time that flood inflows to the reservoir occur. Concurrent inflows based on historical records should be adjusted so they are compatible with the magnitude of the flood inflow computed for the dam under study.

- Concurrent inflows can be developed from flood studies for downstream reaches when they are available. However, if these concurrent floods represent inflows to a downstream reservoir, suitable adjustments must be made to properly distribute flows among the tributaries.

- Concurrent inflows may be assumed equal to the mean annual flood (approximately bankfull capacity) for the channel and tributaries downstream from the dam. The mean annual flood can be determined from flood flow frequency studies. As the distance downstream from the dam increases, engineering judgment may be required to adjust the concurrent inflows selected.

In general, the study should be terminated when the potential for loss of life and property damage caused by routing floodflows appears limited. This point could occur when the following takes place:

- There are no habitable structures, and anticipated future development in the floodplain is limited.

- Floodflows are contained within a large downstream reservoir.

- Floodflows are confined within the downstream channel.

- Floodflows enter a bay or ocean.

The failure of a dam during a particular flood may increase the area flooded and also alter the flow velocity and depth of flow as well as the rate of rise of flood flows. These changes in flood flows could also affect the amount of damage. To fully evaluate the hazard created by a dam, a range of flood magnitudes needs to be examined. Water surface profiles, flood wave travel times, and rates of rise should be determined for each condition.

The results of the downstream routing should be clearly shown on inundation maps with the breach-wave travel time, maximum depth of flow, and maximum velocity, indicated at critical downstream locations. The inundation maps should be developed at a scale sufficient to identify downstream habitable structures within the impacted area. **The current recommended method for dambreak analysis is the unsteady flow and dynamic routing method used in the National Weather Service (NWS) model.**

Most of the methods used for estimating dambreak hydrographs, including the widely used NWS model, required selecting the size, shape, and time of formation of the dam breach as input parameters for the computations. Therefore, **sensitivity analyses are considered necessary.** Sensitivity analyses, based on varying flood inflow conditions and breach parameters, should be performed only to the extent necessary to make a decision.

Dambreak studies should be performed in accordance with accepted Guidelines. Refer to Appendix A for a list of sources of information related to dambreak studies.

6. Incremental Hazard Evaluation for Inflow Design Flood Determination. The appropriate IDF for a project is selected based on the results of the incremental hazard evaluation. This evaluation involves simulating a dam failure during normal and floodflow conditions and routing the water downstream. The additional down-stream threat due to the incremental increase in water surface elevation from dam failure is assessed for each failure scenario.

To evaluate the incremental increase in consequences due to dam failure, begin with the normal inflow condition and the reservoir at normal full reservoir level with normal streamflow conditions prevailing. That condition should be routed through the dam and downstream areas, with the assumption that the dam remains in place. The same flow should then be routed through the dam with the assumption that the dam fails.

The incremental increase in downstream water surface elevation between the with-failure and without-failure conditions should then be determined, *i.e.*, how much higher would the water downstream be if the dam failed than if the dam did not fail? The consequences that could result should then be identified. If the incremental rise in flood water downstream results in unacceptable additional consequences, assess the need for remedial action.

If the study under normal flow conditions indicates no adverse consequences, the same analyses should be done for several larger flood levels to determine the greatest unacceptable consequences. Under each incrementally larger inflow condition, identify the consequences of failure. For each larger assumed flood inflow condition (which can be percentages of the probable maximum flood (PMF)):

- assume the dam remains in place during the nonfailure conditions; and
- assume the dam fails when the *peak* reservoir elevation is attained for the assumed inflow condition.

It is not appropriate to assume that a dam fails on the rising limb of the inflow hydrograph. For example, current methods cannot accurately determine the extent of overtopping that an earth dam can withstand or how rapidly the dam will erode and ultimately breach from overtopping. Therefore, until such methodologies are available and proven, a conservative approach should be followed which assumes that failure occurs at the peak of the flood hydrograph. The assumption should also be made that the dam has been theoretically modified to contain or safely pass all lower inflow floods. This is an appropriate assumption because this procedure requires that the dambreak analyses start at the normal operating condition, with incremental increases in the flood inflow condition for each subsequent failure scenario up to the point where a failure no longer constitutes unacceptable additional consequences. In summary, before selecting larger floods for analysis, determine what failure at a lower flood constituted a threat to downstream life and property.

The above procedure should be repeated until the flood inflow condition is identified such that a failure at that flow or larger flows (up to the PMF) will no longer result in unacceptable additional consequences. The resultant flood flow is the IDF for the project. The maximum IDF is always the PMF, but in many cases the IDF will be substantially less than the PMF.

A PMF should be determined if it is needed for use in the evaluation. If a PMF value is already available, it should be reviewed to determine if it is still appropriate. The probable maximum precipitation (PMP) for the area should be determined either through the use of the Hydrometeorological Reports (HMR's) developed by the NWS or through the services of a qualified hydrometeorologist. In addition, the hydrologic characteristics of the drainage basin that would affect the runoff from the PMP into the reservoir should be determined. After this information is evaluated, the PMF can be determined.

Once the appropriate IDF for the dam has been selected (whether it is the PMF or something less), it should then be determined whether the dam can safely withstand or pass all floodflows up through the IDF. If it can, then no further evaluation or action is required. If it cannot, then measures must be taken to enable the project to safely accommodate all floods up through the IDF to alleviate the incremental increase in unacceptable additional consequences a failure may have on areas downstream.

It is important to investigate the full range of flood flow conditions to verify that a failure under flood flows larger than the selected IDF up through the PMF will not result in any additional hazard. In addition, once the design for remedial repairs is selected, the IDF should be verified for that design.

Appendix B provides specific guidance and procedures, including a comprehensive flowchart, for conducting an incremental hazard evaluation to select the appropriate IDF for a dam and determine the need for remedial measures.

7. Criteria for Selecting the Inflow Design Flood. Ideally, dams should be able to safely accommodate floodflows in a manner that will not increase the danger to life and property downstream. However, this situation is not always the case, and may not always be achievable.

There are various methods or reasons for selecting the inflow design flood and determining whether the dam can safely accommodate the flood. The method chosen may be determined by the amount of time and/or funds available to conduct an evaluation. For example, if time and funds are scarce, a conservative inflow design flood (*e.g.*, the PMF) can be selected.

Sometimes, inflow design flood selection is straightforward, *i.e.*, given certain criteria, a specific inflow design flood must be used, due to political decisions and policies established by government agencies. For example, statutes may require that a flood such as the PMF, a specific fraction of the PMF, or a flood of specific frequency be selected for a dam with a certain hazard classification. Fortunately, the most widely accepted approach involves incremental hazard evaluations to identify the appropriate IDF for a dam.

There is not a separate IDF for each section of a dam. A dam is assigned only **one** IDF, and it is determined based on the consequences of failure of the section of the dam that creates the greatest hazard potential downstream. This should not, however, be confused with the design criteria for different sections of a dam which may be based on the effect of their failure on downstream areas.

The PMF should be adopted as the IDF in those situations where consequences attributable to dam failure for flood conditions less than the PMF are unacceptable.

A flood less than the PMF may be adopted as the IDF in those situations where the consequences of dam failure at flood flows larger than the selected IDF are acceptable. In other words, where detailed studies conclude that the risk is only to the dam owners' facilities and no increased damage to downstream areas is created by failure, a risk-based approach is acceptable. Generally, acceptable consequences exist when evaluation of the area affected indicates the following:

- There are no permanent human habitations, known national security installations, or commercial or industrial developments, nor are such habitations or commercial or industrial developments projected to occur within the potential hazard area in the foreseeable future.

- There are permanent human habitations within the potential hazard area that would be affected by failure of the dam, but **there would be no significant incremental increase in the threat to life or property resulting from the occurrence of a failure during floods larger than the proposed IDF.** For example, if an impoundment has a small storage volume and failure would not add appreciably to the volume of the outflow flood hydrograph, it is likely that downstream inundation would be essentially the same with or without failure of the dam.

The consequences of dam failure may not be acceptable if the hazard potential to these habitations is increased appreciably by the failure flood wave or level of inundation. **When a dambreak analysis shows downstream incremental effects of approximately two feet or more, engineering judgment and further analysis will be necessary to finally evaluate the need for modification to the dam. In general, the consequences of failure are considered acceptable when the incremental effects (depth) of failure on downstream structures are approximately two feet or less. However, the two-foot increment is not an absolute decision-making point. Sensitivity analyses and engineering judgment are the tools used in making final decisions.** For example, if it is determined that a mobile home sitting on blocks can be moved and displaced by as little as six inches of water, then the acceptable incremental impact would be much less than two feet. As a second example, if a sensitivity analysis demonstrates that the largest breach width recommended is the only condition that results in an incremental rise of two feet, then engineering judgment becomes necessary to determine whether a smaller breach having acceptable consequences of failure is more realistic for the given conditions, *e.g.*, flow conditions, characteristics of the dam, velocity in vicinity of structures, location, and type of structures.

In addition, selection of the appropriate magnitude of the IDF may include consideration of whether a dam provides vital community services such as municipal water supply or energy. Therefore, a higher degree of protection may be required against failure to ensure those services are continued during and following extreme flood conditions when alternate services are unavailable. If losing such services is economically acceptable, the IDF can be less conservative. However, loss of water supply for domestic purposes may not be an acceptable public health risk.

Flood frequency and risk-based analyses may be used to hold operation and maintenance costs to a reasonable level, to maintain public confidence in owners and agencies responsible for dam safety, and to be in compliance with local, state, or other regulations

applicable to the facility. Generally, it would not be an appropriate risk to design a dam having a potential for failure at a flood frequency of less than once in 100 years.

When determining the effect flood inflows will have on dam safety, a hydrologic approach may be used. Simply stated, when determining the effect flood inflows will have on dam safety, the following approach establishes the IDF for the project, and either:

- determines whether an existing project can safely accommodate the IDF; or
- determines how a new project will be designed to safely accommodate the IDF.

Because the entire spectrum of floods up to the PMF level generally needs to be considered in selecting the IDF, it is usually necessary to determine the PMP magnitudes and to develop the PMF based on that information.

The effort involved in conducting PMP and PMF analyses is quite detailed. Depending on the significance of the study being pursued, these analyses should be directed by an engineer trained and experienced in this specialized field.

The incremental hazard evaluation procedure presented in the previous section is the most direct method for selecting an inflow design flood. However, there are times when selection becomes difficult and it may be necessary to conduct further analyses with a risk-based approach. The incremental hazard evaluation is, in essence, a risk-based approach.

C. PMFs for Dam Safety. The PMF is the upper limit of floods to be considered when selecting the appropriate IDF for a dam.

1. General. A deterministic methodology should be used to determine the PMF. In the deterministic methodology, a flood hydrograph is generated by modeling the physical atmospheric and drainage basin hydrologic and hydraulic processes. This approach attempts to represent the most severe combination of meteorologic and hydrologic conditions considered reasonably possible for a given drainage basin. The PMF represents an estimate of the upper limit of run-off that is capable of being produced on the watershed. Refer to Appendix A for a list of sources of information related to flood studies.

2. PMP. The concept that the PMP represents an upper limit to the level of precipitation the atmosphere can produce has been stated in many hydrometeorological documents. The commonly used approach in deterministic PMP development for non-orographic regions is to determine the limiting dew point temperature at the surface (used to obtain the moisture maximization factor) and to collect a "sufficient" sample of extreme storms. These extreme storms are moved to other parts of the study area. The latter are done through a method known as storm transposition, *i.e.,* the adjustment of moisture observed in a storm at its actual site of occurrence to the corresponding moisture level at the site from which the PMP is to be determined. Storm transposition is based on the concept that all storms within a meteorologically

homogeneous region could occur at any other location within that region with appropriate adjustments for effects of elevation and moisture supply. The maximized transposed storm values are then enveloped both depth-durationally and depth-areally to obtain PMP estimates for a specific basin. Several durations of PMP should be considered to ensure the most appropriate duration is selected.

In orographic regions, where local influences affect the delineation of meteorological homogeneity, transposition is generally not permitted. Alternative procedures are offered for these regions that are less reliant on the adequacy of the storm sample. Most of these procedures involve development of both nonorographic and orographic components (sometimes an orographic intensification factor is used) of the PMP. Orographic and nonorographic PMPs are then combined to obtain total PMP estimates for an orographic basin. Currently, generalized PMP estimates are available for the United States (see Figure 3).

As our understanding and the availability of data increases, the "particular" PMP estimates that appear in NWS HMRs may require adjustment to better define the conceptual PMP for a specific site. Therefore, **it may be appropriate to refine PMP estimates with site-specific or regional studies.** The results of available research, such as that developed by the Electric Power Research Institute, should be considered in performing site-specific studies. Because these studies can become very time consuming and costly, the benefit of a site-specific study must be considered carefully. Currently, generalized NWS PMP estimates are available for the entire conterminous United States, as well as Alaska, Hawaii, and Puerto Rico.

D. Floods To Protect Against Loss of Benefits During the Life of the Project - Applicable Only to Low-Hazard Dams

Dams identified as having a low-hazard potential should be designed to at least meet a minimum standard to protect against the risk of loss of benefits during the life of the project, hold operation and maintenance costs to a reasonable level, maintain public confidence in owners and agencies responsible for dam safety, and be in compliance with local, state, or other regulators applicable to the facility. Floods having a particular frequency may be used for this analysis. In general, it would not be appropriate to design a dam having a low-hazard potential for a flood having an average return frequency of less than once in 100 years.

IV. ACCOMMODATING INFLOW DESIGN FLOODS

A. Flood Routing Guidelines

1. General. Site-specific considerations should be used to establish flood routing criteria for each dam and reservoir. The criteria for routing any flood should be consistent with the reservoir regulation procedure that is to be followed in actual operation. The general guidelines to be used in establishing criteria are presented below and should be used if applicable.

2. Guidelines for Initial Elevations. In general, if there is no allocated or planned flood control storage (*i.e.*, run-of-river), the flood routing usually begins with the reservoir at the normal maximum pool elevation. If regulation studies show that pool levels would be lower than the normal maximum pool elevation during the critical inflow design flood (IDF) season, then the results of those specific regulation studies should be analyzed to determine the appropriate initial pool level for routing the IDF.

3. Reservoir Constraints. Flood routing criteria should recognize constraints that may exist on the maximum desirable water surface elevation. A limit or maximum water surface reached during a routing of the IDF can be achieved by providing spillways and outlet works with adequate discharge capacity. Backwater effects of floodflow into the reservoir must specifically be considered when constraints on water surface elevation are evaluated. Reservoir constraints may include the following:

- Topographic limitations on the reservoir stage which exceed the economic limits of dike construction; public works around the reservoir rim, which are not to be relocated, such as water supply facilities and sewage treatment plants; dwellings, factories, and other developments around the reservoir rim, which are not to be relocated. If there is a loss of storage capacity caused by sediment accumulation in portions of the reservoir, then this factor should be accounted for in routing the IDF. Sediment deposits in reservoir headwater areas may build up a delta, which can increase flooding in that area, as well as reduce flood storage capacity, thereby having an effect on routings.

- Geologic features that may become unstable when inundated and result in landslides, which would threaten the safety of the dam, domestic and/or other developments, or displace needed storage capacity.

- Flood plain management plans and objectives established under federal or state regulations and/or authorities.

4. Reservoir Regulation Requirements. Considerations to be evaluated when establishing flood routing criteria for a project include the following:

- Regulation requirements to meet project purposes, the need to impose a maximum regulated release rate to prevent flooding or erosion of downstream areas and control rate of drawdown, the need to provide a minimum regulated release capacity to recover flood control storage for use in regulating subsequent floods, the practicability of evacuating the reservoir for emergencies and for performing inspection, maintenance, and repair. Spillways, outlet works, penstocks, and navigation locks for powerplants are sized to satisfy project requirements and must be operated in accordance with specific instructions if these project works are relied upon to make flood releases, subject to the following limitations:

    - Only those release facilities which can be expected to operate reliably under the assumed flood condition should be assumed to be operational for flood routing. Reliability depends upon structural competence and availability for use. Availability and reliability of generating units for flood release during major floods should be justified. Availability of a source of auxiliary power, for gate operation, effects of reservoir debris on operability and discharge capacity of gates and other facilities, accessibility of controls, design limits on operating head, reliability of access roads, and availability of operating personnel at the site during floods are other factors to be considered in determining whether to assume release facilities are operational. A positive way of making releases to the natural watercourse by use of a bypass or wasteway must be available if canal outlets are to be considered available for making flood releases. Bypass outlets for generating units may be used if they are or can be isolated from the turbines by gates or valves.

    - In flood routing, assumed releases are generally limited to maximum values determined from project uses, by availability of outlet works, tailwater conditions including effects of downstream tributary inflows and wind tides, and downstream nondamaging discharge capacities until allocated storage elevations are exceeded. When a reservoir's capacity in regulating flows is exceeded, then other factors, particularly dam safety, will govern releases. During normal flood routing, the rate of outflow from the reservoir should not exceed the rate of inflow until the outflow begins to exceed the maximum project flood discharge capacity at normal pool elevation, nor should the maximum rate of increase of outflow exceed the maximum rate of increase of inflow. This is to prevent outflow conditions from being more severe than pre-dam conditions. An exception to the above would be where streamflow forecasts are available and pre-flood releases could reduce reservoir levels to provide storage for flood flows.

5. Evaluation of Domino-like Failure. If one or more dams are located downstream of the site under review, the failure wave should be routed downstream to determine if any of the

downstream dams would breach in a domino-like action. The flood routing of flows entering the most upstream of a series of such dams may be either dynamic or level pool. The routing through all subsequent downstream reservoirs should be a dynamic routing. Tailwater elevations should consider the effect of backwater from downstream constrictions.

B. Spillway and Flood Outlet Selection and Design

1. General. Spillways and flood outlets should be designed to safely convey major floods to the watercourse downstream from the dam. They are selected for a specific dam and reservoir on the basis of release requirements, topography, geology, dam safety, and project economics.

2. Gated or Ungated Spillways. An ungated spillway releases water when-ever the reservoir elevation exceeds the spillway crest level. A gated spillway can regulate releases over a broad range of water levels.

Ungated spillways are more reliable than gated spillways. Gated spillways provide greater operational flexibility. Operation of gated spillways and/or their regulating procedures should generally ensure that the peak flood outflow does not exceed the natural downstream flow that would occur without the dam.

The selection of a gated or ungated type of spillway for a specific dam depends upon site conditions, project purposes, economic factors, costs of operation and maintenance, the IDF itself, and other considerations.

The following paragraphs focus on considerations that influence the choice between gated and ungated spillways:

- Discharge capacity - For a given spillway crest length and maximum allowable water surface elevation, a gated spillway can be designed to release higher discharges than an ungated spillway because the crest elevation may be lower than the normal reservoir storage level. This is a consideration when there are limitations on spillway crest length or maximum water surface elevation.

- Project objectives and flexibility - Gated spillways permit a wide range of releases and have capability for pre-flood drawdown.

- Operation and maintenance - Gated spillways may experience more operational problems and are more expensive to construct and maintain than ungated spillways. Constant attendance or several inspections per day, by an operator during high water levels, is highly desirable for reservoirs with gated spillways, even when automatic or remote controls are provided. During periods of major flood inflows, the spillway should be closely monitored. Gated spillways are more subject to clogging from debris and jamming from ice, whereas properly designed ungated spillways are basically free from these problems. Gated spillways require regular maintenance and periodic testing of gate operations. However, ungated spillways can have flashboards, trip gates, and stop log

sections, which can have operational problems during floods and may require constant attendance or several inspections per day during high water levels.

- Reliability - The nature of ungated spillways reduces dam failure potential associated with improper operation and maintenance. Where forecasting capability is unreliable, or where time from the beginning of runoff to peak inflow is only a few hours, ungated spillways are more reliable, particularly for high-hazard structures. Consequences of failure of operation equipment or errors in operation can be severe for gated spillways.

- Data and control requirements - Operational decisions for gated spillways should have real time hydrologic and meteorologic data to make proper regulation possible.

- Emergency evacuation - Unless ungated spillways have removable sections, such as flashboards, trip gates, or stop log sections, they cannot be used to evacuate a reservoir during emergencies. The capability of gated spillways to draw down pools from the top of the gates to the spillway crest can be an advantage when emergency evacuation to reduce head on the dam is a concern.

- Economics and selection - Designs to be evaluated should be technically adequate alternatives. Economic considerations often indicate whether gated or ungated spillways are selected. The possibility of selecting a combination of more than one type of spillway is also a consideration. Final selection of the type of crest control should be based on a comprehensive analysis of all pertinent factors, including advantages, disadvantages, limitations, and feasibility of options.

3. Design Considerations. Dams and their appurtenant structures should be designed to give satisfactory performance. These Guidelines identify three specific classifications of spillways (service, auxiliary, and emergency) and outlet works that are used to pass floodwaters, each serving a particular function. The following paragraphs discuss functional requirements.

Service spillways should be designed for frequent use and should safely convey releases from a reservoir to the natural watercourse downstream from the dam. -Considerations must be given to waterway free-board, length of stilling basins, if needed, and amount of turbulence and other performance characteristics. It is acceptable for the crest structure, discharge channel (*e.g.*, chute, conduit, tunnel), and energy dissipator to exhibit marginally safe performance characteristics for the IDF. However, they should exhibit excellent performance characteristics for frequent and sustained flows, such as up to the 1-percent chance flood event. Other physical limitations may also exist that have an effect on spillway sizing.

Auxiliary spillways are usually designed for infrequent use and it is acceptable to sustain limited damage during passage of the IDF. The design of auxiliary spillways should be based on economic considerations and should be subject to the following requirements:

- The auxiliary spillway should discharge into a watercourse sufficiently separated from the abutment to preclude abutment damage and should discharge into the main stream a sufficient distance downstream from the toe of the dam so that flows will not endanger the dam's structural integrity or usefulness of the service spillway. The auxiliary spillway channel should either be founded in competent rock or an adequate length of protective surfacing should be provided to prevent the spillway crest control from degrading to the extent that it results in an unacceptable loss of conservation storage or a large uncontrolled discharge which exceeds peak inflow.

Emergency spillways may be used to obtain a high degree of hydrologic safety with minimal additional cost. Because of their infrequent use, it is acceptable for them to sustain significant damage when used and they may be designed with lower structural standards than those used for auxiliary spillways.

An emergency spillway may be advisable to accommodate flows resulting from misoperation or malfunction of other spillways and outlet works. Generally, they are sized to accommodate a flood smaller than the IDF. The crest of an emergency spillway should be set above the normal maximum water surface (attained when accommodating the IDF) so it will not overflow as a result of reservoir setup and wave action. The design of an emergency spillway should be subject to the following limitations:

- The structural integrity of the dam should not be jeopardized by spillway operation. Large conservation storage volumes should not be lost as a result of degradation of the crest during operation. The effects of a downstream flood resulting from uncontrolled release of reservoir storage should not be greater than the flood caused by the IDF without the dam.

Outlet works used in passing floods and evacuating reservoir storage space should be designed for frequent use and should be highly reliable. Reliability is dependent on foundation conditions, which influence settlement and displacement of waterways, on structural competence, on susceptibility of the intake and conduit to plugging, on hydraulic effects of spill-way discharge, and on operating reliability.

C. Freeboard Allowances

1. General. Freeboard provides a margin of safety against overtopping failure of dams. It is generally not necessary to prevent splashing or occasional overtopping of a dam by waves under extreme conditions. However, the number and duration of such occurrences should not threaten the structural integrity of the dam, interfere with project operation, or create hazards to personnel. Freeboard provided for concrete dams can be less conservative than for embankment

dams because of their resistance to wave damage or erosion. If studies demonstrate that concrete dams can withstand the IDF while overtopped without significant erosion of foundation or abutment material, then no freeboard should be required for the IDF condition. Special consideration may be required in cases where a powerplant is located near the toe of the dam. The U.S. Bureau of Reclamation has developed guidelines (See Appendix A) that provide criteria for freeboard computations.

Normal freeboard is defined as the difference in elevation between the top of the dam and the normal maximum pool elevation. Minimum freeboard is defined as the difference in pool elevation between the top of the dam and the maximum reservoir water surface that would result from routing the IDF through the reservoir. Intermediate freeboard is defined as the difference between intermediate storage level and the top of the dam. Intermediate freeboard may be applicable when there is exclusive flood control storage.

2. Freeboard Guidelines. Following are guidelines for determining appropriate freeboard allowances:

- Freeboard allowances should be based on site-specific conditions and the type of dam (concrete or embankment). Both normal and minimum freeboard requirements should be evaluated in determining the elevation of the top of the dam. The resulting higher top of dam elevation should be adopted for design. Freeboard allowances for wind-wave action should be based upon the most reliable wind data available that are applicable to the site. The significant wave should be the minimum used in determining wave runup, and the sum of wind setup and wave runup should be used for determining requirements for this component of freeboard.

- Computations of wind-generated wave height, setup, and runup should incorporate selection of a reasonable combined occurrence of pool level, wind velocity, wind direction, and wind durations based on site-specific studies. It is highly unlikely that maximum winds will occur when the reservoir water surface is at its maximum elevation resulting from routing the IDF, unless the reservoir capacity is small compared to flood volume because the maximum level generally persists only for a relatively short period of time (a few hours). Consequently, winds selected for computing wave heights should be appropriate for the short period the pool would reside at or near maximum levels. Normal pool levels persist for long periods of time. Consequently, maximum winds should be used to compute wave heights.

- Freeboard allowance for settlement should be applied to account for consolidation of foundation and embankment materials when uncertainties exist in computational methods or data used yield unreliable values for camber design. Freeboard allowance for settlement should not be applied where an accurate determination of settlement can be made and is included in the camber. Freeboard allowance for embankment dams for estimated earthquake-generated movement, resulting seiches, and permanent embankment displacements or deformations should be considered if a dam is located in

an area with potential for intense seismic activity. Reduction of freeboard allowances on embankment dams may be appropriate for small fetches, obstructions that impede wave generation, special slope and crest protection, and other factors.

- Freeboard allowance for wave and volume displacement due to potential landslides, which cannot be economically removed or stabilized, should be considered if a reservoir is located in a topographic setting where the wave or higher water resulting from displacement may be destructive to the dam or may cause serious downstream damage.

- Total freeboard allowances should include only those components of freeboard which can reasonably occur simultaneously for a particular water surface elevation. Components of freeboard and combinations of those components, which have a reasonable probability of simultaneous occurrence, are listed in the following paragraphs for estimating minimum, normal, and intermediate freeboards. The top of the dam should be established to accommodate the most critical combination of water surface and freeboard components from the following combinations.

For **minimum** freeboard combinations, the following components, when they can reasonably occur simultaneously, should be added to determine the total minimum freeboard requirement:

- Wind-generated wave runup and setup for a wind appropriate for the maximum reservoir stage for the IDF.

- Effects of possible malfunction of the spillway and/or outlet works during routing of the IDF.

- Settlement of embankment and foundation not included in crest camber.

- Landslide-generated waves and/or displacement of reservoir volume (only cases where landslides are triggered by the occurrence of higher water elevations and intense precipitation associated with the occurrence of the IDF).

For **normal** freeboard combinations, the most critical of the following two combinations of components should be used for determining normal freeboard requirements:

Combination 1 -

- Wind-generated wave runup and setup for maximum wind, and settlement of embankment and foundation not included in camber.

Combination 2 -

- Landslide-generated waves and/or displacement of reservoir volume, settlement of embankment and foundation not included in camber, and settlement of embankment and foundation or seiches as a result of the occurrence of the maximum credible earthquake.

For **intermediate** freeboard combinations, in special cases, a combination of inter-mediate winds and water surface between normal and maximum levels should be evaluated to determine whether this condition is critical. This may apply where there are exclusive flood control storage allocations.

Appendix B – Inflow Design Flood Selection Procedures

IDF SELECTION PROCEDURES: OVERVIEW

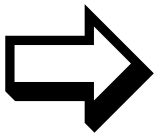
HOW IS THE IDF SELECTED?

The purpose of this Appendix is to describe the procedures used to select the appropriate inflow design flood (IDF) for a dam, and to determine the need for remedial action. These procedures are presented in two flowcharts. The first flowchart describes the steps needed to determine:

- **If the probable maximum flood (PMF) was used in the original design of the dam.**
- **If the PMF or some lesser flood is the appropriate IDF.**
- **Whether remedial action at the dam is needed to enable it to safely accommodate the appropriate IDF.**

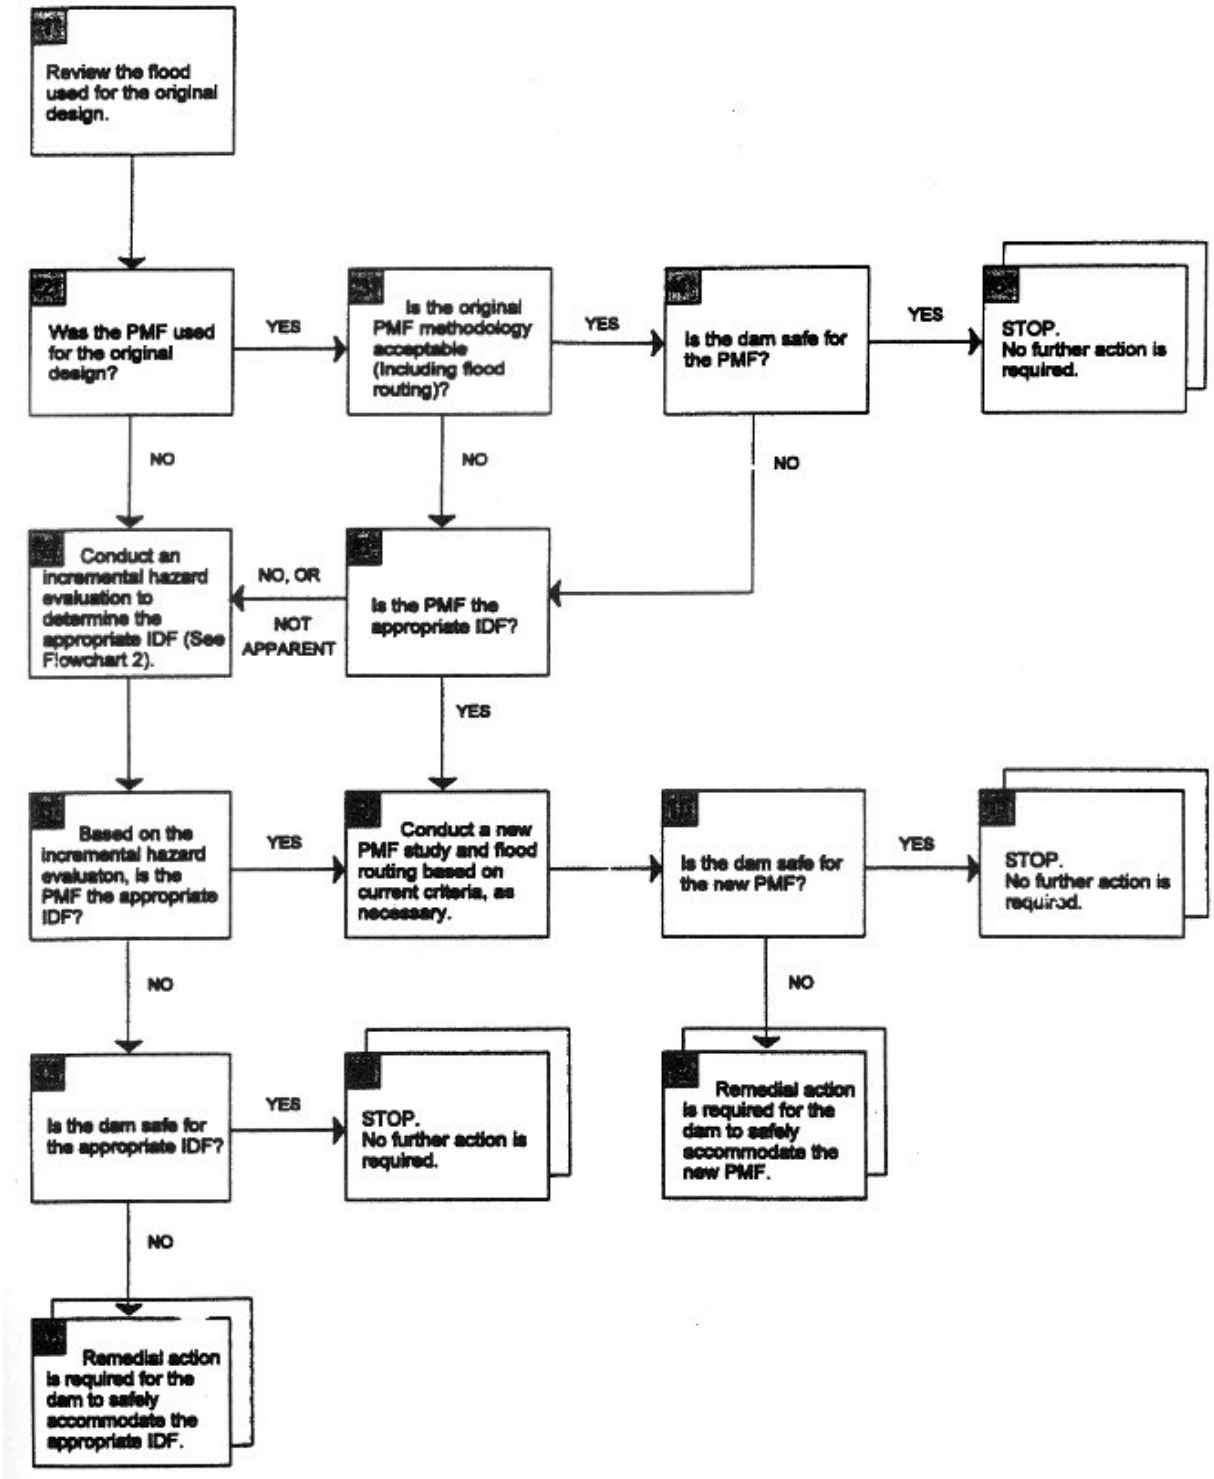
To determine whether the PMD or some lesser flood is the appropriate IDF, it may be necessary to conduct an incremental hazard evaluation. This process is presented in the second flowchart.

Following each flowchart is a breakdown of the procedures. Each block is presented individually, and includes an explanation of the steps taken.



IDF SELECTION PROCEDURES: SELECTING THE APPROPRIATE IDF

INTRODUCTION



PROCEDURES FOR DETERMINING THE APPROPRIATE IDF AND THE NEED FOR REMEDIAL ACTION

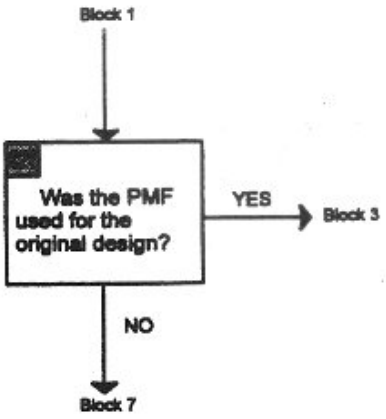
Flowchart 1 presents a logical, step-by-step approach for evaluating the hydrologic design of an existing dam, and determining the appropriate IDF for the dam and whether remedial action is needed in order for the dam to safely accommodate the IDF.

Flowchart 1 is on the next page.

FLOWCHART 1 – PROCEDURES FOR DETERMINING THE APPROPRIATE INFLOW DESIGN FLOOD (IDF) AND THE NEED FOR REMEDIAL ACTION

IDF SELECTION PROCEDURES: DETERMINING THE APPROPRIATE IDF

EXPLANATION OF FLOWCHART 1 **– An explanation of the IDF flowchart is presented below.**

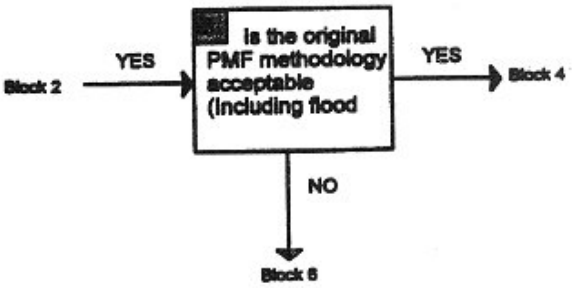


Block 1

The initial step in selecting the appropriate IDF and determining the need for dam safety modification is to review the basis for the original hydrologic design of an existing dam. This information will provide valuable insight regarding whether the flood originally used for design purposes satisfies current criteria or whether detailed investigations and analyses will be required to determine the appropriate IDF for the dam.

In those situations where the original design information has been lost, detailed investigations and analyses will normally be required.

Block 2



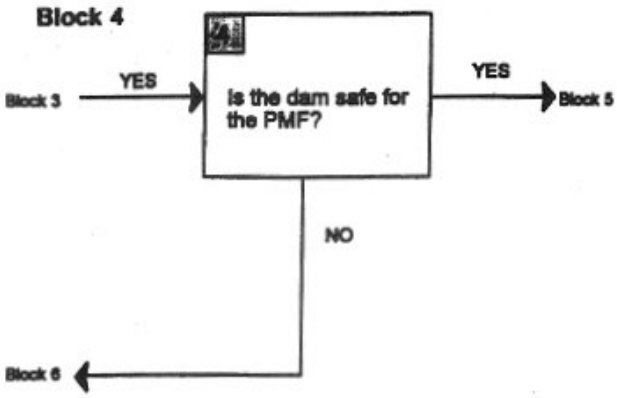
Once you have identified the basis for the original hydrologic design, the next step is to determine if the flood used for the original design is the probable maximum flood (PMF). This question is important, since the upper limit of the IDF is the PMF.

If your answer is YES, continue to Block 3.

If your answer is NO, go to Block 7. In Block 7 you will perform an incremental hazard evaluation to determine the appropriate IDF.

Block 3

To ensure the reliability of the original PMF study or the assumptions made on the various parameters affecting the study, it is necessary to determine if the PMF methodology originally used is still acceptable under current criteria.



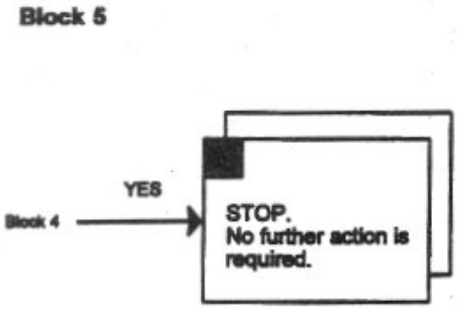
If your answer is YES, continue to Block 4.

If your answer is NO, go to Block 6. In Block 6, you will answer the question: Is the PMF the appropriate IDF?

Continued…

IDF SELECTION PROCEDURES: DETERMINING THE APPROPRIATE IDF

EXPLANATION OF FLOWCHART 1 (Continued)

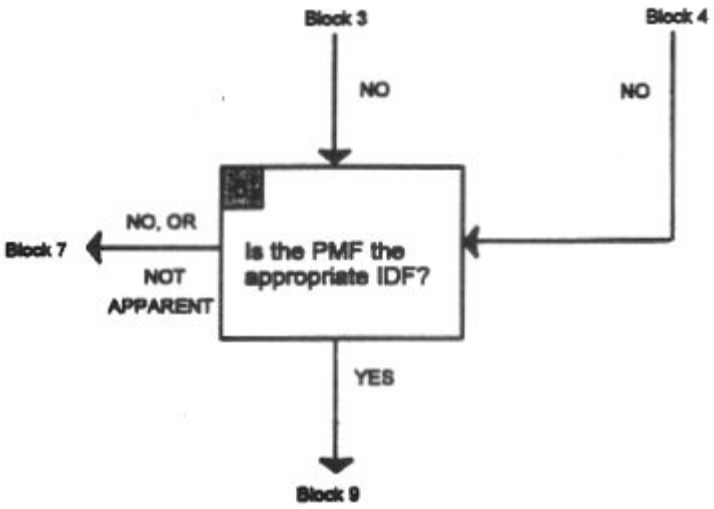


Determine if the dam is safe for the PMF. Your answer to this question will indicate whether remedial action will be required.

If your answer is YES, continue to Block 5.

If your answer is NO, go to Block 6. In Block 6, you will answer the question:

Is the PMF the appropriate IDF?



If the PMF is considered to be the appropriate IDF for the dam, no further investigations or remedial work for hydrologic conditions will be required.

Continued…

IDF SELECTION PROCEDURES: DETERMINING THE APPROPRIATE IDF

EXPLANATION OF FLOWCHART 1 (Continued)

Block 6

IF…

In Block 3 you determined that the original PMF methodology is NOT acceptable,

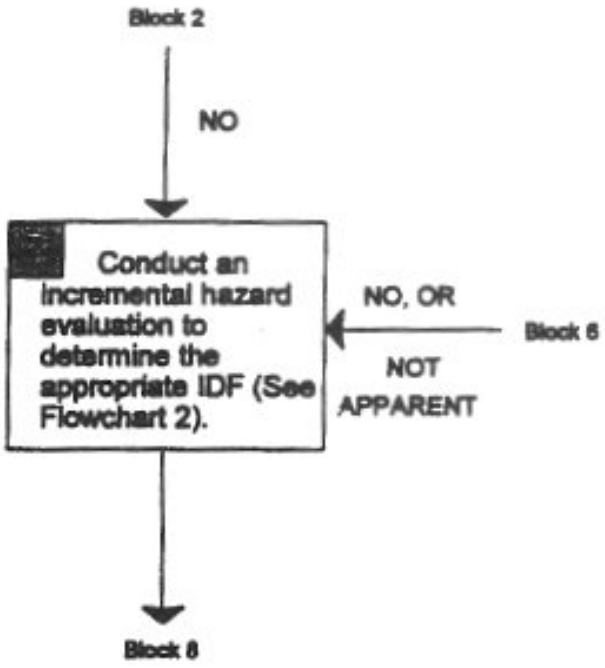
OR…

In Block 4 you determined that the dam is NOT safe for the PMF,

THEN…

You need to determine if the PMF is the appropriate IDF.

In some cases, such as when the dam is totally submerged during the PMF, it may be obvious that the appropriate IDF is something less than the PMF. In other cases, it will not be apparent whether the IDF should be the PMF or something less. In these two cases, it will be necessary to perform an incremental hazard evaluation to determine the appropriate IDF for the dam. Continue to Block 7.



Sometimes, based on the size and volume of the dam and reservoir, the proximity of the dam to downstream communities, or even because of political decisions, it will be obvious that the IDF should be the PMF. If this is the case, a new PMF study will be required. Go to Block 9.

Continued…

IDF SELECTION PROCEDURES: DETERMINING THE APPROPRIATE IDF

EXPLANATION OF FLOWCHART 1 (Continued)

Block 7

IF…

In Block 2 you determined that the flood used in the original design is NOT the PMF,

OR…

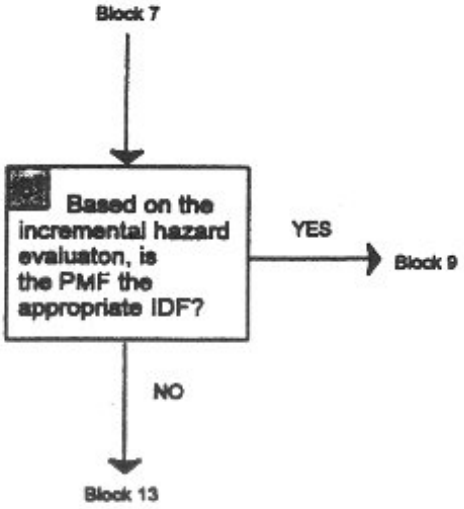
In Block 6, you determined that it is obvious that the IDF should be less than the PMF or it is not apparent if the IDF should be the PMF or something less,

THEN…

You need to perform an incremental hazard evaluation to determine the appropriate IDF. Performing the incremental hazard evaluation involves:

Conducting dambreak sensitivity studies, reviewing incremental rises between with-failure and without-failure conditions for a range of flood inflows (see Flowchart 2), and

Selecting the appropriate IDF on the basis of the dambreak studies and incremental impacts on downstream areas.



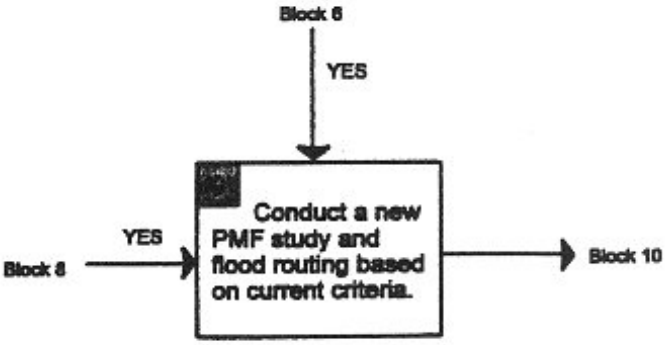
A procedural flowchart for performing a hazard evaluation appears in Flowchart 2, followed by an explanation of the procedure.

Continued…

IDF SELECTION PROCEDURES: DETERMINING THE APPROPRIATE IDF

EXPLANATION OF FLOWCHART 1 (Continued)

Block 8



You should use the results of the incremental hazard evaluation and dambreak studies conducted in Block 7 to determine if the PMF is the appropriate IDF.

The IDF should be the PMF when the incremental consequences of failure are unacceptable, regardless of how large the assumed flood inflow becomes.

If your answer is YES, continue to Block 9.

If your answer is NO, go to Block 13. In Block 13 you will answer the question: Is the dam safe for the appropriate IDF?

Block 9

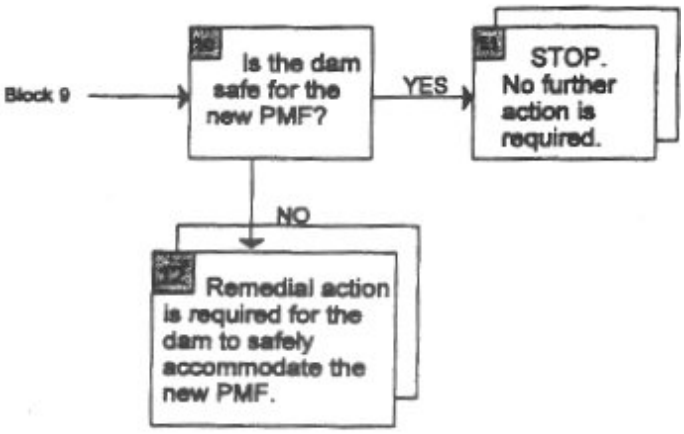
IF…

In Block 6 you determined that the PMF is obviously the appropriate IDF,

OR…

If, based on the incremental hazard evaluation conducted in Block 8, the PMF is the appropriate IDF,

THEN…



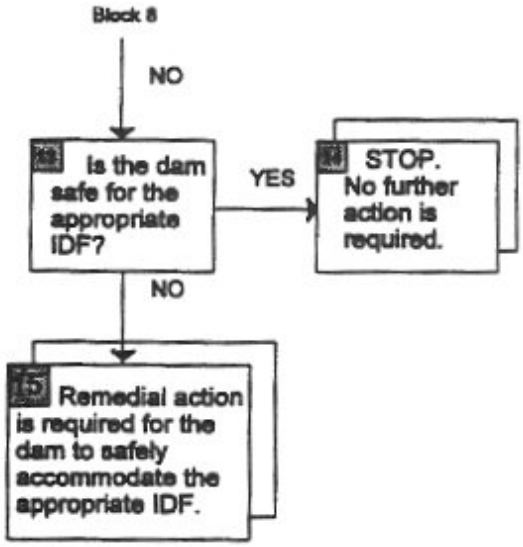
You should conduct a new PMF study and flood routing based on current criteria, unless it was determined in Block 3 that the original PMF is acceptable under current criteria.

Continued…

IDF SELECTION PROCEDURES: DETERMINING THE APPROPRIATE IDF

EXPLANATION OF FLOWCHART 1 (Continued)

Blocks 10, 11, And 12



Once the new PMF is calculated, you should determine if the dam is safe for the new PMF.

If the dam is SAFE for the new PMF no further investigations or remedial actions for hydrologic conditions are required.

If the dam is NOT SAFE for the new PMF, remedial action is required for the dam to safely accommodate the PMF.

Blocks 13, 14, And 15

IF…

In Block 8 you determined that the PMF is NOT the appropriate IDF,

THEN…

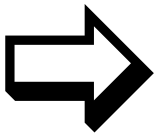
You need to determine if the dam is safe for the appropriate IDF.

If the dam is SAFE for the appropriate IDF, no further investigations or remedial action for hydrologic conditions are required.

If the dam is NOT SAFE for the appropriate IDF, remedial action is required for the dam to safely accommodate the appropriate IDF.

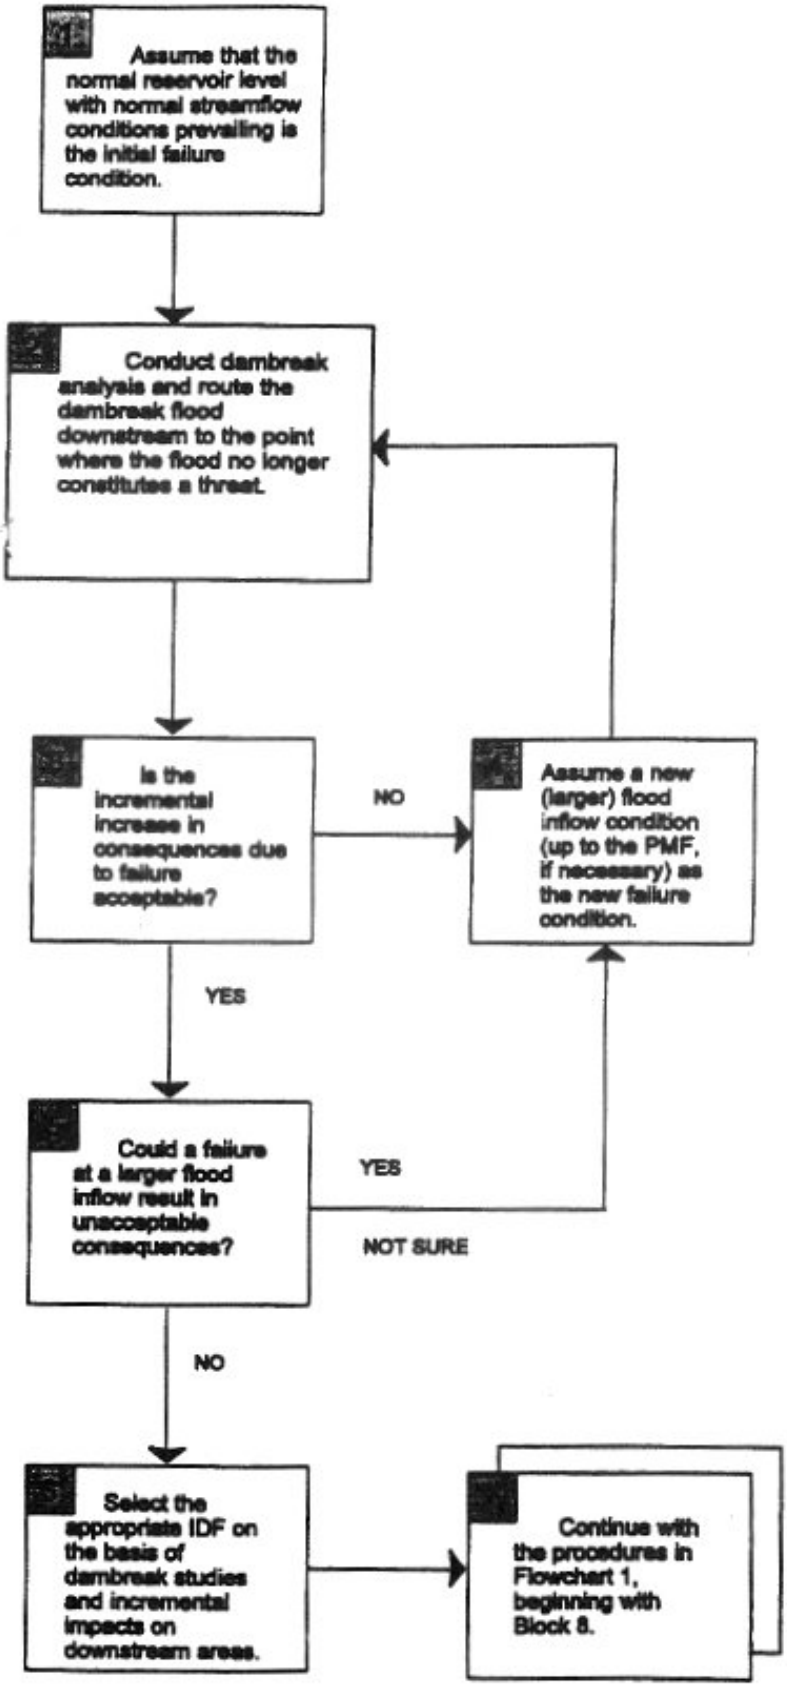
Depending on the type of remedial action considered, it may be necessary to reevaluate the IDF to ensure that the appropriate IDF has been selected for the design of any modification.

IDF SELECTION PROCEDURES: PERFORMING A HAZARD EVALUATON



INTRODUCTION

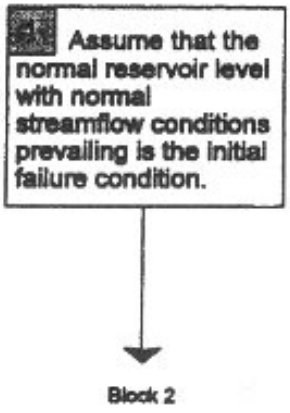
As stated previously, if the PMF was not used for the original design of a dam, or if the PMF is not the appropriate IDF, an incremental hazard evaluation must be performed to determine the appropriate IDF.



PROCEDURES FOR CONDUCTING AN INCREMENTAL HAZARD EVALUATION

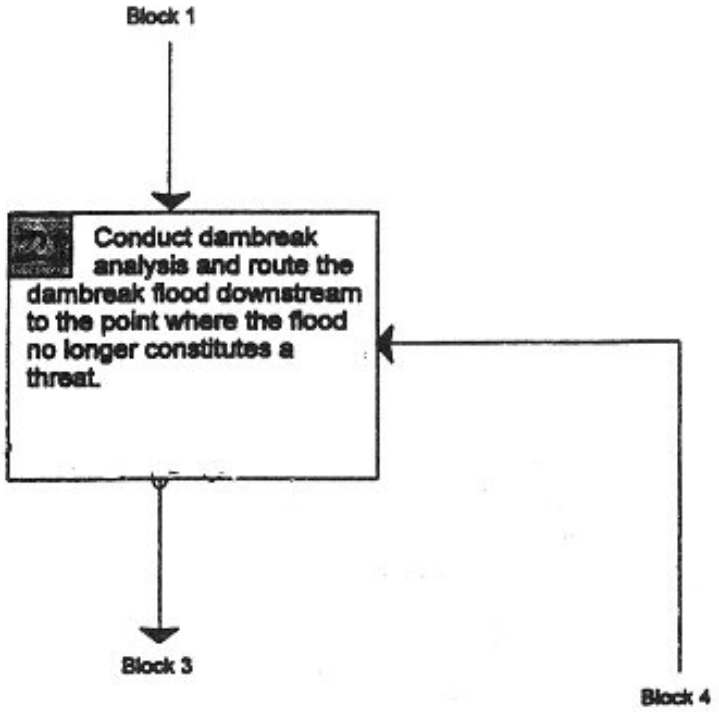
Flowchart 2 shows the procedures for performing an incremental hazard evaluation. This flowchart is an expansion of Block 7 in Flowchart 1.

Flowchart 2 is on the next page.



FLOWCHART 2 – PROCEDURES FOR CONDUCTING AN INCREMENTAL HAZARD EVALUATION

IDF SELECTION PROCEDURES: PERFORMING A HAZARD EVALUATON

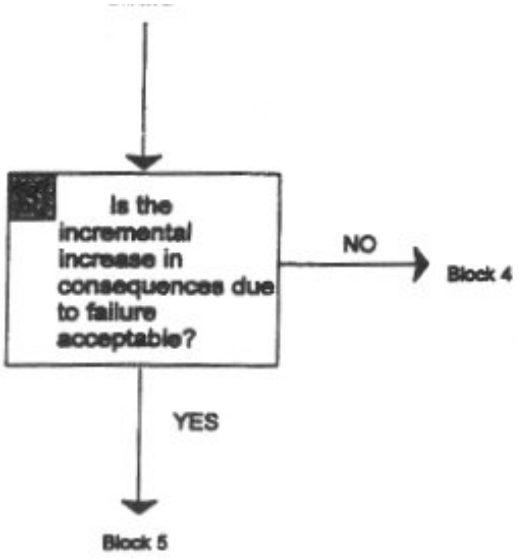


EXPLANATION OF FLOWCHART 2 **– An explanation of the Hazard Evaluation Flowchart is presented below.**

Block 1

Assume that the normal reservoir level with normal streamflow conditions prevailing is the initial failure condition. Starting at this point will ensure that the full range of flood inflow conditions will be investigated and will include the "sunny day" failure condition. It will also assist in verifying the initial hazard assigned to the dam. Using the normal maximum water surface level as the initial condition is particularly important if the initial hazard rating was low.

Block 2



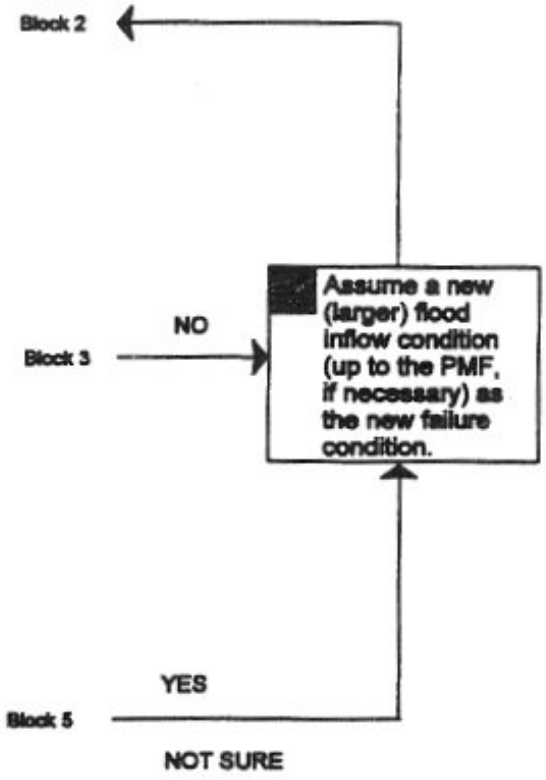
Next, conduct dambreak sensitivity studies (of various breach parameters) and route the dambreak flood to the point downstream where it no longer constitutes a threat to downstream life and property.

It is important to remember that the incremental increases should address the differences between the nonfailure condition with the dam remaining in place and the failure condition. Also, the dam should not be assumed to fail until the peak reservoir water surface elevation is attained for the assumed flood inflow condition being analyzed. Dams should be assumed to fail as described in these guidelines.

Continued…

IDF SELECTION PROCEDURES: PERFORMING A HAZARD EVALUATON

EXPLANATION OF FLOWCHART 2 (continued)



Now, determine – if the additional increase in consequences due to failure is acceptable. Answering this question is critical in the incremental hazard evaluation, and doing so involves an estimate of loss of life and property with and without dam failure.

If the consequences of failure under the assumed floodflow condition are NOT ACCEPTABLE go to Block 4.

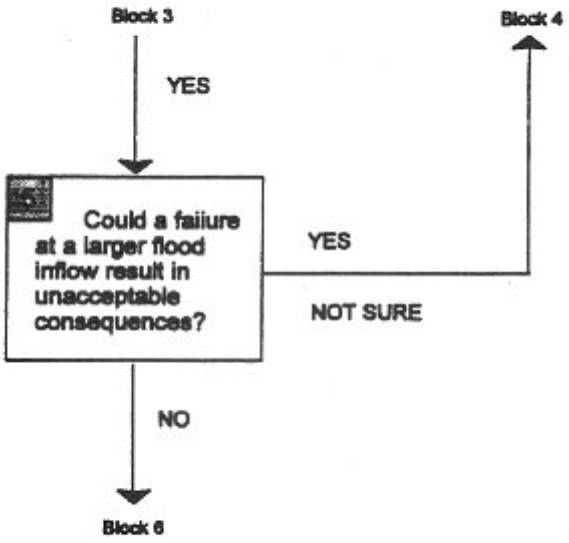
If the consequences of failure ARE ACCEPTABLE, continue to Block 5.

Block 4

IF…

In Block 3 it was determined that the consequences of failure under the assumed floodflow conditions are NOT ACCEPTABLE,

THEN…



Assume a new (larger) flood inflow condition (*e.g.,* some percentage of the PMF) and perform a dambreak analysis (see Block 2). This procedure should be repeated until an acceptable level of flooding is identified, or the full PMF has been reached.

Continued…

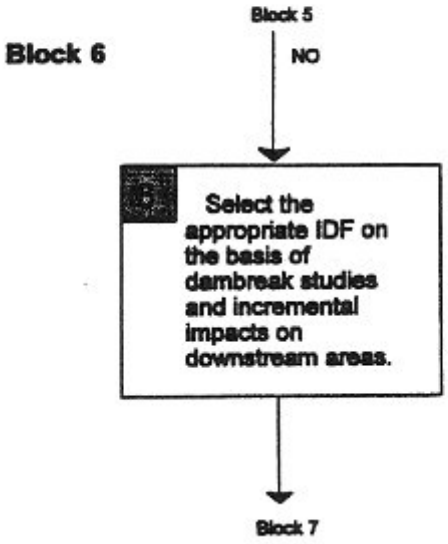
IDF SELECTION PROCEDURES: PERFORMING A HAZARD EVALUATON

EXPLANATION OF FLOWCHART 2 (continued)

Block 5

IF…

In Block 3 you determined that the consequences of failure under the assumed floodflow conditions are ACCEPTABLE; *i.e.,* failure of the dam under "sunny day" conditions was insignificant,



THEN…

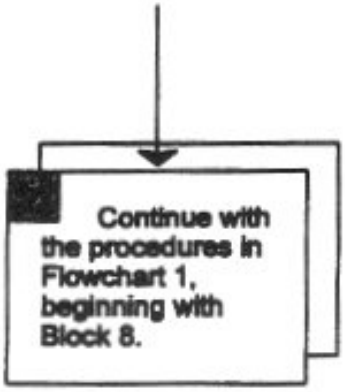
Determine if failure at a larger flood inflow condition will result in unacceptable consequences. This question is very important. For example, situations exist where a failure during normal water surface conditions results in the flood wave being contained completely within the banks of a river and obviously would not cause a threat to life and property downstream. However, under some floodflow conditions, the natural river flows may go out-of-bank, and a failure on top of that flood condition will result in an additional threat to downstream life and property.

If failure at another flood level will result in UNACCEPTABLE additional incremental consequences, or if you are NOT SURE, return to Block 4. Assume larger flood inflow conditions and perform new dambreak studies. This procedure should be repeated to determine the acceptable level of flooding.

If failure at another flood level will NOT result in unacceptable consequences, continue to Block 6.

Block 6

You should now select the appropriate IDF based on the results of dambreak studies and incremental impacts on downstream areas.



Continued …

IDF SELECTION PROCEDURES: PERFORMING A HAZARD EVALUATON

EXPLANATION OF FLOWCHART 2 (continued)

Block 7

Continue this process with the steps in Flowchart 1, starting with Block 8. In Block 8 you will answer the question: Based on the incremental hazard evaluation, is the PMF the appropriate IDF?

IDF SELECTION PROCEDURES: SUMMARY

SUMMARY: INFLOW DESIGN FLOOD (IDF) SELECTION PROCEDURES

This Appendix described the procedures used to select the appropriate IDF for a dam and to determine the need for remedial action.

The steps involved to select the appropriate IDF for a dam were presented in Flowchart 1. If you determine that the PMF was used for the original design of the dam, and that the PMF is the appropriate IDF, further investigation or remedial action for hydrologic, conditions is not necessary.

If you determine that the PMF was not used for the original design of the dam, or if the PMF was not the appropriate IDF, conduct an incremental hazard evaluation to determine the appropriated IDF. Flowchart 2 presented the procedures for conducting an incremental hazard evaluation.

Then, if it is determined that the dam is not safe for the new PMF or the appropriate IDF, remedial action must be taken.

Note:

* HMR 58 to be Published in 1997

FEMA Workshop on Hydrologic Research Needs for Dam Safety Analysis
Federal Energy Regulatory Commission

By
Michael S. Davis, P.E.[2]

The purpose of this paper is to discuss the Federal Energy Regulatory Commission's (Commission) current practice in evaluating the adequacy of the spillway capacity of hydroelectric projects under it's jurisdiction, and to suggest areas where future research would be a benefit to these projects.

Current Practice

Regulations and Procedures

Since Order 122 was issued in 1981[3], the current practice of the Commission to ensure that the spillway capacity of all high and most significant hazard potential project is adequate has been governed by Sections 12.35(b) and 12.35(b)(1) of the Commission's regulations, which are as follows:

> 12.35(b) *Evaluation of spillway adequacy.* The adequacy of any spillway must be evaluated by considering the hazard potential which would result from failure of the project works during flood flows.
>
> 1235(b)(1) If structural failure would present a hazard to human life or cause significant property damage, the independent consultant must evaluate (i) the ability of the project works to withstand the loading or overtopping which may occur from a flood up to the probable maximum flood (PMF), or (ii) the capacity of spillways to prevent the reservoir from rising to an elevation that would endanger the project works.

The Commission's regulations require that for all high hazard potential dams and most significant hazard potential dams[4], an independent consultant must inspect the project and evaluate its stability and spillway adequacy every five years. To give the Commission staff and the independent consultant guidance and criteria for this evaluation, the Commission developed the Engineering Guidelines for the Evaluation of Hydropower Projects.

---

[2] Lead Engineer, Federal Energy Regulatory Commission, Office of Energy Projects, Division of Dam Safety and Inspections, Chicago Regional Office.

[3] Order 122 established the current regulations for independent consultants inspecting and evaluating projects on a five-year cycle.

[4] Any significant hazard potential dam that is less than 32.8 feet high and impounds less than 2,000 acre-feet is not subject to this regulation.

For most projects, the first step for the independent consultant is to develop the PMF for the project and to evaluate the spillway capacity and stability of the project during the PMF. If the project can safely pass the PMF, then the spillway is adequate and no further studies are needed. If, however, the PMF exceeds the spillway capacity of the project, then the independent consultant is required to perform a dambreak analysis in accordance with Chapter 2 of our engineering guidelines, or the licensee may choose to modify the dam to safely pass the PMF.

If the dambreak analysis for all flood flows between the existing spillway capacity and the PMF show that the incremental increase in downstream flooding due to the failure is not a threat to downstream life or could cause significant property damage, then the spillway is adequate and no further studies are needed. However, this may need to be re-evaluated during future inspections if there are any changes downstream.

If there is a potential hazard to life or property downstream for these flood flows, then remedial measures are required to either increase the spillway capacity or increase the stability of the project structures to withstand the overtopping. Usually, an inflow design flood (IDF) analysis is done considering various alternatives for increasing the spillway capacity or the stability of the structures, and the IDF can vary depending on the type of fix. But once a fix is proposed for a flood less than the PMF, the license must demonstrate that the incremental increase in downstream flooding due to failure of the dam for all flood flows between the IDF and the PMF is not a threat to downstream life or could cause significant property damage.

In a few cases, a PMF study is not needed if the consultant can demonstrate through a dambreak analysis that either the spillway capacity is adequate or that the IDF will be considerably less than any estimates of the PMF. But in most cases, a PMF study is needed to establish the upper bound of the IDF.

Probable Maximum Flood Studies

Chapter 8 of the Commissions Engineering Guidelines, entitled, “Determination of the Probable Maximum Flood”, was first developed in 1993, and was recently revised in September 2001. The purpose of these guidelines is to provide systematic procedures that will consistently produce a reasonable PMF hydrograph and appropriate reservoir flood levels for evaluation of project safety, given the limitations of basic hydrologic and meteorological data. Although the guidelines give procedures and make recommendations for parameters, alternate procedures and parameters outside the recommended ranges can be used provided they are justified for the basin under study and supported with adequate documentation.

Runoff Model. This chapter recommends the use of the unit-hydrograph theory as the preferred runoff model. It also recommends that the Corps of Engineer’s HEC-1 or

HEC-HMS computer programs be used to model the runoff because of their widespread use and experience.

Channel Routing. Channel routing should be done using the Muskingum-Cunge method, which is incorporated into these computer models. However, any acceptable dynamic routing model such as the National Weather Service (NWS) DAMBRK computer program can be used instead if the consultant chooses to refine the model.

Probable Maximum Precipitation (PMP). The PMP should be developed from the latest NWS Hydrometeorological Reports (HMR). However, a licensee may choose to develop a site-specific PMP study, although this is usually very costly. This may done if the basin under study (1) is not adequately covered by the HMRs, has unusual site conditions that may not be addressed by the HMRs, or can benefit from a refinement of the HMR PMP values. To conduct a site-specific PMP study, the Commission requires that a Commission-approved Board of Consultants consisting of at least a hydrologist, a meteorologist, and a hydrometeorologist review the study. As an example of an approved study, the Commission accepted the 1993 EPRI PMP study for the States of Wisconsin and Michigan, which resulted in PMP values as much as 15 percent lower than HMR No. 51. The 1993 EPRI study also refined the procedures in HMR 52 for developing the probable maximum storm from the PMP values. As a result, the PMF's for many projects in these two States were reduced considerably, resulting in a significant cost savings to the licensee's of these projects. Figure 8.8-1 of Chapter 8 shows the limitations of the latest HMRs and the 1993 EPRI study.

Antecedent and Coincident Conditions. Rather than route an antecedent storm through the model, this chapter recommends that the reservoir level be assumed at its annual maximum operating level and that saturated conditions exist in the entire basin at the onset of the PMP. Several alternatives for the starting reservoir level may be considered which would required an analysis of the historical records or routing of the 100-year 24-hour antecedent storm 3 days prior to the start of the PMP. In most cases, using the annual maximum operating level gives satisfactory results.

Loss Rates This subject received the most attention when Chapter 8 was recently revised. The preferred method is to use the uniform loss rate method. Consistent with the premise that saturated antecedent conditions exist in the basin prior to the start of the PMP, it is acceptable to assume the initial loss rate is set to zero.

The losses in a basin can be developed either by the area-weighted basin-averaging of the loss rates of the hydrologic soil groups, or by a distributed loss rate method. The basin-averaged method is the traditional method that has been used for many years, and simply involves computing the average loss rate based on the percentage of the four hydrologic spoil groups. Chapter 8 recommends that the minimum loss rates from the National Resources Conservation Services (NRCS) 1955 Yearbook of Agriculture be used unless higher loss rates could be justified.

Instead of lumping the loss rates together in each basin, the distributed loss rate method divides each basin into pseudo subbasins corresponding to each loss rate class. The rainfall is then applied to each pseudo subbasin to determine the rainfall excess hyetographs. Then the rainfall excess hyetographs for all pseudo subbasins within a basin are summed to determine the rainfall excess hyetograph for that basin. These rainfall excess hyetographs are then input in HEC-1 with the loss rates set to zero for that basin. This method also works for larger basins that are subdivided into subbasins.

The distributed loss rate method was developed in the 1990's primarily to address an inconsistency with the basin-average method. Our procedures allows you to calibrate loss rates based on 3 to 5 historical events that meet certain criteria. However, loss rates calibrated using the basin-average method were found to be storm specific, particularly for basins with spatially diverse characteristics. A basin with a calibrated average loss rate for a specific storm may actually have a significantly higher loss rate for the PMF since significantly more portions of the basin contribute to the runoff during the PMF than did during the specific storm.

The second reason this method was developed was to incorporate the availability of the digitalization of soil databases such as NRCS State Soil Geographic (STATSGO) database. The STATSGO database contains many properties of the soil for several layers up to 60 inches deep. One such property is the hydraulic conductivity, which is the rate of flow through saturated soil, normally given as a range of values. The Commission's current criteria is to use the minimum value of the range for the least permeable layer, unless higher values can be justified through calibration or additional investigation of the geological make-up of the soils, the review of more detailed soils information such as county or local soils maps, or actual data obtained from any site investigations within the basin.

Dam Break Studies

Guidelines and Criteria

The Commission's criteria for conducting dam break studies is discussed in Chapter 2 of the Engineering Guidelines. The NWS DAMBRK and FLDWAV computer programs are the recommended unsteady flow model computer programs that can be used to route the flow downstream of the dam. However, the Commission has accepted studies using other programs as well. The NWS SMPDBK program has been accepted in a few cases where the accuracy of the results is not as critical. In some cases, if a field reconnaissance shows that there are no structures downstream, a computer analysis is not necessary.

In general, the consequences are considered to be acceptable when the incremental increase in flooding on downstream structures due to dam failure is approximately 2.0 feet or less. However, the 2.0-foot increment is not an absolute

decision-making point. Sensitivity analyses and engineering judgment are required. For instance, inhabited trailers sitting on blocks can be moved with less than 2.0 feet of rise, and should be considered in this evaluation.

The Commission's guidelines for breach parameters is given in Table 1 of Appendix A of Chapter 2. In general, the average breach width should be between 2 and 4 times the height of the dam for earth or rock fill dams, and one or more monoliths up to one-half the length of the dam for gravity dams. Failure times range from 0.1 to 1.0 hours for earth or rock fill dams, and from 0.1 to 0.3 hours for gravity dams. For arch dams, it's appropriate to assume the entire dam fails in 0.1 hours or less.

Because of the uncertainty of breaches, the consultant should perform a sensitivity analysis of these parameters. For projects with large reservoirs, conservative breach parameters should be adopted since the rate of draw down of the reservoir during a breach is significantly slower than it is for projects with smaller reservoirs. In some cases, larger breach widths with longer failure times should be considered, such as for a long 20-foot high earth embankment that impounds a large storage reservoir.

Common Modeling Problems

1. Failure to model the entire reservoir. If dynamic routing of the reservoir instead of level pool routing is done, the consultant needs to make sure the cross-sections extend upstream of the reservoir to the point where backwater effects no longer exist. The shape of the cross-sections also needs to be examined to make sure all the storage between the cross-sections is accounted for. In some cases, the consultant extended the cross-sections only part way into the reservoir, effectively negating the storage upstream that could be released through a breach.

2. No sensitivity studies. Although the selected breach width may be at the conservative end of the accepted range given in our criteria, a larger breach width may result in a substantially higher incremental rise downstream. If the incremental rise is highly sensitive to the breach width, then this needs to be considered when selecting the breach width.

3. Improper use of the Manning's n values. The NWS DAMBRK program requires the user to provide the composite Manning's n values at each elevation. Therefore, for out-of-bank flood elevations the consultant needs to compute the composite Manning's n value based on the weighted wetted perimeter. In many cases, the consultant will select too high of a Manning's value for the out-of-bank elevations. Although not a major factor, this can effect the results in some analyses.

4. Improper spillway rating curve. In some cases, the reservoir was allowed to draw down during the beginning of the routing because the consultant did not

adjust the rating curve for when the gates are closed to maintain the normal pool level. In other cases, the consultant adjusted the rating curve to correct this, but the simulation then appeared as though the licensee closed all the gates instantaneously when the reservoir receded below the normal maximum pool after the breach developed.

5. The breach was assumed to initiate on the rising limb of the inflow hydrograph. It's imperative that a non-failure case be run first so that the peak headwater elevation at the dam can be determined and used in the failure case. This becomes more complex when conducting a domino-type failure analysis of downstream dams.

Research Needs

The following items are research needs that should be considered:

Probable Maximum Flood Studies

1. PMP. Many of the HMR's cover very large areas that don't take into account local terrain affects that may reduce the PMP for that area. Other refinements can be done that could reduce the probable maximum storm such as the EPRI Wisconsin/Michigan study.

2. Snowmelt. The HMR's in the western states have very approximate methods for combining snowmelt with the PMP. More research is needed in this area as it may be too conservative in some cases to combine 100-year snowpack with extreme temperatures, and the PMP.

3. Loss Rates. The changes in our guidelines point out the need for more research in using the distributed loss rate method with STATSGO data, particularly since the PMF can be very sensitive to the selected loss rates.

Dam Break Studies.

1. Breach Parameters. More research is needed on the proper selection of breach parameters, particularly for earth and rock fill dams. The FEMA/USDA Workshop on Issues, Resolutions, and Research Needs Related to Dam Failure Analysis, in Oklahoma City, OK, June 26-28, 2001, addressed this concern.

2. Computer models. Research is needed on ways the current computer models for unsteady flow can be made easier to use and more flexible to allow users to model more complex dams with multiple spillways.

[Proposed Rules]
[Page 49429-49432]

DEPARTMENT OF LABOR
Mine Safety and Health Administration

30 CFR Parts 56 and 57

RIN 1219-AB70

Metal and Nonmetal Dams

AGENCY: Mine Safety and Health Administration, Labor.

ACTION: Advance Notice of Proposed Rulemaking (ANPRM).

SUMMARY: Dam failures at metal and nonmetal mines have exposed miners to life-threatening hazards. The Mine Safety and Health Administration (MSHA) is reviewing its existing metal and nonmetal standards for dams. The Agency is concerned that some dams pose hazards because they are not designed, constructed, operated, and maintained to accepted dam safety practices. MSHA is considering approaches to better protect miners from the hazards of dam failures and is soliciting information to help determine how best to proceed.

DATES: Comments must be received by midnight Eastern Daylight Saving Time on October 12, 2010.

ADDRESSES: Comments must be identified with ``RIN 1219-AB70'' and may be sent to MSHA by any of the following methods:
(1) Federal E-Rulemaking Portal: http://www.regulations.gov. Follow the on-line instructions for submitting comments.
(2) Electronic mail: zzMSHA-Comments@dol.gov. Include ``RIN 1219- AB70'' in the subject line of the message.
(3) Facsimile: 202-693-9441. Include ``RIN 1219-AB70'' in the subject line of the message.
(4) Regular Mail: MSHA, Office of Standards, Regulations, and Variances, 1100 Wilson Boulevard, Room 2350, Arlington, Virginia 22209- 3939.

(5) Hand Delivery or Courier: MSHA, Office of Standards, Regulations, and Variances, 1100 Wilson Boulevard, Room 2350, Arlington, Virginia. Sign in at the receptionist's desk on the 21st floor.

MSHA will post all comments on the Internet without change, including any personal information provided. Comments can be accessed electronically at http://www.msha.gov under the ``Rules and Regs'' link. Comments may also be reviewed in person at the Office of Standards, Regulations, and Variances, 1100 Wilson Boulevard, Room 2350, Arlington, Virginia. Sign in at the receptionist's desk on the 21st floor.

MSHA maintains a list that enables subscribers to receive e-mail notification when the Agency publishes rulemaking documents in the Federal Register. To subscribe, go to http://www.msha.gov/subscriptions/subscribe.aspx.

FOR FURTHER INFORMATION CONTACT: Patricia W. Silvey, Director, Office of Standards, Regulations, and Variances, MSHA, at silvey.patricia@dol.gov (E-mail), 202-693-9440 (Voice), or 202-693-9441 (Fax).

SUPPLEMENTARY INFORMATION:

I. Background

MSHA's database contains information on nearly 2000 dams at metal and nonmetal mines. Mine operators have constructed these structures for various purposes, such as disposing of tailings or mine waste, processing minerals, treating or supplying water, and controlling run- off and sediment. Although many of these dams are designed, constructed, operated, and maintained according to accepted dam safety practices, others are not and dam failures and near failures continue to occur.

Since 1990 to the present, MSHA investigated dam failures at metal and nonmetal mines in virtually every region of the country and at small and large operations. Failures or near failures have occurred at copper, phosphate, sand and gravel, trona, gypsum, and limestone mines, among others.

Failures have damaged property and equipment, but no deaths or serious injuries have occurred. Examples of dam failures include:

- A 1990 failure of a 100-foot high dam at a limestone mine in Puerto Rico released over 10 million gallons of water and tailings. The failure flooded eight lanes of a major highway, depositing tailings up to eight feet thick. The dam failed about 2 a.m. when no miners were present. The mine operator did not use an engineer to design the dam; several design and construction deficiencies, such as poor compaction, steep slopes, and absence of internal drains, contributed to the failure.
- A 70-foot high tailings dam failed at an andesite quarry in Wisconsin in 1992, tearing apart a railroad track and leveling a power line at the mine. The dam failed at 3 a.m. when no miners were present. The dam was not designed by an engineer. After a

slope failure in 1987, the mine operator installed instruments in the dam to monitor internal water pressures. Pressures beyond a certain level would lead to structural instability. In the 18 months before the 1992 failure, however, the operator checked the instruments only twice. A combination of steep slopes and high internal water pressure contributed to the failure.

- In 1997, a dam at an Arizona copper mine released tailings for over a half mile downstream and to depths of 30 feet. Four miners, one in a haul truck, one in a bulldozer, and two in a pickup truck, were carried down-slope with the slide. One miner injured his back running from the pickup but the others were not injured. The dam was designed by an engineer; however, the mine operator's rate of placement of waste rock on top of the tailings created pressures that contributed to the failure.
- In August 2002, a 450-foot section of dam failed at a sand and gravel mine in Georgia, sending a wave of water and tailings through the shop area. The 30-foot high dam failed shortly after 8 p.m. The wave of water and tailings moved a scraper, backhoe and front-end loader, which were parked in the area. Three miners, near the shop, saw the dam failing and escaped in a pickup truck. The dam, built without being designed by an engineer, had a weak foundation, among other deficiencies.
- In 2004, a dam failure at a sand and gravel mine in California released over 200 million gallons of water and tailings, inundating a hydraulic excavator in an adjacent pit. The failure occurred shortly after 6 p.m., at the start of the maintenance shift. About 15 minutes before the failure, the excavator operator had gone home and a bulldozer operator had parked his machine on the top of the dam. A miner who lubricated the equipment was driving into the pit when he noticed the rising water, halted his truck, and backed up the access road. The dam was not properly designed. The investigation revealed that the design of the dam failed to include an evaluation of the foundation and embankment material strengths, and stability analyses to verify that the slopes of the dam would have adequate factors of safety.

MSHA investigators have found that design, construction, operation, or maintenance deficiencies have contributed to failures of dams at metal and nonmetal mines and exposed miners to hazards.

Since the early 1970's, Congress has enacted laws to create a national program to reduce the risks of dam failures. The Federal Emergency Management Agency (FEMA) is charged with administering the national dam safety program and has issued a series of Federal Guidelines for Dam Safety (Guidelines) (http://www.fema.gov/library/ viewRecord.do?id=1578).

The Guidelines address, among other things, practices and procedures for the design, construction, operation, and maintenance of all types of dams. In the Guidelines, FEMA recommends that dams:

- Be designed by a competent engineer;
- Be constructed under the general supervision of a competent engineer knowledgeable about dam construction;
- Be inspected and monitored at frequent intervals by a person trained to recognize unusual conditions; be inspected by a competent engineer with knowledge of dam safety at a frequency consistent with the dam's hazard potential; and
- Have an emergency action plan, if dams are classified as having high or significant hazard potential in the event of failure. Every two years, MSHA reports on the status of its dam safety program to FEMA, which then sends Congress an evaluation of each Federal agency's program and how it complies with the Guidelines. FEMA has recommended, in biennial reports to Congress and in meetings of the Interagency Committee on Dam Safety, that MSHA promulgate standards to encompass all aspects of design, construction, and inspection for dams at metal and nonmetal mines.

The existing requirements for dams at metal and nonmetal mines, 30 CFR 56.20010 and 57.20010, are derived from the Metal and Nonmetallic Mine Safety Act of 1966. The standards state: ``If failure of a water or silt retaining dam will create a hazard, it shall be of substantial construction and inspected at regular intervals.'' The standards promulgated for coal mines under the Federal Coal Mine Health and Safety Act of 1969 were similar, but specified that the mine operator inspect the dams at least once per week and record inspection findings.

The requirements for coal mines were revised in 1975 after the Buffalo Creek dam failure. For dams which can present a hazard or are of a certain size, the existing standards require a coal mine operator to:

- Have a registered professional engineer certify the dam's design;
- Develop plans for the design, construction, maintenance, and abandonment of the dam and have the plans approved by MSHA;
- Have a qualified person inspect the dam weekly;
- Have instrumentation monitored weekly;
- Correct any hazardous conditions and make required notifications; and
- Submit an annual report with a registered, professional engineer's certification that construction, operation, and maintenance of the dam have been in accordance with approved plans.

II. Key Issues on Which Comment Is Requested

MSHA is asking interested parties to comment on measures to assure that mine operators design, construct, operate and maintain dams to protect miners against the hazards of a dam failure.

MSHA seeks comments on the questions below. If a commenter refers to a particular dam as an example, please identify the mine, or provide the number of miners and the mine's commodity. Also, include the dam's storage capacity, height, and hazard potential and characterize its complexity. Provide enough detail with the comments that the Agency can understand the issues raised and give them the fullest consideration. Comments should include alternatives, rationales, benefits to miners, technological and economic feasibility, impact on small mines, and supporting data. Please include any information that supports your conclusions and

recommendations: Experiences, data, analyses, studies and articles, and standard professional practices.

General Questions

1. MSHA is seeking information concerning current dam safety practices at metal and nonmetal mines. What measures do mine operators currently take to design, construct, operate, and maintain safe and effective dams? What measures do mine operators currently take to safely abandon their dams? For mine operators with dams, please provide your experiences.

2. MSHA is required to inspect every mine in its entirety, which includes dams of all sizes and hazard potential. A common approach for dam safety is to have tiered requirements based on a dam's size and hazard potential. How should MSHA determine safety requirements based on a dam's size and hazard potential? Please include specific recommendations and explain your reasoning.

3. What non-Federal authority regulates the safety of dams at metal and nonmetal mines in your state, territory, or local jurisdiction? Please discuss the specific requirements, including the principles that they address. If possible, please provide information about relevant non-federal dam safety requirements through a hyperlink or other means.

4. What records should be kept of activities related to the safety of dams? Please be specific and include your rationale. What records should be provided to miners if hazardous conditions are found?

Design and Construction of Dams

MSHA's existing standards do not include specific requirements for design of dams. MSHA found that inadequate design contributed to some of the metal and nonmetal dam failures. In responding to the following questions, please discuss how any requirements should vary according to the size or hazard potential of a dam, and why.

5. How should mine operators assure that dams are safely and effectively designed? Please suggest requirements that MSHA should consider for safe design of dams. Please be specific and include your rationale.

6. Please suggest requirements for review of dam designs by mine operators and MSHA and include your rationale for specific recommendations and alternatives.

7. With new standards, operators may need to evaluate and upgrade existing dams. Please elaborate on how the safety of existing dams should be addressed.

8. MSHA's existing standards for dams at metal and nonmetal mines do not address whether a dam is constructed as designed. What measures are necessary to ensure that mine operators construct dams as designed?

9. How should MSHA verify that dams have been constructed as designed? Please explain your rationale.

Operation and Maintenance of Dams

MSHA's existing standards do not contain specific requirements addressing the operation and maintenance of dams.

10. What should a mine operator do to operate and maintain a safe dam? How should MSHA verify that dams are safely operated and maintained? Please be specific.

MSHA's existing standards require dams to be inspected at regular intervals if failure would create a hazard. Inspections can identify hazardous conditions, allowing a mine operator to take corrective action to prevent a failure. The Agency will be referring to two types of inspections in this document, ``routine'' and ``detailed.'' Mine operators should perform frequent, routine dam inspections, which may include monitoring instrumentation, to identify unusual conditions and signs of instability. Personnel with more specialized knowledge of dam safety should conduct detailed inspections to identify less obvious problems and evaluate the safety of the dam. Detailed inspections, occurring less often, would include an examination of the dam and a review of the routine inspections and monitoring data. The Guidelines recommend that inspection personnel be qualified for their level of responsibility and trained in inspection procedures.

11. What measures should mine operators take to assure that dams are adequately inspected for unusual conditions and signs of instability?

12. How often are routine inspections of dams conducted? How often should they be conducted? What determines the frequency? Who conducts the routine inspections? Please be specific and include your rationale.

13. Instruments, such as weirs, provide information on the performance of a dam. How frequently should mine operators monitor dam instrumentation? Please provide your rationale.

14. What information should be documented during routine dam inspections? Please provide your rationale.

15. Does a competent engineer inspect your mine's dam? If so, at what frequency? Please explain the rationale for these

inspections and what is evaluated.

16. How often should detailed inspections be conducted? Please include your rationale.

17. What information and findings should be documented during detailed dam inspections? Please be specific and include your rationale.

18. How should MSHA verify that mine operators conduct routine and detailed inspections? Please explain how your suggestion would work.

Qualifications of Personnel

A mine operator is responsible for the design, construction, operation, and maintenance of dams. For an effective dam safety program, an operator must use personnel who are knowledgeable about dam safety.

19. What qualifications do mine operators currently require of persons who design, inspect, operate, and manage dams? In what capacities are engineers used? Please be specific in your response.

20. The Guidelines recommend that dams be designed by competent engineers. What specific qualifications or credentials should persons who design dams possess? Please include your rationale.

21. The Guidelines recommend that a dam be constructed under the general supervision of a competent engineer knowledgeable about dam construction. What specific qualifications or credentials should a person have who verifies that a dam is being constructed as designed? Please provide your rationale.

22. What training should personnel receive who perform frequent, routine inspections and who monitor instrumentation at dams? In your response, please suggest course content and the frequency of the training, including the rationale for your recommendations.

23. What qualifications or credentials should be required of persons who perform detailed inspections to evaluate the safety of a dam? Please be specific and include your rationale.

Abandonment of Dams

24. Some regulatory authorities require that dam owners obtain approval of a plan to cap, breach, or otherwise safely abandon dams. What actions should mine operators take to safely abandon dams? Please include specific suggestions and rationale.

25. How can MSHA verify that a mine operator has safely abandoned a dam?

Economic Impact

MSHA seeks information to assist the Agency in deriving the costs and benefits of any regulatory changes for dams at metal and nonmetal mines. In answering the following questions, please indicate the dam's storage capacity, height, and hazard potential and characterize the complexity of each dam referenced. Also, please include the state where each dam is located, and the number of employees at the mine.

26. What are the costs of designing a new dam? Please provide details such as hours, rates of pay, job titles, and any contractual services necessary. How often is the design of an existing dam changed? What are the costs of a redesign?

27. What are the costs of constructing a dam? Please provide details based on: Size of dam; labor costs, including hours, rates of pay, job titles; costs of equipment and materials; and any contractual services necessary.

28. Please describe the oversight you provide during dam construction to assure it complies with the design plan. How much does it cost per year per dam for oversight and quality control? What special knowledge, qualifications, or credentials do you require of those who provide oversight?

29. How often do you add height to an existing dam or modify it in some other way? Who supervises the design and construction of these modifications, for example, a professional engineer, competent engineer, contractor, etc? Please be specific and provide rationale for your answer. How much does it cost? Please provide details such as labor costs, including hours, rates of pay, job titles, and costs of equipment and materials and any contractual services necessary.

30. How much does it cost per year per dam for routine inspections? If you incur separate costs for monitoring instrumentation, how much is that cost? How often do you have a detailed inspection conducted? How much does it cost per year for these inspections?

31. Does the state or local jurisdiction in which you operate require you to use a professional engineer? If so, when is a professional engineer specifically required? (If you have dams in more than one state please identify which states require a professional engineer and which do not).

32. What are the costs associated with training personnel who conduct frequent, routine inspections and monitor instrumentation at dams?

33. What costs are involved in capping, breaching, or otherwise properly abandoning a dam? Please provide details of your experience and what was involved when you properly abandoned a dam. Describe any impact of a properly abandoned dam.

34. What are the costs to a mine operator if a dam fails? Please characterize other impacts such as loss of life, environmental damage, etc.

35. Do you have insurance against a dam failure? If so, please specify cost and coverage. Does the insurance carrier require the use of a professional engineer for specific dam activities? If a professional engineer is not required, does the insurance carrier give a discount if one is used? Does your insurance company have any other requirements related to dam safety?

36. What quantifiable and non-quantifiable costs and benefits for the downstream community are involved when a dam is properly designed and constructed? In addition, MSHA welcomes comments on other relevant indirect costs and benefits.

Dated: August 9, 2010.
Joseph A. Main,
Assistant Secretary of Labor for Mine Safety and Health.

D.4. National Park Service

UNITED STATES DEPARTMENT OF THE INTERIOR
NATIONAL PARK SERVICE

Dams and Appurtenant Works Maintenance, Operation, and Safety

Reference Manual 40

Release No. 1
April 2005

This guideline provides an outline of responsibilities for NPS personnel in the planning, design, preservation, rehabilitation/construction, maintenance and operation, inspection, acquisition or disposal of dams under NPS management. Instructions on recommended coordination with local officials and non−NPS dam owners are given also: It is not intended as a technical manual but as a management guideline. A list of recommended technical references is provided in Appendix B.

Application of the guideline by NPS personnel should be commensurate with each dam's size, complexity, operational importance, hazard potential classification, and ownership. Inquires about the application of the guideline may be made to the park, regional, or Washington Office NPS Maintenance, Operation, and Safety of Dams (MOSD) Program coordinators.

CHAPTER ONE
INTRODUCTION

A. General

Dams and their appurtenant works represent a valuable resource to the National Park System and require careful management. The purpose of this guideline is to outline management responsibilities for the preservation/maintenance, operation, and safety of dams under NPS jurisdiction as respectively required by Statute 16 U.S.C. 1 and Departmental Manual Part 758.

These responsibilities include, but are not limited to, planning, design, preservation, rehabilitation/construction, maintenance and operation, inspection, acquisition or disposal of dams under NPS management, and coordination with local officials.

The guideline is not intended as a standard for technology of dams. Current references dealing with the technology of dams and appurtenant works are provided in Appendix B. The guideline may be used, as appropriate, when coordinating with non−NPS dam owners.

Application of this guideline by Regional Directors, Superintendents, and Manager, Denver Service Center (DSC), should be commensurate with each dam's size, complexity, operational importance, hazard potential, and ownership.

Non−NPS dams also will be monitored carefully and information about them kept within the NPS inventory data base management system. These are dams and appurtenant works for which NPS managers have no direct operational responsibility; but where their failure or misoperation could have a definite effect on park safety or operations. Regional Directors and Superintendents will request observer status during inspections and in the preparation and review of emergency action plans at non−NPS dams that significantly affect park areas. A list of such dams is available in the most current NPS Inventory of Dams, Appendix A.

The NPS Park Facility Management Division has overall responsibility for the coordination of the Maintenance, Operation, and Safety of Dams (MOSD) Program; however, there are many NPS programs−land acquisition, cultural resources management, design, construction, law enforcement, security, and public safety that are closely interrelated and should be properly coordinated. A qualified engineer should be assigned by each Regional Director to assure the implementation of all appropriate portions of this guideline when a major action is undertaken in the acquisition, advance planning; preservation/design/construction formal inspection, or disposal of either high (1) or significant (2) hazard potential dams under NPS management. Low (3) hazard potential dams will still receive periodic inspections to assess any changes in their hazard potential, to evaluate maintenance and repair needs, and to determine if they are still essential to park operations. Non−essential dams and appurtenant works should be dewatered and removed in an environmentally sound manner.

Regional Directors and Superintendents will provide, as appropriate for each type and size dam, documentation and reporting as indicated in Chapter Two, section F.

B. Management Objectives

The following objectives are given for the Maintenance, Operation, and Safety of Dams (MOSD) Program:

−Establishment of MOSD Program within WASO and Regional Park Facility Management Divisions with designated program coordinators and/or project engineers;

−Assure management control of technical activities;

Maintain inventory data base on any size, type, owner, or status dam that will affect or is affecting park operations or safety,

Conduct proper planning, design, construction management, or periodic inspection of all dams under NPS management,

Perform corrective action or disposal of deficient dams under NPS management,

−Provide sufficient funding and personnel to support these responsibilities;

−Integrate MOSD Program into other NPS activities, funding sources, and programs;

Routine Maintenance (park facility and maintenance staff),

Cyclic Maintenance (park facility and maintenance staff),

Repair and Rehabilitation (park facility and maintenance staff),

Cyclic Maintenance of Cultural Resources (cultural resources and facility/maintenance staff),

Cultural Resources Preservation Fund (cultural resources staff),

Construction and Major Rehabilitation (park facility/maintenance and Denver Service Center staff),

Risk Management (occupational and public type safety at dam as pertains to heights/depths, dangerous flows and equipment),

Visitor Services Division (guard against vandalism and coordinate emergency action plans at certain NPS and non−NPS dams),

Land and Structures Acquisition (purchase of dams and appurtenant works).

This is not an all−inclusive list. NPS managers should be constantly alert to what impact both NPS and non−NPS dams have on park safety and operations.

C. Applicability

Regional Directors and Superintendents will be responsible for the upkeep of the NPS inventory data base system (Appendix A) for any size, type, owner, or status dam (planned acquisition or disposal) that affects park maintenance, operations, resource, or safety. Where projects do not have any purpose, they should be dewatered and removed under the supervision of qualified personnel and project areas restored. For those dams that are used for park management and operations, NPS managers will annually schedule, as appropriate, funding and personnel to assure that their structures are properly planned, designed, rehabilitated, constructed, maintained, operated and periodically inspected. MOSD program personnel should be contacted immediately when a dam is planned for acquisition or disposal. They will be responsible for the evaluation and inventory of the structure into the MOSD program. A formal safety report including cost estimates to correct identified deficiencies should precede the appraisal of a dam site. The condition of the dam may have a bearing on the fair market value of the property.

D. Definitions

1. General. The following definitions apply to this guideline. More detailed definitions are provided in the explanation of terms used in the NPS inventory of dams database management system as given in Appendix A.

2. Dam or Project. Any artificial or natural barrier including appurtenant works (spillways, inlet and outlet works, tunnels, pipelines, penstocks, power stations, diversions. penstocks, canals, gates, conduits, navigation locks, instrumentation, or mechanical and electrical equipment) that impounds, controls, stores, or diverts streamflow and affects park maintenance, operation, resource, or safety. In some cases these structures will include embankments used for trails, roads, or railroads and during heavy runoff would act as dams and thus pose a possible hazard potential. Also landslides and ice formations need to be evaluated as a possible dam. For the management of NPS dams, there is no limitation to size, type, or status (proposed acquisition or disposal) in regard to these criteria. Dams not essential for environmental preservation, management, or operation of parks should be dewatered and breached under the supervision of qualified personnel and the project area restored. In some cases, the impoundment areas have become filled with sediment or covered by vegetation such that removal or restoration is too expensive or damaging to park resource. In these cases, the dam will still need to be maintained to prevent the impounded sediment or any other material from being discharged downstream if the dam were to fail. This guideline applies with equal force whether the dam has a permanent reservoir or is a detention dam for temporary storage of floodwaters.

In addition to conventional structures, this definition of "dam" specifically includes "tailing dams," embankments built by waste products disposal and retaining a disposal pond.

3. Hazard Potential. Potential loss of life or property or resource damage downstream of a dam from floodwaters released at the dam, or water released by partial or complete failure of the dam, and upstream of the dam from effects of rim slides or upstream dam failure. Also the effect of a failure, partial failure, or other incident should be considered for highways, roads, or trails crossing over the dam. A hazard potential is considered significant if there is a potential to cause loss of life or major damage to permanent structures, utilities, or transportation facilities. A detailed description of hazard potential is provided below. It is not an indicator of structural, maintenance, operational or safety condition.

HAZARD POTENTIAL CLASSIFICATION		
CATEGORY	**Loss of Life (Extent of Development)**	**Economic or Environmental Loss (Extent of Development or Resource)**
5=Deactivated	Not possible including any serious injury from remnants of	None Possible

		deactivated projects	
See Note 1	4 = Unknown	Unknown (A hazard assessment should be performed promptly)	Unknown (A hazard assessment should be performed promptly)
	3 = Low	None expected (No permanent facilities, campsites, or other visitor use areas)	Minimal (Undeveloped to occasional facilities or agriculture. No significant park resources)
See Notes 1 and 2	2 = Significant	Few (No urban developments and no more than a small number of inhabitable facilities, or visitor use areas)	Appreciable (Notable agriculture, industry structures, or park resources)
	1 = High	More than few	Excessive (Extensive community, industry or agriculture, or park resources)

Note 1: Annual Informal Inspection required. See Chapter 6, section C, 2, a.

Note 2: Formal Inspection required every five years. Intermediate Inspection required every two years. See Chapter 6; section C, 2, b and c.

4. Occupational and Public Type Safety. See Chapter 6, section B, 2. The following features or conditions may exist at a structurally sound dam but still pose a hazard potential to NPS personnel or public safety:

a. Waterways
(1) Spillways
(2) Sluices
(3) Intake and release structures
(4) Submerged objects

b. Structural Heights
(1) Embankments
(2) Walls
(3) Cat Walks

c. Mechanical or electrical equipment at dam

5. Dam Failure. Catastrophic type of failure characterized by the sudden, rapid, and uncontrolled release of impounded water. It is recognized that there are lesser degrees of failure and that any malfunction or abnormality outside the design assumptions and parameters which adversely affects a dam's primary function of impounding water is properly considered a failure. They are, however, normally amenable to corrective action.

6. Maintenance. Maintaining structures and equipment in intended operating condition; equipment repair and minor structure repair.

7. Listed are some of the essential National Park Service Operations for dams.

a. Irrigation
b. Hydroelectric Power Generation
c. Flood Control
d. Navigational Lockage
e. Water Supply
f. Recreation
(1) Camping, Sunbathing, or Sightseeing
(2) Swimming and Bathing
g. Conservation of Natural Habitat and Cultural Resources
h. As Bridges, Roadways, and Hiking Trails

8. Rehabilitation or Improvement. Repair of structural deterioration to restore original condition; alteration of structures to improve dam stability; enlarge reservoir capacity, or increase spillway and outlet works capacity; replacement of equipment.

9. Emergency Action Plan. Formal plan of procedures to alleviate dangers during construction of or after completion of a dam to reduce loss of life or damages if conditions develop in which dam failure or misoperation is likely or unpreventable.

CHAPTER TWO
ORGANIZATIONAL MANAGEMENT

A. Authorities

1. 16 U.S.C. 1. General legislative authority for the management and operation of park areas. It includes the maintenance and rehabilitation of those facilities as designated an integral part of the park operation.

2. Public Law 107-310 (The Dam Safety and Security Act of 2002) Re-authorization of the National Inventory for Federal and non−Federal dams, safety inspections of non−Federal dams, development of a comprehensive program for the inspection and regulation of dams for safety purposes, and inclusion of security.

3. Federal Guidelines for Dam Safety, June 25, 1979. Recommendations for a systematic program for the maintenance, operation, safety, or disposal (non-essential) of federal dams.

4. Executive Memorandum, October 4, 1979, Implements Federal Guidelines for Dam Safety as appropriate for each agency.

5. Departmental Manual Part 753 − Specific implementation of DOI program

a. Each agency has responsibility of operating own program.

b. Bureau of Reclamation coordination and advice on DOI agency programs.

c. Important objectives:

(1) Complete an accurate inventory,

(2) Initiate periodic inspections and necessary corrective action,

(3) Develop emergency action plans at appropriate dams.

6. NPS Management Policies, sections 1.5, External Threats and Opportunities; 8.2.5.2, Emergency Preparedness and Emergency Operations; and 9.5 Dams and Reservoirs

B. Management Responsibilities

1. General. The Director is responsible for the development and implementation of policy, resources, and procedures for the maintenance, operation, safety, or else deactivation (non-essential) of each dam under his control. The Associate Director of Park Planning, Facilities, and Lands, with her/his park facility management staff, assists the Director in discharging this responsibility and shares in it. The Maintenance, Operation, and Safety of Dams Program is established as a component of the Park Facility Management Division. The field directorate is responsible for obtaining compliance with this guideline and assuring that procedures are carried out.

Regional Directors, Superintendents, and Manager, Denver Service Center, will establish a Maintenance, Operation, and Safety of Dams Coordinator within their respective organizations as appropriate. See Appendix C for listing. The coordinator will be responsible for ensuring that every effort is made to enhance the maintenance, operation, and safety of dams under NPS control, and to coordinate with non−NPS dam owners about the condition of their structures if they affect park safety, operations, or resource.

Refer to Appendix G for an example letter for coordinating with non-NPS dam project owners and/or regulators. Duties of the office 'will include surveillance and evaluation of administrative, technical, and regulatory practices related to the acquisition, design, preservation/rehabilitation/ construction, maintenance and operations, inspection of dams, and upkeep of the NPS inventory for both NPS and non−NPS dams that affect park safety and operations. The coordinator will represent NPS in the field of dam structures, ownership, reconstruction, management, ecology and cultural significance. The coordinator will be a key spokesperson in resolving interagency water and related land resources conflicts as pertains to dams and appurtenant works.

2. Design Responsibility. The design function can never be considered finished as long as the dam remains in place; design involvement should continue throughout construction and operation of the project. Regional Directors should establish appropriate programs for on−site construction and operational inspections for review by appropriate design personnel and technical specialists.

The program will include frequent and mandatory inspections during construction to confirm that site conditions conform to those assumed for design or to determine if design changes may be required to suit the actual conditions.

The design function includes responsibility for planning any dam instrumentation to be installed during construction and/or operation to monitor conditions that could potentially threaten dam safety.

An initial reservoir filling and surveillance plan will be prepared by the design staff.

3. Construction Responsibility. The responsibility for administering construction and supply contracts, for understanding the design and contract intent, for maintaining technical coordination between design and construction engineers, and for managing the construction staff to assure compliance with specifications should be vested in an identified engineer at the construction project for important dams. Important dams are those classified as high (1) or significant (2) hazard potential, those whose failure would significantly impact park operations or resources, or involving substantial investment. The project engineer should have the administrative and technical control of all resources necessary to accomplish safe construction of the dam. Construction personnel should understand the conditions upon which the design is based and the relationship between these conditions and the design features. When unanticipated conditions are encountered, design personnel should be involved in determining their effect.

4. Maintenance and Operation. The responsibility for project maintenance and operation is assigned to the facility/maintenance or engineering staff. They will handle any requirements for coordination with the Denver Service Center Regional Team or an engineering firm. They will be responsible for preparing annual informal inspection reports for all dams and appurtenant works under NPS management and assure that periodic formal and intermediate type inspection reports are prepared by qualified and licensed engineers for high (1) and significant (2) hazard potential dams under NPS management responsibility.

5. Technical Coordination. A project engineer should be assigned technical coordination responsibility for each dam under NPS management that has either a high (1) or significant (2) hazard potential classification. He should handle necessary technical coordination within the agency and with private and public organizations.

6. Emergency Action Planning. An emergency plan should be formulated by the appropriate Park Manager and his maintenance and law enforcement staff for each NPS dam that has either a high (1) or significant (2) hazard potential. The plan should be in the detail warranted by the size and location of the dam and reservoir. It should evaluate inundation areas resulting from floods or dam failure, and upstream conditions that might result from major land displacements or increased flood flows, including the effects from failure of upstream dams. Regional Directors and Superintendents will coordinate with non−NPS dam owners when applicable to assure that appropriate emergency action plans are implemented for areas within park boundaries.

Where applicable, the plan should include inundation maps for the flows resulting from design floods and from possible failure of the dam. The complete emergency plan should be transmitted to appropriate local, state and Federal governmental bodies. The plan should be periodically reviewed and kept up to date, and periodically publicized to maintain awareness of its existence.
In addition to the emergency plan for the complete dam, a similar plan should be prepared for the construction period, including area facilities that may remain during the period and floods that may be anticipated.

7. Risk−Based Analysis During Floodplain Evaluations. NPS managers should evaluate potential losses due to failure or misoperation, particularly when considering non−structural alternatives in correcting dam deficiencies. Although the value of potential property losses can be estimated,, it is recognized that potential loss of lives can only be quantified, but not evaluated. On new dams, potential losses can be used in study of project alternatives and in assessment of additional safety incorporated into the dam facilities. On existing dams, a risk−based analysis should be considered in establishing priorities for examining and rehabilitating the dams for improving their safety or for the disposal of the dam.

C. Inventory Data Base Management (Reference Appendix A)

In compliance with Public Law 107-310 and Departmental Manual Part 753, the National Park Service has developed an inventory of dams based upon information from the U.S. Army Corps of Engineers National Inventory of Dams (NID), Bureau of Reclamation Inspections, and NPS field reports. See Appendix A. This inventory lists both NPS and non−NPS dams that are located within or immediately adjacent to park boundaries and affect safety, operations, property, or resource. Dams are sorted in the following sequence:

1. Regional codes in alphabetical order;
2. Park Codes in alphabetical order;
3. Hazard Potential classification
4. Size Classification;
5. Structural height in feet;
6. Maximum impounding capacity in acre feet.

The current inventory provides information about inspection results, corrective action, emergency action plans (EAP's) and financial information. This data base will be reviewed periodically by NPS field management for completeness and accuracy and any changes submitted annually by September 30 to the Washington Office of the Park Facility Management Division. More frequent updating should be performed whenever any formal inspection reports or corrective actions are completed on either high (1) or significant (2) hazard potential dams.

Dams in this inventory are classified primarily by their hazard potential which is an indicator of risk and not structural condition. Dams are classified as high (1) or significant (2) hazard potential when their failure or misoperation would jeopardize life or damage significant park resources or facilities. Low (3) hazard potential dams normally would not.

NPS structures will receive annual informal inspections to evaluate operational reliability, maintenance, and any changes in hazard potential classification. Inspection and other evaluation results will be used to update the NPS inventory of dams.

Information requests from, and coordination with, non−NPS dam owners should be well documented.

D. Staffing

1. Technical and Support. NPS managers should assure adequate and competent technical staffing or consultants from other agencies or engineering firms are available to perform the essential functions in planning, design, construction, operation and maintenance, acquisition, or disposal of dams under NPS management. These personnel should be well supported by administrative, clerical, and other elements to ensure that technical staff is not diverted from technical work.

Construction inspection staffing should assure quality as well as quantity inspection coverage. Staffing should be reviewed by higher authority than the local construction office.

The operating personnel must be qualified to perform the many functions required in the operation, including the recognition of conditions possibly detrimental to dam safety. Operation and maintenance staffing requires careful attention to personnel responsible for operating inspections, and to personnel who participate in the periodic inspection program. It is essential that support personnel and equipment are provided to accomplish needed maintenance activities.

2. Professional Advancement. NPS managers should maintain a positive program for advancement of technical personnel in recognition of acquired experience, training and education, and increased competence. It is essential that technical as well as the managerial expertise be required for safe, effective dam design, construction, and operating programs. Professional registration and active membership in professional and technical societies should be given due consideration in assessing qualifications for higher technical positions. Provision should be made for the establishment of procedures to screen and disseminate information on technical advances relating to dam design, construction, and maintenance and operation. Programs for continuing professional training should be oriented toward keeping the technical staff abreast of improved technology.

3. Training. To supplement technical staffing, NPS managers should provide internal personnel training. Provisions should be made for technical personnel to observe and participate in decision−making meetings and to make site visits with more experienced staff. Staff members should be allowed to attend consultants meetings in order to gain valuable experience.

Technically qualified maintenance personnel should be trained in problem detection and evaluation, and application of appropriate remedial (emergency and non-emergency) measures.

Personnel involved in inspections should be trained for the requirements of these duties. The training should cover the types of information needed to prepare for the inspections, critical features that should be observed, inspection techniques, and preparation of inspection reports.

MOSD coordinators, maintenance personnel, and park emergency action plan (EAP) coordinators should complete training every two years to assure they stay abreast of developments in the maintenance, operation and safety of dams. Training for the inspection of dams is normally provided by the Bureau of Reclamation (USBR) on an annual basis. These courses are geared to persons not familiar with engineering or geology but who are responsible for the safety and maintenance of small dams. Contact Inspections and Emergency Management Group, Bureau of Reclamation, 303-445-2740 for further details.

Designated park emergency operations plan coordinators should attend training in the preparation, exercising, or use of EAP's and ensure their integration into the park's overall emergency operations plan.

E. Funding and Personnel Resources

1. General. Continuity and adequacy of funding and personnel are essential to carry out the MOSD program objectives. The NPS budget formulation and execution system offers an opportunity for managers to identify funding priority for those activities, programs, staff levels, or other operating requirements to assure a sound MOSD program. Long−term programming objectives should be developed and adhered to in order to establish a systematic program. To meet these objectives, the following activities should be properly staffed, funded and scheduled by Regional Directors and Superintendents:

Period	**Activity/Resource**
As necessary	Staff
Every two years	Training
Annually	Update NPS Inventory of Dams

Periodic Inspections:	
Annually	Annual Informal Inspections − All dams under NPS management responsibility and essential to park management and operations.
Every two years	Intermediate Inspection − high (1) or significant (2) hazard potential dams only.
Every five years	Formal Inspections − same type as above.
As necessary	Acquisition
As necessary	Project engineer assigned to either high (1) or significant (2) hazard potential dam during major rehabilitation or construction.
As necessary	Design, Plans, Specifications
As necessary	Independent Review of Design.(high (1) or significant (2) hazard potential dams)
As necessary	Major preservation, rehabilitation, or construction
As necessary	Independent Review of Construction (high (1) or significant (2) hazard potential dams)
Annually	Maintenance and Operations
Prepare or update annually	Emergency Action Plans
As necessary	Disposal (sale or removal)

A base level program will be established in each applicable region, park, and DSC to assure that routine and recurring activities are properly funded and staffed. To assure cost effective management of NPS dams, the above sequence should be followed as closely as possible, particularly the periodic inspections which give a comprehensive evaluation of the dam's purpose and condition in relationship to park objectives.

2. Sources. The primary funding and personnel source for this program is the maintenance, repair/rehabilitation, or construction programs. Although Servicewide funding for the MOSD program has been made available out of the Washington Office Park Facility Management Division, it is now the responsibility of Regional Directors, Superintendents, and Manager, Denver Service Center, to assure adequate funding and personnel to meet: MOSD program objectives. There are several other funded programs which are interrelated to the maintenance, operation and safety of dams. The following list is provided to alert NPS managers as to the need for well coordinated and funded programs to prevent overlap and duplication of funding and personnel:

- −Cultural Resources Cyclic Maintenance
- −Preservation, Design and Construction
- −Risk Management Division (occupational and public type safety)
- −Law enforcement and ranger Activities (evacuation during imminent disasters)
- −Land Acquisition (acquire existing dams during land purchases).

3. Methods. There are several methods of requesting funding and personnel to assure the maintenance and safety of NPS dams. Reprogramming of funds/personnel is only for extremely, urgent action within the current fiscal year. This type of programmatic change would occur only when an NPS dam is found to be seriously deficient and poses an imminent threat to life and significant property, and immediate corrective action is necessary. Supplemental budget requests may be used during the current budget year to provide urgently needed funds or personnel, but some delay is allowable in performing corrective action. The regular budget formulation and execution process is used to program funds for routine but yet necessary activities. The NPS Operating Financial System (OFS) is used for preparing requests of annual operating type funding or personnel increases. Activities that would be programmed with this form are as follows:

- −Staff
- −Inventory Data Base Management −Training
- −Travel
- −Periodic Inspections
- −Routine Maintenance, Repairs, and Operation
- −Develop and Update Emergency Action Plans

The NPS Project Management Information System (PMIS) is normally used for multi−year funding for substantial development projects involving major rehabilitation, reconstruction, or acquisition. In developing these funding and personnel resources, close coordination should be made with the budget officer.

4. Cost Accounting. Cost accounting should be used to assure cost effective management of funds and manpower utilized in the

maintenance, operation, and safety of dams.

F. Documentation

1. General. Throughout project acquisition, development, and operation, all data, computations, engineering and management decisions should be documented for planning, site investigation, design, construction, initial reservoir filling, maintenance and operations, or disposal of dams under NPS management. The amount of documentation should vary with the level of hazard potential or operational importance of the structure. Dams under NPS management that have either a high (1) or significant (2) hazard potential classification will receive full documentation.

2. Design/Construction. Written documentation should be maintained in standardized format on all designs for the project. All phases of the construction should be documented, including reporting of routine and special activities. Changes in construction plans and departures from expected site conditions should be documented, with any consequent design changes. As−built drawings should be prepared as facilities are completed, and should be made available to operation and maintenance personnel and to the dam inspection staff. An initial reservoir filling and surveillance plan should be prepared by the design staff. Initial filling should be well documented, including a record of reservoir elevations arid controlled water releases during the filling.

3. Operation and Maintenance Log. Operation and maintenance should. be fully documented, including the routine activities and systematic inspection processes, and complete information on project maintenance, rehabilitation, and improvements. In addition to records on the actual operations, the operating record should include data on reservoir levels, inflow and outflow, drainage system discharge and structural behavior.

If there are maintenance problems that require continuing remedial work, a thorough record of the work should be maintained, and a final report made after complete remedy of the problem.

4. Data Books. Data Books will be prepared by the Bureau of Reclamation (USBR) or other inspecting organization for all NPS high (1) or significant (2) hazard potential dams which are scheduled for formal inspection. Appendix E is a checklist of the types of existing data which will be valuable for evaluating the safety, maintenance, and operation of these dams. Existing information for these Data Books should be prepared and distributed by Regional Directors or Superintendents to USBR or other inspecting organization two months prior to the actual on−site examination.

5. Required Reports. At the indicated times, Regional Directors and Manager, DSC, will submit the following reports or documents to the Director, Attention: Park Facility Management Division:

a. Immediately, report any partial or total dam or appurtenant works failure, misoperation, or uncontrolled release of reservoir affecting park resources, operations, or safety.

b. Immediately, report any injury, death, or significant property or resource loss because of dam failure, misoperation, or uncontrolled release of reservoir. Items wand b should be combined if appropriate.

c. Immediately, report any dam in seriously deficient condition, as so determined from a formal inspection, and whose failure or misoperation would affect park safety or operations. State what corrective action is being taken and when it will be completed.

d. Inventory update at least annually by September 30, on any size, type, owner or status dam (planned acquisition or disposal) 'that affects park resources, operations, or safety.

e. Report annually, by September 30, on any planned or actual major preservation, rehabilitation, construction, acquisition, or disposal of dams that affect park safety or operations.

f. Submit annually, by September 30, list of personnel responsible for coordination of maintenance, operation, and safety of dams program and any training that has been attended.

g. Submit annually, by September 30, a brief financial summary of funding, either programmed or spent by fiscal year, for this program. Items e and g should be combined if appropriate.

h. Distribute annually, by September 30, copies of completed and approved NPS Annual Informal Inspection (AII) reports.

i. Report annually, , by September 30, on the status of park emergency operations plans (EOP's) in which are integrated emergency action plans for any High or Significant hazard potential dams affecting the park. Also for NPS affected areas, an Early Flood Warning, Search/Rescue, Evacuation, and Recovery Plan (ESEP) should be integrated in the park's EOP.

G. Technical Reviews

1. Extent. All factors affecting the safety of high (1) or significant (2) hazard potential dams under NPS management will be reviewed during design, construction, and operation on a systematic basis. Reviews include those internal to the agency and those external to the agency by individuals or boards (consultants) with recognized expertise in dams.

2. Internal. Provision should be made for automatic internal review of all design and construction decisions, methods, and procedures related to dam safety. Reviews should be at levels of authority above the design section or designer−supervisor relation.

3. External. An appropriate level of independent review by a qualified engineering firm or other Federal agency (i.e., Bureau of Reclamation) with safety of dams expertise should be performed during design or construction of dams under NPS management.

CHAPTER THREE
NPS PLANNING AND ENVIRONMENTAL EVALUATION PROCESS
FOR PROPOSED OR EXISTING DAMS

A. General

Considerable information has been compiled in Appendix A about dams that affect park maintenance, operations and safety. Information on these facilities is updated periodically in the NPS inventory of dam data base which is discussed in Chapter Two, section C, and is readily available upon request. These dams should be appropriately considered during the NPS planning and environmental evaluation process in the following sequence of activities to assure their systematic management:

−Inventory of any size, type, owner, or status (proposed acquisition or disposal) dams that affect park maintenance, operations, or safety; −Periodic inspection of any of the above dams under NPS management, including dams proposed for acquisition. If possible, estimates of funding and personnel should be included for corrective action or disposal;

−Acquisition of dams. A formal safety report including cost estimates to correct identified deficiencies should precede the appraisal of a dam site. The condition of the dam may have a bearing on the fair value of the property.

−Qualified NPS project engineer or coordinator assigned to any high (1) or significant (2) hazard potential dam undergoing detailed investigation to assure coordination with guideline;

−Preparation of design, plans, and specifications for major preservation, rehabilitation, or construction;

−Independent review of design, plans, and specifications of high (1) or significant (2) hazard potential dams;

−Performing preservation, major repair or rehabilitation, reconstruction, or construction;

−Independent review of preservation, major repair or rehabilitation, reconstruction, or construction on any high (1) or significant (2) hazard potential dams;

−Maintenance and operations;

−Emergency action plans at either high (1) or significant (2) hazard potential dams; and

−Disposal (sale or removal and restoration of drained impoundment).

B. Acquisition, Holding, or Disposal

During the acquisition, holding, or disposal of dams at NPS administered areas, proper planning should be undertaken to assure compliance with the National Environmental Protection Act (NEPA) of 1969, Public Law 91−190, as amended; various Executive orders on floodplains, wetlands, and safety of dams; and the Section 404 Permit Program by the U.S. Army Corps of Engineers. The objectives of these regulatory requirements are to help provide a safe, ecologically and culturally complementary, and favorable benefit/cost ratio project. This guideline on the maintenance, operation and safety of dams should be properly integrated into the NPS planning and environmental evaluation process. Any dam, regardless of owner, that has a high (1) or significant (2) hazard potential or is/will be important to park management should be discussed in the General Management Plan and its associated environmental document in regard to is purpose and required care. Dams that are not essential to park management and operation should be properly disposed. Information should be requested from non−NPS dam owners during the NPS planning and environmental evaluation process to determine the safety and operational significance of their structures on NPS floodplain management and the need for any emergency action plans. Refer to Appendix G for an example letter for coordinating with non-NPS dam project owners and/or regulators. The Corps will assist in providing information about non−NPS dams and hydrologic and hydraulic analyses in determining the 100 and 500−year floodplains. When possible, the floodplain and emergency action plan inundation mapping should be combined. Flood profiles should be presented with the mapping. A current list of these dams by region and hazard potential is also given in Appendix A.

C. Floodplain Management and Wetland Protection

The NPS floodplain/wetland protection guidance should be carefully reviewed with proper consideration as to the effects of dam safety and operation on floodplains in NPS administered areas. Any dam having a high (1) or significant (2) hazard potential that is located upstream, at, or downstream of a particular floodplain study reach under NPS investigation will be evaluated as part of the environmental assessment process and reported in the "Statement of Finding" as to its safety and operational effects on floodplain

development. The Regional Dams Coordinator will provide the necessary evaluation. Many of the older high (1) or significant (2) hazard potential dams in or adjacent to park boundaries were not designed or maintained to safely operate during the 100 and 500−year base floods which are used for park planning in floodplains. Consequently, because the probable failure of these older dams would produce significant flooding above the natural 100 or 500−year floods, it is paramount that these types of structures receive periodic inspection and appropriate corrective action. For non−NPS dams whose operational safety cannot be ascertained, conservative design and operational procedures in park administered areas should be utilized to compensate for this condition. Inhabitable facilities, utilities or transportation systems will not be built or operated in floodplains subject to the effects of dams in seriously deficient conditions, and there are no active and funded programs for corrective action.

D. U.S. Army Corps of Engineers Section 404 Permit Program

The protection of wetlands is interrelated to the U.S. Army Corps of Engineers Section 404 Permit Program for dredging (digging) or filling in or near any significant stream, river, lake, or harbor. This dredging or filling permit requirement is applicable for new dams or existing dams proposed for modification or disposal. Requirements are based upon volume of material and other considerations. Local U.S. Army Corps of Engineer Districts will provide advice on the applicability of the Section 404 Permit Program for dams and appurtenant works under NPS management.

CHAPTER FOUR
MANAGEMENT OF TECHNICAL ACTIVITIES - SITE INVESTIGATION
AND DESIGN FOR PROPOSED OR EXISTING DAMS

A. General

This section of the guideline outlines the site investigation and design technical activities that Regional Directors, Superintendents, and Manager, Denver Service Center, should ensure are undertaken to obtain safe design or evaluation of dams. It is recognized that the extent of application of this guideline will vary depending on the size, function, and hazard potential classification of the dam.

B. Hydrology

1. Hazard Evaluation. Areas impacted by dam construction and existing dams should be examined for potential hazards to present and future developments in the event of major flooding by controlled flood discharges or flooding induced by dam failure or misoperation. This hazard evaluation is the basis for selection of the performance standards to be use in am design or in evaluation of existing dams. See Chapter 1, Section D, 3.

2. Flood Development. Hypothetical floods, generally of severe magnitude, should be developed for use in design or evaluation of major dam and reservoir features, including development of appropriate floods for the construction period.

3. Flood Selection for Design (or Evaluation). The selection of the design flood should be based on an evaluation of the relative risks and consequences of flooding, under both present and future conditions. Higher risks may have to be accepted for some existing structures because of irreconcilable conditions. Reference should be made to U.S. Army Corps of Engineers Publication, ER 1110-2-106, National Program for Inspection of Non-Federal Dams, Washington, D.C., September 26, 1979, page D-11, for assistance in making the determination.

When flooding could cause significant hazards to life or major property damage, the flood selected for design should have virtually no chance of being exceeded. If lesser hazards are involved, .a smaller flood may be selected for design. Ideally, spillway operation should be evaluated in such a way that dam failure resulting from overtopping would not-significantly increase the hazard to loss of downstream life or property from that flooding condition which would exist just before overtopping failure.

To reduce hydrologic and hydraulic engineering costs, systematized computer programs like HEC-1 Dam Break by U.S. Army Corps of Engineers could be utilized effectively for many small National Park Service dams. This computer program will generate an inflow design flood, route the flood through and/or over the dam (including outflow from any defined hypothetical dam failure), and then route the flood wave to a downstream damage reach for evaluation, all in a single operation. This systematic method allows for a rapid optimization of spillway requirement to adequately protect existing and any anticipated downstream development.

4. Hydrologic Design of Reservoir. In addition to selection of a design flood, the hydrologic design of a new reservoir or the evaluation of an existing project involves consideration of discharge and storage capacities, reservoir regulation plans including constraints, land requirements, and wind/wave effects.

Reservoir regulation plans should be developed in the planning of projects so that realistic release rates will be used in routing the design flood. Regulation plans should include the construction period.

The reservoir regulation plans; water control management plan, and data. Information systems should be periodically reviewed for deficiencies and potential for misoperation during both severe flood events and normal conditions. Necessary corrections should be made as soon as practicable.

5. Downstream Effects. Safety design includes studies to ascertain areas that would be flooded during occurrence of the design flood and in the event of dam failure. The areas downstream from the project should be evaluated to determine the need for land acquisition, flood plain management, Flood Insurance Program or other methods to prevent major damage. Information should be developed and documented suitable for releasing to downstream interests regarding remaining risks of flooding.

6. Warning Systems. Safety design should include an emergency flood warning system and action plan that would effectively notify all concerned in ample time for appropriate action.

C. Earthquake Investigation and Design

1. Investigation Factors. The following factors should−be considered in selection of design earthquakes.

a. Geologic and tectonic setting of the site area by analysis of the lithology, stratigraphy, structural geology, and tectonic history.

b. Historic earthquake record to include the size, location, and other seismological characteristics as available, and the relationship, if possible, with the tectonic setting of the area−in which the earthquakes have occurred.

c. Influence of the properties of the surficial materials on the determination of the size of historical earthquakes.

d. Influence of faulting or other tectonic features on the estimate of the occurrence, size and location of possible future earthquakes.

2. Selection of Design Earthquakes. From the above factors, earthquakes should be selected that have sufficient potential of occurring to require consideration in the dam design. Earthquake description should include estimates to the extent practical of' the size, location, depth, focal mechanism, and frequency of occurrence.

3. Engineering Seismology. Determination should be made of the characteristics of ground motion that would be expected from the design earthquakes, to the extent possible, to include amplitude (displacement, velocity and acceleration), frequency content, and duration.

4. Need for Earthquake Analysis. The probable effects of earthquakes on the dam and its appurtenant structures should be evaluated to determine the need for inclusion of earthquake forces in the structures analyses. Evaluation includes consideration of factors such as the project stage, hazard and risk factors, the size of the dam and reservoir, the potential ground motion at the site, site geology, and type of structure. Where determination is made that no earthquake forces are required in analysis, the determination should be justified.

5. Seismic and Geologic Studies.

a. Earthquake Sources. The essential first step is determination of the design seismic events (usually the maximum credible earthquakes) and an estimate of the ground motion: at the site due to these events. From a study of the regional tectonics and seismicity, and both regional and local− geology, potential sources for seismic events are identified, and the maximum credible earthquake magnitudes postulated.

b. Design Events. A maximum credible earthquake (MCE) is defined herein as the hypothetical earthquake from a given source that could produce the severest vibratory ground motion at the dam. Time histories of the estimated rock motion (accelerograms) at the dam for the various seismic events are selected to characterize the severity of the strong motions by their peak accelerations, frequency content, and duration.

6. Design for Earthquake Forces.

a. Safety Concerns. All earthquake−related safety concerns should be identified. Potential safety concerns include but should not be limited to dam foundation integrity stability, unacceptable stress levels, fault displacements; abutments stability; effects of dam overtopping; dam stability; susceptibility of embankment dams to embankment or foundation liquefaction, cracking or excessive deformation.

b. Analysis Method. Determination of appropriate earthquake analysis methods for evaluation of safety concerns may be, as appropriate, by qualitative evaluations, pseudostatic analysis, and dynamic analysis. The methods selected should be appropriate to the identified safety concerns in accordance with good engineering practice and with currently available technology.

c. Structural Adequacy. Structural adequacy assessments should be made of all safety−related components and concerns identified. These assessments should incorporate all applicable data and analysis.

D. Geotechnics

1. General.

a. Site specifics. After a site is selected, a program for the geotechnical exploration, design, and analysis of that specific site is required. No checklist can be made which would cover all eventualities at all sites, or at any one site, and attempts to formulate such a list would be counterproductive to the intent to ensure dam safety. The best insurance for adequate geotechnical work is a well−trained and experienced staff actively involved in field inspections throughout all phases of the development of the site.

b. Documentation. Because many evaluations are possible for a given set of geotechnical conditions, it is important that full documentation be made of the reasoning process involved in geotechnical decisions. General guidelines for documentation are given in Chapter Two, section F.

c. Management of Diverse Technical Expertise. Geotechnical work encompasses the expertise of geologists, geophysicists, and engineers−all with diverse experience, training, and technical terminology. The administrative and technical supervision

of these experts should be structured to optimize coordination and cooperation. Management should encourage intellectual curiosity and an inquisitive approach to all geotechnical work. Since the field of geotechniques is rapidly expanding, Regional Directors and Manager, Denver Service Center, should assure that those persons associated with site exploration and development, maintain currency with the state of the art.

2. Exploration and Identification of Geotechnical Problems. The exploration program needs to be site specific, flexible, and executed so as to obtain the maximum data from each part of the program. Regional Directors and Manager, Denver Service Center, should ensure sufficient funding for an orderly development of the exploration program in order to reduce uncertainties and to make adequate provisions for required corrective measures.

3. Geotechnical Design. Geotechnical design considerations for the dam foundation and reservoir area are essentially defined after the geologic conditions of the site, the type of dam, and the magnitude of the stresses imposed on the foundation by the dam and reservoir have been determined.

4. Foundation Treatment.

a. General. The preparation of the foundation, including the abutment, is one of the most important phases of construction. The primary purposes of foundation treatment are to provide stability, obtain positive control of seepage, and minimize adverse deformation. The geology, foundation conditions, foundation treatment, and proposed structure should be considered together.

b. Stability. Surfaces should be prepared to provide a satisfactory contact between the foundation and the overlying structure by removal of unsuitable materials. Deficiencies in the foundation which are not removed should either be treated by modification of the structure or by appropriate foundation treatment tailored to handle the conditions encountered.

c. Positive Control of Seepage. Highly permeable foundations should be treated by such measures as cutting off the pervious material, grouting, increasing the seepage path by upstream blankets, or controlling the seepage with drainage systems. Where appropriate, surficial cavities should be traced, cleaned out, and backfilled with material satisfying the design requirements. When cavities exist at depth, measures should be taken to ensure against the migration of cavity material.

d. Control of Piping. Silts and fine sands in the foundation, which are susceptible to piping, should be removed if practical, cut off near the downstream limits of the dam, covered with impervious material, or provided with filtered drainage systems. If pipable material is used in the dam, the foundation surface treatment should prevent migration of dam material into the foundation.

e. Deformation. Foundations subject to differential settlement or foundations having highly compressible anomalies can cause stress concentrations or cracking in dams. The foundation excavation should be shaped to remove abrupt changes in elevation to preclude excessive differential settlement or stress concentrations. Low shear strength material in a foundation can cause shear failure. Excavation and replacement of low strength material is a positive method for treating a foundation that has either or both of these unfavorable conditions.

5. Instrumentation. Although a well conceived foundation instrumentation program serves to monitor the foundation and give an indication of distress, it cannot of itself certify the safety of the foundation. , The expertise of the engineer/geologist to analyze, design and prepare a foundation that will safely carry the loads and water pressure imposed by the dam and the reservoir is fundamental to the design adequacy of the foundation. The purposes of foundation instrumentation are fourfold: to (1) provide data to validate design assumptions; (2) provide information on the continuing behavior of the foundation; (3) observe the performance of critical known features; and (4) advance the state of the art of foundation engineering.

6. Inspection and Continuing Evaluation During Construction. Those responsible for the investigation and design of the foundation should make on−site evaluations to confirm that actual conditions conform to those assumed in the design and to review documentation of site conditions.

7. Reevaluation at Existing Structures. Older dams under NPS jurisdiction may not have been designed to standards equal to current criteria. Also, a substantial portion of safety−related dam incidents are associated with foundation problems which develop in a time−dependent fashion after construction. For these reasons, systematic reevaluations of existing dams should be made for appropriate structures.

E. Hydraulic Appurtenances

1. General.

a. Protective Measures. All hydraulic appurtenances used for releasing water should be designed to preclude jeopardy to the damming provisions.

b. Blockage. Allowances for or preclusion of blockage of hydraulic facilities should be incorporated in the design.

c. Reliability. When operational failure of a gated passage would jeopardize the damming provisions, alternate capacity should be provided. When operation of a gated passage is essential to safety, reliable manpower, communications and accessibility should be assured.

d. Hydraulics and Hydrology. Hydraulics and hydrologic design considerations should be correlated with Chapter 4, B.

2. Design Flood Releases.

a. Spillway and Outlets. Gated spillways are the usual hydraulic appurtenances for control of all, or the major portion of, the design flood and major emergency releases. Outlets (sluiceways, conduits and tunnels) may be used alone or in conjunction with spillways to control flood discharges.

b. Selection of Type. Spillways and outlets should be selected to meet the site specific purposes of the project. For a drainage area with short concentration time combined with reservoir storage capacity that is small relative to the flood volume, especially for embankment dams, (1) the spillway should usually be uncontrolled, and (2) outlets should not normally be used for sole or part control of the design flood except in special cases where the outlet can be uncontrolled.

3. Other Water Releases. Other water release hydraulic appurtenances such as navigation facilities, locks, fish facilities, ice sluices, trash sluices, and water quality facilities should conform to the requirements of section E.1.

4. Reservoir Evacuation. Where practicable, reservoir release facilities ' should be provided to lower the pool to a safe level adequate to correct conditions that might threaten the integrity of the dam.

5. Control of Flows During Construction. The provisions of section E.1 also apply generally to the design of hydraulic appurtenances used during construction. The capacity of these appurtenances should be sufficient to satisfy the discharge requirements of the regulation plan for control of water during construction.

6. Design Criteria and Guidance. If existing design criteria and guidance from past projects and experience are used for design of the hydraulic appurtenances, their sufficiency should be documented.

F. Concrete Dams and Concrete Elements of Embankment Dams

1. Site Specific Design. Because all dam sites are unique, the type of dam and its appurtenances should be specifically matched to site conditions and project requirements. It is essential when reviewing the safety of−existing dams to consider conditions which may have changed physically, new concepts resulting from new technology, and additional project information since construction, i.e., foundation deterioration, increased flood hydrographs, or larger design earthquakes.

2. Materials. Concrete for the structures requires competent investigation of material sources and adequacy of supply testing of materials properties in accordance with accepted standards, and proper proportioning of concrete mixes (including additives) for strength, durability, control of thermal properties, and economy.

3. Design of Structures. There are three components of a dam which must be considered for safety; the foundation, the dam, and its appurtenant structures.

a. Foundation. Proper design of a concrete dam requires information on the foundation geological conditions and material properties to assure its capabilities to support the loads of the dam and reservoir, in its natural state or as improved by foundation treatment.

b. Dam. Concrete dams should be designed to be safe against overturning and sliding without exceeding allowable stresses of the foundation and the concrete for all loading conditions imposed on the dam. The shape and/or curvature of a dam and its contact with the foundation are extremely important in providing stability and favorable stress conditions. Proper consideration should be given to ensure the dam's safety in the event of overtopping.

c. Appurtenances. Safety−related appurtenances such as outlet works structures, spillways, penstocks, powerhouses, and navigation locks should be designed with the same degree of safety as the main dam. If the project has a powerhouse as an integral part of the dam, it should be designed for the same safety requirements as the dam.

4. Definition of Loads. The dam and appurtenances should be designed or evaluated for all static and dynamic loads to which they will be subjected.

5. Design Methods. The methods required for design of the several types of concrete dams and their appurtenances vary from simple to complex, depending on the type and size of the structure, the hazard potential, the site, the kinds of loading, and foundation conditions. The design process involves judgment and analytical expertise to select appropriate methods to analyze

a structure whether it requires a simple or complex analysis and to determine design input that is representative of the range and variation of foundation and structural material properties. The selection of input parameters is just as important as the mechanics of the analysis used.

6. Design Evaluation. Technically qualified supervisory personnel should assure that structures are designed to meet the requirements for safety. This includes confirmation of design input parameters, design methods, and utilization of allowable factors of safety against overturning, sliding, and stressing appropriate to the probability of the loading conditions.

7. Instrumentation. Knowledge of the behavior of structures and their foundations may be given by studying the service action of the structures using observations on embedded and other internal instrumentation and external measurements.

8. Construction and Operational Follow−up. It is necessary that the designers should be involved in the construction and operation processes to confirm that the design intent is carried out, and to allow changes and modifications resulting from redesign necessitated by differences between assumptions and actual field or operating conditions.

G. Embankment Dams

Section F contains general dam considerations. The following additional considerations are applicable to embankment dams:

1. Site Specific Design. Embankment design should be developed for specific site conditions and based on adequate exploration and testing to determine all pertinent geologic and material factors with particular emphasis on shear strength and stability, permeability and control of seepage, and consolidation and settlement

2. Materials. Embankments can generally be designed to utilize locally available construction materials; investigation of materials characteristics is required and problem materials should be either discarded or protected by defensive design. There is often a need for importing special materials for slope protection, filters, and drainage systems. Any embankment zoning should consider the properties and quantities of available materials and the effect of their characteristics on the construction process.

3. Design Constructibility. Embankment designs should be constructible with regard to such items as location of borrow areas with respect to flooding, in situ moisture conditions, climatic effects on construction schedules, width of zoning, and needs for special material processing Design should include protection of critical features from overtopping by floods during construction.

4. Embankment Design. The safety of an embankment is dependent on its continued stability without excessive deformation under all conditions of environment and operation, and on control of seepage to preclude adverse effects on stability and prevent migration of soil materials. Design considerations given below are specific to embankment dams.

a. Seismic. Where earthquake design is necessary, consideration should be given to earthquake−related concerns of soil liquefaction and cracking potential, stability and excessive deformation, abutment stability, overtopping effects, and required defensive measures.

b. Stability. Embankment stability should be analyzed for all pertinent static and dynamic loading conditions without exceeding allowable shearing stresses in the embankment or foundation.

c. Settlement and Cracking. The potential for transverse cracking of the embankment caused by differential settlement, tension zones, and possible hydraulic fracturing should be minimized by careful consideration of abutments, foundation and cutoff trenches, and their geometry and treatment.

d. Seepage. The design should attempt to prevent or minimize seepage through the embankment and its foundation and abutments; however, the designer should recognize that seepage usually occurs and that protective control measures must be provided. Filtering transition zones and foundation and abutment treatment to seal openings should be provided wherever necessary to preclude migration of soil materials into or out of all embankment element contacts both upstream and downstream. Filters, drainage blankets, and transitions should be of a quality and size to conservatively control and safely discharge seepage for all conditions for the life of the project. Particular attention should be given to contacts with foundation, abutments, embedded structures, and the end slope of closure sections to ensure adequate compaction and bonding to control seepage.

e. Zoning. Embankment zoning when used should ensure adequate stability for all pertinent conditions, and should control seepage through the embankment and provide filter action to prevent migration of material.

f. Erosion. Upstream and downstream slopes and foundation and abutment contacts should be protected against erosion from surface runoff, wave action, and impinging currents. Spillways and outlet works should be located and designed so that discharges do not erode the embankment or its foundation.

5. Instrumentation. Embankment design and prediction of embankment performance are based on an imprecise combination of theory and empirical procedure; consequently, performance during construction and operation should be monitored by a design system of external measurements and/or installed instrumentation.

6. Construction and Operational Follow−up: Stability should be evaluated during and after construction using strength parameters from as−placed materials and observations of pore pressure and seepage if and when condition, warrant. Designers should inspect and review performance of embankments during and after reservoir impoundment to detect and provide prompt remedial treatment for problems. While major emphasis is placed on initial impoundment the surveillance should continue for the life of the project

CHAPTER FIVE
MANAGEMENT OF TECHNICAL ACTIVITIES – CONSTRUCTION OR REHABILITATION OF DAMS

A. Introduction

This section of the guideline outlines the construction technical activities that Regional Directors, Superintendents, and Manager, Denver Service Center, should ensure are undertaken to obtain safe construction of dams. The principles and guideline are prepared in a broad sense to ensure that construction of a safe structure is the prime requisite. It is recognized that the extent of application of this guideline will vary depending upon the size, function, and hazard potential.

1. Construction Contracts. Construction contracts should be based on site conditions as interpreted at the time of contract award. All anticipated work on foundation cleanup, preparation, and treatment should be included as specified items of the work. Contract provisions should require the contractor to submit to the construction engineer advance notice of significant shift change to enable adequate inspection coverage of multi-shift operation.

2. Construction/Design Interface. Many aspects of construction directly overlap in design considerations. Reference is made below to numbered paragraphs in Chapter 4, Management of Technical Activities − Site Investigation and Design, which concern such common interests:

a. Geotechnics
- (1) General
  - (i)Site Specifics
- (2) Exploration and Identification of Geotechnical Problems
- (3) Geotechnical Design
- (4) Foundation Treatment
- (5) Instrumentation
- (6) Inspection and Continuing Evaluation During Construction

b. Hydraulic Appurtenances
- (1) Control of Flows During Construction

c. Concrete Dams and Concrete Elements of Embankment Dams
- (1) Site Specific Design
- (2) Materials
- (3) Design of Structures
  - (i) Foundation
- (4) Instrumentation
- (5) Construction and Operational Follow−up

d. Embankment Dams
- (1) Site Specific Design
- (2) Materials
- (3) Design Constructibility
- (4) Embankment Design
  - (i) Settlement and Cracking
    - (ii) Seepage
  - (5) Instrumentation
- (6) Construction and Operational Follow−up

B. Evaluation During Construction. Field personnel must be highly trained and experienced in the design principles and site

conditions are to be understood and a safe structure is to be constructed.

When differing site conditions (different from those anticipated) are encountered construction supervisory forces must have authority to suspend any or all portion of the work affected until the design engineers, with assistance as needed, can evaluate the condition and determine if design modification is required.

Construction milestones should be identified when the design engineers will inspect the work and concur with the progress of construction.

C. Orientation of Construction Engineers and Field Inspectors. Construction engineers need to e aware of design philosophies and assumptions as to site conditions and function of project structures, and must understand the designers' intent concerning technical provisions in the specifications.

Construction specifications, supplemental reports, and conferences to orient field personnel to the particular site, the features of the dam, and the designers' intent for construction should, as applicable, include the following:

1. Design Related

a. Design concepts. An explanation should be given of philosophies and assumptions and the reasons for special requirements in the specifications to assure accomplishment of design intent.

b. Construction sequence. Identification and explanation of the dates to which construction progress must conform to satisfy project requirements, and the special sequences for construction activities that are required by design.

c. Instrumentation systems. Description should be given of the instrument types, their purpose, the procedures for installation of each instrument type, the method and time interval for reading each instrument, and the importance of prompt data transmission for analysis and feedback.

d. Care and diversion of water. Description of the design features included to prevent and/or control flooding and turbidity and accomplish diversion and closure of the dam. This should also contain the design requirement for controlling normal flows through the work area to assure that construction is always accomplished under dry conditions. Critical aspects of the construction schedule related to flood problems should be emphasized.

2. Foundation

a. Description. Discussion of the type of foundation conditions expected to exist, i.e., overburden, general rock description, formation weaknesses (such as joints, shears and faults), and acceptable foundation conditions.

b. Excavation. Discussion of the depth and nature of materials expected to be encountered, the controls for dewatering and blasting, identification of critical areas, quantity estimates, and an acceptable foundation.

c. Preparation. Review of the methods of rock foundation preparations such as: cleaning; the use of wire mesh, mortar, shotcrete, or cock bolts; grouting, and treatment of faults, shears and joints; as well as subsequent exploration to assure desired results. Review of methods of earth foundation preparation.

3. Materials

a. Materials from required excavation. Definition should be given of acceptable and unacceptable properties of materials, the usage and the processing required if used, and identification of waste area locations.

b. Other excavated materials. Identification of the location and amount of useable material, "based on current test data," available from all designated areas, including borrow pits. Review of the blasting methods that are expected to produce the desired rock quality and sizes. Discussion should be given of the expected amounts of waste and the areas where borderline material may be used in lieu of wasting, such as in berms or certain zones of the downstream shell of an earthfill dam.

c. Embankment. Description should be given of both acceptable and unacceptable material properties, placement, and compaction procedures for each zone. Review of required procedures for areas adjacent to abutment, around instruments, and at interfaces between zones and/or structures.

d. Concrete and concrete materials. Identification should be given of acceptable aggregate sources and review of mix designs, joint and surface treatment, finish requirements, form tolerances, and placement procedures. Cooling as well as hot and cold weather protection requirements should be defined.

4. Construction General

a. Field control. Discussion of the quality assurance procedures required to control all phases of construction. Acceptable placement standards should be established for concrete, earth and rock materials, and embankments.

b. Structural. Discussion should be given of structural steel installation, reinforcing steel placement, and anticipated problem areas and specified treatment for such areas.

c. Mechanical−electrical. Description of equipment installation requirements, special procedures, performance tests, protective coatings, and protection devices such as ground fault indicators.

d. Environmental. Identification of those construction controls required to minimize environmental damage, comply with environmental regulations, and assure public involvement.

D. Construction Assurance

1. Construction Procedures. Criteria must assure that acceptable methods and procedures are specified and utilized to accomplish design requirements. At the time, the design and construction organizations must maintain the flexibility necessary to modify design, material requirements, and construction specifications as conditions dictate without altering the basic design intent.

2. Construction Materials Testing. A materials laboratory must be established at the field construction office that is adequately staffed and equipped to accomplish the on−site testing requirements set forth in the engineering considerations and instructions to field inspection personnel.

3. Quality Assurance. It is mandatory that adequate construction quality assurance systems and procedures be established to assure safe dam construction. The quality assurance system must guarantee, by direct inspection and testing, that construction is accomplished in compliance with the contract plans and specifications. Daily inspector's reports, laboratory test data records, and photographs are the minimum mandatory methods of documentation. General guidelines for documentation are given in Chapter two, section F.

As part of the quality assurance program, the contractor should normally be required to submit various plans for approval not limited to, but including, the following:

Construction Schedule
Safety Program
Care and Diversion of Water (including pollution control)
Fire Protection
Plant layout (including haulroads)
Environmental measures
Equipment Inventory
Dewatering Foundations and Borrow Areas
Excavation Sequence of Foundations and Borrow Areas
Drilling and Blasting Procedures
Concrete Placement
Restoration of Construction Area

CHAPTER SIX
MANAGEMENT OF TECHNICAL ACTIVITIES − OPERATION AND MAINTENANCE FOR PROPOSED OR EXISTING DAMS AND APPURTENANT WORKS

A. General

This section of the guideline outlines the management responsibilities for operation and maintenance, periodic inspection program, and emergency action planning that Regional Directors, Superintendents, and the Manager, Denver Service Center, should ensure are undertaken to obtain the safe and economic operation of dams under their jurisdiction. It is recognized that the extent of application of this guideline will vary depending on the size, function, and hazard potential classification of the dam.

B. Operation and Maintenance

1. General. All features of NPS dams and appurtenant works should receive maintenance or operation as recommended from

inspection reports−annual informal, intermediate, or formal. These reports should be prepared by trained and experienced engineers familiar with the maintenance and operation of small dams.

Unless it is an extenuating condition, extensive maintenance or testing of dam equipment should only be performed because of recommendations in an inspection report. These recommendations should be performed by personnel familiar with the maintenance and operation of small dams.

Serious maintenance, operational, or safety problems that are discovered during maintenance or operation work should be reported immediately to the Park Superintendent and personnel responsible for inspections as to the proper action to be taken. Maintenance and operations should be scheduled far enough in advance to take advantage of good weather periods, terrain conditions, and manpower and equipment availability to assure safe and economic work.

A log of maintenance and any required operation will be maintained and filed with the previous Annual Informal Inspection. The log will list the crew supervisor's name, date, activity accomplished or attempted, if incomplete, and total cost (overhead, materials, and labor, if readily available). Information about failures (partial or total), misoperation, accidents, floodings, or instrumentation readings should also be kept in the log.

2. Operating Procedures. Operations consist of the periodic testing of gates or any other type equipment to assure reliable use, establishing instrumentation as required, or reviewing any operating manuals or emergency action plans for completeness and accuracy. When appropriate, written operating instructions should be prepared for the dam and its associated structures and equipment. The instructions should cover the functions of the dam and reservoir and describe procedures to follow during flood conditions to ensure dam safety.

If appropriate for more critical NPS dams, reservoir operating rule curves should be available for each normal mode of operation and for emergency conditions.

An auxiliary power system, such as a gasoline, crane or diesel−operated generator, is essential if the outlet and spillway gates and other dam facilities are electrically operated.

All spillway and outlet gates should be tested on a regular schedule. The tests should include use of both the primary and the auxiliary power systems.

Project security is a matter of concern at important dams and appurtenant works. This includes preventing structural damage by vandals or saboteurs and unauthorized operation of outlet or spillway gates. In some cases restricting public access is essential and security patrols may be necessary.

Occupational and public type safety is of paramount importance at certain dams and reservoirs. Specifically, this type safety at the dam, appurtenant works, on and around reservoirs, and below the dam should be considered, particularly in recreational areas. Safety measures should include identification of high watermarks to indicate past or probable reservoir levels and streamflows, posting of safety instructions at highly visible and key locations, and providing audible safety warnings upstream of and below outlets as appropriate.

When applicable, occupational and public safety should be evaluated by personnel from the Safety Division. They should accompany the engineering team for the dam inspection to evaluate hazard potentials to personnel and visitors such as heights, depths, dangerous flows, mechanical and electrical equipment, and supplies. Their recommendations should be referenced in the inspection report.

Communication should be maintained among affected governmental bodies and with the public to enhance the safety aspects of the operation of the dam, if warranted. Communication alternatives include written communications, radio, telephone, television, and newspapers.

In the following sections, outlets or outlet gates refer to gates or valves on any outlets such as sluices, conduits or tunnels, pumps, generating units, and infrequently operated plant intake and discharge gates. If the project has a navigation lock, emergency closure and other infrequently operated equipment should also be included.

3. Maintenance. Maintenance is normally the preserving of structures, appurtenant works and equipment in intended operating condition by the proper control of vegetation, removal of debris and trash, equipment repair, and minor structural repair. It is not the repair of structural deterioration to restore original condition, improvements for dam safety, enlarging reservoir capacity, increased spillway and outlet capacity, or the replacement of equipment. Such major rehabilitation of construction should be carried out with the assistance of NPS, Denver Service Center (DSC), and Bureau of Reclamation (USBR).

The following list of typical maintenance work is provided:

−harmful vegetation, debris, and trash should be removed from the dam, appurtenant works, immediate upstream and

downstream areas, and access roads to assure structural integrity, reliable operation, visual observation, and accessibility. Undesirable material should be removed and properly disposed of so as to prevent problems during high water, winds, fire, or vandalism; −vegetation maintenance for erosion control and esthetics;

−large vegetation which has become an integral part of the dam or appurtenant works needs to be carefully evaluated to determine if removal is warranted;

−lubrication of equipment;

−painting;

−maintaining internal drainage systems; −minor mechanical and structural repairs;

−correcting minor deterioration of concrete and embankment surfaces;

−taking measurements from instrumentation;

−placement of signs warning of heights/depths, dangerous flows, and equipment, when applicable;

−placement of barriers to prevent unauthorized access;

−all maintenance work is to be performed in a safe manner. The use of personal−protective and safety devices is required when so determined by the supervisor or the Superintendent in consultation with the area safety officer or Regional Safety Manager.

C. Periodic Inspection Program

1. General. The purpose of the NPS periodic inspection program is to verify throughout the operating life of the project the structural integrity of the dam and appurtenant structures and assure the protection of human life and property.

All NPS dams will receive some level of evaluation based on current technical guidelines and criteria prior to any significant repairs, rehabilitation, or construction. New dams added to the inspection program should be planned, designed, and constructed in accordance with current technical criteria. Improvements in dam technology require that dams and appurtenant structures be reassessed to assure dam safety for more stringent design and materials criteria.

Regional Directors and Superintendents are responsible for assuring that the existing dams for which they are responsible are periodically inspected, and that new dams are inspected initially upon completion of construction and periodically thereafter.

2. Types and Frequencies of Inspections. The inspection types and intervals herein recommended are for guidance in developing inspection programs for all dams under NPS management. This guideline does not preclude other inspections or more frequent inspections if deemed necessary, depending on project history and importance of the facility.

Inspection personnel should be selected carefully, have qualifications commensurate with their assigned levels of responsibility, and receive training in the inspection procedures. Qualifications and training required for inspection personnel may vary with the complexity of the facility and with the level of the inspection.

a. Annual Informal Inspection. All dams and appurtenant works under NPS management will receive this type of inspection. Inspection is performed annually by NPS or contract personnel to evaluate hazard potential classification, maintenance, structural and mechanical integrity for operational reliability, visitor safety on or around the dam and updating or completing the NPS inventory of dams data base management system. Immediately after any unusual event such as large floods, earthquakes, suspected sabotage, vandalism, or structural or operational failure, an inspection will be performed by NPS personnel. Particular attention should be given to detecting evidence of (or changes in) leakage, erosion,−sinkholes, boils, seepage, slope instability, undue settlement, displacement, tilting, cracking, deterioration, and improper function of drains and relief wells.

The checklist given in Appendix C of Safety Evaluation of Existing Dams, USBR, 1980, or equivalent form, should be used to assure thoroughness. Previous inspection reports should be reviewed to see what earlier corrective action recommendations were or were not performed. −A brief explanation should be written as to why previously recommended maintenance or operations were not performed.

The annual informal inspection report package should consist of the following items:

−Map;

−Any photographs or drawings;

−Completed checklist of dam and appurtenant features

−Very brief memorandum with recommended corrective action for use by maintenance and operations personnel;

−Operational and maintenance condition code specified;

−Updated inventory listings or forms;

The following codes should be used to describe the operational and maintenance condition of structures and related equipment, and reported into the NPS Inventory:

1−Will fulfill intended purpose and required annual maintenance or operations are performed;

2−Will fulfill intended purpose but required maintenance, operations, or minor repairs is needed;

3−May not fulfill intended purpose and maintenance or major repair is needed;

4−Will not fulfill intended purpose and major repair or rehabilitation is needed.

Reports should receive review and be given signature approval, and the following distribution made:

1−Director (Park Facility Management Division)
1−Regional Director (Park Facility Management Division)
1−Park Superintendent

b. Intermediate Inspections. This type inspection is required of dams under NPS management that have either a high (1) or significant (2) hazard potential. For low hazard potential dams, intermediate inspections are not required. Intermediate inspections should include a thorough field inspection of the dam and appurtenant structures, and a review of the records of inspections made at, and following, the last formal inspection.

If unusual conditions are observed that−are outside the expertise of these inspectors, arrangements should be made for inspections to be conducted by specialists.

(1) Frequency of intermediate inspections. Intermediate inspections, should be performed every three years where there is a high probability that dam failure or misoperation could result in loss of life or significant property damage.

(2) Qualifications of personnel for intermediate inspections. Intermediate inspections should be performed by technically qualified engineers, experienced in the operation and maintenance of dams and trained to recognize abnormal conditions. The inspectors should have access to and be familiar with all pertinent histories for the dam, and should be directly responsible for and intimately familiar with the operating characteristics of the dam. The dam tender or operator should be a participant in these inspections.

(3) Currently this type of inspection will be performed by USBR personnel as deemed necessary.

c. Formal and Special Inspections. This type inspection is required of dams under NPS management that have either a high (1) or significant hazard (2) potential. Formal inspections will not be performed for dams under NPS jurisdiction and classified as low hazard potential. A formal inspection is required periodically to verify the safety and integrity of the dam and appurtenant structures. Formal inspections should include a review to determine if the structures meet current accepted design criteria and practices. The inspection should include a review of all pertinent documents including instrumentation, operation, and maintenance and, to the degree necessary, documentation of investigation, design, and construction. In making the detailed inspection of the dam, appurtenant structures and equipment, diving inspections of−underwater structures affecting the integrity of the dam should be included. All formal inspections should be conducted by a team of highly trained specialists. To assure that a dam and its appurtenant facilities are thoroughly inspected, checklists should be prepared to cover the condition of structural, electrical, and mechanical features. This inspection should also verify that operating instructions are available and understood, instrumentation is adequate and data assessed to

assure structures are performing as designed, and there are emergency provisions for access to and communication with all project operating facilities.

(1) Frequency of formal inspections. Formal inspections should be made periodically at intervals not to exceed 6 years. Depending on past experience or the project history, some dams may require more frequent formal inspections.

(2) Frequency of special inspections. Special inspections should be performed immediately after the dam has passed unusually large floods and after the occurrence of significant earthquakes, sabotage, or other unusual events reported by operating personnel.

(3) Qualifications of personnel for formal and special inspections Formal and special inspections should be conducted under the direction of licensed professional engineers experienced in the investigation, design, construction, and operation of dams. The inspection team should be chosen on a site−specific basis considering the nature and type of the dam. The inspection team should be comprised of individuals having appropriate specialized knowledge in structural, mechanical, electrical, hydraulic, and embankment design; geology; concrete materials; and construction procedures. They must be capable of interpreting structural performance and relating conditions found to current criteria and safety aspects. It is imperative that the inspection team adequately prepare for the inspections by reviewing and discussing all documents relative to the safety of the dam.

(4) The Bureau of Reclamation (USBR) is the preferred organization to perform both formal and intermediate inspections and any special studies or emergency services for NPS, particularly on either the high or significant hazard potential dams. However, NPS managers may, at their discretion, utilize other qualified agencies or contractor services when USBR would not be able to respond in sufficient time. NPS personnel will accompany the team and act as observers during this inspection.

(5) Data Books will be prepared by USBR or other inspecting organization for all NPS high (1) or significant (2) hazard potential dams which are scheduled for formal inspection. Appendix E is a checklist of the types of existing data which will be valuable for evaluating the safety, maintenance, and operation of NPS dams. Existing information for these Data Books should be prepared and distributed by Regional Directors or Superintendents to USBR or other inspecting organization two (2) months prior to the actual on−site examination.

(6) The following classification system will be used to describe safety of dam conditions. One of these classifications is assigned to a dam following an on−site examination and evaluation using available data and current state−of−the−art knowledge:

S−Satisfactory	No existing or potential dam safety deficiencies are recognized. All essential elements can be expected to function under all conditions, including such events as the maximum probable flood (MPF) or maximum creditable earthquake (MCE), which have only a remote chance of occurring;
F−Fair	No existing or potential dam safety deficiencies are recognized for normal operating conditions. All essential elements can be expected to function under normal operating conditions. Remotely occurring events of magnitudes approaching a MPF or MCE will likely cause a dam safety deficiency;
P−Poor	A potential dam safety deficiency for normal operating conditions is recognized. Major damage has occurred at one or more of the essential elements or may be anticipated to occur during normal operating conditions. Immediate corrective actions to resolve the deficiency(s) are recommended and reservoir or other project restrictions may be necessary until problem is resolved;
U−Unsatisfactory	A dam safety deficiency is recognized for normal operating conditions. One or more essential elements will not operate adequately under normal operating conditions. Problem resolution requires immediate action.

In association with any classification term, maintenance work to correct an existing condition of one or more essential elements, or installation of additional equipment to enhance dam safety and/or to monitor performance, may be advised. It is expected that adequate maintenance can prevent many dam safety deficiencies from occurring.

3. Instrumentation. Instrumentation or performance observation devices are used to supplement visual inspections in evaluating the performance and safety of dams. Careful examination of instrumentation data on a continuing basis may reveal a possible critical condition. Conversely, instrumentation may be a means of assuring that an observed condition is not serious and does not require immediate remedial measures.

a. Adequacy of Instrumentation. Instrumentation to monitor structural and functional performance should be installed in dams

where complex or unusual site conditions have been encountered or where there is a high probability that failure could result in loss of life or extensive property damages.

b. Observation of Monitoring Devices. The instrumentation data should be collected by personnel trained specifically for the purpose, including training to recognize and immediately report to those 'responsible for inspections any anomalies in the readings or measurements. Performance observation data should be properly established for record purposes. The frequency of instrument readings should be established at the time the instrumentation system is designed in order to give a timely warning of possible adverse conditions.

c. Data Analysis. It is essential that instrumentation data be processed, reviewed and assessed in a timely manner by a specialist familiar with the design, construction, and operation of the project. Operation manuals and design information should be referred to in the evaluation of possible adverse threats.

4. Correction of Deficiencies. The inspection program could reveal those deficiencies or potential deficiencies which, if uncorrected, could eventually lead to failure or misoperation of the dam. Deficiencies may vary from emergency type items where immediate action is required to non-emergency type items which must be corrected in a timely manner but do not present an immediate danger to the safety of the structure. In all cases, corrective action should be made under the supervision of qualified personnel. Emergency action plans to be implemented when failure has already occurred or is imminent are discussed in Emergency Action Planning.

a. High Priority Corrective Action. High priority corrective action is required for deficiencies which could result in failure of the dam within a short period of time. The Director will be notified immediately by the appropriate Regional Director of any dams (NPS or non−NPS) that are in this condition, and what action is being taken to remove the threat to park safety or operations.

b. Non-emergency Corrective Action. Non-emergency corrective action is action taken when there is no immediate threat to the safety or operation of the dam, or any threat to life or property downstream. The Director will be notified immediately by the Regional Director of any dams (NPS and non−NPS) that are in this condition. The corrective action should be scheduled in advance of the fiscal year in which the work is to be done to allow time for planning, funding through the normal budgeting process, and arranging for special reservoir operations when required. Some of these deficiencies may be corrected through the regular operation and maintenance program discussed in operations and maintenance.

c. Follow−up Action. Periodic inspection reports should continue to list identified deficiencies along with any newly discovered deficiencies and show the status of corrective action., Appropriate inspection personnel should make frequent field examinations, as long as the problem exists, to see that all corrective measures are being completed. When deficiencies are not corrected in a reasonable length of time, an investigation should be made to determine the reason for delay, and the Director should be notified of the findings.

5. Documentation. Proper documentation of the dam's current and past performance is necessary to assess the adequacy of operation, maintenance, surveillance, and proposed corrective actions. A complete record or history of the investigation, design, construction, operation, maintenance, surveillance, periodic inspections, modifications, repair, and remedial work should be established and maintained so that relevant data relating to the dam is preserved and readily available for reference. This documentation should commence with the initial site investigation for the dam and continue through the life of the structure. This information will be collected by NPS personnel and delivered to the USBR to develop Data Books on high (1) and significant (2) hazard potential dams. See Chapter Six, section C.2. The data base management system for NPS dams will be maintained to keep current all data elements.

a. Instrumentation. All instrumentation observation data and evaluation thereof should be properly tabulated and documented for record purposes.

b. Inspections. All inspection observations, especially as related to the safety of the dam, should be documented. The extent and nature of inspection reports required for the annual informal, intermediate formal, and special inspections, will vary in proportion to the intensity of the inspection and the nature of the findings. Informal inspection reports may range from memoranda to brief reports. Intermediate inspection reports may vary from memoranda or trip reports to more formal reports containing substantial records, detail, and recommendations. Formal and special inspections require complete, formal technical reports of all findings, corrective actions and recommendations for permanent record and reference purposes in order to form a basis for major remedial work when required. All reports should be in a self−explanatory form that permits their retention as permanent records and should carefully document times of inspections, inspection personnel, and findings of the inspection.

c. Correction of Deficiencies. All deficiencies corrected as a result of the recommendations contained in periodic inspection reports should be fully documented in report form and made a part of the permanent project record. Alterations made to the facility as a result of changes in criteria to meet current practices or changes in dam technology should be fully documented, including as-constructed drawings. Promptly perform corrective action on deficient dams. Dams listed as **SERIOUSLY DEFICIENT** should be corrected immediately. A dam is **SERIOUSLY DEFICIENT** if:

1 An official inspection report classifies the dam safety condition as:

a **POOR**—this classification is applied when major damage has occurred, or may be anticipated to occur, at one or more of the essential elements during normal operating conditions. Immediate corrective actions to resolve the deficiency(s) are recommended and reservoir or other restrictions may be necessary until problems are resolved; or

b **UNSATISFACTORY**—this classification is applied when one or more essential elements will not operate adequately under normal conditions. Problem resolution requires immediate corrective action; and/or

2 If the maintenance condition is rated:

a "**3"**, which indicates it may not fulfill intended purpose and maintenance or major repair is needed) or;

b "**4"**, which indicates it will not fulfill intended purpose and major repair or rehabilitation is needed.

6. NPS Observer Status at non−NPS Dams. Refer to Appendix G for an example letter for coordinating with non-NPS dam project owners and/or regulators.

a. General. Dams that NPS has no jurisdiction over, but are located immediately adjacent to or within park boundaries and affect safety or operations, will be carefully monitored. Regional Directors, Superintendents, and Manager, DSC, will report and maintain information about these non−NPS dams in our inventory data base system. Regional Directors should request the presence of NPS observers during the inspection of non−NPS dams located within or immediately adjacent to park boundaries and that are in the high (1) or significant (2) hazard potential classification. Such coordination will assure NPS awareness of their condition.

b. U.S. Army Corps of Engineers Safety Condition Codes. The following dam safety assessment codes are from the U.S. Army Corps of Engineers' National Inventory of Dams (NID) data base management system, circa 1981. These safety of dams condition classification are referenced here for non-NPS dams located either within or immediately adjacent to park boundaries.

−For non-NPS dams or appurtenant works may have been assessed as "Unsafe," if deficiencies are assessed to be of such a nature that, if not corrected, they could result in the failure or misoperation of the project with subsequent loss of life and/or substantial property damage. This classification is analogous to the National Park Service and Bureau of Reclamation safety of dams condition classification of Poor (Chapter 6, section C, 2, c, (6)).

−If the probable failure of an "Unsafe" dam or appurtenant works is judged to be an imminent threat to life or substantial property and immediate action is required to reduce or eliminate the deficiencies, the "Unsafe" condition of the dam should be considered an "emergency." . This classification is analogous to the National Park Service and Bureau of Reclamation safety of dams condition classification of Unsatisfactory (Chapter 6, section C, 2, c, (6)). If the probable failure is judged not to be imminent, the "Unsafe" condition should be considered a "non−emergency."

D. Emergency Action Planning

1. General. It is intended that this guideline will minimize the risk of future dam failures. Nevertheless, it is recognized that despite the adequacy of this guideline and its implementation, the possibility of dam failures still exists. Even though the probability of such failures is small, preplanning is required to identify conditions which could lead to failure, in order to initiate emergency measures to prevent such failures as a first priority, and, if this is not possible, to minimize the extent and effects of such failure. This guideline provides operating and mobilization procedures to be followed upon indication of an impending or possible dam failure or a major flood. Project information and inspection results will be used to keep the NPS inventory data base system current.

Emergency Action Plans (EAP) are required for all high (1) or significant' (2) hazard potential dams under Federal regulation or jurisdiction: The purpose of an EAP is to provide early warning and evacuation in the event of either a possible or actual dam failure or misoperation. An example EAP is provided in Appendix F for use by the parks. Superintendents should designate an EAP Coordinator, along with other individuals as given in Appendix F, at appropriate parks, with either NPS or non−NPS dams within the specified hazard potential category (see inventory in Appendix A). EAP coordinators should initiate EAP's for appropriate NPS dams or coordinate with non−NPS dams owners in the implementation of their EAP within park boundaries. Refer to Appendix G for an example letter for coordinating with non-NPS dam project owners and/or regulators.

Pertinent information about EAP's should be recorded into the NP$ Inventory of Dams. Since coordination is needed with state and local officials in implementing EAP's, a list of state dam safety officers has been, provided in Appendix G.

2. Coordination with non−NPS Dam Owners. In those regions where high or significant hazard potential non−NPS dams exist within or immediately adjacent to park boundaries, Superintendents will request from those owners coordination in the preparation and implementation of any Emergency Action Plans as appropriate for park areas.

3. Evaluation of Emergency Potential. Prior to development of an emergency action plan, consideration must be given to the extent of land areas, and types of development within the areas, that would be inundated as a .result of dam failure or flood, and the time available for emergency response.

a. Determination of Mode of Dam Failure. There are many potential causes and modes of dam failure, depending upon the type of structure and its foundation characteristics. Similarly, there are degrees of "failure" and, often, progressive stages of failure. Many dam failures can be prevented from reaching a final catastrophic stage by recognition of early indicators or precursor conditions, and by prompt, effective emergency actions. While emergency planning should emphasize preventive actions, recognition must be given to the catastrophic condition, and hazard potential should be evaluated in that light. Analysis should be made to determine the most likely mode of dam failure under the most adverse condition and the resulting peak water outflow following the failure. Where there is a series of dams on the stream, analyses should include consideration of the potential for progressive "domino" failure of the dams.

b. Inundation Maps. To evaluate the effects of dam failure, maps should be prepared delineating the area which would be inundated in the event of failure. Land uses and significant development or improvements within the area of inundation should be indicated. The maps should be equivalent to or more detailed than the United States Geological Survey (USGS) quadrangle maps, 7−1/2 minute series, or of sufficient scale and detail to identify clearly the area that should be evacuated if there is evident danger of failure of the dams. Since detailed inundation maps may not be readily available or easily used at a disaster area, a concise and clear word description should also be prepared for easy word−of−mouth communication−' The word description would tell potential evacuees how high they should elevate themselves above the river or by horizontal distance to an area known to be safe from inundation. Copies of the maps should be distributed to local government officials for use in the development of an evacuation plan.

c. Classification of Inundation Areas. To assist in the evaluation of hazard potential, areas delineated on inundation maps should be classified in accordance with the degree of occupancy and hazard potential. The potential for loss of life is affected by many factors, including, but not limited to, the capacity and number of exit roads to higher ground and available transportation.

d. Time Available for Response. Analyses should be made to evaluate the structural, foundation, and other characteristics of the dam and determine those conditions which could be expected to result in slow, rapid or practically instantaneous dam failure.

4. Actions to Prevent Failure or Minimize Effects of Failure.

a. Development of Emergency Action Plan. An emergency action plan should be developed for each dam that constitutes a hazard to life or property, incorporating preplanned emergency measures to be taken prior to and following assumed dam failure. The plan should be coordinated with local governmental and other authorities involved in public safety and approved by the Regional Director for NPS dams. To the extent possible, the emergency action plan should define emergency situations that require immediate notification of local officials. The emergency action plan should include notification plans, which are discussed below in section b. A procedure should be established for review and revision, as necessary, of the emergency action plan, including notification plans and evacuation plans, at least once every year.

b. Notification Plans. Plans for notification of key personnel and the public are an integral part of the emergency action plan and should be prepared for slowly developing, rapidly developing, and instantaneous dam failure conditions. Notification plans should include a list of names and position titles, addresses, office and home telephone numbers, and radio communication frequencies and call signals, if available, for Regional Director, Superintendents, and Managers, or non−NPS dam owner personnel, public officials, and other personnel and alternates who should be notified as soon as emergency situations develop.. A procedure should be developed to keep the list current.

Each type of notification plan should contain the order in which key agency or owner supervisory personnel or alternates should be notified. At least one−key supervisory level or job position should be designated to be manned, or the responsible person should be immediately available by telephone or radio 24 hours a day. A copy of each notification plan must be posted in a prominent place at the project site near a telephone and/or radio transmitter.

Where dams located upstream from the dam for which the plan is being prepared could be operated to reduce inflow or where the operation of downstream dams would be affected by failure of the dam, operators of those dams should be kept informed of the current and expected conditions of the dam as the information becomes available.

Civil defense officials having jurisdiction over all or part of the area subject to inundation should receive early notification. Local law enforcement officials and, when possible, local government officials and public safety officials should receive early notification.

The capabilities of the Civil Defense Preparedness Agency's National Warning System (NAWAS) should be determined for the project and utilized as appropriate. Information can be obtained from State or local civil defense organizations.

When it is determined that a dam may be in danger of failing, the public officials responsible for the decision to implement the evacuation plan should be kept informed of the developing emergency conditions.

The news media, including radio, television, and newspapers, should be utilized to the extent available and appropriate. Notification plans should define emergency situations for which each medium will be utilized and should include an example of a news release that would be the most effective for each possible emergency.

Notification of recreation users is frequently difficult because the individuals are often alone and away from any means of ready communication. Consideration should be given to the use of standard emergency warning devices, such as sirens, at the dam site. Consideration should be given to the use of helicopters with bullhorns for areas further downstream. Vehicles equipped with public address systems and helicopters with bullhorns are capable of covering large areas effectively.

c. Evacuation Plans. Evacuation plans should be prepared and implemented by the local jurisdiction controlling inundation areas. This would normally not be the dam agency or owner. Evacuation plans should conform to local needs and vary in complexity in accordance with the type and degree of occupancy of the potentially affected area. The plans may include delineation of area to be evacuated; routes to be used; traffic control measures; shelter; methods of providing emergency transportation; special procedures for the evacuation and care of people from institutions such as hospitals, nursing homes, and prisons; procedures for securing the perimeter and for interior security of the area; procedures for the lifting of the evacuation order and reentry to the area; and details indicating which organizations are responsible for specific functions and for furnishing the materials, equipment, and personnel resources required.

The assistance of local civil defense personnel, if available, should be requested in preparation of the evacuation plan. State and local law enforcement agencies usually will be responsible for the execution of much of the plan and should be represented in the planning effort. State and local laws and ordinances may require that other State, county, and local government agencies have a role in the preparation, review, approval, or execution of the plan. Before finalization, a copy of the plan should be furnished to the dam agency or owner for information and comment.

d. Stockpiling Repair Materials. Suitable construction materials should be stockpiled for emergency use. The amounts and types of construction materials needed for emergency repairs should be determined based on the structural, foundation, and other characteristics of the dam; design and construction history; and history of prior problems.

e. Locating Local Repair Forces. Arrangements should be made with, and a current list maintained of, local entities, including contractors, and Federal, State and local construction departments, for possible emergency use of equipment and labor.

f. Training Operating Personnel. Technically qualified project personnel should be trained in problem detection, evaluation, and appropriate remedial (emergency and non-emergency) measures.

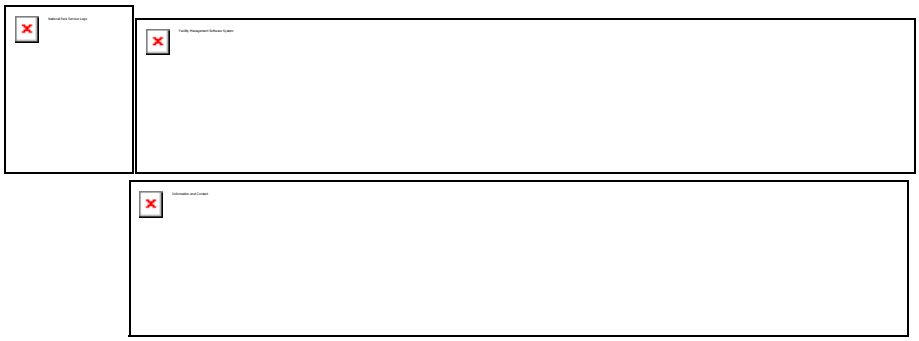
g. Increasing Inspection Frequency. Frequency of appropriate surveillance activities should be increased when the reservoir level exceeds, a predetermined elevation. Piezometers, water level gages, and other instruments should be read frequently and on schedule. The project structures should be inspected as often as necessary to monitor conditions related to known problems and to detect indications of change or new problems that could arise. Hourly or continuous surveillance may be mandated in some instances. Any change in conditions should be reported promptly to the supervisor for further evaluation.

The supervisor should issue additional instructions, as necessary and alert repair crews and contractors for necessary repair work if developing conditions indicate that emergency repairs or other remedial measures may be required.

5. Actions Upon Discovery of a Potentially Unsafe (Seriously Deficient) Condition. Action to be taken will depend on the nature of the problem and the time estimated to be available for remedial or mitigating measures. As time permits, one or more of the following actions will be required.

a. Notification of Supervisory Personnel. This is essential, if time permits, since development of failure could vary in some or many respects from previous forecasts or assumptions, and advice may be needed.

b. Initiation of Predetermined Remedial Action. It is imperative that at least one technically qualified individual, previously trained in problem detection, evaluation, and remedial action, be at the project or on call at all−times. Depending on the nature and seriousness of the problem and the time available, emergency actions can be limited, such as lowering the reservoir and holding water in upstream reservoirs. Other actions to be taken include notifying appropriate highway and traffic control officials promptly of any rim slides or other reservoir embankment failures which may endanger public highways.



c. Determination of Need for Public Notification. To the extent possible, emergency situations that will require immediate notification of public officials in time to allow evacuation of the potentially affected areas should be predefined for the use of management and project personnel. If sufficient time is available, the decision to notify public officials that the dam can be

expected to fail will be made at a predetermined supervisory level within the agency or owner organization. If failure is imminent or has already occurred, project personnel at the dam site would be responsible for direct notification of the public officials. The urgency of the situation should be made clear so that public officials will take positive action immediately.

APPENDIX D
DATA BOOK LISTING

I. TYPICAL DATA RECORDS

A. Typical Types of Records - The following outline represents information needed by the Bureau of Reclamation or other inspecting organization in the MOSD program to adequately prepare a Technical Data Book. The data book will be used to evaluate the safety, maintenance, and operation of a dam. Information should be presented to inspection teams 2 months prior to on-site inspection.

l. Document verifying NPS ownership or dam safety responsibility
2. Copy of any contractual agreements between NPS and lessee of NPS dams therein relating to acquisition, planning, safety inspections, design, maintenance, operation, construction, financial arrangements, disposal, or any other activity significantly affecting park safety, maintenance, or operations
3. Most current information from any type inventory of NPS dams
4. Aerial photographs of damsite and reservoir area
5. Design criteria and technical records
6. Construction reports
7. Project history
8. Correspondence
9. Previous Safety of Dams report
10. Emergency Preparedness Plan
11. Pertinent photographs
12. Hydrology studies (most recent inflow design flood, other floods considered at the time of design, and flood routings)
13. Instrumentation monitoring records
14. Operation and Maintenance Reports
15. Reservoir operation record
16. SOP (Standard Operating Procedures)
17. DOC (Designers' Operating Criteria)
18. Statistics of dam, powerplant (if applicable), and reservoir
19. Design and as-built drawings
20. Reservoir area and capacity curves
21. Discharge curves for all water control structures and conduits
22. Monthly maximum and minimum reservoir elevations since first filling
23. Average daily inflow to reservoir (include the source of the information and the period of record used)
24. Any current operating restrictions (maximum water surface elevation, maximum discharge of spillway(s) and outlet works, etc.)
25. Records of any known problems experienced in operating and maintaining the dam, spillway, and outlet works (seepage, sinkholes, sloughing of slopes, offsets, displacements, cracking, erosion, mechanical equipment failure, debris, etc.)

B. Geology

1. Topographic maps, USGS quadrangle maps
2. Geologic reports (general regional, specific data on damsite and reservoir, geologic profile along axis of dam, landslide surveillance data, and geologic interpretation)
3. Seismicity [shear and fault zone data, seismic risk zone, MCE (maximum credible earthquake), and seismic considerations in design]
4. Geologic and seismic maps and drawings
5. Liquefaction studies
6. Geophysical data
7. Volcanic activity in area
8. Local petrochemical activity

C. Concrete Dams

1. Drawings: section through crown cantilever including lines of centers for an arch dam, plan view of dam, profile of dam-foundation contact, and surface contour map (most detailed USGS map of damsite)
2. Tailwater data
3. Most recent reservoir silt survey data (including density of silt)
4. Maximum and minimum reservoir temperatures - relative to depth in reservoir
5. Most recent concrete tests and properties to include data on compressive, tensile and shear stresses, density, modulus of elasticity, Poisson's ratio, and diffusivity
6. Contraction joint grout closure temperatures
7. Depth of ice in reservoir at dam
8. Location and monitoring data for major cracks in dam
9. Design and measured uplift pressures

D. Embankment Dams

1. Type of dam (homogeneous, zoned, etc.)
2. Gradation of construction materials
3. Surface and internal drainage features
4. Upstream and downstream slope protection
5. Freeboard
6. Crest details (including camber)
7. Placement densities and moisture content
8. Materials testing (laboratory and field tests performed)
9. Filter design criteria
10. Toe drain system
11. Soil parameters (including strength, permeability, void ratio, etc.)
12. Foundation and abutment conditions
13. Stability, settlement, and seepage measurements and analyses
14. Preconstruction and postconstruction investigations (test pits, drill holes, etc.)
15. History of reservoir filling and drawdown rates
16. Piezometer data

E. Mechancial Equipment

1. Descriptions
2. Design data on gates, valves, etc.
3. Installation-related problems
4. Air venting system (including test results available)
5. Emergency gate closure report
6. Manual or automatic operation of equipment
7. Remote control
8. Auxiliary power
9. Steel pipe and its drainage system
10. Trashracks
11. Special operating conditions and restrictions
12. Control equipment
13. Corrosion protection
14. Additional equipment needed to pass the design flood or to evacuate the reservoir
15. History of gate or valve operation and associated problems

II. TYPICAL LOCATIONS OF RECORDS

Suggested locations for obtaining the engineering-related records are:

A. Washington, D.C. office
B. Regional office
C. District office
D. Subdistrict office
E. Area office
F. Agency office
G. Project office

H. State Department of Water Resources
I. State Engineer
J. State Dam Safety Program Officer (See Appendix C)
K. City and County Engineer
L. Private owners
M. Soil Conservation Service
N. National Archives
O. Consulting engineers
P. U.S. Army Corps of Engineers (Regional Hydrology, Floodplain and Flood Insurance Studies, Hydraulics, Geology, and hypothetical dam break studies)
R. Tennessee Valley Authority
S. Federal Energy Regulatory Commission
T. Federal Emergency Management Agency (National Flood Insurance Program)
U. NPS Regional and Park Historic or Cultural Divisions
V. NPS Denver Service Center, Graphic System Division (FTS 234-2654)

Suggested locations of obtaining geologic records are:

1. U.S. Geological Survey
2. State Geological Survey
3. U.S. Bureau of Mines
4. State Bureau of Mines
5. State and local university libraries
6. State, city and other local libraries
7. Consulting geologists

APPENDIX E
EXAMPLE EMERGENCY ACTION PLAN

The purpose of the EAP is to facilitate the early warning and, if necessary, evacuation of persons in areas that would be affected by possible dam or appurtenant works failure or misoperation. Superintendents should develop an appropriate EAP for either high (1) or significant (2) hazard potential dams under their jurisdiction or coordinate with non−NPS dam owners to assure implementation of their EAP in affected park areas. Personnel designations, mapping, and local government contacts should have been made by September 30, 1982, and recorded into the NPS Inventory of Dams.

BASIC SYSTEM ELEMENTS

An effective Emergency Action Plan incorporates several essential elements.

These are:

1. Dependable and responsible rainfall and staff gage observers. Their duties are to report to the Dam Operator the rainfall accumulation over− a given period of time and the elevation of the reservoir pool or flow in the emergency spillway, if any. One of these observers should also give the dam a brief visual inspection at each gage reading to see if it is in danger of failing from reasons other than overtopping. The equipment needed to make these measurements can be a simple plastic rain gage and some sort of pole or staff in the reservoir or spillway area with elevations indicated clearly on it. There are more elaborate instruments available such as automatic rain and water level gages, but at a respectively higher cost. Their use is optional, but not essential.

2. Reliable and rapid local communications system with an emergency backup. This system is used to communicate the data gathered by the gage observers to the Dam Operator and by the Dam Operator in notifying the proper authorities of the need to initiate the warning plan and the evacuation plan. It can be by telephone, ham radio, CB radio, or police, fire, and other emergency radio systems. It is important that any system chosen have an emergency backup.

3. Dam Operator and Alternate. These persons' duties are to interpret the rainfall, streamflow, and spillway flow data given to them by the observers and other available weather information and, when necessary, notify the park EAP Coordinator or other authorities of the need to initiate the warning and evacuation plan.

4. Dam Hydraulic and Hydrologic Data. This information developed by a qualified engineer or gathered from other competent sources is used to establish the various trigger points (rainfall measurements, pool or spillway flow elevations, or other pertinent facts) at which the several progressive phases of the emergency warning system are initiated. This information is obtained from an engineer study which com pares various rainfalls on the watershed with the spillway discharges they create and reservoir elevations. The Bureau of Reclamation is developing some of this type of information during their assessments of NPS Dams classified as high or significant hazard potential.

5. A Warning Dissemination Plan. This basically consists of a list of people to be notified if the conditions dictate. This should include the local government Emergency Services Coordinator or other designated local government officials who will in turn notify the people directly affected by flooding outside the park and carry out the Evacuation Plan, if that becomes necessary.

6. The Evacuation Plan. This consists of a list of homes, businesses, campsites, stream crossings, recreation activities, highways and roads, with their locations clearly identified on an inundation map, that are to be evacuated if necessary, and a means of transporting the people to a designated emergency shelter. Mapping should be of sufficient detail and scale to show where possible homes, businesses, campsites, stream crossings, highway and roads, and recreational activities are located in relationship to the dam and estimated flooding. Access routes should be clearly marked. Since detailed inundation maps may not be readily available or easily used at a disaster area, a concise and clear word description should also be prepared for easy word−of−mouth communication. Time word description would tell potential evacuees how high they should elevate themselves above the river or by horizontal distance to an area known to be safe from inundation. The EAP with the map should be filed with the park EAP Coordinator and the local Emergency Services Coordinator or other local government officials. The plan should also pro vide for the protection of the evacuated area until the residents can return to their areas. The local Emergency Services Coordinator or other local government officials are responsible for preparing and carrying out the Evacuation Plan if located outside the park. Proper coordination should be assured with these officials.

EXAMPLE EMERGENCY WARNING SYSTEM

The following is a fictitious example of a well−organized Emergency Action Plan for a city and is based on one prepared by the Tennessee Valley Authority for the City of Norton, Virginia. This is not necessarily the type of system that will be best suited to your situation, but it should give you a general idea of how one is set up.

STAGE I

1. Rain measuring equipment will be inspected and measurements begun initially upon notice of a flood watch or warning. This warning would come from the National Weather Service.

2. Rainfall measured by the gage observer will be compared by the Dam Operator with the rainfall of other weather observers such as local government Emergency Service officials during flood watches and warnings.

3. Rainfall will be monitored around the clock and reported to the Dam Operator on a 24−hour basis by the rainfall gage observer.

4. Upon receiving notice that two (2) inches of rain in any 24−hour period has fallen, the Dam Operator will initiate State II by notifying the EAP Coordinator who will notify the:
   A. Superintendent
   B. Park Ranger,
   C. Administrative Manager

STAGE II

1. Every four hours after Stage II is affected, the staff gage observer will personally read the gage at the spillway and record the reading and report it to the Dam Operator.

2. When a depth of two (2) feet in the spillway exists, the frequency of the readings will be increased every two flours, or will be made even more frequently if desired by the Dam Operator.

3. In the event the spillway readings reach three (3) feet, Stage III will be put into effect by the Dam Operator. The Dam Operator will notify the EAP Coordinator of Stage III, who will in turn notify the:
   A. Superintendent
   B. Park Ranger
   C. Administrative Manager
   D. Local Government Emergency Official

Stage III

1. The Emergency Action Plan Coordinator will initiate the Evacuation Plan.

2. The Evaluation Plan will be implemented by the Ranger Division under the direction of the Park Ranger, with assistance from all available Fire, Rescue, and other appropriate personnel.

3. Necessary transportation from the affected area will be provided by a school bus or other means as determined by the EAP Coordinator.

4. Evacuated persons will be sheltered as designated in the evacuation notice.

5. Once the area is evacuated, persons designed by the Park Ranger will secure the area from access except for official business.

6. Readings of the spillway level will continue to be, read by the gage observer and be reported hourly to the EAP Coordinator during Stage III until water recedes to one foot or less over the spillway.

CONCLUSION

The local government Emergency Services Coordinator in your city or county should be notified, if appropriate, of your plans to establish the EAP, and its development must be closely coordinated with him so that he will be completely familiar with it. Once the plan is established it should be reviewed annually and updated if the conditions downstream have changed enough, to dictate it.

The Warning Dissemination and Evacuation Plans can also be used if the dam is failing from reasons other than flooding and overtopping. On new or rehabilitated structures this Emergency Action Plan should be established prior to the beginning of

impoundment so that an evacuation can be carried out−if a failure prone situation develops. Hopefully you will never need to use it, but if the need ever arises, such a system will greatly reduce the chance of any loss of life.

APPENDIX G
Example Letter To Non−NPS Dam Owner or Regulatory Agency (Preferably)

Certified Mail, Receipt Requested
Ms. Francis Doe, Chief, Engineering Division
South Lakes, Inc.
176 Water Street
Riverton, Texas 99999

Subject: Back River Dam

Dear Ms. Doe:

As discussed during our telephone conversation on July 15, 1982, certain information about your dam, which affects Waterway National Park, is needed.

As you can well understand, we need this information so that appropriate steps can be taken to assure that park visitors and resources are protected in those areas for which we have warning, rescue and evacuation responsibilities, in the event of spillway releases, possible dam failure, or accidents at the dam or reservoir.

Please send the following items to this park periodically and by certified mail:

1. A copy of your most current formal safety of dams inspection report, and if the dam has any serious deficiencies, an explanation of how and when corrective action will be performed. Please review and revise the attached NPS Inventory of Dams Report listing for your dam based upon this report. To be able to assign a safety of dams condition code [data element 27], this report will need to include a recent stability analysis including the use of criteria for the Maximum Probable Flood (MPF) and Maximum Credible Earthquake (MCE). If the project is proposed for construction or reconstruction, the National Park Service would appreciate the opportunity to review and comment on your design and construction documents.

2. Permission granting NPS observer status during your next formal safety of dams inspection.

3. Please incorporate the park into your Emergency Action Plan (EAP) and send us a copy. This EAP contains early warning, flood mapping, and evacuation procedures and is given to those jurisdictions that would be affected by spillway releases, possible dam failure, misoperation, or even an accident at the dam or reservoir. Your Notification Directory or Call-up List should state that the park is immediately affected and should be contacted directly by the dam operator/tender. Based upon these documents, the park will include your EAP into the park's Early Flood Warning, Search/Rescue, Evacuation, and Recovery Plan (ESEP) for those areas which it has warning, rescue, and evacuation responsibility. Your EAP and the park's ESEP will become part of the park's Emergency Operations Plan. This responsibility is described in the U.S. Department of the Interior, National Park Service Reference Manual -40 , Dams and Appurtenant Works, Chapter 6, Section D, and is in accordance with the Federal Guidelines for Dam Safety, pages 10 and 36.

If you have any questions or comments about this request, please contact (Park Official) at 999−999−9999.

Sincerely,

Regional Director/Superintendent

IN REPLY REFER TO:
A5623(610)

October 9, 1987

Special Directive 87 - 4 Annual Review

To: Directorate, Field Directorate, Washington Office (WASO)
Division Chiefs, and All Superintendents

From: Acting Director

Subject: Dams and Appurtenant Works - Desk Reference Manual for Maintenance, Operation, and Safety

This Directive replaces and updates Staff Directive 86-2 of the same subject. It provides a brief explanation of the National Park Service (NPS) Maintenance, Operation, and Safety of Dams (MOSD) program responsibilities.

Complete management responsibilities are outlined in more detail in NPS-40, Dams and Appurtenant Works, Chapter 2. The key action responsibilities are as follows:

° Prepare, review, and update annually Emergency Action Plans (EAP's) for any NPS dams that are classified as Downstream HIGH or SIGNIFICANT Hazard Potential. Use NPS-40, Chapter 2, Section B, paragraph 6 and Chapter 6, Section D.

° Prepare, review, and update annually Emergency Action Plans for park areas that are affected by non-NPS dams. Information about contacting State dam safety officials regarding private dams that affect park areas is provided in NPS-40, Appendix F and attachment 2 of this Directive.

° Prepare or obtain official inspection reports for all NPS and non-NPS dams and incorporate findings into the Inventory of Dams. Use NPS-40, Chapter 6, Section C and Dam Inventory Users Guide, Revised February 1985.

° Promptly perform corrective action on deficient dams. Dams listed as SERIOUSLY DEFICIENT should be corrected immediately. A dam is SERIOUSLY DEFICIENT if an official inspection report classifies the safety condition as POOR or UNSATISFACTORY or the maintenance condition as 3, 4, or 5. Use the current Inventory of Dams and NPS-40, Chapter 3, Section C and Chapter 6, Section C, paragraph 4.

° Maintain accurately the NPS Inventory of Dams for any size, type, or owner (NPS or non-NPS) of dams that affect park resources, safety, maintenance, or operations. Dams that are proposed, existing, or deactivated and either within, adjacent to, or upstream of park areas will be included. Use NPS-40, Chapter 2, Section C and Dams Inventory Users Guide, revised February 1985.

° Dams and appurtenant works including adjacent areas out to 15 feet will be kept free of any woody vegetation, trees, roots, bushes, debris, or any other material which interferes with the access, visibility, inspection, operation, or maintenance of the facility. Grass will be mowed at prescribed intervals, particularly before inspections. Complete inspections cannot be performed when access or visibility is impaired by vegetation or debris. Spillways and other water control devices should be kept clear of obstructions and debris and seepage monitored on a regular basis. Use NPS-40, Chapter 6, Section B and the Operations and Maintenance Guidelines for Small Dams.

° Maintain operations and maintenance logs for NPS dams. Use NPS-40, Chapter 6, Section B and the Operations and Maintenance Guidelines for Small Dams, page 13 and Appendix B.

° Retain only essential dams. Dams, appurtenant works, and impoundments unauthorized by legislation or not approved in a General Management Plan should be deactivated, particularly if they are deficient. Deficient dams should not be acquired. Use NPS-40, Chapter 1, Section C and Chapter 3.

A list of official guidelines, an example letter for initiating contact with a non-NPS dam owner, and a list of NPS and Bureau of Reclamation engineers for special assistance, particularly during emergencies, are provided in attachments 1, 2, and 3 respectively.

For additional information, contact your Regional Dams Coordinator or Mr. Charles Karpowicz, NPS Dams Officer, at 202-565-1249 if you have any questions.

Subject: Back River Dam

Dear Madam:

As discussed during our telephone conversation on July 15, 1982, certain information about your dam which affects Waterway National Park is needed.

You can well understand our need for this information so that appropriate steps can be taken to assure that park visitors and resources are protected in those areas for which we have warning, rescue, and evacuation responsibilities in the event of spillway releases, possible dam failure, or accidents at the dam or reservoir.

Please place this park on your mailing list to receive periodically and by certified mail the following items:

1. A copy of your most current formal safety of dams inspection report, and if the dam has any serious deficiencies, an explanation of how and when corrective action will be performed. Please review and revise the attached NPS Inventory of Dams Report listing for your dam based upon this report. To be able to assign a safety of dams condition code [data element 27], this report will need to include a recent stability analysis including the use of criteria for the Maximum Probable Flood (MPF) and Maximum Credible Earthquake (MCE). If the project is proposed for construction or reconstruction, the National Park Service would appreciate the opportunity to review and comment on your design and construction documents.

2. Permission granting NPS observer status during your next formal safety of dams inspection.

3. Incorporation of the park into and a copy of your Emergency Action Plan (EAP). This EAP has early warning, flood mapping, and evacuation procedures and is given to those jurisdictions who would be affected by spillway releases, possible dam failure, misoperation, or even an accident at the dam or reservoir. Your Notification Directory or Call-up List should state that the park is immediately affected and contacted directly by the dam operator/tender. Based upon these documents the park will prepare its own EAP for those areas which it has warning, rescue, and evacuation responsibility. The NPS prepared EAP is part of the park's Emergency Operations Plan. This responsibility is described in the U.S. Department of the Interior, National Park Service management guideline, NPS-40, Dams and Appurtenant Works..., Chapter 6, Section D, and is in accordance with the Federal Guidelines For Dam Safety, pages 10 and 36.

If you have any questions or comments about this request, please contact (Park Official) at commercial telephone 999-999-9999.

Sincerely,

Regional Director/Superintendent

Earth Dams and Reservoirs

TR–60

Issued July 2005

The U.S. Department of Agriculture (USDA) prohibits discrimination in all its programs and activities on the basis of race, color, national origin, sex, religion, age, disability, political beliefs, sexual orientation, or marital or family status. (Not all prohibited bases apply to all programs.) Persons with disabilities who require alternative means for communication of program information (Braille, large print, audiotape, etc.) should contact USDA's TARGET Center at (202) 720-2600 (voice and TDD).

To file a complaint of discrimination, write USDA, Director, Office of Civil Rights, Room 326W, Whitten Building, 14th and Independence Avenue, SW, Washington, DC 20250-9410 or call (202) 720-5964 (voice and TDD). USDA is an equal opportunity provider and employer.

Preface

This Technical Release (TR) describes design procedures and provides minimum requirements for planning and designing earth dams and associated spillways. This TR was developed to provide uniform criteria for earth dams and reservoirs. NRCS plans, designs, and constructs complex dams under widely varying conditions. It is essential that these dams be constructed with uniform criteria to ensure consistent performance. As new experience, materials, and knowledge become available, this document will be revised.

This TR applies to all Low Hazard Class dams with a product of storage times the effective height of the dam of 3,000 acre-feet[2] or more, those more than 35 feet in effective height, and all Significant and High Hazard Class dams. Requirements are stated as maximum or minimum limits and may not be satisfactory design criteria for all sites. In some cases, problems may arise where proven solutions are not available or alternate procedures may need to be evaluated before the best solutions can be developed and selected. Experience, state laws and regulations, investigations, analysis, expected maintenance, environmental considerations, or safety laws may dictate more conservative criteria to ensure satisfactory performance.

This edition of the TR incorporates all previously issued revisions and amendments, as well as significant changes in chapters 2 (24-hour Design Storms), 5 (Slope Stability Analysis), and 7 (New Earth Spillway Breach Model) that were widely distributed and reviewed. This edition also makes numerous editorial corrections, including SCS to NRCS; emergency spillway to auxiliary spillway; and Class a, b, c to Low, Significant, High Hazard Class, respectively.

Technical Release Number 60

Earth Dams and Reservoirs

General

Dam classification

In determining dam classification, a number of factors must be considered. Consideration must be given to the damage that might occur to existing and future developments should the dam suddenly release large quantities of water downstream due to a breach, failure, or landslide into the reservoir. The effect of failure on public confidence is an important factor. State and local regulations and the responsibility of the involved public agencies must be recognized. The stability of the spillway materials, the physical characteristics of the site and the valley downstream, and the relationship of the site to industrial and residential areas including controls of future development all have a bearing on the amount of potential damage in the event of a failure.

Dam classification is determined by the above conditions. It is not determined by the criteria selected for design. The policy on classification is in 210-V-NEM (*National Engineering Manual*), Part 520, Subpart C, DAMS.

Classes of dams

The following classes of dams have been established by policy and repeated here for convenience of the user.

- Low Hazard Class—dams located in rural or agricultural areas where failure may damage farm buildings, agricultural land, or township and country roads.
- Significant Hazard Class—dams located in predominantly rural or agricultural areas where failure may damage isolated homes, main highways or minor railroads, or cause interruption of use or service of relatively important public utilities.
- High Hazard Class—dams located where failure may cause loss of life, serious damage to homes, industrial and commercial buildings, important public utilities, main highways, or railroads.

Peak breach discharge criteria

Breach routings are used to help delineate the area potentially impacted by inundation should a dam fail and can be used to aid dam classification.

Stream routings made of the breach hydrograph will be based upon topographic data and hydraulic methodologies mutually consistent in their accuracy and commensurate with the risk being evaluated.

The minimum peak discharge of the breach hydrograph, regardless of the technique used to analyze the downstream inundation area, is:

1. For depth of water at the dam at the time of failure where $H_w \geq 103$ ft

$$Q_{max} = (65) H_w^{1.85}$$

2. For depth of water at the dam at the time of failure where $H_w < 103$ ft

$$Q_{max} = (1{,}100) B_r^{1.35} \qquad \text{where } B_r = \frac{(V_s)(H_w)}{A}$$

but not less than $Q_{max} = (3.2) H_w^{2.5}$ nor more than $Q_{max} = (65) H_w^{1.85}$

3. When the width of the valley, L, at the water surface elevation corresponding to the depth, H_w, is less than,

$$T = \frac{(65) H_w^{0.35}}{0.416}$$

replace the equation, $Q_{max} = (65) H_w^{1.85}$, in 1 and 2 above with,

$$Q_{max} = (0.416)(L) H_w^{1.5}$$

where:

Q_{max} = the peak breach discharge, ft^3/sec

B_r = breach factor, acre

V_s = reservoir storage at the time of failure, acre-ft

H_w = depth of water at the dam at the time of failure; however, if the dam is overtopped, depth is set equal to the height of dam, ft

A = cross-sectional area of embankment at the assumed location of breach, usually the template section (normal to the dam longitudinal axis) at the general flood plain location, ft^2

T = theoretical breach width at the water surface elevation corresponding to the depth, H_w, for the equation, $Q_{max} = (65)H_w^{1.85}$, ft

L = width of the valley at the water surface elevation corresponding to the depth, H_w, ft

The peak discharge value determined by using principles of erosion, hydraulics, and sediment transport may be used in lieu of the peak discharge computed using the above equations.

Utility cables and pipelines

Existing pipelines, cables, and conduits of a wide variety of sizes, materials, and functions are frequently encountered at dam sites. These conduits are usually located at shallow depths in the flood plain. They constitute a hazard to the safety of the dam and must be either relocated away from the site or reconstructed or modified to provide the durability, strength, and flexibility equal in all aspects to the principal spillway designed for the site, in accordance with service criteria and procedures. Overhead cables or power lines must be relocated or raised as necessary to prevent damage or hazard to the public.

Every reasonable effort should be made to have such conduits, cables, and pipelines removed from the site. Most utilities and industries will want their facility removed from the site for easy maintenance. Only as a last resort and under the limitations imposed below are conduits permitted to remain under an earth dam embankment.

Conduits permitted to remain under any part of the embankment below the crest of the auxiliary spillway are to be:

- provided with seepage control against potential piping;
- properly articulated on all yielding foundations;
- encased in concrete or otherwise treated to ensure durability and strength equal to that of the principal spillway; and
- made watertight against leaking either into or out of the pipe.

Enclosure of the conduit cable or pipeline within another conduit that meets the requirements of this section and is positively sealed at the upstream end to prevent seepage into the enclosing conduit is acceptable. Such an enclosing conduit must extend the full distance through which the conduit, cable, or pipeline being enclosed is beneath the embankment.

Cut slope stability

Natural and excavation cut slopes must be planned and formed in a stable and safe manner. Spillways, inlet and outlet channels, borrow pits, reservoir edges, abutment areas, and foundation excavations are all locations where these considerations are needed. Field investigations, methods of analysis, design and construction requirements, and resultant specifications must recognize and provide for safe functional performance.

Joint use of reservoir capacity

A reservoir site may be used more efficiently where hydrologic conditions permit joint use of storage capacity by flood water and conservation storage. The following requirements must be met for joint use storage dams.

- There is reasonable assurance that water will be available to meet objectives.
- Flood protection objectives of the project are satisfied.
- Spillway conditions are such that the dam will perform safely.

Special hydrologic studies must be made to show that the requirements can be met. This may include hydrometeorologic instrumentation and analysis.

Hydraulic features must include an ungated spillway outlet at the top of the joint use pool. A gated opening must be provided at the bottom of the joint use pool adequate for use of the conservation storage and evacuation of the joint use pool.

Provisions must be made for operation of the joint use pool to ensure functioning of the dam as designed. These must include a competent operating and maintaining organization and a specific operation and maintenance plan. These requirements must be a part of the planning process and agreed to by the sponsors or owner.

Visual resource design

The public generally prefers lake or waterscape scenery. Therefore, when permanent pools are created by dam construction, they can enhance the visual resource if the water views are emphasized. A visual design objective must focus public views toward the permanent pool and reduce the visual focal effects of the structural elements.

Visual focus on the lake is achieved by locating roads and walkways so that the entering or first perceptions of the site are of the waterscape scenery. In most landscapes, the lake will automatically predominate if other elements are visually designed to be subordinate.

Borrow areas must be shaped to blend with the surrounding topography. These areas must be revegetated with herbaceous and woody plants to visually fit the existing surrounding vegetation. Fences must be constructed parallel to the contour as much as possible, be located behind existing vegetation, as seen from the major viewpoints, and be placed low in the landscape. Dams must be shaped to blend with the natural topography to the extent feasible.

Safety and protection

Many dams are hazardous to the public. Features designed for recreation or fish and wildlife are especially attractive to the public since they provide an opportunity to use the water. All dams must be designed to avoid hazardous conditions where possible. Open-top risers, steep-walled channels and chutes, plunge pools, and stilling basins are hazardous and require special attention. All dams must be provided with safety fences, guard rails, or other safeguards as necessary to protect the public and operation and maintenance personnel.

The embankment and spillways must be fenced where necessary to protect the dam from livestock and foot and vehicular traffic.

Water supply pipes

Water supply pipes or conduits for other purposes installed under any part of the embankment below the crest of the auxiliary spillway are to:

- provide durability, strength, and flexibility equivalent to the principal spillway;
- be watertight against anticipated pressures;
- be adequate for their intended use; and
- be provided with seepage control against potential piping.

Streamflow diversion during construction

Streamflow past the dam site, unless controlled, occurs at a somewhat random time with variable frequency and magnitudes. A hazard exists during dam construction beginning when the embankment, cofferdam, or other ancillary structures obstruct the natural streamflow. During construction, a greater risk usually exists for some time than after the dam is completed. The risk is different for each dam because of the varying factors of construction time, climate, watershed size, and diversion capacity. An evaluation should be made of the risk from embankment failure by overtopping and other similar hazards during construction. The risk involved in overtopping during construction increases with the following factors:

- dams of higher hazard class
- greater volume of reservoir storage
- dams with larger watersheds
- longer critical construction time periods
- smaller diversion “release” rates (less unit discharge per unit watershed area)

The consequence of overtopping during construction may vary from a slight amount of erosion on a homogeneous clay dam to a breach of an embankment including loss of a temporary diversion coffer dam. The erosion or breach causes increased inundation and sedimentation of downstream areas.

The risk may be evaluated based upon experience of comparable dams constructed in the same hydrologic setting. An evaluation may also be made using available streamflow records to obtain stage-duration-frequency information for a range of diversion rates. Streamflow data should be used when available; otherwise, an evaluation may be made using climatological record data for generation of synthetic hydrographs to develop stage duration-frequency information for a range of diversion rates.

The size of diversion must be designed to provide an acceptable level of risk. The probability required to protect against overtopping varies from 20 percent to 5 percent chance in any one year. A 10 percent chance probability is frequently used when the critical con-

struction period is limited to one construction season. An alternative to a larger diversion capacity is to provide protection against erosion to the embankment surface (reinforcement) up to the desired elevation of acceptable risk.

Reservoir conservation storage

Reservoirs with water stored for conservation purposes must be analyzed using a water budget to determine a dependable water supply.

For most purposes, a dependable water supply is defined as one that is available at least 8 out of 10 years or has a probability of 80 percent chance in any one year. A purpose such as municipal and industrial water may require a 95 percent chance probability of existing in any one year. Other purposes, such as recreation, require an analysis of the reservoir surface elevation fluctuation to evaluate the acceptable percent chance of occurrence.

Hydrology

This section describes hydrologic criteria for determining spillway discharges and floodwater storage volumes. Detailed procedures for developing principal spillway, auxiliary spillway, and freeboard hydrographs are found in the NRCS *National Engineering Handbook*, chapter 21, section 4, Hydrology (NEH-4). Methods of flood routing hydrographs through reservoirs and spillway systems are contained in chapter 17, NEH-4. Special studies, as used in this text, refer to all site-specific studies with prior concurrence of selected procedures.

Precipitation and runoff amounts

Principal spillway

Precipitation data must be obtained from the most recent National Weather Service (NWS) reference which is applicable to the area under study. References that contain precipitation data for return periods up to 100 years and for durations up to 10 days are listed in sections A and B of table 2-1.

The return period for design precipitation amounts is dependent on the dam classification, purpose, size, location, and type of auxiliary spillway. Table 2-2 shows minimum return period. The minimum allowable areal adjustment ratios for 1- and 10-day precipitation amounts are tabulated in table 2-3 (a).

A storm duration of not less than 10 days must be used for sizing the principal spillway. The procedure in chapter 21, NEH-4 for developing the storm distribution uses both the 1-day and 10-day runoff volumes.

The procedure for estimating runoff volumes must be selected based on which one requires the higher auxiliary spillway crest elevation when the principal spillway hydrograph is routed through the structure. Procedures to be used to estimate runoff volumes include:

- The runoff curve number (CN) procedure described in NEH-4. Use average antecedent runoff conditions (ARC II) or greater unless a special study shows that a different condition is justified. The CN adjustment for 10-day storm is estimated from table 2-3(b).
- Runoff volumes, based on stream gage studies which also account for snow melt, from figures 2-1(a) and (b) or 2-2(a) and (b).

A special study may show that local streamflow records can be used directly or regionalized to develop design runoff volumes.

Transmission losses reducing the runoff volume in arid and semiarid climatic areas may be used if the climatic index, as defined in chapter 21, NEH-4, is less than one. If transmission losses appear to be significant even though the climatic index is one or more, such as in cavernous areas, special studies are required.

Obtain quick return flow from the map, figure 2-1(c), or table 2-4, as appropriate.

Auxiliary spillway and freeboard

The most recent NWS references applicable to the location of the dam site shall be used to determine precipitation amounts, spatial distributions, and temporal distributions. Table 2-1 provides references current as of date of this publication. See the NWS Web site, *http://www.nws.noaa.gov/oh/hdsc/index.html*, for the most current references.

Minimum precipitation amounts shall be in accordance with table 2-5.

The discharge capacity, stability (surface erosion potential), and integrity (breaching potential) of the auxiliary spillway shall be evaluated as follows:

- Both a short duration (6 hour or longer) and a long duration (24 hour or longer) storm shall be analyzed and the most critical results used to check the discharge capacity and the integrity of the auxiliary spillway.
- Only the short duration storm shall be used to check the stability of the auxiliary spillway.
- For locations where NWS references provide estimates of local storm and general storm values, both storms shall be analyzed. For other locations, at least a 6-hour and a 24-hour duration storm shall be analyzed.

In areas without applicable NWS references for spatial distribution, minimum areal adjustment ratios shown in figure 2-3 may be used. Spatial adjustments shall not be applied for drainage areas less than 10 square miles.

In areas without applicable NWS reference for temporal distribution, the dimensionless auxiliary and freeboard storm distribution shown in figure 2-4 may be used. Alternately, the 24-hour storm can be constructed by critically stacking incremental rainfall amounts of successive 6-, 12-, and 24-hour durations as described in Hydrometeorological Report 52 (HMR52).

Table 2-2 Minimum principal spillway hydrologic criteria

Class of dam	Purpose of dam	Product of storage X effective height	Existing or planned upstream dams	Precipitation data for maximum frequency of use of auxiliary spillway types: [1]	
				Earth	Vegetated
Low	single irrigation only [2]	less than 30,000	none	1/2 design life	1/2 design life
		greater than 30,000		3/4 design life	3/4 design life
	single or multiple [4]	less than 30,000	none	P_{50}	P_{25} [3]
		greater than 30,000		1/2 (P_{50} + P_{100})	1/2 (P_{25} + P_{50})
		all	any [5]	P_{100}	P_{50}
Significant	single or multiple	all	none or any	P_{100}	P_{50}
High	single or multiple	all	none or any	P_{100}	P_{100}

[1] Precipitation amounts by return period in years. In some areas, direct runoff amounts determined by figure 2-1 and 2-2 or procedures in chapter 21, NEH-4 should be used in lieu of precipitation data.

[2] Applies to irrigation dams on ephemeral streams in areas where the annual rainfall is less the 25 inches.

[3] The minimum criteria are to be increased from P_{25} to P_{100} for a ramp spillway.

[4] Low Hazard Class dams involving industrial or municipal water are to be designed with a minimum criteria equivalent to that of Significant Hazard Class.

[5] Applies when the upstream dam is located so that its failure could endanger the lower dam.

The maximum 6-hour rainfall should occur in the second 6-hour quadrant. The next highest 6-hour incremental rainfall should occur in the third 6-hour quadrant, the next highest in the first, etc.

The NRCS runoff curve number procedure defined in NEH-630 and NEH-4 shall be used to determine runoff volumes. Antecedent runoff condition (ARC) II or greater shall be assumed. The same curve number shall apply throughout the entire storm.

Special probable maximum precipitation (PMP) studies can be considered and may be conducted by NWS or other hydrometeorologists with experience in such work. Useful special studies may have been conducted by federal or state agencies or major dam owners. Special studies should be considered especially for large drainage areas, areas of significant variation in elevation, or areas located at the boundary of two studies where discontinuities occur.

Methods in the *Federal Guidelines for Dam Safety – Inflow Design Floods*, FEMA 94, may alternately be used to proportion the embankment and auxiliary spillway, provided downstream land use controls exist to prevent voiding incremental risk assumptions after the dam is completed.

Design hydrographs

Principal spillway hydrographs
Procedures in chapters 16 and 21, NEH-4 and applicable national computer programs shall be used to develop the principal spillway hydrograph using precipitation and runoff amounts as described in the preceding section.

When the area above a proposed dam is hydrologically complex, the area should be divided into two or more hydrologically homogeneous sub-basins for developing the design hydrograph.

Streamflow records may be used to develop the principal spillway hydrograph where a special study shows they are adequate for this purpose.

Stability design (auxiliary spillway) and freeboard hydrographs
Procedures in chapters 16 and 21, NEH-4 and applicable national computer programs shall be used to develop stability design (auxiliary spillway) and freeboard hydrographs using precipitation and runoff amounts and sub-basins, if necessary, as described in the preceding sections.

Dams in series

Upper dam
The hydrologic criteria and procedures for the design of an upper dam in a system of dams in series must be the same as, or more conservative than, those for dams downstream if failure of the upper dam could contribute to failure of the lower dam. The dam breach criteria described earlier will be used to develop the breach hydrograph peak discharge.

Lower dam
For the design of a lower dam, hydrographs shall be developed for the areas controlled by the upper dams based on the same hydrologic criteria as the lower dam. The hydrographs are routed through the spillways of the upstream dams and the outflows routed to the lower dam where they are combined with the hydrograph from the intermediate uncontrolled drainage area. The combined principal spillway hydrograph is used to determine the capacity of the principal spillway and the floodwater retarding storage requirement for the lower site. The combined stability design (auxiliary spillway) hydrograph is used to evaluate the stability (erosion resistance) of any vegetated or earth spillway at the lower site. The combined freeboard hydrograph is used to determine the height of dam and to evaluate the integrity of any vegetated or earth spillway at the lower site.

If upon routing a hydrograph through the upper dam, the dam is overtopped, or its safety is questionable, it is considered breached. For design of the lower dam, the breach hydrograph must be routed downstream to the lower dam and combined with the uncontrolled area hydrograph.

In design of the lower dam, the time of concentration (T_c) of the watershed above an upper dam is used to develop the hydrographs for the upper dam. The T_c of the uncontrolled area above the lower site is used to develop the uncontrolled area hydrographs. If the T_c for the total area exceeds the storm duration, the precipitation amounts for the stability design (auxiliary spillway) and freeboard hydrographs must be increased by the values in the applicable NWS references (table 2-1).

The minimum precipitation amounts for each of the required hydrographs may be reduced by the areal reduction factor for the total drainage area of the dam system.

Large drainage areas

When the area above a proposed dam approaches 50 square miles, it is desirable to divide the area into hydrologically homogeneous sub-basins for developing the design hydrographs. Generally, the drainage area for a sub-basin should not exceed 20 square miles. Watershed modeling computer programs, such as the NRCS Technical Release (TR) 20 – Project Formulation-Hydrology or NRCS SITES – Water Resources Site Analysis, may be used for inflow hydrograph development. This software can be downloaded from *http://www.wcc.nrcs.usda.gov/hydro/hydro-tools-models.html*.

If the T_c for the entire drainage area is greater than 24 hours, storm durations longer than the T_c should be tested to determine the duration that gives the maximum reservoir stage for the routed stability design (auxiliary spillway) and freeboard hydrographs.

Precipitation amounts may exhibit marked variation in a large watershed. This variation is based upon topographical and meteorological parameters such as aspect, orientation, mean elevation of sub-basin, and storm orientation. Consideration shall be given to having the NWS make a special PMP study for large watersheds with drainage areas more than 100 square miles. Individual watershed PMP studies can take into account orographic features that are smoothed in the generalized precipitation studies. A special study also may be warranted in areas where significant snowmelt can occur during the design storms.

Studies to make use of available stream flow records are encouraged for purposes such as unit hydrograph development, watershed storage and timing effects, and calibration of watershed models.

Table 2-3 Principal spillway volume adjustments

(a)

Area (m^2)	–Area/point ratio– 1 day	10 days	Area (m^2)	–Area/point ratio– 1 day	10 days

* Change in tabulation interval

** For Ci greater than 3, use:

$QRF\ (ft^3/sec/mi^2) = 9(Ci-1)^{0.5}$

or

$QRF\ (in/d) = 0.03719\ [QRF\ (ft^3/sec/mi^2)]$

where:

QRF = quick return flow
Ci = climatic index
in/d = inches per day

Table 2-5 Minimum auxiliary spillway hydrologic criteria

Class of Dam	Product of storage X effective height	Existing or planned upstream dams	Precipitation data for [1]	
			Auxiliary spillway hydrograph	Freeboard hydrograph
Low [2]	less than 30,000	none	P_{100}	$P_{100} + 0.12(PMP - P_{100})$
	greater than 30,000		$P_{100} + 0.06(PMP - P_{100})$	$P_{100} + 0.26(PMP - P_{100})$
	all	any [3]	$P_{100} + 0.12(PMP - P_{100})$	$P_{100} + 0.40(PMP - P_{100})$
Significant	all	none or any	$P_{100} + 0.12(PMP - P_{100})$	$P_{100} + 0.40(PMP - P_{100})$
High	all	none or any	$P_{100} + 0.26(PMP - P_{100})$	PMP

[1] P_{100} = Precipitation for 100-year return period. PMP = Probable maximum precipitation
[2] Dams involving industrial or municipal water are to use minimum criteria equivalent to that of Significant Hazard Class.
[3] Applies when the upstream dam is located so that its failure could endanger the lower dam

Sedimentation

Reservoirs used to store or retard water from surface runoff will trap and store a large portion of the sediment in the runoff water. Therefore, allocate storage capacity for the calculated sediment accumulation during the design life of the reservoir. Criteria and general procedures needed to determine the volume required for sediment accumulation and its allocation in the reservoir are contained in NEH-3, Sedimentation. The latter also includes procedures for determining:

- sediment yield for present conditions and for the future after planned land treatment and other measures are applied in the drainage area of the dam;
- trap efficiency of the reservoir;
- distribution and types of sediment expected to accumulate;
- proportion of the sediment that will be continuously submerged vs. that aerated; and
- densities to which the sediment will become compacted.

If the amount of sediment accumulation calculated exceeds two watershed inches in 50 years for the uncontrolled drainage area of the dam, reevaluate the entire watershed to determine if more economical methods of reducing sediment yield or trapping sediment may be feasible and applicable.

Geologic investigations

The intensity and detail of geologic site investigations shall be consistent with the class of dam, complexity of site geology, and the data needed for design. General requirements, procedures, and criteria are set forth in the NEM-531 and NEH-8.

Following are the geologic conditions that require special consideration beyond the minimum investigations spelled out in the above reference.

Seismic assessment

Dams in zones 3 and 4, Alaska, Puerto Rico, and the Virgin Islands, and High Hazard Class dams in zone 2 (fig. 4-1) require special investigations to determine liquefaction potential of noncohesive strata, including very thin layers, and the presence at the site of any faults active in Holocene time. As part of this investigation, a map must be prepared showing the location and intensity of magnitude of all intensity V or magnitude 4 or greater earthquakes of record, and any historically active faults, within a 100-kilometer (62-mile) radius of the site. (Obtain earthquake information for this map from NOAA at *www.ngdc.noaa.gov/seg/hazard/int_srch.shtml* and USGS at *wwwneic.cr.usgs.gov/*.) The report should also summarize other possible earthquake hazards such as ground compaction, landslides, excessive shaking of unconsolidated soils, seiches, and in coastal areas, tsunamis.

Subsidence

Investigate the potential for surface subsidence due to past or future solid, liquid (including ground water) or gaseous mineral extraction. NEM-531, subpart B sets forth criteria for these evaluations.

Evaluate the impact of the preemption of mineral deposits, including sand and gravel, by dams and reservoirs.

In arid and semiarid areas and in eolian deposits, determine the potential of moisture deficient soil materials to collapse upon saturation or wetting. If the potential exists, make extensive and intensive site investigations to provide quantitative information for design and construction.

Auxiliary spillways

Large dams with auxiliary spillways in soft rock or cemented soil materials that cannot be classified as soil as defined in NEH-628, chapter 52 or as rock, as generally defined for engineering purposes, and spillways in rocks with extraordinary defects require a special individual evaluation.

Mass movements

Evaluate landslides and landslide potential at dam and reservoir sites, especially those in shales and where unfavorable dip-slope or other adverse rock attitudes occur. Summarize the history of mass movement in the project area. Auxiliary spillway cuts and reservoir effects must be given careful consideration.

Karstic areas

Limestone and gypsum in reservoirs and at dam sites require special investigational methods and careful evaluation of subsidence, leakage hazards, and construction costs. Multipurpose structures in these areas are especially critical.

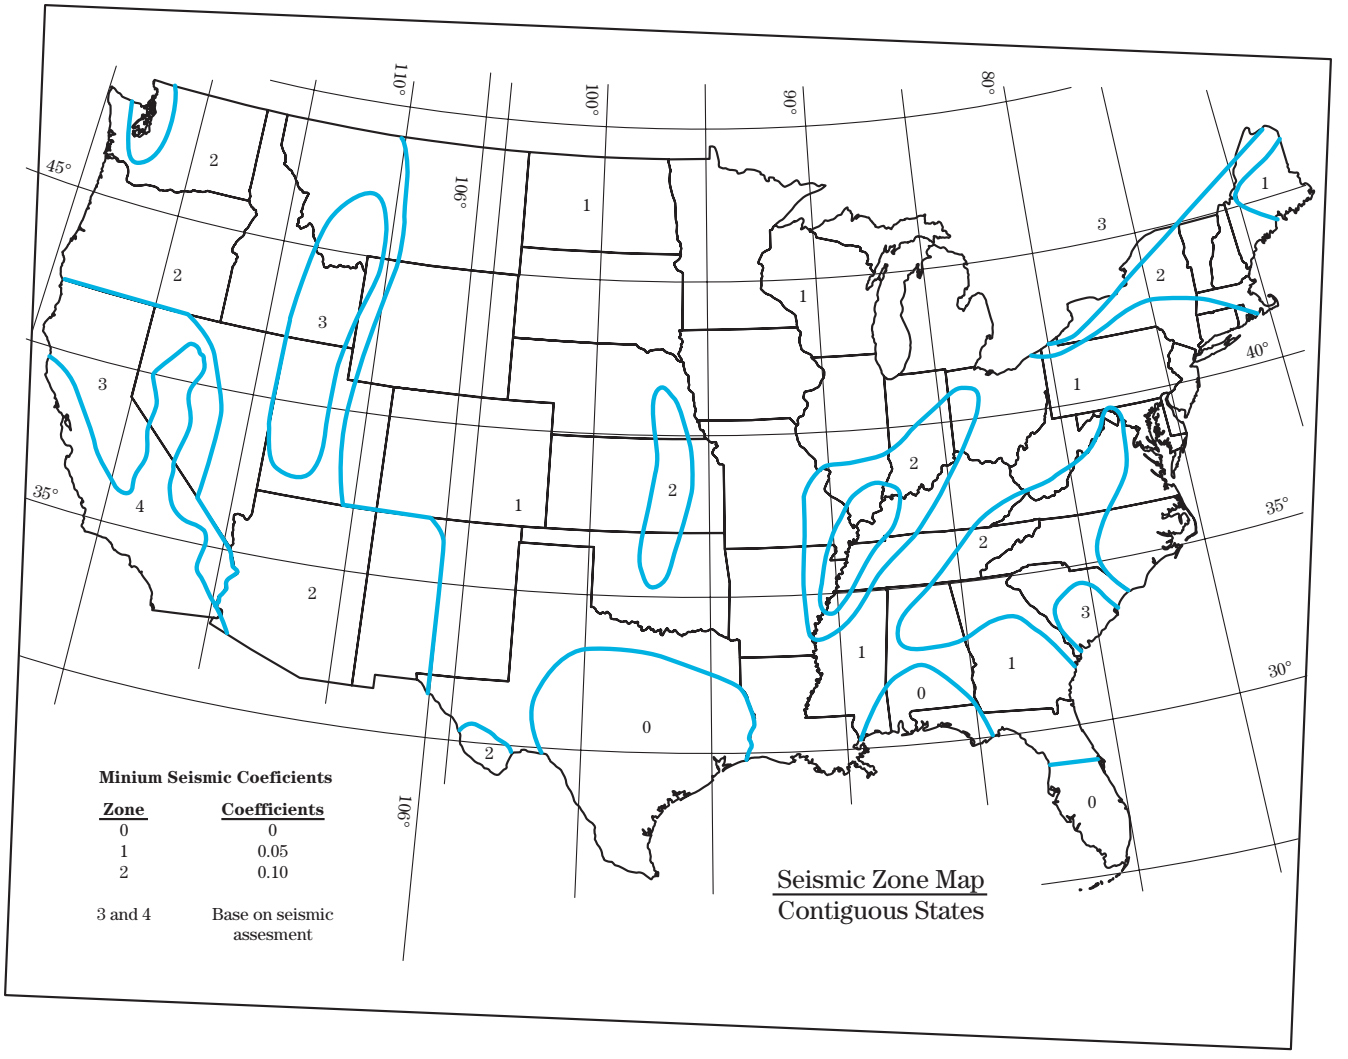
Multipurpose dams

Investigate the ground water regime and hydraulic characteristics of the entire reservoir area of water storage dams and evaluate for leakage. Use the water budgets to determine the need for reservoir sealing.

Other

Special studies and evaluations may be necessary where compaction shales; some types of siliceous, calcareous or pyritic shales; rebound joints; dispersed soils; or artesian waters occur at a site.

Figure 4-1 Seismic zone map



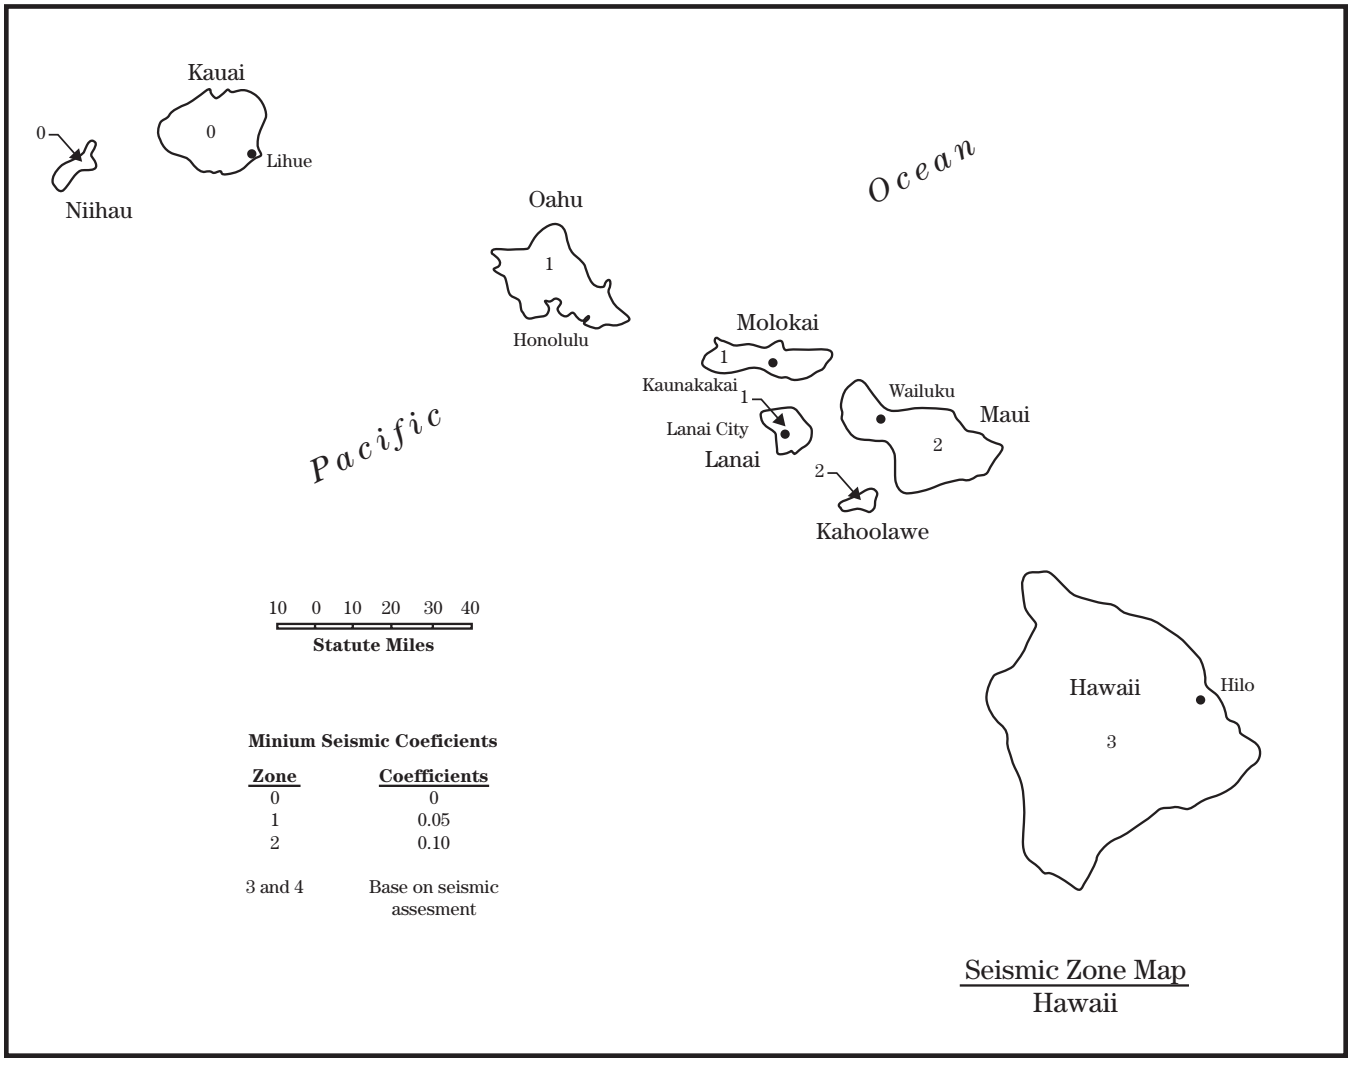


Figure 4-1 Seismic zone map—continued

Earth embankments and foundations

Earth embankments constructed of soil and rock are the principal means of impounding water. The earth embankment and its foundation must withstand the anticipated loads without movements leading to failure. Measures must be provided for adequate seepage control.

Height

The design height of an earth embankment must be sufficient to prevent overtopping during passage of either the freeboard hydrograph or stability design hydrograph plus the freeboard required for frost conditions or wave action, whichever is larger. The design height must also meet the requirements for minimum auxiliary spillway depth. The design height of the dam must be increased by the amount needed to compensate for settlement.

Top width

The minimum top width of embankment is shown in table 5-1.

The width may need to be greater than the above minimums to:

- meet state and local standards;
- accommodate embankment zoning;
- provide roadway access and traffic safety; and
- provide structural stability.

An increase in top width is a major design feature in preventing breaching after embankment slumping caused by earthquake ground motion.

When the embankment top is used as a public roadway, the minimum width shall be 16 feet for one-way and 26 feet for two-way traffic. Guardrails or other safety measures shall be used and must meet the requirements of the responsible road authority.

Embankment slope stability

Analyze the stability of embankment slopes using generally accepted methods based on sound engineering principles. Document all analyses including assumptions regarding shear strength parameters for each zone of the embankment and each soil type or horizon in the foundation. Documentation should include methods used for analyses and a summary of results. Design features necessary to provide required safety factors should be noted.

Table 5-1 Minimum top width of embankment

Total height of embankment, H, (ft)	Top Width (ft)		
	All dams	Single purpose floodwater retarding	Multipurpose or other purposes
14 or less	8	N/A	N/A
15–19	10	N/A	N/A
20–24	12	N/A	N/A
25–34	14	N/A	N/A
35–95	N/A	14	(H+35)/5
Over 95	N/A	16	26

Use the appropriate degree of conservatism in the analysis that is consistent with the adequacy of the site investigation and the soil-testing program. Consider the complexity of the site and consequences of failure in determining the level of detail in the analyses. Minimum required safety factors are summarized in table 5-2 for each condition analyzed.

Evaluate the effect of seismicity on each site. Determine whether the site is in a seismically active area, its proximity to active faults, and the predicted ground motion intensity at the site. If the site is located in zone 3 or 4 shown in figure 4-1, perform special seismic studies. Otherwise, use the horizontal acceleration factors shown in figure 4-1 in a pseudo-static stability calculation using conditions summarized in table 5-2.

Analyze embankment stability for each of the following conditions in the design life of the structure that are appropriate to the site. If a condition is not analyzed, clearly document the reasons. Document any correlated shear strength parameters, including correlations to field performance, used to justify a lack of detailed analyses of a particular condition.

End of construction

This case should be analyzed when either embankment or foundation soils (or both) are predicted to develop significant pore pressures during embankment construction. Factors determining the likelihood of this occurring include the height of the planned embankment, the speed of construction, the saturated consistency of foundation soils, and others. Perform appropriate shear tests to model placement conditions of embankment soils, as summarized in table 5-2. Consider the highest likely placement water content of embankment soils in the shear-testing program. Either field vane shear tests or laboratory tests should determine the unconsolidated/undrained strength of slowly permeable foundation soils. The undrained strength of foundation clays should be corrected for plasticity index when field vane shear tests are used for measurement.

Rapid drawdown

Analyze the stability of the upstream embankment slope for the condition created by a rapid drawdown of the water level in the reservoir from the reservoir level from which a phreatic line is likely to develop. Ordinarily, assume a phreatic line has developed from the normal full reservoir elevation. Then, assume the water in the reservoir is rapidly lowered to the elevation of the lowest gated or ungated outlet and analyze the stability of the embankment following this drawdown. For rare situations, the upstream drawdown condition should be analyzed assuming that soils are saturated from temporary pool storage to the elevation of the auxiliary spillway. This condition should be analyzed if it is possible that in the future the riser could become plugged or other circumstances could cause the temporary impoundment to this higher elevation. For this condition, assume a zone of saturated soils in the embankment occurs based on transient flow nets that determine the portion of the embankment likely to become saturated during the temporary storage. Transient flow nets may be used to examine the temporary saturation of the portion of the embankment above permanent normal pool. Select shear parameters for the analyses according to table 5-2, as illustrated in figure 5-1.

Use infinite slope equations and appropriate safety factors in analyzing the stability of zones in the exterior slope of the embankment with soils having zero effective cohesion parameters, when the critical failure is wholly within soils of this character. If cohesionless zones occur with other soil types in a cross section being analyzed, circular arc or wedge-shaped surfaces should also be explored that intersect the soil zones with cohesion to locate the minimum safety factor. Note that different safety factors are considered adequate for infinite slope analyses than for failure surfaces that are deeper within the profile. See table 5-2 for details.

Figure 5-1 Mohr-Coulomb Envelope for upstream drawdown

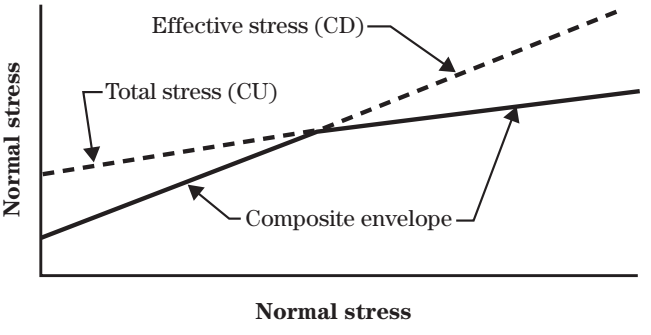

Table 5-2 Slope stability criteria

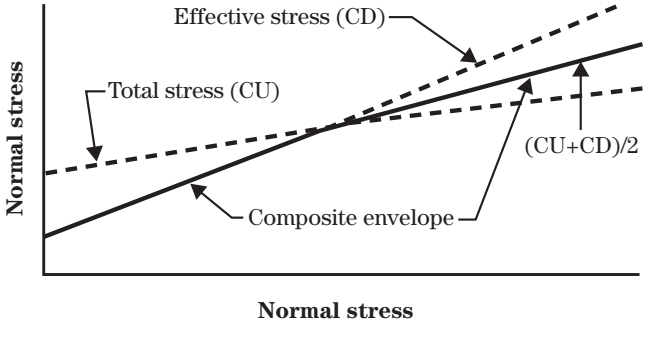
Design condition	Primary assumption	Remarks	Shear strength to be used	Minimum safety factor
1. End of construction (upstream or downstream slope)	Zones of the embankment or layers of the foundation are expected to develop significant pore pressures during construction	Embankment soils that are slowly permeable should be tested at water contents that are as wet as likely during construction (usually wet of optimum) Saturated slowly permeable foundation soils that are not predicted to fully consolidate during construction Permeable embankment zones and/or foundation strata	UU – includes triaxial UU tests, unconfined compression (qu) tests, and field vane shear tests CU' or CD	1.4 for failure surfaces extending into foundation layers 1.3 for embankments on stronger foundations where the failure surface is located entirely in the embankment
2. Rapid drawdown (upstream slope)	Drawdown from the highest normal pool to the lowest ungated outlet	Consider failure surfaces both within the embankment and extending into the foundation	Lowest shear strength from a composite envelope of CU and CD envelopes (fig. 5-1)	1.2 1.1 for infinite slope analysis
3. Steady seepage without seismic forces (downstream slope)	Phreatic line developed from pool at the principal spillway crest Uplift pressure simulated by phreatic line developed from auxiliary spillway crest applied to saturated embankment and foundation soils	Consider failure surfaces both within the embankment and extending into the foundation	Lowest shear strength from a composite envelope of CU and (CU+CD)/2 envelopes (fig. 5-2)	1.5 1.1 for infinite slope analysis
4. Steady seepage with seismic forces (downstream slope)	Phreatic line developed from principal spillway crest with no uplift	Consider failure surfaces both within the embankment and extending into the foundation	Lowest shear strength from a composite envelope of CU and (CU+CD)/2 envelopes (fig. 5-2)	1.1



Steady seepage without seismic forces
Using shear parameters, as specified in table 5-2 and illustrated in figure 5-2, analyze the downstream slope considering a phreatic line developed from the reservoir at the principal spillway crest. Subject saturated soils below the phreatic line to an uplift force simulated by a phreatic surface developed from the auxiliary spillway crest. Phreatic surfaces for the analyses may be developed using flow nets or Casagrande procedures.

Use infinite slope equations and appropriate safety factors as under Rapid Drawdown condition.

Steady seepage with seismic forces
Using shear parameters, as specified in table 5-2, analyze the downstream slope considering a phreatic line developed from a pool at the principal spillway crest. Apply a horizontal acceleration constant appropriate to the seismic zone in which the site is located, as specified in figure 4-1. Do not use uplift forces due to a reservoir stage at the auxiliary spillway because the likelihood of a simultaneous occurrence of an earthquake and an auxiliary spillway flow event is extremely remote.

Use infinite slope equations and appropriate safety factors in analyzing the stability of zones in the exterior slope of the embankment with soils having zero effective cohesion parameters. The equations should incorporate the horizontal acceleration constant specified in figure 4-1.

Figure 5-2 Mohr-Coulomb Envelope for downstream steady seepage

Consider following additional guidance in analyzing slope stability.

- Only effective stress (CD) parameters are appropriate for soils that will consolidate as rapidly as load is applied. These parameters are applicable for all conditions of stability analyzed for these soil types.
- The end of construction condition is usually the one that controls the design of embankments when it is applicable. Special designs including staged construction or monitoring pore pressures during construction may be required to achieve objectives for some site conditions such as soft clay foundation soil horizons.
- Total stress parameters used in the construction of composite shear strength envelopes should not consider large negative pore pressures that may develop during shear testing. Either maximum deviator stress or maximum principal effective stress ratio failure criteria should usually be used to define total stress parameters. Total stress parameters interpreted from maximum arbitrary strain criteria should be used only when other criteria are less limiting.
- Infinite slope equations should model the predicted seepage pattern in the slope being analyzed. The three equations used are for no seepage, for horizontal seepage paths, and for seepage paths parallel to the slope face.
- Residual effective stress parameters should be used for modeling slope stability analyses involving fissured clays or shales if pre-existing movements have occurred. These parameters are based on drained shear strength tests where stresses are determined at high strain values beyond the peak strength. Residual parameters may also be considered for designing against shallow slope failures in desiccated clay embankments.

Seepage

To the extent needed, an analysis shall be made of anticipated seepage rates and pressures through the embankment, foundation, abutments, and reservoir perimeter (when storage is desired). Controls and treatment should be adequate to:

- accomplish the intended reservoir function;
- provide a safely operating structure; and
- prevent damage to downstream property.

Zoning

Embankment zoning can be used when needed to:

- obtain a stable structure with the most economical use of available materials;
- control seepage in a safe manner; or
- reduce to a minimum the uncertainties of material strengths and resultant stability.

Embankment zones should be a minimum of 10 feet wide except for filters and drains with specified and controlled gradation. Drains and filters should meet the requirements contained in Soil Mechanics Notes.

Soil materials which exhibit significant shrinkage, swell or dispersion should be used only with extreme care. If possible, they should not be used for embankment construction. When there is no economical alternative to their use, they must be:

- treated to improve their performance;
- placed in zones where effects will not be detrimental; or
- protected by use of filters and drains or self-healing transition zones.

Surface protection

Embankment surfaces must be protected against surface erosion. Protection may be vegetative, gravel, rock riprap, soil cement, structural, or similar treatment of durable quality and proven satisfactory performance.

Vegetative protection

Vegetative protection may be used on surfaces where the following conditions can be met:

- inundation of the surfaces is of such frequency that vegetative growth will not be inhibited;
- vigorous growth can be sustained under average climatic conditions by normal maintenance without irrigation; and
- stable protection can be designed according to the procedures in TR-56.

Structural protection

Protection against wave erosion by riprap or other structural measures shall be provided for:

- dams where vegetation will not provide effective control;
- multiple purpose dams; and
- dams with fluctuating normal water levels.

Protection must extend from the lowest drawdown elevation that presents an erosion hazard, to a few feet above the crest of the lowest ungated spillway. The upper limit shall be based on an analysis of anticipated wave height and run up.

Quality of riprap and other structural protection must be consistent with the anticipated life of the dam and designed to be structurally stable.

Principal spillways

The structural design and detailing of principal spillways must conform to the recommendations of NEH-6, Structural Design, and NRCS standard drawings. All component parts of principal spillways except easily replaceable parts such as gates and trash racks shall be equally durable.

Capacity of principal spillway

The required capacity of the principal spillway depends on the:

- purpose of the dam;
- amount of storage provided by the retarding pool;
- kind of auxiliary spillway;
- stream channel capacity and stability downstream;
- potential damage from prolonged storage in the retarding pool;
- potential damage downstream from prolonged high outflow rates;
- possibility of substantial runoff from two or more storms in the time required to empty the retarding pool;
- limitations imposed by water rights or other legal requirements;
- environmental concerns;
- planned or potential alterations of the channel downstream; and
- necessity to pass base and flood flows during construction.

The principal spillway may be single-stage, having an ungated inlet at only one elevation, or multiple-stage, having inlets at two or more elevations. In the case of multiple-stage spillways, the lower stage or stages usually perform the primary flood control function, and the high stage has the capacity needed to prevent the auxiliary spillway from functioning more frequently than permissible.

The principal spillway capacity should be adequate to empty the retarding pool in 10 days or less. This requirement is considered met if 15 percent or less of the maximum volume of retarding storage remains after 10 days. Where low release rates are required to meet the objectives of the project, a longer period than 10 days may be needed. For these situations, additional storage is required to minimize the opportunity for increased frequency of auxiliary spillway flow due to recurring storms.

Compute the 10-day drawdown from the time the maximum water surface elevation is attained during the passage of the principal spillway hydrograph. The entire design inflow hydrograph including quick return flow, upstream releases, and outflow must be considered in determining the evacuation time of the retarding storage. The inflow from storm runoff must be considered for the entire evacuation time.

For dams where more than 15 percent of the retarding storage volume remains after 10 days, the elevation of the crest of the auxiliary spillway must raised. The raised crest elevation is determined by adding the remaining retarding storage volume to the initial retarding storage volume.

Elevation of principal spillways

Single-purpose floodwater retarding dams
The crest of the principal spillway or of the low stage inlet of a two-stage principal spillway shall be set at the submerged sediment pool elevation. For dry dams, the elevation of the principal spillway inlet shall be placed as described above and provisions made to drain the reservoir in a reasonable time and, thus, satisfy the functional or legal requirements of the dam.

Other dams
When conservation storage will be provided, the elevation of the crest of the lowest ungated inlet of the principal spillway is determined by the volume, area, or depth of water required for the planned purpose or purposes and the required sediment storage. The lowest crest may be the crest of the low-stage inlet, single-stage inlet, or an open spillway.

Routing of principal spillway hydrographs

Reservoir flood routing used to proportion dams and associated spillways shall be based on the assumption that all sedimentation expected in the reservoir during its design life has occurred. The reservoir stage-storage curve used for routing should reflect the anticipated accumulation of sediment. The initial reservoir stage for principal spillway hydrograph routing shall be at the crest of the lowest ungated inlet or (if not subtracted from the stage-storage curve) the anticipat-

ed elevation of the sediment storage, whichever is higher, except as provided below.

- For dams with significant base flow, principal spillway hydrograph routings must start not lower than the elevation of the water surface associated with the base flow. Significant base flow is average annual or seasonal flow that would produce at least 0.5 feet of head over the lowest principal spillway inlet immediately prior to a flood or occupy more than 10 percent of the floodwater storage capacity.
- For dams with joint use storage capacity, when one of the uses is floodwater detention, routing of the principal spillway hydrograph may begin at the lowest anticipated elevation of the joint use pool in accordance with the operation plan.
- Single purpose, low hazard class irrigation dams with gated outlets and earth or vegetated auxiliary spillways, which are located on ephemeral streams in areas where the average annual precipitation is less than 25 inches, may be considered to have discharged up to 70 percent of the storage, exclusive of sediment storage in determining the elevation to start routing.

Design of principal spillways

Hydraulics

The principal spillway must be designed to carry the planned flow for expected head and tailwater conditions. TR-29, Design Note No. 8, NEH-5, the Engineering Field Handbook for Conservation Practices and other appropriate references shall be used for hydraulic design.

Risers

Risers for drop inlet spillways must be designed to maintain the reservoir pool level at or near the inlet crest elevation during low flow periods, to establish full pipe flow at as low a head over the crest as practical, and to operate without excessive surging, noise, vibration, or vortex action at any reservoir stage. This requires the riser to have a larger cross-sectional area than the conduit. Standard risers have an inside width equal to the width (diameter) D, of the conduit and an inside length equal to three times the width (diameter) of the conduit (D x 3D cross section).

Risers shall be designed to exclude trash too large to pass freely through the spillways, including the outlet structure, and to facilitate the passage of smaller trash. Standard D x 3D risers tend to line up longer pieces of trash and facilitate their passage into and through the conduit. Covered risers with standard skirted or baffle inlets should be used in most cases because they are most effective in excluding trash without becoming clogged. Skirted inlets, having a cover with skirts extending below the weir crest elevation, are applicable where backfill or settlement levels will be at least two times the conduit width (diameter) below the crest. Baffle inlets are applicable for risers that will be backfilled to the crest elevation or where sediment is expected to build up to the crest elevation.

Risers shall be designed structurally to withstand all water, earth, ice, and earthquake loads to which they may be subjected. Articulation must be provided to allow movement of the riser with respect to the conduit.

Risers with low-stage inlets at or near the bottom must be provided with concrete aprons to prevent erosion of soil and undermining of the riser footing by high velocity flow approaching the inlet.

Standard risers must be used where applicable for low hazard class dams with an effective height of more than 35 feet and for all significant and high hazard class dams. Prefabricated pipe risers are permissible, where hydraulically and structurally adequate, for low hazard class dams not more than 35 feet in effective height. The riser pipe must be of the same material as the conduit and at least one standard pipe size larger than the conduit pipe.

Special riser designs are required for spillways having maximum conduit velocities more then 30 feet per second and for spillways having conduits larger then 48 inches in width (diameter). Generally, these should be similar to standard risers, but a special elbow and transition is required at the junction of the riser and conduit, and special design of the inlet may be necessary. Hydraulic model testing should be considered if the maximum total head on the spillway is more than 75 feet or the conduit velocity exceeds 50 feet per second.

Conduit

The conduit should be straight in alignment when viewed in plan. Changes from straight alignment, if required, must be accomplished by watertight angle changes at joints or by special elbows having a radius equal to or greater than the diameter or width of the conduit. Thrust blocks of adequate strength must be provided if special pipe elbows are used. They must be designed to distribute the thrust due to change in direction for the maximum possible discharge. Drop inlet

conduits shall be installed with enough slope to ensure free drainage to the outlet of all parts of the conduit (including camber) at the time of construction and under the maximum anticipated settlement.

All conduits under earth embankments must support the external loads with an adequate factor of safety. They must withstand the internal hydraulic pressures without leakage under full external load and settlement. They must convey water at the design velocity without damage to the interior surface of the conduit.

Principal spillway conduits under earth dams may be designed to support fill heights greater than the original constructed height if there is a reasonable possibility that the embankment height may be raised later to incorporate additional storage for some approved beneficial use.

Rigid principal spillway conduits shall be designed as positive projecting conduits in accordance with the principles and procedures given in TR-5.

Principal spillway conduits must be of reinforced concrete pressure pipe or cast-in-place reinforced concrete, unless corrugated steel or welded steel pipe is used.

Cast-in-place rectangular reinforced concrete conduits must be designed in accordance with principles and procedures in TR-42, TR-45 or other appropriate design aids.

For Reinforced Concrete Water Pipe—Steel Cylinder Type, Prestressed, meeting specification AWWA Standard C301, the 3-edge bearing strength at the first 0.001-inch crack shall be used with a safety factor of at least one.

For Reinforced Concrete Water Pipe—Steel Cylinder Type, Not Prestressed, meeting specification AWWA Standard C300; for Reinforced Concrete Water Pipe Noncylinder Type, Not Prestressed, meeting specification AWWA Standard C302, and for other types of reinforced concrete pipe, the 3-edge bearing strength at the first 0.01-inch crack shall be used with a safety factor of at least 1.33.

Elliptical or other systems of reinforcement requiring special orientation of pipe sections are not permitted in spillway conduits.

Reinforced concrete pipe must be designed to support at least 12 feet of earth fill above the pipe at all points along the conduit.

- Reinforced Concrete Pipe
  - Minimum inside diameters on yielding foundations

    Low hazard class dams: The minimum diameter of the principal spillway conduit must be 30 inches, unless a joint extension safety margin of at least 1.5 inches is used, in which case, the minimum diameter shall be 18 inches for maximum fill heights up to 50 feet at the centerline of the dam and 24 inches for greater fill heights.

    Significant hazard class dams: The minimum diameter of the principal spillway conduit must be 30 inches, unless a joint extension safety margin of 1.5 inches is used, in which case, the minimum diameter shall be 24 inches.

    High hazard class dams: The minimum diameter of the principal spillway conduit must be 30 inches.

  - Minimum inside diameters on nonyielding foundations: The minimum diameter of the principal spillway conduit for low hazard class dams must be 18 inches for heights up to 50 feet at the centerline of the dam and 24 inches for heights greater than 50 feet, and 24 inches for all significant and high hazard class dams. The conduit and cradle or bedding must rest directly on firm bedrock thick enough so that there is essentially no foundation consolidation under the conduit. Under these conditions, the cradle or bedding under the conduit need not be articulated.
- Corrugated steel pipe or welded steel pipe

  Principal spillways of corrugated steel or welded steel pipe may be used for single purpose low hazard class dams with the product of storage times effective height of dam less than 10,000. While installation costs of steel pipes may be less, concrete may compare favorably with steel when replacement costs and associated problems are considered.

In each case, the following limitations apply:

- diameter of pipe not less than 18 inches;
- height of fill over the pipe not more than 25 feet;
- provision for replacement if the materials will not last for the design life of the structure;
- pipe structurally strong enough to withstand outside loads and hydraulic pressure; and

- pipe watertight.

Corrugated steel pipe shall be polymer-coated with watertight connecting bands. The minimum gage must be designed for 35 feet of fill over the pipe.

Welded steel pipe conduits must be structurally designed as rigid pipe. A joint extension safety margin of 1.5 inches shall be provided for conduits on yielding foundation. Welded steel pipe must be protected by a Class A exterior coating as defined in Conservation Practice Standard 430-FF, Irrigation Water Conveyance, Pipeline, Steel, or by an exterior coating of coal tar-epoxy paint conforming to Paint System F, Construction Specification 82 (NEH-645).

Joints between lengths of corrugated steel or welded steel pipe, other than welded joints, are to be electrically bridged on the outside of the pipe with insulated copper wire, #6 AWG or larger, securely attached to the uncoated pipe metal at both sides of the joint. This requirement applies whether or not the cathodic protection is completed by the installation of anodes, etc. The wire should have a tough, waterproof insulation designed for direct burial, with a rating of at least 600 volts. Bare wire and exposed pipe metal at the points of connection are to be thoroughly coated with a coating equivalent to the original pipe coating to prevent the entry of moisture.

Soil investigations for resistivity and pH of the subgrade and backfill materials to be adjacent to the conduit shall be made. The resistivity measurements are made on saturated samples.

Cathodic protection must be provided for welded steel pipe conduits according to the criteria in Conservation Practice Standard 432-FF in the National Handbook of Conservation Practices (NHCP).

Cathodic protection meeting the above requirements must be provided for corrugated steel pipe in soil whose resistivity in a saturated condition is less than 4000 ohms-cm or whose pH is lower than 5.0.

If cathodic protection is not required according to the above criteria and anodes are not installed during construction of the dam, pipe-to-soil potentials must be measured within the first 2 years after construction or after the water level has stabilized and when the soil around the conduit is estimated to be at its normal post-construction moisture content. Cathodic protection must be installed at this time if such measurements indicate it is needed.

Joints

Conduit joints shall be designed and constructed to remain watertight under maximum anticipated hydrostatic head and maximum probable joint opening as computed from Standard Drawing ES-146 and related procedures of TR-18, including the effects of joint rotation and the required margin of safety. The required joint extensibility is equal to the unit horizontal strain in the earth adjacent to the conduit multiplied by the length (in inches) of the section of conduit between joints plus the extension (in inches) due to calculated joint rotation plus a margin of safety.

A margin of safety of not less than 0.5 inch shall be used. The required joint extensibility plus the maximum permissible joint gap equals the required joint length. The required joint extensibility depends on the maximum potential foundation consolidation under the spillway barrel. For significant and high hazard class dams, the consolidation must be estimated from adequate foundation borings and samples, soil mechanics laboratory tests, and engineering analysis. For low hazard class dams where undisturbed foundation samples are not taken for other purposes, approximate procedures based on soil classification and experience may be used for estimating foundation consolidation.

Only joints incorporating a round rubber gasket set in a positive groove which will prevent its displacement from either internal or external pressure under the required joint extensibility shall be used on precast concrete pipe conduits. Concrete pipe must have steel joint rings providing rubber to steel contact in the joint.

Articulation of the conduit (freedom for required rotation) shall be provided at each joint in the conduit, at the junction of the conduit with the riser and any outlet structure. Concrete bedding for pipe conduits need not be articulated. Cradles must be articulated if on yielding foundations. Welded steel pipe conduits need not be articulated if the pipe and bedding rest directly on firm bedrock.

Piping and seepage control—Use a filter and drainage diaphragm around any structure that extends through the embankment to the downstream slope. Design the diaphragm with single or multiple zones to meet the requirements of NEH-633, chapter 23.

Locate the diaphragm aligned approximately parallel to the centerline of the dam or approximately perpendicular to the direction of seepage flow. Extend the diaphragm horizontally and vertically into the adjacent

embankment and foundation to intercept potential cracks, poorly compacted soil zones or other discontinuities associated with the structure or its installation.

Design the diaphragms to extend the following minimum distances from the surface of rigid conduits:

- horizontally and vertical upward 3 times the outside diameter of circular conduits or the vertical dimension of rectangular box conduits except that:
  - vertical extension need be no higher than the crest of the auxiliary spillway, or higher than 2 feet below the embankment surface, and
  - horizontal extension need be no further than 5 feet beyond the sides and slopes of any excavation made to install the conduit.
- vertically downward:
  - for conduit settlement ratios (δ) of 0.7 and greater (reference NRCS Technical Release No. 5), the greater of (1) 2 feet or (2) 1 foot beyond the bottom of the trench excavation made to install the conduit. Terminate the diaphragm at the surface of bedrock when it occurs within this distance. Additional control of general seepage through an upper zone of weathered bedrock may be needed.
  - 1.5 times the outside diameter of circular conduits or the outside vertical dimension of box conduits for conduit settlement ratios (δ) less than 0.7.

Design the diaphragms to extend in all directions a minimum of two times the outside diameter from the surface of flexible conduits, except that the diaphragm need not extend beyond the limits in the above or beyond a bedrock surface beneath the conduit.

Provide minimum diaphragm thickness of 3 feet and minimum thickness of 1 foot for any zone of a multizone system. Use larger thickness when needed for capacity, tying into embankment or foundation drainage systems, accommodating construction methods, or other reasons.

For homogeneous dams, locate the diaphragm in the downstream section of the dam such that it is:

- downstream of the cutoff trench;
- downstream of the centerline of the dam when no cutoff trench is used; and
- upstream of a point where the embankment cover (upstream face of the diaphragm to the downstream face of the dam) is at least one-half of the difference in elevation between the top of the diaphragm and the maximum potential reservoir water level.

For zoned embankments, locate the diaphragm downstream of the core zone and/or cutoff trench, maintaining the minimum cover as indicated for homogeneous dams. When the downstream shell is more pervious than the diaphragm material, locate the diaphragm at the downstream face of the core zone.

It is good practice to tie these diaphragms into the other drainage systems in the embankment or foundation. Foundation trench drains and/or embankment chimney drains that meet the minimum size and location limits are sufficient and no separate diaphragm is needed.

Design the minimum capacity of outlets for diaphragms not connected to other drains by assuming the coefficient of permeability (k) in the zone upstream of the diaphragm is 100 times the coefficient of permeability in the compacted embankment material. Assume this zone has a cross-sectional area equal to the diaphragm area and the seepage path distance equal to that from the embankment upstream toe to the diaphragm. This higher permeability simulates a sealed filter face at the diaphragm with partially filled cracks and openings in the upstream zone.

For channels, chutes or other open structures, seepage and piping control can be accomplished in conjunction with drainage for reduction of uplift and water loads. The drain, properly designed to filter the base soils, is to intercept areas of potential cracking caused by shrinkage, differential settlement, or heave and frost action. These structures usually require the use of footings, keywalls and counterforts, and drainage is properly located immediately downstream of these features. This drainage when properly designed can control piping and provide significant economies due to the effect on soil loads, uplift pressures, overturning forces and sliding stability.

Outlets

The choice of outlet is to be based on a careful consideration of all site and flow conditions that may affect operation and energy dissipation.

- Cantilever outlet and plunge pools may be

installed where their use:

- does not create a piping hazard in the foundation of the structure.
- is compatible with other conditions at the site.

Plunge pools shall be designed to dissipate the energy and be stable. Unless the pool is to be in bedrock or very erosion resistant materials, riprap will be necessary to insure stability. Design Note 6, Armored Scour Hole for Cantilever Outlet, shall be used for design.

Cantilever outlets shall be supported on bents or piers and must extend a minimum of 8 feet beyond the bents or piers. The bents must be located downstream from the intersection of the downstream slope of the earth embankment with the grade line of the channel below the dam. They must extend below the lowest elevation anticipated in the plunge pool. The invert of the cantilever outlet must be at least 1 foot about the tailwater elevation at maximum discharge.

- SAF basins may be used when there is adequate control of tailwater. Use TR-54 for structural design and NEH-14 for hydraulic design.
- Impact basins may be used where positive measures are taken to prevent large debris from entering the conduit. TR-49 is to be used for hydraulic design.

Trash racks

Trash racks shall be designed to provide positive protection against clogging of the spillway under any operating level. The average velocity of flow through a clean trash rack must not exceed 2.5 feet per second under the full range of stage and discharge. Velocity must be computed on the basis of the net area of opening through the rack.

If a reservoir outlet with a trash rack or a ported concrete riser is used to keep the sediment pool drained, the trash rack or riser must extend above the anticipated sediment elevation at the riser to provide for full design flow through the outlet during the design life of the dam. The velocity through the net area of the trash rack above the maximum sediment elevation must not exceed 2 feet per second when the water surface in the reservoir is 5 feet above the top of the trash rack or riser inlet.

Antivortex device

All closed conduit spillways designed for pressure flow must have adequate antivortex devices.

High sulfate areas

Under certain conditions, concrete is susceptible to deterioration from sulfate ions, especially those derived from sodium and magnesium sulfates. In areas where experience or soil tests indicate the potential for problems, the following shall be used for design purposes.

Sulfate concentration [1/] (parts per million)	Hazard	Corrective measures
0 – 150	Low	None
150 – 1,000	Moderate	Use Type II Cement. (ASTH C-150). Adjust mix to protect against sulfate action.
1,000 – 2,000	High	Use Type V Cement (ASTM C-150). Adjust mix to protect against sulfate action. Use soils in contact with concrete surfaces that are low in sulfates.
2,000 – UP		Do not use concrete materials unless measures are taken to protect concrete surfaces from sulfates. Product manufacturers should be consulted.

[1/] Sulfate concentration is for soil water at the concrete surface.

Auxiliary spillways

Auxiliary spillways are provided to convey excess water through, over, or around a dam. They are usually open channels excavated in natural earth, earthfill, rock, or constructed of reinforced concrete.

Closed type spillways

An open channel auxiliary spillway must be provided for each dam except as provided below:

- Low hazard class dams with a product of storage times the effective height of the dam of less than 10,000 – a closed conduit principal spillway having a conduit with a cross-sectional area of 12 square feet or more, an inlet which will not clog, an elbow designed to facilitate the passage of trash, and large enough to pass the routed freeboard hydrograph is the minimum acceptable design without an open channel auxiliary spillway.
- Dams with drainage areas of 10 square miles or less (except those covered by item 1) – a closed conduit principal spillway having a conduit with a cross-sectional area of 20 square feet or more, an inlet which will not clog, an elbow designed to facilitate the passage of trash and large enough to pass the routed freeboard hydrograph peak discharge without overtopping the dam is the minimum acceptable design without an open channel auxiliary spillway.
- Dams with drainage areas greater than 10 square miles (except those covered by item 1) – a closed type primary auxiliary spillway may be used in lieu of an open channel auxiliary spillway. Drop inlet spillways with a standard two-way covered top inlet must have a minimum unobstructed cross-sectional area of each opening of the conduit of 40 square feet. All other closed type primary auxiliary spillways must have a minimum unobstructed cross-sectional area of each opening of 80 square feet. The ratio of width to height in both cases is must be between 0.75 and 1.33. The spillways must be large enough to pass the routed freeboard hydrograph peak discharge without overtopping the dam.

Spillway requirements

Capacity of auxiliary spillways

Auxiliary spillways must be proportioned so they will pass the stability design hydrograph at the safe velocity determined for the site. They must have sufficient capacity to pass the freeboard hydrograph with the water surface in the reservoir at or below the elevation of the design top of the dam. In no case is the capacity of the auxiliary spillway to be less than 200 ft^3/sec or 237 $DA^{0.493}$. The minimum difference in elevation between the crest of the auxiliary spillway and the settled top of the dam is 3 feet. State law may establish minimum capacity or depth greater than those given above.

Elevation of the crest of the auxiliary spillway

Table 2-2 gives the maximum allowable frequency of use of earth and vegetated auxiliary spillways. The minimum retarding storage volume and the associated principal spillway discharge must be such that the discharge through the auxiliary spillway will not occur during the routing of the principal spillway hydrograph and the 10-day drawdown requirement is met or the crest elevation of the auxiliary spillway is raised as noted under Capacity of Principal Spillway.

For earth spillways, it refers to sites where peak flows of short duration may be expected and where erosion resistant soils and moderate slopes exist. When vegetated spillways are used, the sites must have these same characteristics, and in addition, conditions must be such that vigorous vegetation can be maintained without irrigation. When conditions are less favorable, auxiliary spillways shall be designed for less frequent use. This may be done by raising the crest elevation, increasing the capacity of the principal spillway, adding a structural primary auxiliary spillway, or a combination of the above.

The maintenance required for the auxiliary spillway will be increased as the frequency and duration of flow increase. Good design requires balancing the spillway maintenance cost against the increased cost of modifying the other elements of the dam to reduce the flow frequency.

Auxiliary spillway routings

The stability design and the freeboard hydrographs must be routed through the reservoir starting with the water surface at the elevation of the lowest ungated principal spillway inlet, the anticipated elevation of the sediment storage, the elevation of the water surface associated with significant base flow or the pool elevation after 10 days of drawdown from the maximum

stage attained when routing the principal spillway hydrograph, whichever is higher, except as provided in the following:

- dams with gated spillways and joint use storage capacity – stability design and freeboard hydrograph routings are to be started at or above the elevation of the lowest ungated outlet or at the elevation of the water surface associated with the average annual base flow, whichever is higher.
- single purpose, low hazard class irrigation dams – stability design and freeboard hydrograph routings are to be started at or above the water surface elevation of the irrigation storage.

Hydraulic design
The relationship between the water surface elevation in the reservoir and the discharge through the auxiliary spillway shall be evaluated by computing the head losses in the inlet channel upstream of the control section or, if a control section is not used, by computing the water surface profile through the full length of the spillway. Bernoulli's equation and Manning's formula shall be used to evaluate friction losses, compute water surface profiles and determine velocities. Policy on the selection of flow resistance values is given in the discussion of the various types of auxiliary spillways.

Structural stability
The spillway must be investigated, analyzed, designed and constructed adequately to establish and maintain stability during the passage of design flows without blockage or breaching. Excavated open cut spillways must have cut and fill slopes in earth and rock which are stable against sliding. Cut slope stability must be evaluated for the long-term weathered, natural moisture condition and for adverse moisture conditions associated with rapid drawdown from the auxiliary spillway design discharge.

Vegetated and earth auxiliary spillways

Vegetated and earth auxiliary spillways are open channels and usually consist of an inlet channel, a control section, and an exit channel. Subcritical flow exists in the inlet channel and the flow is usually supercritical in the exit channel.

Vegetated auxiliary spillways are usually trapezoidal in cross-section and are protected from damaging erosion by a grass cover. They are adapted to sites where a vigorous grass growth can be sustained by normal maintenance without irrigation.

Earth spillways are used in those areas where vegetative growth cannot be maintained. They are similar to vegetated spillways, but are designed for lower velocities, lower stresses, and less frequent use. Normally, they require more maintenance after a flow occurs.

Earth and vegetated auxiliary spillways are designed on the basis that some erosion or scour will occur during passage of infrequent storms, but the spillway will not breach during passage of the freeboard storm.

Hydraulic data in TR-39 Hydraulics of Broad Crested Spillways can be used in the design of vegetated or earth auxiliary spillways. A minimum vegetal retardance curve index of 5.6 as defined in Agriculture Handbook 667 (AH-667) Stability Design of Grass-Lined Open Channels shall be used to determine hydraulic capacity and vegetal stress in vegetated spillways. A minimum Manning's n of 0.02 shall be used for earth spillways. Actual hydraulic capacity of the spillway will be based on an appraisal of the roughness condition at the site.

Layout
Guidance on the layout of auxiliary spillways is provided in NEH-628.50, Earth Spillway Design. Spillways must be located away from the dam whenever possible. The layout and profile of vegetated or earth spillways should provide safety against breaching of the spillway during the passage of the freeboard hydrograph. Both extending the length and flattening the grade of the exit channel to delay or prevent headcut formation, and maximizing the bulk of material to contain any headcut advancement should be considered.

The inlet channel must be level for a minimum distance of 30 feet upstream from the exit channel. This level part of the inlet channel (control section) must be the same width as the exit channel, and its centerline must be straight and coincident with the centerline of the exit channel. A curved centerline is permissible in the inlet channel upstream from the level part, but it must be tangent to the centerline of the level part. Any curved inlet channel should be depressed below the level part to reduce velocities.

The exit channel must be straight and perpendicular to the level part of the inlet channel for a distance equal to at least one-half of the maximum base width of the dam. Curvature may be introduced below this point if it is certain that the flowing water will not impinge on the dam should the channel fail at the curve.

When the upstream edge of the exit channel is considered as a control section for hydraulic calculations, the exit channel grade shall be sufficient to ensure supercritical flow for all discharges equal to or greater than 25 percent of the maximum discharge through the spillway during the passage of the freeboard hydrograph. However, the slope in the exit channel need not exceed 4 percent (s = 0.04 ft/ft) to meet this requirement.

The exit channel can be terminated at some point above the maximum tailwater elevation, or can be extended to the principal spillway outlet or natural stream channel below the dam. The exit channel can contain several different grades. In either layout, erosion will occur wherever allowable stresses are exceeded and maintenance is required to protect the integrity of the spillway. Land rights must be considered in making the decision on how to handle the return flow to the natural or constructed stream channel downstream from the dam, and where eroded materials will be deposited.

Stability design of earth and vegetated earth spillways

Limitations during routing of the stability design (auxiliary spillway) hydrograph – the maximum stress limitations given below for vegetated or earth spillways apply to the exit channel. They must not be exceeded in the reach where an exit channel failure might cause the flow to impinge on the toe of the dam. The stress limitations are based on the maximum discharge in routing the stability design (auxiliary spillway) hydrograph and the assumption that uniform flow conditions exist in the exit channel.

When the anticipated average use of an earth or vegetated spillway is more frequent than once in 50 years, the allowable stress will be determined in accordance with AH-667. The allowable values may be increased 20 percent when the anticipated average use is once in 50 years, or 50 percent when the anticipated average use is once in 100 years. The allowable stress shall be determined for the actual vegetal cover conditions that can be reasonably expected to exist at the time of the flow. Values for grasses or mixtures not included in AH-667 shall be determined by comparing their characteristics with those that are described. Where special studies or investigations have been made to determine the allowable stress for a species, soil, and condition, those values may be used in lieu of those shown in the handbook.

Ramp spillways are not generally favored by the dam engineering profession, but may be used where alternate solutions are not practical. Ramp spillways shall not be steeper than 10 per cent. Ramp spillways must be constructed with the same compaction procedures and quality control as the earth embankment. The upper one foot of vegetated ramp spillways should be top soil.

Integrity design of earth and vegetated earth spillways

The spillway shall be evaluated for headcut development and advancement during passage of the freeboard storm using the procedures in NEH-628.51, Earth Spillway Erosion Model, and NEH-628.52, Field Procedures Guide for the Headcut Erodibility Index. The spillway design must be such that the spillway will not breach (i.e., headcut will not advance beyond the upstream edge of the level part of the inlet channel) during passage of the freeboard storm.

Special precautions for high hazard class dams— Special consideration must be given to the layout of spillways on high hazard class dams to assure the spillway will not breach under the most extreme conditions of flow. The length of the exit channel is to be increased to the maximum extent possible so that the area most susceptible to erosion is at a considerable distance from the dam. Within the limitations of the site, the profile of the spillway is to be such that a maximum bulk of material is provided.

It is preferable that the flow be confined without the use of levees, but when they are necessary they are to be high enough to contain the peak flow of the routed freeboard hydrograph. Levees must be constructed of erosion resistant materials and compacted to the degree necessary to develop this resistance. They must have a top width not less than 12 feet and, if not protected with riprap, have side slopes not steeper than 3 horizontal to 1 vertical on the side where water flows. When constructed on a foundation subject to piping or undermining, they must be keyed into the foundation with a compacted core having a bottom width not less than the top width of the levee and of sufficient depth to reach sound material, or to a depth equal to the height of the levee, whichever is less.

Crest control structures shall be provided to maintain a uniform surface where the soils are highly erodible from on-site runoff and very low flows through the spillway. The effective bulk length may be increased by installing barriers that will effectively stop a gully advancing through the spillway. Consideration should be given to the reduction of the duration and volume

of flow through the auxiliary spillway by raising the elevation of the crest of the spillway, thereby increasing the volume of storage in the retarding pool. An alternate or complementary procedure is to increase the capacity of the principal spillway by means of a two stage inlet of sufficient size to carry an appreciable amount of the outflow hydrograph.

Rock auxiliary spillway

Some of the principles used for the layout of earth auxiliary spillways are applicable to rock auxiliary spillways. Allowable average frequency of use and permissible velocities must be ascertained for the specific site based on knowledge of the hardness, condition, durability, attitude, weathering characteristics, and structure of the rock formation. An individual appraisal is necessary to determine the proper roughness coefficient, n. The design is to be such that the auxiliary spillway will not breach during passage of the freeboard storm.

Structural auxiliary spillways

Structural spillways shall be designed so that the passage of the freeboard hydrograph will not cause serious damage to the embankment or the structures themselves. The configuration of a structural spillway must be compatible with the foundation conditions at the site, the channel stability downstream from the spillway, the possible range of tailwater depth, and the proximity of the spillway to the embankment. The inlet portion of a chute spillway shall consist of a straight inlet, a box drop inlet, an ogee crest, or other appropriate hydraulic structure which will produce critical flow at the crest and result in a determinate stage-discharge relationship.

The hydraulic design of structural auxiliary spillways shall be in accordance with the principles set forth in NEH-5, Hydraulics; NEH-11, Drop Spillways; NEH-14, Chute Spillways; and U.S. Department of Interior, Bureau of Reclamation publications, or based on model studies, with consideration given to the effects of air entertainment by water traveling at supercritical velocities.

The design discharge for hydraulic proportioning of structural auxiliary spillway must not be less than two-thirds of the planned structure capacity during passage of the routed freeboard hydrograph, except that all headwalls and sidewalls shall be designed to prevent overtopping during passage of the full maximum freeboard discharge. When the magnitude of a structural auxiliary spillway exceeds that of structures commonly designed by NRCS, model studies or other special studies shall be made.

The outlet section of concrete chute spillways must consist of a hydraulic jump basin, such as a SAF, deflector bucket, roller bucket, or other appropriate hydraulic structure which will dissipate the energy of the high velocity discharge.

Structural auxiliary spillways must be designed to withstand lateral earth pressures, uplift, seepage and other hydrostatic and hydrodynamic pressures. They must be structurally designed for the full maximum freeboard discharge with uplift and sliding safety factors of not less than 1.0 and in accordance with the principles set forth in NEH-6, Structural Design; NEH-11, Drop Spillways and NEH-14, Chute Spillways, utilizing TR-50, TR-54; and other appropriate and available design working aids.

Glossary

Auxiliary spillway. The spillway designed to convey excess water through, over, or around a dam.

Auxiliary spillway system. A single auxiliary or combination of auxiliary spillways designed to work together.

Base flow. The sustained or fair-weather discharge which persists after storm runoff and associated quick return flow have been depleted. It is usually derived from groundwater discharge or gradual snow or ice melt over extended periods of time, but need not be continuous flow. (It can be based on annual or seasonal periods, depending upon when major floods usually occur.)

Breach hydrograph. The outflow hydrograph attributed to the sudden release of water in reservoir storage due to a dam breach.

Conservation storage. Water impounded for consumptive uses such as municipal, industrial and irrigation and nonconsumptive uses such as recreation and fish and wildlife.

Control section. In an open channel spillway, it is that section where accelerated flow passes through critical depth.

Dam. An artificial barrier together with any associated spillways and appurtenant works that do or may impound or divert water.

Design life. A period of time during which a dam is designed to perform its assigned functions satisfactorily.

Dry dam. A dam that has an ungated outlet positioned so that essentially all stored water will be drained from the reservoir by gravity. The reservoir will normally be dry.

Earth dam. A dam in which the principal barrier is an embankment of earth or rock fill or combination of earth and rock fill.

Earth spillway. An open channel spillway in earth materials without vegetation.

Economic life. The period of time during which economic benefits accrue to a dam.

Effective height of dam. The difference in elevation in feet between the lowest open channel auxiliary spillway crest and the lowest point in the original cross section on the centerline of the dam. If there is no open channel auxiliary spillway, the top of the dam becomes the upper limit.

Exit channel of an open channel spillway. The portion downstream from the control section which conveys the flow to a point where it may be released without jeopardizing the dam.

Freeboard hydrograph. Used to evaluate the total spillway flow capacity of the dam and, consequently, establish the minimum settled elevation of the top of the dam. It is also used to evaluate the integrity (breaching resistance) of a vegetated or earth auxiliary spillway.

Inlet channel of an open channel spillway. The portion upstream from the control section.

Joint extensibility. The amount of a pipe joint that can be extended from the fully engaged position without losing strength or watertightness. In case of rubber gasket joints, it is measured from the center of the gasket to the point of flare of the bell ring or collar when the joint is fully closed.

Joint gap. The longitudinal dimension between the end face of the spigot end of a pipe joint and the corresponding face of the bell end of the connecting pipe. It does not include the beveled portion designed for sealing compounds.

Joint use pool. The portion of a reservoir which serves two or more purposes; for instance, conservation storage and floodwater storage.

Primary auxiliary spillway. The spillway with the lowest crest elevation in an auxiliary spillway system.

Principal spillway. The lowest ungated spillway designed to convey water from the reservoir at predetermined release rates.

Principal spillway hydrograph. The hydrograph used to determine the minimum crest elevation of the auxiliary spillway. It is used to establish the principal spillway capacity and determine the associated minimum floodwater retarding storage.

Quick return flow. The diminishing discharge directly associated with a specific storm that occurs after surface runoff has reached its maximum. It includes base flow, prompt subsurface discharge (commonly called interflow), and delayed surface runoff.

Ramp spillway. A vegetated spillway constructed over an earth dam in a manner such that the spillway is a part of the embankment.

Retarding pool. The portion of the reservoir allotted to the temporary impoundment of floodwater. Its upper limit is the elevation of the crest of the auxiliary spillway.

Retarding storage. The volume in the retarding pool.

Rock spillway. An open channel spillway through competent, nonerodible, natural rock materials.

Sediment pool. The portion of the reservoir allotted to the accumulation of submerged sediment during the design life of the dam.

Sediment pool elevation. The elevation of the surface of the anticipated submerged sediment accumulation at the dam.

Sediment storage. The reservoir capacity allocated to total sediment (submerged and aerated) accumulation during the life of the dam.

Spillway. An open or closed channel, conduit or drop structure used to convey water from a reservoir. It may contain gates, either manually or automatically controlled, to regulate the discharge of water.

Stability design hydrograph. The hydrograph used to establish the dimensions of the auxiliary spillway.

Storage. The capacity of the reservoir below the elevation of the crest of the auxiliary spillway.

Vegetated spillway. A vegetated open-channel spillway in earth materials.

Visual focal. An element in the landscape upon which the eyes automatically focus because the element's size, form, color, or texture contrasts clearly with its surroundings.

REGULATORY GUIDE 1.102

FLOOD PROTECTION FOR NUCLEAR POWER PLANTS

A. INTRODUCTION

General Design Criterion 2, "Design Bases for Protection Against Natural Phenomena," of Appendix A, "General Design Criteria for Nuclear Power Plants," to 10 CFR Part 50, "Licensing of Production and Utilization Facilities," requires that structures, systems, and components important to safety be designed to withstand the effects of natural phenomena such as floods, tsunami, and seiches without loss of capability to perform their safety functions. Criterion 2 also requires that the design bases for these structures, systems, and components reflect:

1. Appropriate consideration of the most severe natural phenomena that have been historically reported for the site and surrounding region, with sufficient margin for the limited accuracy and quantity of the historical data and the period of time in which the data have been accumulated;

2. Appropriate combinations of the effects of normal and accident conditions with the effects of the natural phenomena; and

3. The importance of the safety functions to be performed.

Paragraph 100.10(c) of 10 CFR Part 100, "Reactor Site Criteria," requires that physical characteristics of the site, including seismology, meteorology, geology, and hydrology, be taken into account in determining the acceptability of a site for a nuclear power reactor.

Appendix A, "Seismic and Geologic Siting Criteria for Nuclear Power Plants," to 10 CFR Part 100 identifies the investigations necessary for a detailed study of seismically induced floods and water waves. The appendix requires that design bases for seismically induced floods and water waves take into consideration the results of geologic and seismic investigations and that these design bases be taken into account in the design of the nuclear power plant.

Regulatory Guide 1.59, "Design Basis Floods for Nuclear Power Plants," describes acceptable methods of determining the design basis flood conditions that nuclear power plants located on sites along streams must withstand without loss of safety-related functions. It also discusses the phenomena producing comparable design basis floods for coastal, estuary, and Great Lakes sites. The guide states that examples of the type of flood protection to be provided for nuclear power plants will be the subject of a separate regulatory guide.

This guide describes types of flood protection acceptable to the NRC staff for the safety-related structures, systems, and components identified in Regulatory Guide 1.29.* In addition, this guide describes acceptable

*Regulatory Guide 1.29, "Seismic Design Classification," identifies structures, systems, and components of light-water-cooled nuclear power plants that should be designed to withstand the effects of the Safe Shutdown Earthquake and remain functional. These structures, systems, and components are those necessary to ensure (1) the integrity of the reactor coolant pressure boundary, (2) the capability to shut down the reactor and maintain it in a safe shutdown condition, or (3) the capability to prevent or mitigate the consequences of accidents that could result in potential offsite exposures comparable to the guideline exposures of 10 CFR Part 100. These structures, systems, and components should also be designed to withstand conditions resulting from the design basis flood and remain functional.

It is expected that safety-related structures, systems, and components of other types of nuclear power plants will be identified in future regulatory guides. In the interim, Regulatory Guide 1.29 should be used as guidance when identifying safety-related structures, systems, and components of other types of nuclear power plants that need to be protected from floods by methods such as those suggested in this guide.

USNRC REGULATORY GUIDES

Regulatory Guides are issued to describe and make available to the public methods acceptable to the NRC staff of implementing specific parts of the Commission's regulations, to delineate techniques used by the staff in evaluating specific problems or postulated accidents, or to provide guidance to applicants. Regulatory Guides are not substitutes for regulations, and compliance with them is not required. Methods and solutions different from those set out in the guides will be acceptable if they provide a basis for the findings requisite to the issuance or continuance of a permit or license by the Commission.

Comments and suggestions for improvements in these guides are encouraged at all times, and guides will be revised, as appropriate, to accommodate comments and to reflect new information or experience. This guide was revised as a result of substantive comments received from the public and additional staff review.

Comments should be sent to the Secretary of the Commission, U.S. Nuclear Regulatory Commission, Washington, D.C. 20555, Attention: Docketing and Service Section.

The guides are issued in the following ten broad divisions:

1. Power Reactors
2. Research and Test Reactors
3. Fuels and Materials Facilities
4. Environmental and Siting
5. Materials and Plant Protection
6. Products
7. Transportation
8. Occupational Health
9. Antitrust Review
10. General

Copies of published guides may be obtained by written request indicating the divisions desired to the U.S. Nuclear Regulatory Commission, Washington, D.C. 20555, Attention: Director, Office of Standards Development.

methods of protecting nuclear power plants from the effects of Probable Maximum Precipitation (PMP) falling directly on the site.*

B. DISCUSSION

Nuclear power plant structures, systems, and components important to safety should be designed to withstand, without loss of capability to perform their safety functions, the most severe flood conditions that can reasonably be postulated to occur at a site as a result of severe hydrometeorological conditions, seismic activity, or both. The flood protection features necessary to protect the safety-related structures, systems, and components should be designed for the range of precipitation, wind, and seismically induced flood conditions identified in Regulatory Guide 1.59. The water-induced effects, both static and dynamic, on the flood protection features are considered to constitute normal environmental forces for use in the design of such features. The forces are developed from the hydrologic engineering analysis of the flood conditions.

For purposes of this guide, the Design Basis Flooding Level (DBFL) is defined as the maximum water elevation attained by the controlling flood, including coincident wind-generated wave effects. The wind-generated wave component of elevation is generally controlled by fetch and water depth and may differ at locations around the plant. Further distinction must be made between estimates of "structural" effects (i.e., static and dynamic forces) and flooding or inundation effects. Additionally, the controlling flood event may be different for evaluating structural effects than for evaluating inundation effects. For example, the Probable Maximum Flood (PMF) may produce the highest water level and static forces on a given structure, but the total static and dynamic forces on the structure may be greater during a smaller (in elevation) flood wave from the seismically induced failure of an upstream dam.

For structural purposes, the significant wave height is used; for inundation considerations, the one-percent wave height is used. *Significant wave height* (H_s) is the average of the highest one-third of wind-generated waves in a representative spectrum. *One-percent wave height* (H_1), sometimes erroneously called the *maximum wave height*, is the average of the highest 1 percent of wind-generated waves in a representative spectrum. Use of the relation $H_1 = 1.67H_s$ is acceptable for determining the one-percent wave height.

Methods of flood protection for nuclear power plants fall into one of the following three types (local flooding induced by severe local precipitation will be discussed later):

1. Dry Site

The plant is built above the DBFL, and therefore safety-related structures, systems, and components are not affected by flooding.

2. Exterior Barrier

Safety-related structures, systems, and components are protected from inundation and static and dynamic forces thereof by engineered features external to the immediate plant area. Such features may, when properly designed and maintained, produce the equivalent of a dry site, although care must be taken to ensure that safety-related structures, equipment, and components are not adversely affected by the differential hydraulic head.

3. Incorporated Barrier

Safety-related structures, systems, and components are protected from inundation and static and dynamic effects by engineered features in the structure/environment interface.

Regulatory Position 2 of Regulatory Guide 1.59 provides that those structures, systems, and components necessary for safe shutdown and maintenance thereof should be protected against the DBFL. The position also suggests that, if sufficient warning time is shown to be available to bring the plant to a safe shutdown condition, some of the other safety-related structures, systems, and components identified in Regulatory Guide 1.29 do not require protection against a flood as severe as the DBFL. Use of this method of protection as an acceptable alternative requires development of emergency procedures and technical specifications. Substantiation of the adequacy of the time available will require, in part:

1. Estimating the time required to bring the plant from full-power operation to a safe shutdown mode.

2. Establishing the warning indicators that will initiate shutdown procedures. Flood stage and rate of rise are common and generally acceptable indicators. However, sites along streams downstream from the confluence of major tributaries may require an assessment of flooding potential from floods that are less than the PMF, but could exhibit faster rates of rise than the PMF.

*Suggested criteria for the consideration of localized severe precipitation are contained in Section 2.4.2.3 of Regulatory Guide 1.70, "Standard Format and Content of Safety Analysis Reports for Nuclear Power Plants." The definition of Probable Maximum Precipitation is contained in Regulatory Guide 1.59.

**Lines indicate substantive changes from previous issue.

3. Documenting that sufficient time will remain after the warning for the safe shutdown to be accomplished before water can flood any safety-related structures, systems, or components.

The regulatory positions of this guide identify several key items to be considered in developing acceptable flood-related emergency procedures.

Local PMP may produce flooding at sites otherwise considered immune from flooding. The intensity of this rainfall and the usual design of the drainage system may result in ponding in the plant yard that could produce the DBFL. Also, roofs may receive more precipitation than the roof drains are designed to discharge.

Final plant grading is usually designed to cause ponded water to flow away from safety-related buildings. Even so, some temporary ponding is to be expected. Such ponding is generally accommodated by locating penetrations above the level of temporary ponding. Plant structures, systems, and components subject to ponding are also subject to the static and dynamic forces of the ponded water. These forces are usually less, however, than the forces from other design basis events.

C. REGULATORY POSITION

1. The following paragraphs provide working definitions of the various types of flood protection acceptable to the NRC staff.

a. Dry Site

The dry site may be the result of natural terrain or it may be constructed using engineered fill. The latter type refers to the "plant island" concept, rather than the minor fill used to dress plant grade. When fill is required to raise the plant access level above design basis flood conditions, the fill is safety related and must be protected from flood effects in the same manner as safety-related dams, dikes, etc.

b. Exterior Barriers

(1) *Levee.* "A dike or embankment to protect land from inundation."* Levees are generally earthen structures, trapezoidal in cross section, and protected from erosion by armor on the face exposed to waves and current.

(2) *Seawall or Floodwall.* "A structure separating land and water areas, primarily designed to prevent erosion and other damage due to wave action."* Seawalls are massive structures designed to take the full impact of the design wave. The seawall dissipates wave energy by throwing the water upward and downward. The upward deflection may result in wind-blown overtopping; the downward deflection can cause severe erosion at the toe of the seawall.

(3) *Bulkhead.* Similar to a seawall. The prime purpose is to restrain the land area. A bulkhead should not be used where it may be subject to direct wave attack.

(4) *Revetment.* "A facing of stone, concrete, etc., built to protect a scarp, embankment, or shore structure against erosion by wave action or currents."* Revetments are alternatives to seawalls and bulkheads. They protect the shore from direct wave attack by absorbing the wave energy in their interstices and on the surface of the revetment material. In this regard, riprap is more effective than smoother surfaces. Wave runup on the revetment is a function of incident wave height, revetment slope, and the nature of the revetment material. Rough surfaces reduce runup. When riprap is used, the placement of the material is critical to the effectiveness of the feature. Filling of the interstices with finer material destroys much of the energy-absorbing capabilities of the installation and may result in overtopping a structure that is otherwise adequate to prevent such overtopping.

(5) *Breakwater.* "A structure protecting a shore area, harbor, anchorage, or basin from waves."* Breakwaters may be connected to the shore or may be located entirely offshore. Wave energy is dissipated in the same manner as it is by revetments. Offshore breakwaters are used principally to reduce the wave effects that might otherwise reach safety-related structures, facilities, or components. Shore-connected breakwaters may serve the same purpose and also may be used to train discharge or intake water flow paths to limit recirculation.

c. Incorporated Barriers

Protection is provided by special design of walls and penetration closures. Walls are usually reinforced concrete designed to resist the static and dynamic forces of the DBFL and incorporate special waterstops at construction joints to prevent inleakage. Penetrations include personnel access, equipment access, and through-wall piping. Pipe penetrations are usually sealed with

*Definition from the U.S. Army Coastal Engineering Research Center, "Shore Protection Manual," Kingman Building, Fort Belvoir, Virginia 22060. Copies may be obtained from the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402.

special rubber boots and flanges. Personnel access closures that have been found acceptable include submarine doors and hatches. The hydraulic and seismic design bases for all types of closures, including waterstops, boots, and flanges, are the same as for the wall (i.e., water tightness and resistance to static and dynamic forces). In addition, the doors should open outward to ensure closure if the door is inadvertently opened during the flood event. Additionally, the plant should be designed and operated to keep doors necessary for flood protection closed during normal operation. Penetrations that are too large to close with a single door (e.g., equipment and fuel loading access) generally require stop logs or flood panels for closure. The design bases for these features are the same as above, as is the need to maintain them normally in a closed position.

Temporary flood barriers, such as sandbags, plastic sheeting, portable panels, etc., which must be installed prior to the advent of the DBFL, are not acceptable for issuance of a construction permit. However, unusual circumstances could arise after construction that would warrant consideration of such barriers. One example of unusual circumstances that might justify use of temporary barriers is a post-construction change in the flood-producing characteristics of the drainage area, as discussed in Regulatory Position 3 of Regulatory Guide 1.59, "Design Basis Floods for Nuclear Power Plants." In such circumstances, and with strong justification, the staff may accept temporary barriers.

2. Past experience suggests the need for guidance in establishing the shutdown technical specifications or emergency operating procedures necessary to utilize Regulatory Position 2 of Regulatory Guide 1.59. The following should be used in establishing the necessary procedures:

a. Stage (elevation)-time relations should be developed using the appropriate flood hydrograph (with coincident wind-generated wave effects) and site characteristics. River sites downstream from the confluence of major tributaries may require assessment of the flood potential from less severe flood events that may exhibit faster rates of rise than the PMF.

b. The flood stage, including design basis wind-generated wave effects and the time of occurrence within the flood event, at which any safety-related structure, system, or component (as defined in Regulatory Guide 1.29) may become degraded or inoperative should establish the completion time for all shutdown procedures.

c. Estimates of the time required for safe shutdown should be based on average rather than best-time operator performance. This time interval should be less than the time for occurrence of the event in Regulatory Position 2.b to establish the limiting values of the selected warning indicators. The procedures should consider the total DBFL; however, the indicators (usually flood stage and rate of rise) should be based on the stillwater level (i.e., DBFL less wind-generated wave effects). This precludes the masking of flood potential by less than design basis wind at the time of observation.

d. A communication system should be established to alert both onsite and offsite company personnel of flood conditions that may require subsequent shutdown of the plant. Such a system may use offsite facilities and services, such as upstream river gages and flood forecasting services, as well as direct communication between onsite and offsite company personnel.

e. The procedures in 2.c should specify that onsite plant personnel will initiate a safe shutdown on their own volition when the limiting values of the indicators are attained. Only those warning systems located at the site and under control of plant personnel should be needed to determine the limiting values of the indicators.

3. Analysis supporting the invulnerability of safety-related structures, systems, and components from the effects of local PMP should be performed using the point rainfall value of the PMP for the site area.

a. Regulatory Guide 1.59 provides guidance on obtaining PMP estimates. An analysis of the estimated depth of ponding in the plant area should also be made.

b. Roofs are usually provided with drains designed to discharge precipitation intensities considerably less than that of the PMP. The following methods of preventing undesirable buildup of standing water on the roofs of safety-related buildings have been found acceptable to the NRC staff:

(1) The parapets (a common architectural feature of nuclear power plant structures) may be deleted on one or more sides of the building. This is the most common method.

(2) The parapet height may be limited to preclude buildup of water in excess of the structural capacity of the roof for design loads.

(3) Scuppers may be installed through the parapets to discharge the standing water over the edge of the building.

(Note that limiting the parapet height or lip of the scupper to, for example, 6 inches above the roof will not necessarily limit the depth of water on the roof to 6 inches. Consideration should be given to the hydraulic head necessary to initiate flow.)

c. The load induced by the maximum depth of standing water on the roofs (including antecedent or coincident snow or ice) during the design basis event should be less than the structural capacity of the roof for design loads, and the discharge capacity of roof drains should be compared with the design basis discharge.

D. IMPLEMENTATION

The purpose of this section is to provide information to license applicants and licensees regarding the NRC staff's plans for using this regulatory guide.

This guide reflects current NRC staff practice. Therefore, except in those cases in which the license applicant or licensee proposes an acceptable alternative method for complying with specified portions of the Commission's regulations, the method described herein is being and will continue to be used in the evaluation of submittals for operating license or construction permit applications until this guide is revised as a result of suggestions from the public or additional staff review.

Regulatory Guide 1.59, Revision 2, August 1977

"Design Basis Floods for Nuclear Power Plants"

New information that affects the Probable Maximum Flood (PMF) isolines for the Upper Ohio River for drainage areas of 10,000 and 20,000 square miles has been identified. The changes to the isolines affect only a small area in the Upper Ohio River Basin and do not have any significant impact on the Design Basis Flood for existing plants.

As a result of the new information, revised Figures B.6 and B.7 transmitted herewith should be used in future PMF discharge determinations when the simplified methods presented in Appendix B to the Regulatory Guide are being used. In addition, appropriate changes have been made to the PMF data on pages 28 and 30 of Table B.1, which are also transmitted herewith.

A. INTRODUCTION

General Design Criterion 2, "Design Bases for Protection Against Natural Phenomena," of Appendix A, "General Design Criteria for Nuclear Power Plants," to 10 CFR Part 50, "Licensing of Production and Utilization Facilities," requires, in part, that structures, systems, and components important to safety be designed to withstand the effects of natural phenomena such as floods, tsunami, and seiches without loss of capability to perform their safety functions. Criterion 2 also requires that design bases for these structures, systems, and components reflect (1) appropriate consideration of the most severe of the natural phenomena that have been historically reported for the site and surrounding region, with sufficient margin for the limited accuracy and quantity of the historical data and the period of time in which the data have been accumulated, (2) appropriate combinations of the effects of normal and accident conditions with the effects of the natural phenomena, and (3) the importance of the safety functions to be performed.

Paragraph 100.10(c) of 10 CFR Part 100, "Reactor Site Criteria," requires that physical characteristics of the site, including seismology, meteorology, geology, and hydrology, be taken into account in determining the acceptability of a site for a nuclear power reactor.

Section IV(c) of Appendix A, "Seismic and Geologic Siting Criteria for Nuclear Power Plants," to 10 CFR Part 100 suggests investigations for a detailed study of seismically induced floods and water waves. The appendix also suggests [Section IV(c)(iii)] that the determination of design bases for seismically induced floods and water waves be based on the results of the required geologic and seismic investigations and that these design bases be taken into account in the design of the nuclear power plant.

This guide discusses the design basis floods that nuclear power plants should be designed to withstand without loss of capability for cold shutdown and maintenance thereof. The design requirements for flood protection are the subject of Regulatory Guide 1.102, "Flood Protection for Nuclear Power Plants."

The material previously contained in Appendix A, "Probable Maximum and Seismically Induced Floods on Streams," has been replaced by American National Standards Institute (ANSI) Standard N170-1976, "Standards for Determining Design Basis Flooding at Power Reactor Sites,"[1] which has been endorsed as acceptable by the NRC staff with the exception noted in Appendix A. In addition to information on stream flooding, ANSI N170-1976 contains methodology for estimating probable maximum surges and seiches at estuaries and coastal areas on oceans and large lakes. Appendix B gives timesaving alternative methods of estimating the probable maximum flood along streams, and Appendix C gives a simplified method of estimating probable maximum surges on the Atlantic and Gulf coasts. The Advisory Committee on Reactor Safeguards has been consulted concerning this guide and has concurred in the regulatory position.

[1]Copies of ANSI Standard N170-1976 may be purchased from the American Nuclear Society, 555 North Kensington Avenue, La Grange Park, IL 60525.

B. DISCUSSION

Nuclear power plants should be designed to prevent the loss of capability for cold shutdown and maintenance thereof resulting from the most severe flood conditions that can reasonably be predicted to occur at a site as a result of severe hydrometeorological conditions, seismic activity, or both.

The Corps of Engineers for many years has studied conditions and circumstances relating to floods and flood control. As a result of these studies, it has developed a definition for a Probable Maximum Flood (PMF)[2] and attendant analytical techniques for estimating, with an acceptable degree of conservatism, flood levels on streams resulting from hydrometeorological conditions. For estimating seismically induced flood levels, an acceptable degree of conservatism for evaluating the effects of the initiating event is provided by Appendix A to 10 CFR Part 100.

The conditions resulting from the worst site-related flood probable at the nuclear power plant (e.g., PMF, seismically induced flood, seiche, surge, severe local precipitation) with attendant wind-generated wave activity constitute the design basis flood conditions that safety-related structures, systems, and components identified in Regulatory Guide 1.29[3] should be

[2]Corps of Engineers' Probable Maximum Flood definition appears in many publications of that agency such as Engineering Circular EC 1110-2-27, Change 1, "Engineering and Design—Policies and Procedures Pertaining to Determination of Spillway Capacities and Freeboard Allowances for Dams," dated 19 Feb. 1968. The Probable Maximum Flood is also directly analogous to the Corps of Engineers' "Spillway Design Flood" as used for dams whose failures would result in a significant loss of life and property.

[3]Regulatory Guide 1.29, "Seismic Design Classification," identifies structures, systems, and components of light-water-cooled nuclear power plants that should be designed to withstand the effects of the Safe Shutdown Earthquake and remain functional. These structures, systems, and components are those necessary to ensure (1) the integrity of the reactor coolant pressure boundary, (2) the capability to shut down the reactor and maintain it in a safe shutdown condition, or (3) the capability to prevent or mitigate the consequences of accidents that could result in potential offsite exposures comparable to the guideline exposures of 10 CFR Part 100. These same structures, systems, and components should also be designed to withstand conditions resulting from the design basis flood and retain capability for cold shutdown and maintenance thereof of other types of nuclear power plants. It is expected that safety-related structures, systems, and components of other types of nuclear power plants will be identified in future regulatory guides. In the interim, Regulatory Guide 1.29 should be used as guidance when identifying safety-related structures, systems, and components of other types of nuclear power plants.

designed to withstand and retain capability for cold shutdown and maintenance therof.

For sites along streams, the PMF generally provides the design basis flood. For sites along lakes or seashores, a flood condition of comparable severity could be produced by the most severe combination of hydrometeorological parameters reasonably possible, such as may be produced by a Probable Maximum Hurricane[4] or by a Probable Maximum Seiche. On estuaries, a Probable Maximum River Flood, a Probable Maximum Surge, a Probable Maximum Seiche, or a reasonable combination of less severe phenomenologically caused flooding events should be considered in arriving at design basis flood conditions comparable in frequency of occurrence with a PMF on streams.

In addition to floods produced by severe hydrometeorological conditions, the most severe seismically induced floods reasonably possible should be considered for each site. Along streams and estuaries, seismically induced floods may be produced by dam failures or landslides. Along lakeshores, coastlines, and estuaries, seismically induced or tsunami-type flooding should be considered. Consideration of seismically induced floods should include the same range of seismic events as is postulated for the design of the nuclear plant. For instance, the analysis of floods caused by dam failures, landslides, or tsunami requires consideration of seismic events of the severity of the Safe Shutdown Earthquake occurring at the location that would produce the worst such flood at the nuclear power plant site. In the case of seismically induced floods along rivers, lakes, and estuaries that may be produced by events less severe than a Safe Shutdown Earthquake, consideration should be given to the coincident occurrence of floods due to severe hydrometeorological conditions, but only where the effects on the plant are worse than and the probability of such combined events may be greater than an individual occurrence of the most severe event of either type. Appendix A contains acceptable combinations of such events. For the specific case of seismically induced floods due to dam failures, an evaluation should be made of flood waves that may be caused by domino-type dam failures triggered by a seismically induced failure of a critically located dam and of flood waves that may be caused by multiple dam failures in a region where dams may be located close enough together that a single seismic event can cause multiple failures.

Each of the severe flood types discussed above should represent the upper limit of all potential phenomenologically caused flood combinations considered reasonably possible. Analytical techniques are available and should generally be used for prediction at individual sites. Those techniques applicable to PMF and seismically induced flood estimates on streams are presented in Appendices A and B of this guide. For sites on coasts, estuaries, and large lakes, techniques are presented in Appendices A and C of this guide.

Analyses of only the most severe flood conditions may not indicate potential threats to safety-related systems that might result from combinations of flood conditions thought to be less severe. Therefore, reasonable combinations of less-severe flood conditions should also be considered to the extent needed for a consistent level of conservatism. Such combinations should be evaluated in cases where the probability of their existing at the same time and having significant consequences is at least comparable to that associated with the most severe hydrometeorological or seismically induced flood. For example, a failure of relatively high levees adjacent to a plant could occur during floods less severe than the worst site-related flood, but would produce conditions more severe than would result during a greater flood (where a levee failure elsewhere would produce less severe conditions at the plant site).

Wind-generated wave activity may produce severe flood-induced static and dynamic conditions either independent of or coincident with severe hydrometeorological or seismic flood-producing mechanisms. For example, along a lake, reservoir, river, or seashore, reasonably severe wave action should be considered coincident with the probable maximum water level conditions.[5] The coincidence of wave activity with probable maximum water level conditions should take into account the fact that sufficient time can elapse between the occurrence of the assumed meteorological mechanism and the maximum water level to allow subsequent meteorological activity to produce substantial wind-generated waves coincident with the high water level. In addition, the most severe wave activity at the site that can be generated by distant hydrometeorological activity should be considered. For instance, coastal locations may be subjected to severe wave action caused by a distant storm that, although not as severe as a local storm (e.g., a Probable Maximum Hurricane), may produce more severe wave action because of a very long wave-generating fetch. The most severe wave activity at the site that may be generated by conditions at a distance from the site should be considered in such cases. In addition, assurance should be provided

[4]See References 2 and 5, Appendix C.

[5]Probable Maximum Water Level is defined by the Corps of Engineers as "the maximum still water level (i.e., exclusive of local coincident wave runup) which can be produced by the most severe combination of hydrometeorological and/or seismic parameters reasonably possible for a particular location. Such phenomena are hurricanes, moving squall lines, other cyclonic meteorological events, tsunami, etc., which, when combined with the physical response of a body of water and severe ambient hydrological conditions, would produce a still water level that has virtually no risk of being exceeded."

that safety systems necessary for cold shutdown and maintenance thereof are designed to withstand the static and dynamic effects resulting from frequent flood levels (i.e., the maximum operating level in reservoirs and the 10-year flood level in streams) coincident with the waves that would be produced by the Probable Maximum Gradient Wind[6] for the site (based on a study of historical regional meteorology).

C. REGULATORY POSITION

1. The conditions resulting from the worst site-related flood probable at a nuclear power plant (e.g., PMF, seismically induced flood, hurricane, seiche, surge, heavy local precipitation) with attendant wind-generated wave activity constitute the design basis flood conditions that safety-related structures, systems, and components identified in Regulatory Guide 1.29 (see footnote 3) must be designed to withstand and retain capability for cold shutdown and maintenance thereof.

a. The PMF on streams, as defined in Appendix A and based on the analytical techniques summarized in Appendices A and B of this guide, provides an acceptable level of conservatism for estimating flood levels caused by severe hydrometeorological conditions.

b. Along lakeshores, coastlines, and estuaries, estimates of flood levels resulting from severe surges, seiches, and wave action caused by hydrometeorological activity should be based on criteria comparable in conservatism to those used for Probable Maximum Floods. Criteria and analytical techniques providing this level of conservatism for the analysis of these events are summarized in Appendix A of this guide. Appendix C of this guide presents an acceptable method for estimating the still-water level of the Probable Maximum Surge from hurricanes at open-coast sites on the Atlantic Ocean and Gulf of Mexico.

c. Flood conditions that could be caused by dam failures from earthquakes should also be considered in establishing the design basis flood. Analytical techniques for evaluating the hydrologic effects of seismically induced dam failures discussed herein are presented in Appendix A of this guide. Techniques for evaluating the effects of tsunami will be presented in a future appendix.

d. Where upstream dams or other features that provide flood protection are present, in addition to the analyses of the most severe floods that may be induced by either hydrometeorological or seismic mechanisms, reasonable combinations of less-severe flood conditions and seismic events should also be considered to the extent needed for a consistent level of conservatism. The effect of such combinations on the flood conditions at the plant site should be evaluated in cases where the probability of such combinations occurring at the same time and having significant consequences is at least comparable to the probability associated with the most severe hydrometeorological or seismically induced flood. For relatively large streams, examples of acceptable combinations of runoff floods and seismic events that could affect the flood conditions at the plant are contained in Appendix A. Less-severe flood conditions, associated with the above seismic events, may be acceptable for small streams that exhibit relatively short periods of flooding.

e. The effects of coincident wind-generated wave activity to the water levels associated with the worst site-related flood possible (as determined from paragraphs a, b, c, or d above) should be added to generally define the upper limit of flood potential. Acceptable procedures are contained in Appendix A of this guide.

2. As an alternative to designing *hardened protection*[7] for all safety-related structures, systems, and components as specified in Regulatory Position 1 above, it is permissible not to provide hardened protection for some of these features if:

a. Sufficient[8] warning time is shown to be available to shut the plant down and implement adequate emergency procedures;

b. All safety-related structures, systems, and components identified in Regulatory Guide 1.29 (see footnote 3) are designed to withstand the flood conditions resulting from a Standard Project event[8] with attendant wind-generated wave activity that may be produced by the worst winds of record and remain functional;

c. In addition to the analyses in paragraph 2.b above, reasonable combinations of less-severe flood conditions are also considered to the extent needed for a consistent level of conservatism; and

[6]Probable Maximum Gradient Wind is defined as a gradient wind of a designated duration, which there is virtually no risk of exceeding.

[7]*Hardened protection* means structural provisions incorporated in the plant design that will protect safety-related structures, systems, and components from the static and dynamic effects of floods. In addition, each component of the protection must be passive and in place, as it is to be used for flood protection, during normal plant operation. Examples of the types of flood protection to be provided for nuclear power plants are contained in Regulatory Guide 1.102.

[8]For sites along streams, this event is characterized by the Corps of Engineers' definition of a Standard Project Flood. Such floods have been found to produce flow rates generally 40 to 60 percent of the PMF. For sites along seashores, this event may be characterized by the Corps of Engineers' definition of a Standard Project Hurricane. For other sites, a comparable level of risk should be assumed.

d. In addition to paragraph 2.b above, at least those structures, systems, and components necessary for cold shutdown and maintenance thereof are designed with *hardened* protective features to remain functional while withstanding the entire range of flood conditions up to and including the worst site-related flood probable (e.g., PMF, seismically induced flood, hurricane, surge, seiche, heavy local precipitation) with coincident wind-generated wave action as discussed in Regulatory Position 1 above.

3. During the economic life of a nuclear power plant, unanticipated changes to the site environs which may adversely affect the flood-producing characteristics of the environs are possible. Examples include construction of a dam upstream or downstream of the plant or, comparably, construction of a highway or railroad bridge and embankment that obstructs the flood flow of a river and construction of a harbor or deepening of an existing harbor near a coastal or lake site plant.

Significantly adverse changes in the runoff or other flood-producing characteristics of the site environs, as they affect the design basis flood, should be identified and used as the basis to develop or modify emergency operating procedures, if necessary, to mitigate the effects of the increased flood.

4. Proper utilization of the data and procedures in Appendices B and C will result in PMF peak discharges and PMS peak stillwater levels which will in many cases be approved by the NRC staff with no further verification. The staff will continue to accept for review detailed PMF and PMS analyses that result in less conservative estimates than those obtained by use of Appendices B and C. In addition, previously reviewed and approved detailed PMF and PMS analyses will continue to be acceptable even though the data and procedures in Appendices B and C result in more conservative estimates.

D. IMPLEMENTATION

The purpose of this section is to provide information to license applicants and licensees regarding the NRC staff's plans for using this regulatory guide.

This guide reflects current NRC practice. Therefore, except in those cases in which the applicant or licensee proposes an acceptable alternative method for complying with specified portions of the Commission's regulations, the methods described herein are being and will continue to be used in the evaluation of submittals for construction permit applications until this guide is revised as a result of suggestions from the public or additional staff review.

APPENDIX A

PROBABLE MAXIMUM AND SEISMICALLY INDUCED FLOODS ON STREAMS AND COASTAL AREAS

The material previously contained in Appendix A has been replaced by American National Standards Institute (ANSI) Standard N170-1976, "Standards for Determining Design Basis Flooding at Power Reactor Sites," with the following exception:

Sections 5.5.4.2.3 and 5.5.5 of ANSI N170-1976 contain references to methods for evaluating the erosion failure of earthfill or rockfill dams and determining the resulting outflow hydrographs. The staff has found that some of these methods may not be conservative because they predict slower rates of erosion than have historically occurred. Modifications to the models may be made to increase their conservatism. Such modifications will be reviewed by the NRC staff on a case-by-case basis.

B.1 INTRODUCTION

This appendix presents timesaving alternative methods of estimating the probable maximum flood (PMF) peak discharge for nuclear facilities on nontidal streams in the contiguous United States. Use of the methods herein will reduce both the time necessary for applicants to prepare license applications and the NRC staff's review effort.

The procedures are based on PMF values determined by the U.S. Army Corps of Engineers, by applicants for licenses that have been reviewed and accepted by the NRC staff, and by the staff and its consultants. The information in this appendix was developed from a study made by Nunn, Snyder, and Associates, through a contract with NRC (Ref. 1).

PMF peak discharge determinations for the entire contiguous United States are presented in Table B.1. Under some conditions, these may be used directly to evaluate the PMF at specific sites. In addition, maps showing enveloping isolines of PMF discharge for several index drainage areas are presented in Figures B.2 through B.7 for the contiguous United States east of the 103rd meridian, including instructions for and an example of their use (see Figure B.8). Because of the enveloping procedures used in preparing the maps, results from their use are highly conservative.

Limitations on the use of these generalized methods of estimating PMFs are identified in Section B.4. These limitations should be considered in detail in assessing the applicability of the methods at specific sites.

Applicants for licenses for nuclear facilities at sites on nontidal streams in the contiguous United States have the option of using these methods in lieu of the more precise but laborious methods of Appendix A. The results of application of the methods in this appendix will in many cases be accepted by the NRC staff with no further verification.

B.2 SCOPE

The data and procedures in this appendix apply only to nontidal streams in the contiguous United States. Two procedures are included for nontidal streams east of the 103rd meridian.

Future studies are planned to determine the applicability of similar generalized methods and to develop such methods, if feasible, for other areas. These studies, to be included in similar appendices, are anticipated for the main stems of large rivers and the United States west of the 103rd meridian, including Hawaii and Alaska.

B.3 PROBABLE MAXIMUM FLOOD PEAK DISCHARGE

The data presented in this section are as follows:

1. A tabulation of PMF peak discharge determinations at specific locations throughout the contiguous United States. These data are subdivided into water resources regions, delineated on Figure B.1, and are tabulated in Table B.1.

2. A set of six maps, Figures B.2 through B.7, covering index drainage areas of 100, 500, 1,000, 5,000, 10,000, and 20,000 square miles, containing isolines of equal PMF peak discharge for drainage areas of those sizes east of the 103rd meridian.

B.3.1 Use of PMF Discharge Determinations

The PMF peak discharge determinations listed in Table B.1 are those computed by the Corps of Engineers, by the NRC staff and their consultants, or computed by applicants and accepted by the staff.

For a nuclear facility located near or adjacent to one of the streams listed in the table and reasonably close to the location of the PMF determination, that PMF may be transposed, with proper adjustment, or routed to the nuclear facility site. Methods of transposition, adjustment, and routing are given in standard hydrology texts and are not repeated here.

B.3.2 Enveloping Isolines of PMF Peak Discharge

B.3.2.1 Preparation of Maps

For each of the water resources regions, each PMF determination in Table B.1 was plotted on logarithmic paper (cubic feet per second per square mile versus drainage area). It was found that there were insufficient data and too much scatter west of about the 103rd meridian, caused by variations in precipitation from orographic effects or by melting snowpack. Accordingly, the rest of the study was confined to the United States east of the 103rd meridian. For sites west of the 103rd meridian, the methods of the preceding section may be used.

Envelope curves were drawn for each region east of the 103rd meridian. It was found that the envelope curves generally paralleled the Creager curve (Ref. 2), defined as

$$Q = 46.0\ CA^{(0.894A^{-0.048})-1}$$

where

Q is the discharge in cubic feet per second (cfs)
C is a constant, taken as 100 for this study
A is the drainage area in square miles.

Each PMF discharge determination of 50 square miles or more was adjusted to one or more of the six selected index drainage areas in accordance with the slope of the Creager curve. Such adjustments were made as follows:

PMF Within Drainage Area Range, sq. mi.	Adjusted to Index Drainage Area, sq. mi.
50 to 500	100
100 to 1,000	500
500 to 5,000	1,000
1,000 to 10,000	5,000
5,000 to 50,000	10,000
10,000 or greater	20,000

The PMF values so adjusted were plotted on maps of the United States east of the 103rd meridian, one map for each of the six index drainage areas. It was found that there were areas on each map with insufficient points to define isolines. To fill in such gaps, conservative computations of approximate PMF peak discharge were made for each two-degree latitude-longitude intersection on each map. This was done by using enveloped relations between drainage area and PMF peak discharge (in cfs per inch of runoff), and applying appropriate probable maximum precipitation (PMP) at each two-degree latitude-longitude intersection. PMP values, obtained from References 3 and 4, were assumed to be for a 48-hour storm to which losses of 0.05 inch per hour were applied. These approximate PMF values were also plotted on the maps for each index drainage area and the enveloping isolines were drawn as shown on Figures B.2 through B.7.

B.3.2.2 Use of Maps

The maps may be used to determine PMF peak discharge at a given site with a known drainage area as follows:

1. Locate the site on the 100-square-mile map, Figure B.2.

2. Read and record the 100-square-mile PMF peak discharge by straight-line interpolation between the isolines.

3. Repeat Steps 1 and 2 for 500, 1,000, 5,000, 10,000, and 20,000 square miles from Figures B.3 through B.7.

4. Plot the six PMF peak discharges so obtained on logarithmic paper against drainage area, as shown on Figure B.8.

5. Draw a smooth curve through the points. Reasonable extrapolations above and below the defined curve may be made.

6. Read the PMF peak discharge at the site from the curve at the appropriate drainage area.

B.3.3 Probable Maximum Water Level

When the PMF peak discharge has been obtained as outlined in the foregoing sections, the PMF stillwater level should be determined. The methods given in Appendix A are acceptable for this purpose.

B.3.4 Wind-Wave Effects

Wind-wave effects should be superimposed on the PMF stillwater level. Criteria and acceptable methods are given in Appendix A.

B.4 LIMITATIONS

1. The NRC staff will continue to accept for review detailed PMF analyses that result in less conservative estimates. In addition, previously reviewed and approved detailed PMF analyses at specific sites will continue to be acceptable even though the data and procedures in this appendix result in more conservative estimates.

2 .The PMF estimates obtained as outlined in Sections B.3.1 and B.3.2 are peak discharges that should be converted to water level to which appropriate wind-wave effects should be added.

3. If there are one or more reservoirs in the drainage area upstream of the site, seismic and hydrologic dam failure[1] flood analyses should be made to determine whether such a flood will produce the design basis water level. Criteria and acceptable methods are included in Appendix A.

4. Because of the enveloping procedures used, PMF peak discharges estimated as outlined in Section B.3.2 have a high degree of conservatism. If the PMF so estimated casts doubt on the suitability of a site, or if protection from a flood of that magnitude would not be physically or economically feasible, consideration should be given to performing a detailed PMF analysis, as outlined in Appendix A. It is likely that such an analysis will result in appreciably lower PMF levels.

[1] In this context, "hydrologic dam failure" means a failure caused by a flood from the drainage area upstream of the dam.

C.1 INTRODUCTION

This appendix presents timesaving methods of estimating the maximum stillwater level of the probable maximum surge (PMS) from hurricanes at open-coast sites on the Atlantic Ocean and Gulf of Mexico. Use of the methods herein will reduce both the time necessary for applicants to prepare license applications and the NRC staff's review effort.

The procedures are based on PMS values determined by the NRC staff and its consultants and by applicants for licenses that have been reviewed and accepted by the staff. The information in this appendix was developed from a study made by Nunn, Snyder, and Associates, through a contract with NRC (Ref. 1).

The PMS data are shown in Tables C.1 through C.21 and on maps of the Atlantic and Gulf Coasts (Figures C.1 and C.2). Suggestions for interpolating between these values are included.

Limitations on the use of these generalized methods of estimating PMS are identified in Section C.4. These limitations should be considered in detail in assessing the applicability of the methods at specific sites.

Applicants for licenses for nuclear facilities at sites on the open coast of the Atlantic Ocean or the Gulf of Mexico have the option of using these methods in lieu of more precise but laborious methods contained in Appendix A. The results of application of the methods in this appendix will in many cases be accepted by the NRC staff with no further verification.

C.2 SCOPE

The data and procedures in this appendix apply only to open-coast areas of the Gulf of Mexico and the Atlantic Ocean.

Future studies are planned to determine the applicability of similar generalized methods and to develop such methods, if feasible, for other areas. These studies, to be included in similar appendices, are anticipated for the Great Lakes and the Pacific Coast, including Hawaii and Alaska.

C.3 PROBABLE MAXIMUM SURGE LEVELS FROM HURRICANES

The data presented in this appendix consist of all determinations of hurricane-induced PMS peak levels at open-coast locations computed by the NRC staff or their consultants, or by applicants and accepted by the staff. The data are shown in Tables C.1 through C.21 and on Figures C.1 and C.2. All represent stillwater levels for open-coast conditions.

C.3.1 Methods Used

All PMS determinations in Table C.1 were made by NRC consultants for this study (Ref. 1) or for earlier studies except Pass Christian, Brunswick, Chesapeake Bay Entrance, Forked River—Oyster Creek, Millstone, Pilgrim, and Hampton Beach.

The computations by the consultants were made using the NRC surge computer program, which is adapted from References 2, 3, and 4. Probable maximum hurricane data were taken from Reference 5. Ocean bottom topography for the computations was obtained from the most detailed available Nautical Charts published by the National Ocean Survey, NOAA. The traverse line used for the probable maximum hurricane surge estimate was drawn from the selected coastal point to the edge of the continental shelf or to an ocean depth of 600 feet MLW and was one hurricane radius to the right of the storm track. The radius to maximum winds was oriented at an angle of 115° from the storm track. The traverse was oriented perpendicular to the ocean-bed contours near shore. The ocean-bed profile along the traverse line was determined by roughly averaging the topography of cross sections perpendicular to the traverse line and extending a maximum of 5 nautical miles to either side. The 10-mile-wide cross sections were narrowed uniformly to zero at the selected site starting 10 nautical miles from shore. It was assumed that the peak of the PMS coincided with the 10% exceedance high spring tide[1] plus initial rise.[2] Slightly different procedures were used for postulating the traverse lines and profiles for the Crystal River and St. Lucie determinations.

In each case the maximum water level resulted from use of the high translation speed for the hurricane in combination with the large radius to maximum wind as defined in Reference 5. Detailed data for the computed PMS values are shown in Tables C.1 through C.20. Ocean-bed profile data for Pass Christian, Crystal River, St. Lucie, Chesapeake Bay Mouth, and Hampton Beach are shown in Table C.21.

The water levels resulting from these computations are open-coast stillwater levels upon which waves and wave runup should be superimposed.

C.3.2 Use of Data in Estimating PMS

Estimates of the PMS stillwater level at open-coast sites other than those shown in Tables C.1 through C.21 and on Figures C.1 and C.2 may be obtained as follows:

[1]The 10% exceedance high spring tide is the predicted maximum monthly astronomical tide exceeded by 10% of the predicted maximum monthly astronomical tides over a 21-year period.

[2]Initial rise (also called forerunner or sea level anomaly) is an anomalous departure of the tide level from the predicted astronomical tide.

1. Using topographic maps or maps showing soundings, such as the Nautical Charts, determine an ocean bed profile to a depth of 600 ft MLW, using the methods outlined above. Compare this profile with the profiles of the locations shown in Tables C.2 through C.21. With particular emphasis on shallow water depths, select the location or locations in the general area with the most similar profiles. An estimate of the wind setup may be interpolated from the wind setup data for these locations.

2. Pressure setup may be interpolated between locations on either side of the site.

3. Initial rise, as shown in Table C.1, may be interpolated between locations on either side of the site.

4. The 10% exceedance high spring tide may be computed from predicted tide levels in Reference 6; it may be obtained from the Coastal Engineering Research Center, U.S. Army Corps of Engineers, Ft. Belvoir, Va.; it may be interpolated, using the tide relations in Reference 6; or it may be obtained from Appendix A.

5. An estimate of the PMS open-coast stillwater level at the desired site will be the sum of the values from Steps 1 through 4, above.

C.3.3 Wind-Wave Effects

Coincident wave heights and wave runup should be computed and superimposed on the PMS stillwater level obtained by the foregoing procedures. Acceptable methods are given in Reference 2 and in Appendix A.

C.4 LIMITATIONS

1. The NRC staff will continue to accept for review detailed PMS analyses that result in less conservative estimates. In addition, previously reviewed and approved detailed PMS analyses at specific sites will continue to be acceptable even though the data and procedures in this appendix result in more conservative estimates.

2. The PMS estimates obtained as outlined in Section C.3.2 are maximum stillwater levels. Coincident wind-wave effects should be added.

3. The PMS estimates obtained from the methods in Section C.3.2 are valid only for open-coast sites, i.e., at the point at which the surge makes initial landfall. If the site of interest has appreciably different off-shore bathymetry, or if the coastal geometry differs or is complex, such as for sites on an estuary, adjacent to an inlet, inshore of barrier islands, etc., detailed studies of the effect of such local conditions should be made. Reference 2 provides guidance on such studies.

4.20 Dam Safety

4.20.1 Introduction

The factors associated with dam safety relative to the proposed changes in system operations include:

Resource Issues

- Reservoir-triggered seismicity
- Dam stability
- Leakage from dams

- Effects on reservoir-triggered seismicity (RTS) due to changes in filling or drawdown rates, or higher than normal reservoir levels;
- Effects on dam stability of changes in seismicity, higher reservoir levels, filling or drawdown rates; and,
- Leakage from dams in response to higher reservoir levels in areas of carbonate rocks with karst development.

Potential impacts on these key elements of dam safety are all indirect effects of the policy alternatives.

4.20.2 Regulatory Programs and TVA Management Activities

The Federal Guidelines for Dam Safety require that dams with a direct federal interest, which includes all dams in the TVA's system, must be designed, inspected, and maintained throughout their operating life to verify and protect the structural integrity of the dam and appurtenant structures to ensure protection of human life and property.

The requirements for design floods for dams that are the responsibility of federal agencies are contained in the following documents:

- Federal Guidelines for Dam Safety, Federal Emergency Management Agency Publication FEMA 93, November 1998.
- Federal Guidelines for Dam Safety: Selecting and Accommodating Inflow Design Floods for Dams, Federal Emergency Management Agency Publication FEMA 94, October 1998.

4.20.3 Seismology

Existing Conditions

Reservoir-triggered seismicity is the initiation of earthquakes by the impoundment or operation of a reservoir. Reservoir-triggered earthquakes can be identified by a change in the pattern of earthquake activity in the immediate vicinity of a reservoir that usually begins during or shortly

after (days to a few years) initial filling of the reservoir. Rapid reservoir elevation changes can also trigger earthquakes.

The mechanisms that control RTS—primarily increased pore pressures in fractured rock surrounding or beneath the reservoir and increased load due to water volume—are generally agreed upon. The relative importance of these mechanisms on a site-specific basis and whether individual reservoirs exhibit RTS are not as clear.

While at least four reservoirs in the Southeastern United States exhibit RTS, the evidence for RTS at TVA reservoirs is weak at best. Many of the TVA reservoirs are located within the Southern Appalachian Seismic Zone, a zone that was active before the introduction of TVA reservoirs and continues to be active today (Reinbold and Johnston 1987). Earthquakes typically associated with RTS are more shallow than most southern Appalachian earthquakes. There have been a few instances of small, shallow earthquakes near TVA reservoirs (e.g., the February 1990 sequence of earthquakes near Tellico Reservoir); there have also been similar sequences of shallow earthquakes in the Southern Appalachians well removed from reservoirs (e.g., Bristol, Virginia in February 1988 and Greeneville, Tennessee in March 1995).

If TVA reservoirs do exhibit RTS, it appears to be rare and would be difficult to confirm. To determine whether RTS is occurring or has occurred at any TVA reservoir, detailed seismic activity records would be required in the vicinity of all reservoirs for a few years before and for several years after the initial filling of the reservoirs. This type of seismic documentation is not available. The question of RTS at TVA reservoirs cannot be answered with confidence. If RTS does occur, however, it is not obvious based on earthquake data collected over the past 20 years (Chapman and Mathena 2001).

Future Trends

No trends have been identified relative to RTS; therefore, future trends are expected to be the same as existing conditions.

4.20.4 Reservoir Levels

Existing Conditions

Water levels at TVA reservoirs fluctuate under normal operations (see Section 2.2). In addition to the normal operating levels, the reservoirs are designed to withstand forces associated with a flood condition. All TVA dams classified as either high or significant hazard potential are capable of passing the applicable inflow design flood (IDF) as required by the federal guidelines with the exception of Chickamauga. Dams classified as high hazard potential are those dams where failure or improper operation probably would cause loss of human life. Dams classified as significant hazard potential dams are those dams where failure or improper operation would result in no probable loss of human life but could cause economic loss, environmental damage, disruption of lifeline facilities, or could affect other concerns. Dams that are classified as significant hazard potential are often located in predominantly rural or agricultural areas but

could be located in areas with higher population and significant infrastructure. The hydrologic design for Chickamauga is under review to determine the applicable IDF and needed modifications, if any.

Future Trends

Reservoirs levels are variable year to year but fall within the flood guides for each reservoir. Levels would not be allowed to fluctuate such that dam safety was compromised.

4.20.5 Reservoir Drawdown Rates

Existing Conditions

Water pressure from a reservoir causes water to gradually infiltrate the surrounding reservoir rimrock, soil embankments, or foundations. Over time, internal pressures, called pore pressures, are created within the surrounding area. These pressures increase until the surrounding area reaches equilibrium. If the reservoir is rapidly drawn down after pore pressures are established, they may create unstable conditions in the surrounding rim that can cause slides or sloughing of the rim material.

The structures that surround reservoirs that are subject to fill and drawdown cycles are designed to withstand the expected fluctuations of external water pressures and internal pore pressures. The design is based on an upper limit on the allowable rate of drawdown. Table 4.20-01 lists the maximum allowable drawdown rates necessary to ensure the stability of the dams within the scope of the EIS.

Future Trends

Under the existing operations policy, future drawdown rates would continue to be maintained within present limits.

4.20.6 Leakage

Existing Conditions

Some leakage, or unintended flow, is expected to occur at all dams either through structural joints, earthen embankments, reservoir rims, or foundation materials. Any leakage is evaluated during periodic dam inspections and a determination is made as to whether the volume, rate of change, and sediment content (if any) of the leak poses structural concerns. When necessary, the leakage is periodically measured and recorded so that trends can be defined. Changes in these trends can indicate that a more detailed evaluation of the seepage is warranted.

Table 4.20-01 Drawdown Limits for Tributary Reservoirs

Project[1]	Description	Drawdown Limits[2]
Apalachia	Concrete	3 feet per day not to exceed 12 feet per week
Blue Ridge	Hydraulic fill	2 feet per day not to exceed 7 feet per week for 28 feet, then 3 feet per week
Chatuge	Impervious rolled fill	2 feet per day not to exceed 7 feet per week for 28 feet, then 3 feet per week
Cherokee	Concrete and impervious rolled fill	2 feet per day not to exceed 7 feet per week for 28 feet, then 3 feet per week
Douglas	Concrete and impervious rolled fill	2 feet per day not to exceed 7 feet per week for 28 feet, then 3 feet per week
Fontana	Concrete	2 feet per day not to exceed 7 feet per week for 28 feet, then 3 feet per day not to exceed 12 feet per week
Great Falls	Concrete	2 feet per day not to exceed 12 feet per week
Hiwassee	Concrete	2 feet per day not to exceed 7 feet per week
Norris	Concrete and earth fill	2 feet per day not to exceed 7 feet per week for 28 feet, then 3 feet per week
Nottely	Impervious rolled fill	2 feet per day not to exceed 7 feet per week for 28 feet, then 3 feet per week
South Holston	Impervious rolled fill	2 feet per day not to exceed 7 feet per week for 28 feet, then 3 feet per week
Watauga	Impervious rolled fill	2 feet per day not to exceed 7 feet per week for 28 feet, then 3 feet per week

[1] For those reservoirs not shown, the drawdown rate would follow the rate shown for Blue Ridge.

[2] Restrictions are based on dam safety and slope stability considerations.

Source: TVA files - Dam Safety Group 2003.

Table 4.20-02 details TVA reservoirs within the scope of the EIS that have been monitored for leakage. This table also indicates whether the amount of leakage would increase as the reservoir headwater elevation increases and, where known, describes the cause of the leakage. The data are reviewed periodically to assess the leakage and ensure the continued safety of the structures. Periodically, an Instrumentation Project Performance Report is issued, which reviews the history of the project, evaluates the appropriateness of the instrumentation and frequency of observation, identifies conditions that might threaten dam safety, and evaluates the structural and geotechnical performance of the dam.

Table 4.20-02 Leakage Monitored at Non-Power and Power Projects

Project	Leakage Increases with Increasing Headwater	Bedrock	Leakage Mechanism
Non-Power Projects			
Bear Creek	Yes	Limestone and shale	Karst
Cedar Creek	No, seasonal	Sandstone	Unknown
Little Bear Creek	No, seasonal	Limestone and shale	Karst
Normandy	Yes	Limestone	Karst
Tellico	No, seasonal	Limestone and shale	Karst

Source: TVA files - Dam Safety Group 2003.

Future Trends

The trends exhibited by the leakage observed at TVA dams are shown in Table 4.20-02. These trends are expected to continue through 2030 due to the continued operation of TVA reservoirs under the existing reservoir operations policy.

Hydrologic Research Needs for Dam Safety Analysis At the Tennessee Valley Authority

By
R. Cris Hughes, P.E., and Gregory W. Lowe, P.E.[1]

Background

The Tennessee Valley Authority (TVA) was created in 1933 to provide for the unified development of the Tennessee River Valley. The purpose of the Act is stated as follows:

"That for the purpose of . . . and to improve navigation in the Tennessee River and to control the destructive flood waters in the Tennessee River and Mississippi River Basins, there is hereby created . . . the 'Tennessee Valley Authority' " - Preamble.

With respect to planning, Section 23 requires the President to recommend to Congress such legislation as he deems proper " . . . for the especial purpose of bringing about . . . in conformity with said general purposes (1) the maximum amount of flood control, (2) the maximum development of said Tennessee River for navigation purposes, (3) the maximum generation of electric power consistent with flood control and navigation; . . ."

On the subject of operation of reservoirs, Section 9a states: "The (TVA) Board is hereby directed in the operation of any dam or reservoir . . . to regulate the stream flow primarily for the purposes of promoting navigation and controlling floods. So far as may be consistent with such purposes, the Board is authorized to provide and operate facilities for the generation of electric energy . . . and the Board is further authorized, whenever an opportunity is afforded, to provide and operate facilities for the generation of electric energy in order to avoid the waste of water power, . . ."

TVA's structural approach to minimizing flood risk was the construction of dams with flood control allocations to "keep the floods away from the people." Today, TVA operates an integrated reservoir system of 49 dams (1 project in the Cumberland River basin), in the 41,000-square mile Tennessee River drainage basin covering portions of seven states. Since these dams were built, significant flood reduction benefits have been realized along the Tennessee River and its tributaries, and along the lower Ohio and Mississippi Rivers. TVA dams also provide additional benefits to the region including navigation, hydropower generation, water supply, recreation, water quality, and land use for economic development.

TVA's reservoir system has been effective in providing over $5B in flood damage reduction benefits. TVA also recognized that structural measures could not eliminate flooding, and that there were about 350 communities in the Tennessee Valley with some degree of flood risk and damage potential.

[1] Tennessee Valley Authority

In response to this situation, TVA initiated a floodplain management assistance program in 1953 based on the concept of averting local flood damages by careful land use planning. This approach of working with state and local governments to deal with flood problems was applied throughout the Tennessee River watershed. During this period, TVA promoted the concept of avoiding development within the 100-year floodplain and encouraging to the extent possible the adoption of higher setback and elevation standards.

In the late 1960s, TVA utilized its floodplain management experience to assist the Federal Emergency Management Agency (FEMA) with the development of what is today the National Flood Insurance Program (NFIP). TVA served as a contractor to FEMA for several years to develop flood information for many communities within the Tennessee Valley. During this period, TVA also demonstrated several different flood damage reduction measures at different communities including channel restoration/modifications, flood warning systems, acquisition and relocation, and flood proofing.

Current Floodplain Management Activities

Since 1994, TVA's floodplain management efforts have focused on the lands and projects that TVA holds in stewardship, and on the floodplains along the rivers and streams, which are affected by regulation from TVA dams. The objective of the program is to minimize flood damages, ensure the safety of floodplain residents (by keeping the people away from the water), preserve TVA's reservoir operating flexibility for flood control purposes, and ensure consistency with local floodplain regulations. TVA's reservoirs and the river reaches below the dams have seen substantial development over the last several years. Thus, flood risk is expected to continue to increase in the future from this one factor alone.

Dam Safety Program Development

TVA has maintained a dam safety program since its establishment in 1933. Following the failure of Teton Dam, President Jimmy Carter issued a 1976 memorandum to all Federal Agencies with responsibilities for dams to develop and implement formal guidelines for dam safety. After participating in the development of the interagency document, *Federal Guidelines for Dam Safety* (Reference 1), TVA formalized its dam safety program in 1982. At that time, TVA evaluated all of its dams for hydrologic and seismic safety, and determined that 23 of its then 53 dams had some degree of deficiency and could be made even safer, consistent with these guidelines. Since that time, TVA has spent more than $75M modifying these dams, with work underway at the remaining two projects to ensure its dams meet these guidelines. Because most of TVA's dams are high hazard structures with significant potential for loss of life and property damage, TVA chose to modify its dams to safely pass the Probable Maximum Flood (PMF).

TVA recognized the need to have an outside authority provide estimates of the Probable Maximum Precipitation (PMP). Further, TVA recognized the need to have studies performed specific to the region rather than using generalized estimates for PMP. The National Weather Service (NWS) was funded by TVA to study two categories of extreme precipitation for the Tennessee Valley which included PMP and a standardized less extreme rainfall referred to as the "TVA precipitation." At this time, the NWS completed Hydrometeorological Reports (HMR) 41 (Reference 2); 47 (Reference 3); and 56 (Reference 4). HMR 45, superseded by HMR 56 in 1986, was used in studies prior to HMR 56. These reports provided estimates of precipitation for large areas such as that above the City of Chattanooga (approximately 21,400 square miles) and for basins up to 3,000 square miles. These reports defined depth-area-duration characteristics and antecedent storm potentials.

Current Research Needs

One of the most controversial aspects of the TVA reservoir system is the annual operating cycle for the tributary projects. There are 10 tributary projects, which have a summer-to-winter fluctuation of from 35 to as much as 90 feet. The seasonally varying allocation of flood storage was designed primarily to provide flood protection for the City of Chattanooga, the major damage center in the Tennessee Valley. These reservoirs provide over 4 million acre-feet of flood storage space needed during the flood season from mid-December through early April. However, the economic benefits attributable to use of these reservoirs have changed over the years and now include enhanced lake front property value, recreational boating, fishing, swimming, wildlife habitat, minimum flow and dissolved oxygen (DO) enhancements, and related functions.

Stakeholders, for many years, have questioned the need for this flood storage (saying it is too conservative) and have requested a delay of the drawdown of these reservoirs until later in the fall. These reservoirs are typically at their highest level by June 1 of each year depending on rainfall/runoff. During June and July, they are gradually drawn down to support downstream water quality and hydropower generation. After August 1 of each year, the reservoirs have an unrestricted drawdown to lower them to their January 1 flood storage levels.

In 1991, TVA completed the *Tennessee River and Reservoir System Operation and Planning Review*, an Environmental Impact Statement (EIS) that resulted in changes to its reservoir operating policies. This was the first comprehensive re-evaluation of reservoir operating policy since the projects were built. However, the focus of this review was on maintaining minimum flow below dams at critical times and locations, increasing DO below 16 dams by aerating releases, and to delay unrestricted summer drawdown until August 1 on ten tributary reservoirs. While flood control was a consideration in review of these alternatives, no alternatives were considered which would change the winter flood storage allocations. However, the review did formalize the requirements for a minimum of one inch of flood storage space during the summer months at 10 of the tributary reservoirs.

TVA established a Regional Resource Stewardship Council in March 2000 under the Federal Advisory Committee Act (FACA). The purpose of the Council was to provide advice to TVA on policies, priorities, and practices for managing its land and water resources and programs as part of its public responsibilities. The Council is made up of 20 representatives from across the Valley. They represent a range of interests in TVA's stewardship activities, including representatives of the Governors of the seven TVA states, power distributors, industry, business, environment, recreation, consumers, and educational and community leadership.

This summer (2001) the Council recommended that TVA undertake a study of its reservoir operating policy to determine if changes could create greater overall value for TVA customers and stakeholders without reducing gains which had been realized in water quality. The study will include evaluation of costs and benefits. The TVA Board responded to this recommendation in October with a commitment to perform a comprehensive evaluation of reservoir operating policy in two years. This study will be conducted within the National Environmental Policy Act (NEPA) framework as an (EIS).

One of the major issues to be addressed will be the evaluation of potential change in flood risk that could result from a change in reservoir operating policy. The evaluation must ensure that the tools and analysis process must be capable of providing a clear understanding of how the flood risks could change. This should include impacts on flood frequency throughout the full range of flood potential from the annual event through the PMF, effect on local floodplain regulations as part of the NFIP, elevation and flow duration, and impact on dam safety.

At this time there are several studies underway to address similar issues across the country (Upper Mississippi River Flow Frequency, Savannah River, and Lower Colorado River Authority). Many factors are driving this need including: (1) the Nation's floodplains continue to be developed increasing the flood risk and damage potential; (2) advances in weather forecast capabilities are viewed by the public as a reliable basis for reservoir operations well in advance of actual events; (3) studies raise questions about previously completed flood frequency analysis and whether these changes in turn should result in changes to published information used for local floodplain regulations for 100- and 500-year flood boundaries and floodways; (4) the hydrologic period of records are increasing, coupled with more sophisticated computational methods and modeling capabilities; and (5) a growing interest on the part of the stakeholders that live along or use the water resource to change the allocation of benefits based on economics.

Conclusion

Research is needed to focus on flood risk assessment methodology that can be supported by the technical community, general public, and local, state, and federal land- and water-use decision makers.

CHAPTER 1

Dam Safety Program – Introduction, Overview, and Guiding Principles

1.1 Purpose. This regulation prescribes the guiding principles, policy, organization, responsibilities, and procedures for implementation of risk-informed dam safety program activities and a dam safety portfolio risk management process within the United States Army, Corps of Engineers (USACE). Risk is defined as a measure of the probability and severity of undesirable consequences or outcome. The purpose and intent of this regulation is to ensure that responsible officials at all levels within the Corps of Engineers implement and maintain a strong dam safety program in compliance with *"Federal Guidelines for Dam Safety"* (reference A.71). The program ensures that all dams and appurtenant structures are designed, constructed, and operated safely and effectively under all conditions, based on the following dam safety and dam safety program purposes, as adopted by the Interagency Committee on Dam Safety (ICODS).

1.2 Applicability. This regulation applies to Headquarters, United States Army, Corps of Engineers (HQUSACE) elements, major subordinate commands (MSC), districts, and the Engineer Research and Development Center (ERDC), having responsibility for planning, site selection, design, construction, operation, maintenance, inspection, evaluation, and rehabilitation of dams and appurtenant structures.

1.3 Distribution Statement. This regulation is approved for public release; distribution is unlimited.

1.4 References. Required references are listed in Appendix A.

1.5 Glossary. Abbreviations and terms, which may not be familiar to the reader, are defined in the Glossary.

1.6 Dam Safety Definition. Dam safety is the art and science of ensuring the integrity and viability of dams such that they do not present unacceptable risks to the public, property, and the environment. It requires the collective application of engineering principles and experience, and a philosophy of risk management that recognizes that a dam is a structure whose safe functioning is not explicitly determined by its original design and construction. It also includes all actions taken to routinely monitor, evaluate, identify or predict dam safety issues and consequences related to failure, and to document, publicize, and reduce, eliminate, or remediate, to the extent reasonably practicable, any unacceptable risks.

1.7 Dam Safety Program. The purposes of a dam safety program are to protect life, property, and the environment by ensuring that all dams are designed, constructed, operated, and maintained as safely and effectively as is reasonably practicable. The Corps has had an active Dam Safety Program since the 1970's. The program was last evaluated using an external peer review in 2001. The results of that evaluation using the Association of State Dam Safety Official Peer Review procedures were published in

a report entitled “Peer Review of the Dam Safety Program of the U.S. Army Corps of Engineers” dated September 30, 2001 (Reference A.81).

1.8 Dam Safety Officers. To comply with the Federal Guidelines for Dam Safety (Reference A.71), the Chief of Engineers has designated a USACE Dam Safety Officer by General Order. This regulation further defines the requirements and responsibilities of the Dam Safety Officers at each level of the command. Commanders and Dam Safety Officers at all levels are responsible to ensure that sufficient highly qualified personnel are available to meet project purposes and that programs related to dam safety are established and funded to achieve compliance with the requirements herein. These responsibilities are further defined in Chapter 4.

1.9 Transition to a Risk Informed Dam Safety Program. USACE is moving from a solely standards-based approach for its dam safety program to a dam safety portfolio risk management approach. The standards-based or essential guidelines approach is included in the risk-informed approach to the dam safety program and dam safety program decisions will now be risk-informed. One of the bases for a risk-informed decision, and prioritization of the work, is a consideration of the achievement of tolerable risk guidelines following implementation of risk reduction measures. In addition, it should be recognized that other non-quantitative factors will influence practical decision making for the dam safety program.

> "There was previously a view in some quarters that risk assessment was a means to justify less costly safety upgrades of dams than those required by the traditional approach. It is now recognized that such a view seriously misunderstands the true aim of risk assessment, which is more informed decision-making than would be possible from reliance on the traditional approach alone. It may be that the additional understanding that comes from the risk assessment process, will reveal that a less costly solution to a dam safety problem could be justified, though a decision that way should be made with great care and having regard to all of the community risk and business risk considerations. But it could as easily be the case that risk assessment shows that a more stringent safety level, and thus a more costly solution, ought to be implemented." (Guidelines on Risk Assessment, Australian National Committee on Large Dams (ANCOLD), October 2003, Reference A.80).

1.10 Principles for Dam Safety Portfolio Risk Management. The following guiding principles, which represent a paradigm shift for USACE, have been established for the USACE Dam Safety Portfolio Risk Management process:

1.10.1 Life Safety is Paramount. A key mission of the USACE dam safety program is to achieve an equitable and reasonably low level of risk to the public from its dams.

1.10.2 Do No Harm. The principle of ‘Do no harm’ should underpin all actions intended to reduce dam safety risk. Applying this principle will ensure that proposed IRRM implementation, emergency or permanent construction, or a temporary or

permanent change in regulation schedules would not result in the dam safety being compromised at any point in time or during measure implementation.

1.10.3 Risk-Informed Corporate Approach. The USACE dam safety program will be managed from a risk-informed USACE-wide portfolio perspective applied to all features of all dams on a continuing basis.

1.10.4 Urgency of Dam Safety Actions. The urgency of actions, including funding, to reduce risks in the short term (i.e., Interim Risk Reduction Measures) and in the long term (i.e., Dam Safety Modifications) will be commensurate with the level of risk based on current knowledge. This may require first addressing only those failure modes that contribute significantly to the overall risk.

1.10.5 Risk Communications. USACE will provide risk information to internal and external stakeholders. An informed and engaged public is an empowered public that understands risk, can contribute to the evaluation of risk reduction options and can take some degree of responsibility for its safety.

1.10.6 Prioritization of Studies and Investigations. Studies and investigations will be scoped with the goal of confirming dam safety issues and prioritized to reduce knowledge uncertainties and risk across the portfolio of dams in a cost effective and timely manner.

1.10.7 Formulation and Prioritization of Risk Management Measures. Where practical, risk reduction measures will be formulated as separable measures and these will be prioritized to achieve tolerable risk as quickly as practicable and in a cost-effective manner across the portfolio of dams.

1.10.8 Level of Detail of Risk Assessments. The level of effort and scope of risk assessments will be scaled to provide an appropriate level of confidence considering the purpose of the risk management decision.

1.10.9 Routine Dam Safety Activities. Execution of inspections, instrumentation, monitoring, Periodic Assessments, operations and maintenance, emergency action planning and other routine dam safety activities are an essential part of effective dam safety risk management for all USACE dams.

1.10.10 Risk Reporting. The current level of risk for USACE dams will be documented and routinely reported. The basis for decisions will be documented.

1.11 Principles for Implementing Interim Risk Reduction Measures at High Risk Dams.

1.11.1 Public Safety. USACE executes its project purposes guided by its commitment and responsibility to public safety. In this context, it is not appropriate to refer to balancing or trading off public safety with other project benefits. Instead, it is after public safety tolerable risk guidelines are met that other purposes and objectives

will be considered. Dam Safety Officers are the designated advisors and advocates for life safety decisions.

1.11.2 Do No Harm. The principle of 'Do no harm' should underpin all actions intended to reduce dam safety risk. Applying this principle will ensure that proposed IRRM implementation would not result in the dam safety being compromised at any point in time or during IRRM implementation.

1.11.3 Risk-Informed – Not Risk Based. Decisions should be risk-informed, not risk-based. Risk-informed decisions integrate traditional engineering analyses with numerical risk estimations of risk through the critical foundation of experience-based engineering judgment. (We no longer refer to risk-based decisions because of the inappropriate implication that life-safety decisions can be reduced to simple, numerical solutions).

1.11.4 Congressional Authorizations. Our projects provide us with specific Congressional authorizations and legal responsibilities that often cover a broad array of purposes and objectives. Because of the complexity of these authorities, the public safety responsibility is critical to informing how we implement these statutory responsibilities. The public safety responsibility requires USACE to assure our projects are adequately safe from catastrophic failure that results in uncontrolled release of the water in the reservoir. We have specific public safety responsibility, when a project has known safety issues, to take appropriate interim risk reduction measures - including reservoir releases - to assure safety of the project and to protect the public. Our statutory responsibilities do not give us authority to operate our dams in a manner that increases the project's probabilities of failure when there are known issues with the integrity of the project.

1.11.5 Manage Flood Waters. We manage risks of flood waters, we do not control them. Our projects do not have unlimited operational capacity to control extreme floods, as Mother Nature can always up the ante. Our outlet works have limited capacity to release flows in a controlled manner, and thus all properly designed projects have a capacity above which the inflow is passed through without attenuation. These are very large releases that may cause damage downstream of the dam but not to a greater degree than would have occurred under pre-project conditions. Decision makers must understand these limitations and operational constraints.

1.11.6 Unique Dynamics Over Time. All projects have unique geographic, physical, social, and economic aspects that are subject to dynamics over time. Decision making within Interim Risk Reduction Measure Plans should not be overly prescriptive because of these complexities.

1.11.7 Tension Between Loss of Life and Economic Damage. The operations of a high risk (unsafe or conditionally unsafe) dam during flood conditions can create a dynamic tension between the potential for loss of life and economic damage resulting from an uncontrolled release due to failure and the surety of economic damages

resulting from operational release to prevent failure. Operational releases can be accompanied with planning, advanced warnings, and evacuations with the goal of avoiding loss of life. Economic impacts may be incurred and options for mitigating these impacts can be explored. The advanced planning and execution of mitigating measures is far more effective with planned, controlled release of the pool than with the case of unplanned, uncontrolled release resulting from failure of the project.

1.11.8 Interim Risk Reduction Measure Plan. The IRRMP, including the supporting Water Control Plan (modified by approved temporary deviations as necessary), is the key document that frames operational decision making for unsafe dams (DSAC I, II, and III). This plan establishes the specific threshold events, decision points, and actions required. As such, the IRRM Plans set the sideboards for decision making, including changes in the regulation schedule from that of the approved Water Control Manual. The IRRM Plan should recognize the need for two primary water control management controls.

1.11.8.1 A recommended safe operating reservoir level that is maintained for the vast majority of time through non damaging releases.

1.11.8.2 A threshold event for which emergency measures such as rapid reservoir drawdown and recommendations on evacuation must occur.

1.11.8.3 This approach to water control management recognizes that pool restrictions established for safety purposes cannot and should not be viewed as “must meet” requirements in all flood events, but that there does come a point when emergency measures are necessary.

1.11.9 In the centrally-led and decentrally-executed USACE Dam Safety Program, responsibilities and decision making for Interim Risk Reduction Measures are vertically distributed:

1.11.9.1 Districts develop IRRM Plans, coordinate plans, and execute all IRRM plans for DSAC III dams.

1.11.9.2 Divisions coordinate, review, and approve plans for DSAC Class I, II, and III dams. In particular, divisions are critical in assuring system and watershed issues are considered and coordinated.

1.11.9.3 Headquarters in consultation with the RMC establishes DSAC class for all dams, reviews and concurs on IRRM Plans for DSAC class I, II, and III dams, and aligns investment strategies for all unsafe dams.

1.12 History of Dam Safety. A history of dam safety within USACE, and how it relates to dam safety in the nation, is provided in Appendix B.

1.13 Federal Guidelines for Dam Safety. A summary of the guidelines is provided in Appendix C. The guidelines are referenced at A.71.

1.14 Levels of USACE Responsibility for Dam Safety. Appendix D provides guidance on USACE responsibility for dam safety at dams where USACE has been involved in one way or another with the dam.

CHAPTER 2

Dam Safety Program Framework

2.1 Scope. This chapter presents the guiding principles and policy for implementation of risk-informed dam safety program within the United States Army, Corps of Engineers (USACE), Office of Management and Budget (OMB) principles for risk analysis, a generalized dam safety framework based on the OMB principles with an elaboration of the concepts of risk assessment, risk management, and risk communication, and the presentation of a generalized dam safety portfolio risk management process.

2.2 OMB Risk Analysis Principles.

2.2.1 Risk is a measure of the probability and severity of undesirable consequences. In 1995 (Principles for Risk Assessment, Management, and Communication, January 12, 1995 (reference A.82) and again in September 2007 (Updated Risk Principles (M07-24), September 19, 2007 (reference A.84) the Office of Management and Budget (OMB) set forth a set of principles to guide policymakers in assessing, managing, and communicating policies to address environmental, health, and safety risk. The OMB intent in presenting these principles was “to provide a general policy framework for evaluating and reducing risk.” Evaluating and reducing risk requires a decision-making framework that explicitly evaluates the level of risk if no action is taken and recognizes the monetary and non-monetary costs and benefits of reducing risks when making decisions. This risk decision framework requires separating the whole of risk into its component tasks by assessing the risk and related uncertainties for the purpose of successful management of the risk, facilitated by effective communication about the risks. In this way, risk analysis comprises three tasks: risk assessment, risk management, and risk communication.

2.2.2 Figure 2.1 shows the interrelatedness of the three OMB risk analysis principles and the notion that risk communication is a vital and joining activity that must take place to achieve an effective risk decision. Note that the technical scientific work takes place in the risk assessment while risk management is more concerned with applying social values and policy to sort through options and tradeoffs revealed in the risk assessment.

2.2.3 Risk Assessment.

2.2.3.1 Risk assessment is a broad term that encompasses a variety of analytic techniques that are used in different situations, depending upon the nature of the risk, the available data, and needs of decision makers. It is a systematic, evidence based approach for quantifying and describing the nature, likelihood, and magnitude of risk associated with the current condition and the values of the risk resulting from a changed condition due to some action.

2.2.3.2 Uncertainty is the result of imperfect knowledge concerning the present or future state of a system, event, situation, or (sub) population under consideration. Uncertainty leads to lack of confidence in predictions, inferences, or conclusions. Here

we distinguish uncertainty that results from a lack of knowledge from variability, although many consider variability a specific source of uncertainty. For example, a risk assessor may be very certain that stream flows vary over a year but may be uncertain about the amount of that variability. Collecting more and better data can often reduce uncertainty, whereas variability is an inherent property of the system/population being evaluated. Variability can be better characterized and addressed quantitatively with more data but it cannot be reduced or eliminated. Efforts to clearly distinguish between variability and uncertainty are important because they can influence risk management decisions.

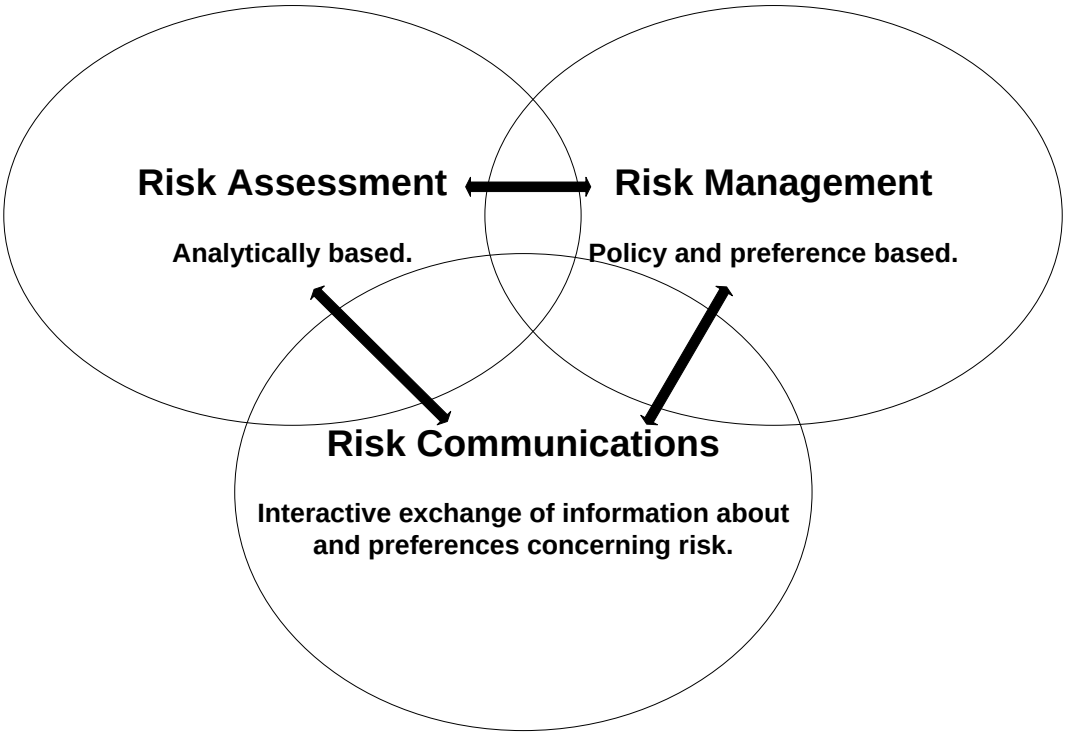

Figure 2.1 OMB Risk Analysis Principles

2.2.4 Risk Management.

2.2.4.1 Risk management is the process of problem finding and initiating action to identify, evaluate, select, implement, monitor and modify actions taken to alter levels of risk, as compared to taking no action. The purpose of risk management is to choose and implement those technically sound integrated actions to reduce risks after consideration of the costs of each increment of risk reduction. Environmental, social, cultural, ethical, political and legal considerations all factor into the decision made on how much cost will be incurred for each increment of risk reduction (how safe is safe enough?). Risk management for dams includes short-term Interim Risk Reduction Measures, long-term structural risk reduction measures, and strengthening recurrent

activities - such as monitoring and surveillance, emergency action planning, operations and maintenance, and staff training.

2.2.4.2 OMB stated, “In choosing among alternative approaches to reducing risk, agencies should seek to offer the greatest net improvement in total societal welfare, accounting for a broad range of relevant social and economic consideration such as equity, quality of life, individual preference, and the magnitude and distribution of benefits and costs (both direct and indirect, both quantifiable and non-quantifiable).” (OMB 2007 memorandum, Subject: Updated Principles for Risk Analysis, Page 10 (reference A.84)).

2.2.4.3 Equity considers placing all members of society on a (more) equal footing in terms of the risks faced. The equity objective is addressed by requiring that all risks higher than a limit value be brought down to below the limit, except in exceptional circumstances.

2.2.4.4 Efficiency considers the following:

2.2.4.4.1 Ensuring that resources and expenditures directed to safety improvements are cost-effective;

2.2.4.4.2 Ensuring an appropriate balance between the monetary and non-monetary benefits and the monetary and non-monetary costs; and

2.2.4.4.3 Achieving the greatest reductions in risk for each unit of resources committed.

2.2.4.4.4 The efficiency objective is recognized by allowing risks to be assessed and addressed on a dam portfolio basis to assign priority and urgency to risk reduction actions, thereby making best use of resources. It can also be addressed for an individual dam through consideration of the cost effectiveness of risk reduction below limit values in tolerable risk guidelines.

2.2.5 Risk Communication. Risk communication is the open, two-way exchange of information and opinion about hazards and risks leading to a better understanding of the risks and better risk management decisions. Risk communication is integrated into the assessment and management processes. It is not a task that occurs only after decisions have been made. Risk communication ensures that the decision makers, other stakeholders and affected parties understand and appreciate the process of risk assessment and in so doing can be fully engaged in and responsible for risk management.

2.3 Dam Safety Risk Framework. A further refinement and consolidation of activities associated with these principles for evaluating and reducing risk in the area of dam safety are presented in Figure 2.2.

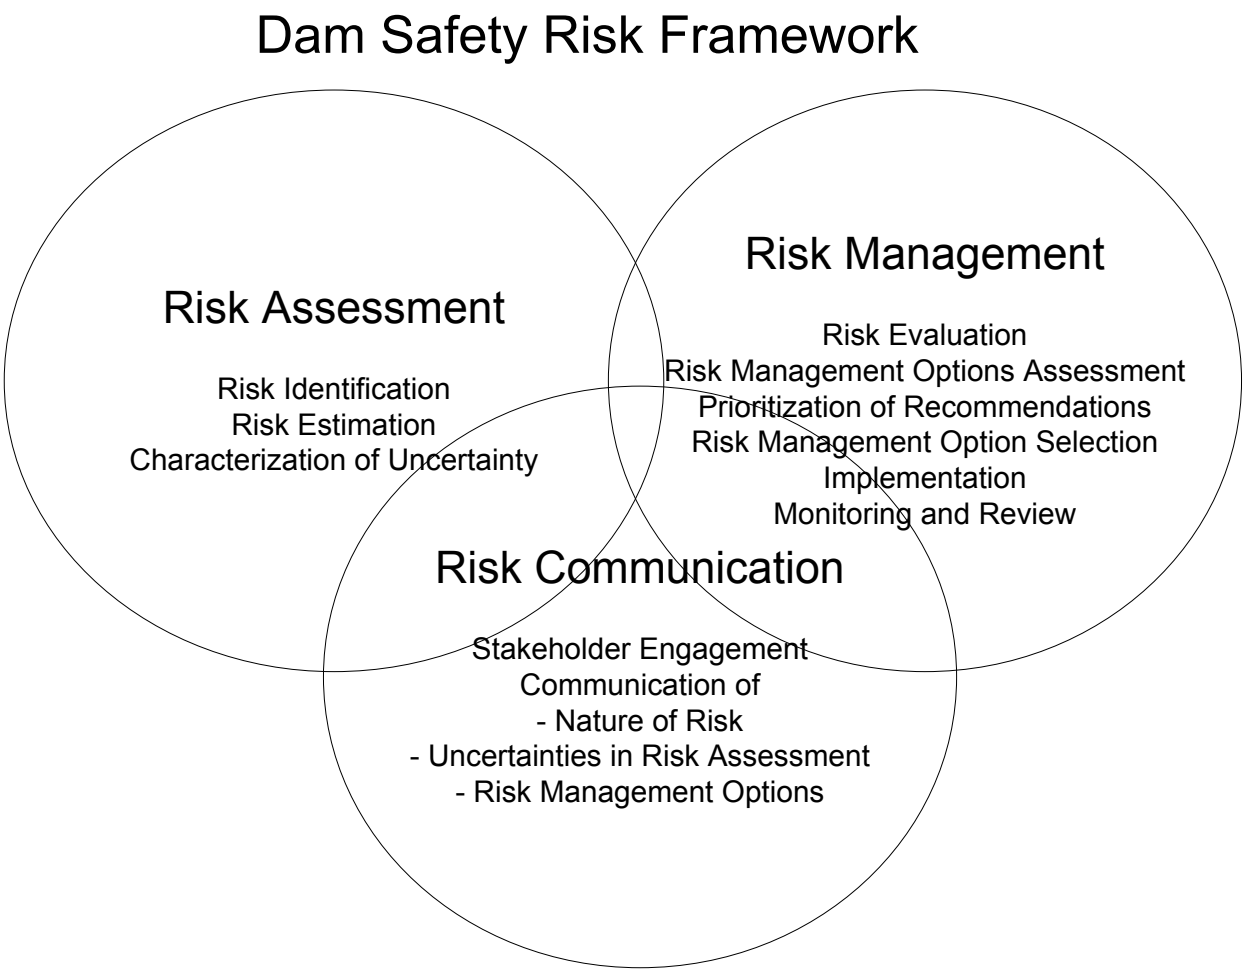

Figure 2.2 – Dam Safety Risk Framework

2.4 Risk Assessment – An Elaboration.

2.4.1 The risk assessment process attempts to answer the following four questions:

2.4.1.1 What can go wrong?

2.4.1.2 How can it happen?

2.4.1.3 What is the likelihood?

2.4.1.4 What are consequences?

2.4.2 Risk assessment has a somewhat different meaning than the USACE terminology of "risk-informed" or "risk and uncertainty." It may be characterized as a more formal and focused effort to describe and define the impacts of risk to facilitate

their effective management. The draft OMB Proposed Risk Assessment Bulletin (January 2006) (reference A.83) defined the term:

> '"risk assessment" means a scientific and/or technical document that assembles and synthesizes scientific information to determine whether a potential hazard exists and/or the extent of possible risk to human health, safety, or the environment."'

2.4.3 Risk assessment would augment the technical work done throughout USACE. An update of the traditional definition of risk assessment taken from the 1983 National Research Council's *Risk Assessment in the Federal Government: Managing the Process* (the so-called "Redbook") (reference A.91) includes the following steps:

2.4.3.1 Hazard Identification (Risk Identification)

2.4.3.2 Hazard Characterization (Risk Identification)

2.4.3.3 Exposure Assessment (Risk Estimation)

2.4.3.4 Risk Characterization (Risk Estimation)

2.4.4 Hazards are the focal point of this process and the major change would be to add an explicit hazard identification step to the various tasks. In a general sense, "hazard" is anything that is a potential source of harm to a valued asset (human, animal, natural, economic, social). It is important that one not limit the notion of a hazard to a natural hazard. So in this sense, a hazard can be thought of as an assumption about some uncertain value or parameter that, if incorrect, can result in the undesirable consequence of the failure to achieve the economic return anticipated.

2.4.4.1 Hazard Identification (Risk Identification). This identifies all biological, chemical, social, economic, and physical agents or natural/anthropogenic events capable of causing adverse effects on people, property, economy, culture, social structure, or environment. The hazard identification step explicitly identifies the hazards that will be of concern in the risk management activity.

2.4.4.2 Hazard Characterization (Risk Identification). Hazard characterization is the qualitative and/or quantitative evaluation of the nature of the adverse effects associated with the identified hazard(s), which may be present in the situation of interest. The hazard characterization step describes the harm that can be done when the hazard is present.

2.4.4.3 Exposure Assessment (Risk Estimation). Exposure occurs when a susceptible asset comes in contact with a hazard. An exposure assessment, then, is the determination or estimation (which may be qualitative or quantitative) of the magnitude, frequency, or duration, and route of exposure. This task describes how the asset/entity/receptor of interest comes in contact with the hazard.

2.4.4.4 Risk Characterization (Risk Estimation). Risk characterization is the qualitative and/or quantitative estimation, including attendant uncertainties, of the probability of occurrence and severity of known or potential adverse effects in a given watershed or decision problem based on the evidence gathered in hazard identification, hazard characterization and exposure assessment. In the dam safety arena the term risk estimation is used due to the significant influence of subjective probability in the risk characterization.

2.5 Risk Management – An Elaboration.

2.5.1 Risk management may be understood as the work required to answer the following questions:

2.5.1.1 What is the problem?

2.5.1.2 What can be done to reduce the likelihood or severity of the risk described?

2.5.1.3 What are the tradeoffs in terms of costs, benefits, and risks among the available options both now and in the future?

2.5.1.4 What is the best way to address the described risk?

2.5.2 In sum, risk management is the process of problem finding and initiating action to identify, evaluate, select, implement, monitor and modify actions taken to alter levels of risk. Figure 2.3 shows a generalized risk management process for dams developed to describe a common approach proposed for use by the Corps of Engineers, Bureau of Reclamation, and the Federal Energy Regulatory Commission. The risk management process emphasizes its ongoing and iterative nature and the usefulness of adapting to new information.

2.5.3 Thinking of risk management as part of risk analysis, some broad categories of risk management activities can be identified as described below.

2.5.3.1 Assess Risk Management Options. Options assessment activities include the process of identifying (optioneering), evaluating, and selecting, actions that can be taken to alter levels of risk. This is a deliberate process of systematically considering all options and their associated trade-offs. Risk management means deciding the level of risk that is tolerable including the consideration of the costs and other consequences of different risk reduction actions. Risk management also means giving appropriate consideration to inherent variability and knowledge uncertainties identified during the risk assessment and other evaluations.

2.5.3.2 Implement Risk Management Decisions. Implementation activities include executing all steps necessary to make the chosen risk management alternative a reality. Part of implementation may include adaptive management processes to learn while

acting when uncertainties identified in the preceding steps are significant and the costs of making a “wrong” decision (economic regret) are deemed to be high.

2.5.3.3 Monitoring and Review. Monitoring and review activities are undertaken to improve understanding and reduce uncertainty over time through learning to assure the success of the implemented risk management measure(s). Over time, with experience, even the goals of the risk management measure(s) may be adjusted. Risk management policies may induce changes in human behaviors that can alter risks (i.e., reduce, increase, or change their character), and these linkages must be incorporated into evaluations of the effectiveness of such policies. (OMB 2007) (reference A.84)

2.6 Risk Communication – An Elaboration.

2.6.1 Beginning with an informal definition, risk communication is the work that must be done to answer the following questions for a risk management activity.

2.6.1.1 Why are we communicating?

2.6.1.2 Who is our audience?

2.6.1.3 What do we want to learn from our audience?

2.6.1.4 What do they want to know?

2.6.1.5 What do we want to get across?

2.6.1.6 How will we communicate?

2.6.1.7 How will we listen?

2.6.1.8 How will we respond?

2.6.2 Effective two-way risk communication has both internal and external communication components. Internal risk communication requires early and continuing communication, coordination, and collaboration among risk assessors and agency officials throughout the decision making process.

2.6.3 Stakeholder Engagement.

2.6.3.1 The external process includes all communication between the agency analysts, officials and affected stakeholders. Stakeholder involvement goes beyond the traditional public participation process of conveying information to the public. It supports decision-making and ensures that public values are considered in the decision making process. Public perceptions are an important source of information.

2.6.3.2 Involvement of stakeholders improves the knowledge base for decision-making and can reduce the overall time and expense involved in decision-making. It may improve the credibility of the agencies responsible for managing risks. It should generate better-accepted, more readily implemented risk management decisions. Furthermore, it is irresponsible and dangerous not to engage stakeholders in meaningful input and feedback opportunities in the risk management process.

2.6.3.3 Successful risk communication leads to a common recognition and understanding of the hazards, risk management options, and shared acceptance of the risk management decisions.

2.6.4 Communicating About the Nature of Risk.

2.6.4.1 Constituents and stakeholders need awareness and an understanding of the characteristics and importance of the hazard of concern. It is important to convey the magnitude and severity of the risk, as well as the urgency of the situation. People must understand whether the risk is becoming greater or smaller (trends) as well the probability of exposure to the hazard.

2.6.4.2 The geographic, temporal, and specific distribution of exposure to the hazard needs to be understood as well as the amount of exposure that constitutes a significant risk. For flood hazards, this is easy to imagine. The nature and size of the population at risk as well as knowledge of who is at the greatest risk all need to be conveyed to stakeholders.

2.6.4.3 Risk is only one part of the issue. People accept higher risk (e.g., living in floodplains) for many good reasons. The actual or expected benefits associated with each risk should be identified and understood. It is important to know who benefits and in what ways. The magnitude and importance of those benefits need to be weighed to find the appropriate tradeoff between risks and benefits.

2.6.5 Communicating Uncertainties in Risk Assessment.

2.6.5.1 One of the challenges of risk communication is conveying the existence and significance of uncertainties encountered in the assessment of the risks to both decision makers and stakeholders as appropriate. The methods used to assess the risk should be described and made available. Significant uncertainties need to be explicitly and specifically identified. The importance of each of the uncertainties, as well as the weaknesses of, or inaccuracies in, the available data need to be communicated. The assumptions on which estimates are based must be identified. Sensitivity analysis of the risk estimates and other decision-making criteria must be conducted and the results communicated. The effects of changes in assumptions on risk management decisions must be thoroughly explored. It is important to objectively assess and convey the assessors' level of confidence in the results of the risk assessment.

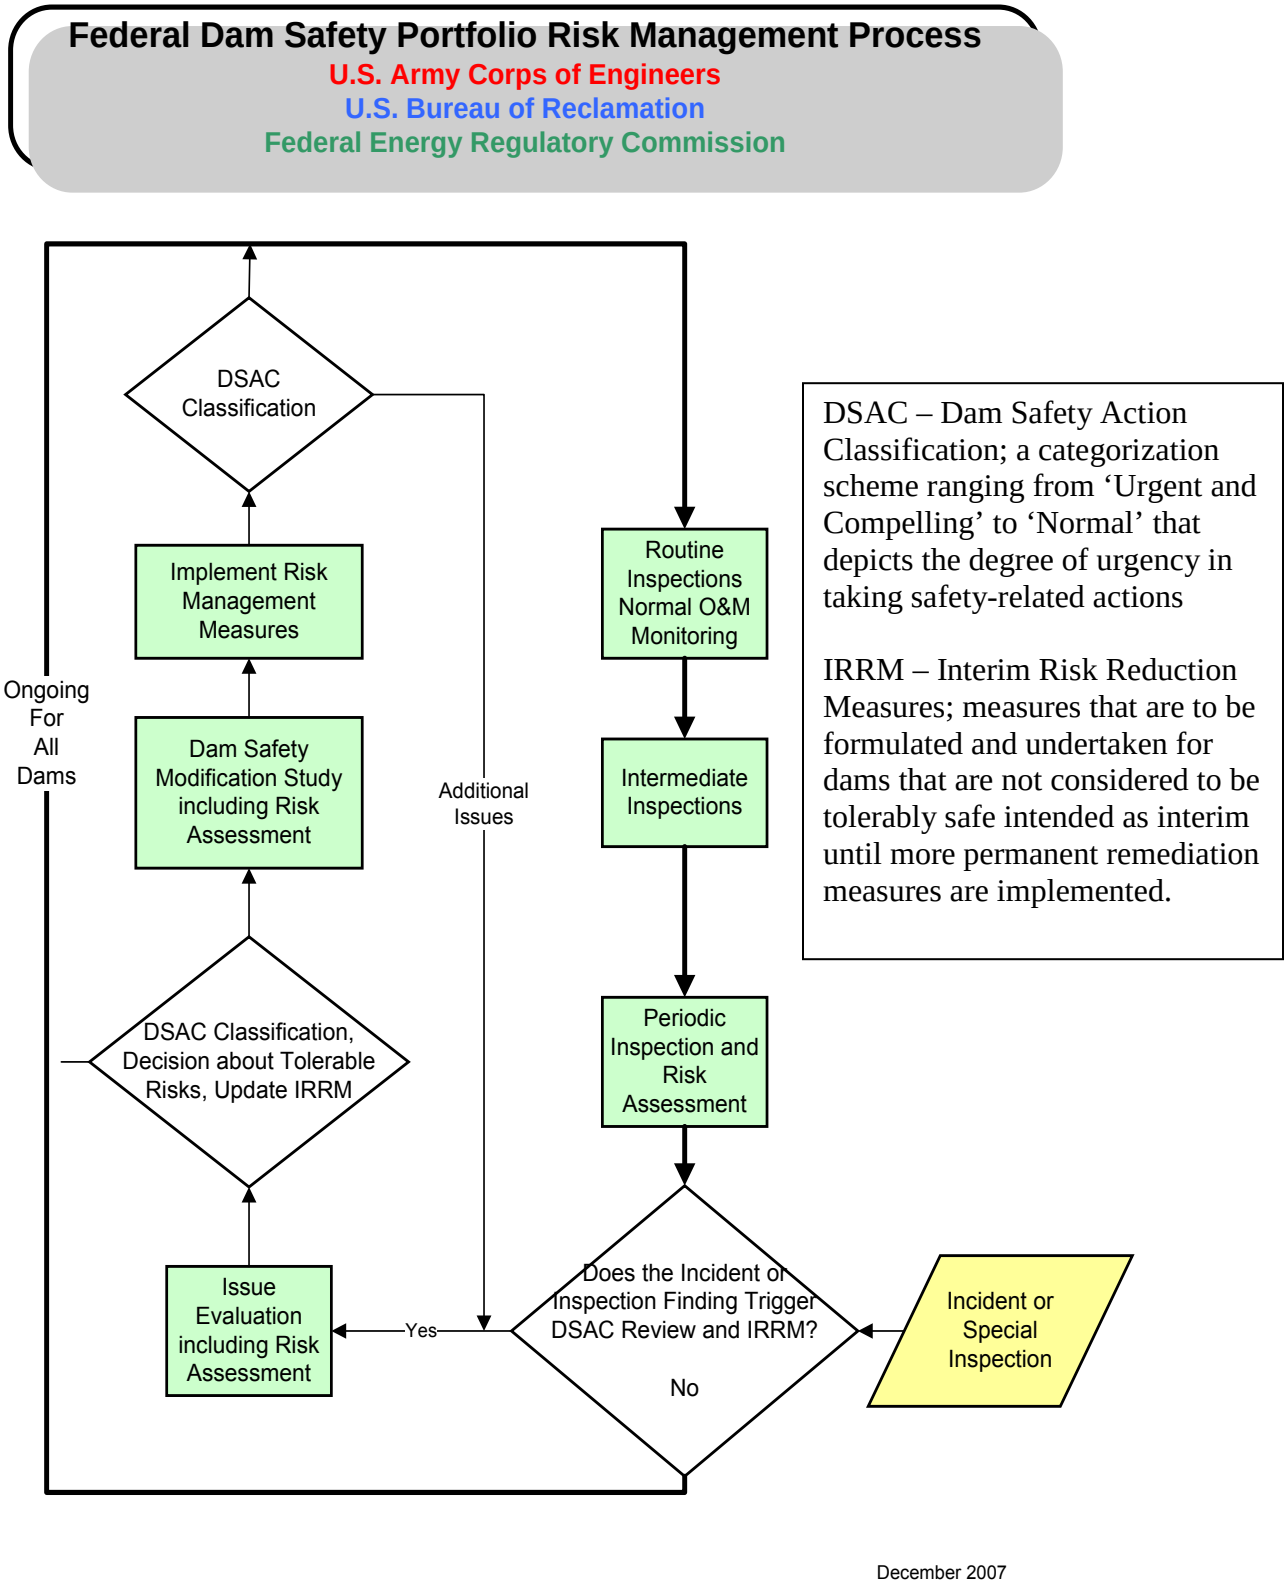

Figure 2.3 – Proposed Generalized Federal Dam Safety Portfolio Risk Management Process

2.6.5.2 The risk assessment should convey the extent and significance of uncertainty in the technical aspects of a decision process. Management needs to weigh its importance in the decision process.

2.6.6 Communicating Risk Management Options.

2.6.6.1 The action(s) taken to control or manage the risk must be carefully communicated and a common understanding about the risk management actions needs to be developed among the affected public. The safety case for justifying the choice of a specific risk management option must be made explicit, transparent, and based on a shared responsibility for the choice made. The effectiveness of a specific option and any residual, transformed or substitute risks must be recognized. The actions individuals may take to reduce personal risk should be carefully communicated as a part of the risk management alternative that is chosen.

2.6.6.2 The benefits of a specific option, the cost of managing the risk, and who pays for each option considered are essential information. The residual risks that remain after a risk management option is implemented need to be clearly understood by all affected parties and decision makers.

CHAPTER 3

Dam Safety Portfolio Risk Management

3.1 Purpose/Objective.

3.1.1 This chapter presents an overview of the USACE Dam Safety Portfolio Risk Management for the USACE portfolio of dams and Dam Safety Action Classification (DSAC) System using the principles outlined in Chapter 2.

3.1.2 The overall Dam Safety portfolio risk management process is a series of hierarchical activities that are used to assess, classify (DSAC), and manage the risks associated with the USACE inventory of dams. The accompanying hierarchical documentation generated by the portfolio risk management process documents the USACE risk assessment and risk management decisions for each dam and facilitates risk communication. The set of documents consists of the reports generated by the normal operations and maintenance (O&M) activities and those documents generated when USACE addresses a dam safety issue. The routine day-to-day dam safety and O&M reports are periodic inspections and periodic assessments; reservoir or water management plans; general operations and maintenance plans; emergency action plans; and instrumentation, monitoring and evaluation plans and reports. The documents generated when addressing a dam safety issue are Screening Portfolio Risk Assessment report; Interim Risk Reduction Measure Plans; Issue Evaluation Study reports; and Dam Safety Modification Reports.

3.2 Dam Safety Action Classification System.

3.2.1 The Dam Safety Action Classification system provides consistent and systematic guidelines for appropriate actions to address the dam safety issues and deficiencies of USACE dams. USACE dams are placed into a Dam Safety Action Classification (DSAC) class based on their probability of failure or the individual dam safety risk estimate considered as a combination of probability of failure and potential life safety, economic, environmental, or other consequences. Until fully evaluated no dam will be considered a DSAC class V, therefore all dams will initially be assigned to classes I - IV. The intent is that the classification of a dam is dynamic over time, changing as project characteristics are modified or more refined information becomes available affecting the loading, probability of failure, or consequences of failure.

3.2.2 DSAC Table Structure. The DSAC table presents different levels and urgencies of actions that are commensurate with the different classes of the safety status of USACE dams. These actions range from immediate recognition of an urgent and compelling situation requiring extraordinary and immediate action for unsafe dams through normal operations and dam safety activities for adequate safe dams.

3.2.3 Reconciliation with Past Dam Safety Management Practices. In the past, the USACE dam safety program essentially recognized two categories of actions: those for dams considered safe, which comprised routine dam safety activities, normal operation

and maintenance; and those for dams that were considered in need of remediation, for which investigations, remediation funding justification documents, and design and construction of remediation measures were additional activities. However, these two categories do not provide formal recognition of an adequate range of actions and degrees of urgency, especially for dams with issues that are very high or extremely high risks, which warrant heightened actions that are not provided for in the traditional standards-based approach. The choice of five action classes is to provide adequate parsing in the range of levels of actions.

3.2.4 DSAC Classes. The five action classes used by the USACE dam safety portfolio risk management program are summarized in Table 3.1 and described below. The five classes depict the range of dams from those critically near failure to those considered adequately safe. Between these two extremes are three classes that define distinctly different levels of actions and urgencies of action that are commensurate with a transition in safety status from critically near failure to adequately safe.

3.2.4.1 Class I (Urgent and Compelling). Class I is for those dams where progression toward failure is confirmed to be taking place under normal operations and the dam is almost certain to fail under normal operations within a time frame from immediately to within a few years without intervention; or, the combination of life or economic consequences with probability of failure is extremely high.

3.2.4.2 Class II (Urgent). Class II is for dams where failure could begin during normal operations or be initiated by an event. The likelihood of failure from one of these occurrences, prior to remediation, is too high to assure public safety; or, the combination of life or economic consequences with probability of failure is very high.

3.2.4.3 Class III (High Priority). Class III dams have issues where the dam is significantly inadequate or the combination of life, economic, or environmental consequences with probability of failure is moderate to high.

3.2.4.4 Class IV (Priority). Class IV dams are inadequate with low risk such that the combination of life, economic, or environmental consequences with a probability of failure is low and the dam may not meet all essential USACE guidelines.

3.2.4.5 Class V (Normal). Class V is for dams considered adequately safe, meeting all essential agency guidelines (see Appendix E) and the residual risk is considered tolerable.

3.2.4.6 Background information on the USACE Dam Safety Action Classification System along with examples of dams in the various classes in provided in Appendix F.

3.3 Dam Safety Portfolio Risk Management Process.

3.3.1 Overview. The flow chart in Figure 3.1 incorporates all USACE dams at the various stages of dam safety portfolio risk management. Exceptions are dams found to have insignificant or no consequences should they fail. At this time, such structures are

to be tagged as exceptions and are exempt from the portfolio management process. These dams will be later considered for decommissioning or transfer.

3.3.2 DSAC Class Assignment. Starting at the top of figure 3.1, the ‘classification’ bar or decision point 1a (D 1a) can be viewed as the sorting or binning point that includes all USACE dams, each of which is classified into one of the five Dam Safety Action Classification (DSAC) classes as presented in Table 3.1. Note that dams in each DSAC class are managed in accordance with their safety status as reflected by their assigned DSAC class.

3.3.3 Role of Prioritization and Queues.

3.3.3.1 There are three prioritization processes and associated queues.

3.3.3.1.1 Prioritization of Issue Evaluation Studies (P1)

3.3.3.1.2 Prioritization of Dam Safety Modification Studies (P2)

3.3.3.1.3 Prioritization of approved remediation projects awaiting design and construction funding (P3).

3.3.3.2 Prioritization and queues are necessary due to resource limitations and the desire to reduce overall portfolio risk as efficiently as possible. The associated queues contain the set of dams awaiting studies or processing to the next step, reflecting their prioritization. While the intent is that the queues are eventually cleared, it is certainly possible that a higher priority dam, from a dam safety issue viewpoint, could come into a queue and move ahead of others already there based on the individual dam’s safety status and circumstance.

3.3.3.3 The responsibility for the management of the prioritization process is presented in chapter 4 - Management of Corps of Engineers Dam Safety Program, the tolerable risk guidelines are presented in chapter 5 - Tolerable Risk Guidelines, and the prioritization for risk management is presented in chapter 6 – Dam Safety Risk Management Prioritization.

3.3.4 Dam Safety Decision Points.

3.3.4.1 There are four major decision points in the dam safety portfolio risk management process.

3.3.4.1.1 Approve Dam Safety Action Classification,

3.3.4.1.2 Selection of Interim Risk Reduction Measures or heightened monitoring,

3.3.4.1.3 Determination if Dam Safety Modification Studies are justified based on the results of the Issue Evaluation Study, and

3.3.4.1.4 Approval of Dam Safety Modification Reports.

3.3.4.2 Decisions dealing with the DSAC determination are located at the following points in the dam safety portfolio risk management process:

3.3.4.2.1 Decision Point D 1a. DSAC classification.

3.3.4.2.2 Decision Point D 1c. Reclassification as a result of an Issue Evaluation Study where the dam can be reclassified to any of the other classes.

3.3.4.2.3 Decision Point D 1d. Incident triggers DSAC review.

3.3.4.2.4 Decision Point D 1e. Post implementation DSAC review and modification of DSAC class as appropriate. Review IRRM plan and modify as appropriate.

3.3.4.3 Decisions dealing with the implementation of IRRM recommendations for DSAC I, II and III dams are located at Decision Point D 2a. The decision related to heighten monitoring for Class IV dams is located at Decision Point D 2b.

3.3.4.4 Decision Point D 3 relates to the determination of the justification of Dam Safety Modification studies for DSAC II, III and IV dams.

3.3.4.5 Decision Point D 4 deals with the approval of Dam Safety Modification study reports.

3.3.5 Screening. Initially, all dams in the USACE inventory will be subjected to a screening level risk assessment called the Screening Portfolio Risk Assessments (SPRA), defined later, and assigned a DSAC class at decision point D 1a.

3.3.6 Routine dam safety activities and normal operations and maintenance (O&M).

3.3.6.1 The outer loop of the chart depicts continuing and recurrent actions of routine dam safety activities and normal O&M, periodic assessments (PA), potential incident identification, review and update of the Dam Safety Program Management Tools data (See Appendix G), and review of the DSAC class. All USACE dams are in the outer loop regardless of their DSAC class. Exceptions are those dams found to have insignificant or no consequences should they fail (see paragraph 3.3.15). The ideal end state for all USACE dams is that they are classified DSAC V and therefore they are only in the outer loop of the Dam Safety Portfolio Risk Management process diagram.

3.3.6.2 Periodic Assessments and Periodic Inspections. All USACE dams will undergo PA on a routine and systematic schedule not to exceed ten years. Periodic Assessments include a revised Periodic Inspections (PI) process (details in Chapter 11) and baseline risk assessment, including potential failure mode analysis. The PI will occur more frequently than PA, typically not more than five year intervals. This ensures that all dams in the USACE portfolio are systematically and routinely evaluated leading to a high

likelihood of detecting dam safety issues in a timely manner. Periodic assessments are described in more detail later in chapter 11.

3.3.7 Interim Risk Reduction Measures Plans and Implementation. Interim Risk Reduction Measure (IRRM) plans will be developed for all DSAC I, II, and III dams. The IRRM plan addresses identified potential failure modes, defines general consequences associated with each identified potential failure mode, quantifies risks for each likely failure mode to the detail required to support the decisions to be made, evaluates loss in project benefits due to the IRRM measures, and evaluates the potential of the IRRM alternatives considered to reduce the probability of failure and/or consequences associated with the failure modes. A risk assessment, scaled to a level of effort related to the decision to be made, may be performed during development of the IRRM plan. Preparation of an Interim Risk Reduction Measures Plan (IRRMP) is required as per guidance associated with the DSAC table and discussed in detail in chapter 7.

3.3.8 DSAC Class I Expedited Process. Because of their urgent and compelling safety issues, dams in DSAC Class I are immediately processed through several key steps to formulate, approve (Decision Point D 2a), and implement interim risk reduction measures. At Decision Point D 2a the USACE Dam Safety senior oversight group (SOG) will review DSAC documentation and make a recommendation to the USACE senior leadership that the agency does or does not accept the DSAC I classification for that dam. The IRRM plan should be developed and implemented as quickly as possible for DSAC I dams. For DSAC I dams the Dam Safety Modification study will be prioritized and scheduled at Prioritization Point P 2 and sent to the funding and resource queue. The next step is the Dam Safety Modification study and decision document process to determine the appropriate risk management measures. See Figure 9.1 for a detailed flow chart of the DSM study and report development, review and approval process. The Dam Safety Modification study report will then be reviewed and approved or returned for more studies and investigation (Decision Point D 4). If the decision is for additional study and investigation the project will be prioritized and scheduled with the other dams recommended for Dam Safety Modification studies (Prioritization Point P 2). If the decision is to approve the report, and risk reduction measures are required, the project will be prioritized for funding (Prioritization Point P 3) and moved to the resource queue to wait for funding to implement the risk reduction measures. Once the approved risk reduction measures are implemented the DSAC class will be reviewed and modified as appropriate and the IRRM plan will be reviewed and modified. This action is taken at Decision Point D1e in the flow chart. The use of approved incremental risk reduction measures may not move a dam from a DSAC I class all the way to a DSAC V.

3.3.9 DSAC Classes II and III Process. All dams placed into DSAC II and III (Decision Point 1a) will have IRRM plans developed and implemented. The IRRM plans identify the risk reduction measures that should be submitted for approval (Decision Point 2a) to the MSC Dam Safety Officer. After the IRRM plan is approved the district is to develop and submit an Issue Evaluation Study Plan for DSAC II and III dams which are prioritized and scheduled for Issue Evaluation Studies (Prioritization Point 1). Once scheduled, the individual projects are put into the funding and resource queue. After the Issue Evaluation Study is completed and based on the results of the study the DSAC is

reviewed and modified as appropriate at Decision Point 1c (D 1c). Based on the risk assessment performed during the Issue Evaluation Study a dam could be reclassified into any DSAC. If a dam is put into the DSAC I, it will then be addressed using the DSAC I Expedited Process. If a dam is in DSAC II, III, or IV it will be reviewed to determine if a Dam Safety Modification study is justified (Decision Point D 3). If the determination is that a Dam Safety Modification study is justified, then the project is prioritized and scheduled (Prioritization Point P 2) and sent to the funding and resource queue. From that point forward the process is the same as for DSAC I dams.

3.3.10 DSAC IV Process. For DSAC IV class dams an IRRM plan is not required but a decision has to be made related to heightened monitoring (Decision Point 2b). From this point forward the process is the same for a DSAC IV class dam as it is for a DSAC II or III class dam.

3.3.11 DSAC V Process. To place a dam in the DSAC V class requires a risk assessment estimate with as low as reasonably practicable (ALARP) considerations included to determine residual risk and an evaluation of compliance with all essential USACE guidelines with no unconfirmed dam safety issues. The risk assessment to determine residual risk and the evaluation of essential guideline compliance can be performed either at the time of the periodic assessment or after the approved risk reduction measures from the DSM report are implemented. The latter should just entail an evaluation of the performance of the risk reduction measures to assure that the risk reduction measures meet the prescribed performance levels and guidelines as outlined in the DSM report.

3.3.12 Baseline risk estimate. The baseline risk estimate is the risk estimate at a point in time. It may change based on changes in: a) information; b) the condition of the dam; c) factors affecting the consequences, or d) from proposed implementation of risk reduction measures. Incorporating any of these changes or a change in the scope, purpose, or decision to be made will result in a new baseline risk estimate.

3.3.12.1 Baseline risk estimates shall encompass all significant failure modes and factors affecting the consequences of failure (*e.g. exposure conditions*). Significant failure modes are a subset of credible failure modes (*i.e. physically possible*). The number of significant failure modes to be considered in a risk assessment should be judged in the context of the purpose of the risk assessment and the decisions that it will inform. The cumulative effect of multiple low risk failure modes shall be considered on the baseline risk estimate. It is important to identify and list all credible failure modes and factors affecting consequences that are not considered “significant” for a risk assessment. These failure modes may be justified as significant in a subsequent risk assessment.

3.3.12.2 Factors to consider include Dam Safety Action Classification, comparisons with tolerable risk guidelines, scoping the next level of study, portfolio roll-up of the risk estimates, the level of confidence in risk estimates, representation of uncertainty in estimates, and prioritization for next phase of work. For example credible failure mode

should be considered significant if the probability of failure and associated consequences approach closely or exceed a tolerable risk limit guideline.

3.3.12.3 Periodic Assessments (PA) and Phase 1 Issue Evaluation Study (IES) baseline risk estimates will use currently-available information for the loading functions, the determination of component and system response curves (conditional probability of failure), and development of the consequence estimate. Additional information and analysis to reduce uncertainty and increase confidence in the baseline risk estimate may be justified to support the Phase 2 IES and the Dam Safety Modification study. In all cases the baseline risk estimate should be obtained with the minimum expenditure of time and resources. The scope of the risk assessment shall be determined on the basis of the decisions to be made.

3.3.13 Issue Evaluation Studies. Issue Evaluation studies (IES) for dams classified in DSAC Classes II, III, and IV are studies to better determine the nature of the safety issue and the degree of urgency for action within the context of the full USACE inventory of dams. The intent of an Issue Evaluation Study is to perform a more robust and detailed level of risk assessment, than used in the SPRA and possibly more robust than the risk assessment used in a periodic assessment, that will enable informed decisions about the need for a Dam Safety Modification study, further investigations, the DSAC reclassification, and interim risk reduction measures implementation. However, the level of detail should only be what is needed to justify the decision to pursue or not to pursue a Dam Safety Modification study. Based on the results of previous or current investigations and an Issue Evaluation Study, a dam could be reclassified as DSAC Class I and thus warrant the expedited process for a DSAC Class I dam as shown on the left side of Figure 3.1. The report documenting the Issue Evaluation Study will have an Agency Technical Review (ATR) performed to include Dam Safety Risk Management Center representatives. The IES report presents the rationale and the justification for a Dam Safety Modification Study and changes to the IRRM plan. The IES report shows the current condition of the dam with respect to the tolerable risk guidelines. Issue Evaluation Studies are discussed in detail in Chapter 8.

3.3.14 Dam Safety Modification Studies and Decision Documentation. Dam Safety Modification Studies may require, beyond the Issue Evaluation Study, additional data gathering and detailed studies. Formulation and evaluation for a full range of risk reduction alternatives with preliminary level cost estimates will be performed at this time. A detailed risk assessment is required and will look at incremental risk reduction alternatives that together meet the tolerable risk guidelines (details in Chapter 5) and cost effectiveness of additional risk reduction below the tolerable risk limit guidelines. However, the level of detail for the risk assessment and DSM study should only be what is needed to justify the modification decision. Related NEPA and ESA studies will be conducted at this time in support of the recommended risk reduction measures. The DSM decision document presents the rationale for the alternative recommended, to include life, economic and environmental risk reduction, and other non-tangible aspects. The report will show how this alternative complies with the tolerable risk guidelines. The Dam Safety Modification decision document will present a comparison of alternatives and the recommended plan to include actions, components, risk reduction by increments,

evaluation of the risk in relation to the tolerable risk guidelines, implementation plan, detailed Risk Cost and Schedule Assessment (per ER 1110-2-1302, Civil Works Cost Engineering (reference A.53), National Environmental Policy Act (NEPA) (reference A.109), and the Endangered Species Act (ESA) determinations). This document will have an ATR performed to include Risk Management Center representatives. Dam Safety Modification Studies process, content, and the approval process are discussed in detail in Chapter 9.

3.3.15 Dams Exempt from the Dam Safety Portfolio Risk Management Process. The Corps inventory has a number of dams and associated structures that no longer serve a beneficial purpose or have been found to have insignificant or no consequences should they fail. At this time, such structures are to be tagged exceptions and are exempt from the portfolio management process. These dams will be handled in accordance with Appendix H and may be considered for decommissioning or transfer.

3.3.16 At any point in the portfolio risk management process a determination may be made that resolution of a dam safety deficiency will cost less than the major rehabilitation threshold funding cap (see annual budget guidance Engineering Circular) or the work can be accomplished in one construction season. If this is the case the district DSO should consider going directly to a major maintenance action. Such minor modifications for dam safety would be funded as major maintenance with Operations and Maintenance funds. If significant risk reduction can be made at high risk dams for amounts less than the major rehabilitation threshold funding cap districts should coordinate with the MSC and HQ dam safety program managers and the O&M appropriation program managers to determine if Operations and Maintenance funds are available.

3.4 Scope of Risk Assessments in Support of Dam Safety Evaluations. There are five specific instances of evaluations in the process- Screening Portfolio Risk Assessment (SPRA), Interim Risk Reduction Measures Plans (IRRMP), Periodic Assessments, Issue Evaluation Studies, and Dam Safety Modification Studies. The USACE Dam Safety Portfolio Risk Management process uses risk assessments in each of the five instances of evaluations. These risk assessments vary in purpose and therefore in the data required, detail and robustness of analysis, and in uncertainty and confidence in the results. Table 3.2 shows the relationships of the primary and secondary uses of the outcomes of the risk assessments with the purpose of the various studies or evaluations. However, in all cases the level of detail should only be what is needed to justify the decision(s) that will be informed by the risk assessment.

3.4.1 General Steps in Risk Assessment. The general steps of a risk assessment (listed below) are scalable to fit the purpose of the risk assessment.

3.4.1.1 Potential failure mode analysis;

3.4.1.2 Develop event trees for potential failure modes;

3.4.1.3 Develop the loading function for each failure mode carried forward in the assessment;

3.4.1.4 Determine the conditional probability of failure and system response curve for each failure mode carried forward in the assessment;

3.4.1.5 Estimate the consequences associated with each failure mode carried forward in the assessment;

3.4.1.6 Risk estimate calculations; and

3.4.1.7 Compare to the USACE tolerable risk guidelines.

3.4.2 Screening for Portfolio Risk Assessment (SPRA). This assessment screens projects to expeditiously identify the dams requiring urgent and compelling action (Dam Safety Action Classification Classes I and II Dams) with low chance of missing any such dams. Also, the SPRA is to provide information for preliminary classification of the remainder of the USACE dams into Dam Safety Action Classes III – IV. SPRA does not provide sufficient information to confirm a dam can be placed in Dam Safety Action Classification Class V. The intent is that SPRA will be performed only once for every dam in the USACE inventory. Once all dams are screened using SPRA, the SPRA DSAC rating will remain the official rating unless a more detailed assessment leads to a reclassification. The SPRA process is described in Appendix I.

3.4.3 Interim Risk Reduction Measures Plans (IRRMP). The risk assessment supporting the IRRM plan will use existing information and easily obtained consequence data. The primary purpose is to support and justify interim risk reduction measures. The risk assessment will have to be scaled depending on the significance of the dam safety issue and the impact of the interim risk reduction measures.

3.4.4 Periodic Assessments (PA). PA's will normally be conducted for all dams on a 10 year cycle, but more frequently as justified. The periodic assessment will consist of a periodic inspection, a potential failure modes analysis, and a risk assessment based on existing data and limited analyses to estimate consequences. The primary purposes of the Periodic Assessment are as follows.

3.4.4.1 Confirm or revise the DSAC classification of a project;

3.4.4.2 Justify interim risk reduction measures;

3.4.4.3 Provide initial input for quantitative risk reporting;

3.4.4.4 Identify needed issue evaluation studies;

3.4.4.5 Provide data to prioritize issue evaluation studies;

3.4.4.6 Identify operations and maintenance, monitoring, emergency action plan, training and other recurrent needs; and

3.4.4.7 Develop or update the baseline risk and confirm that essential USACE dam safety guidelines are or are not met.

3.4.5 Issue Evaluation Study. Risk assessments in support of the Issue Evaluation studies (IES) are conducted for the purposes:

3.4.5.1 Primary. Confirm that dam safety issues do or do not exist and determine if a Dam Safety Modification study is justified.

3.4.5.2 Secondary.

3.4.5.2.1 Verify or reclassify the current DSAC rating based on these findings;

3.4.5.2.2 Determine if a dam should be reclassified as DSAC I and thus warrants the expedited process for a DSAC I dam as shown on the left side of Figure 3.1;

3.4.5.2.3 Verify the adequacy of current or need for additional interim risk reduction measures;

3.4.5.2.4 Provide information to support prioritization of Dam Safety Modification studies; and

3.4.5.2.5 Develop or update the baseline risk estimate.

3.4.5.3 The methodology of this risk assessment/study must be more rigorous than the SPRA methodology. The IES risk assessment is intended to achieve a defensible, risk informed justification for initiating Dam Safety Modification studies with the minimal expenditure of time and resources. This risk assessment will use the USACE dam safety risk assessment and evaluation tools.

3.4.6 Dam Safety Modification Study. The risk assessment supporting the Dam Safety Modification study leads to definitive decisions and documentation to justify dam safety actions to achieve reduction in life, economic, and environmental risk. Additional data will be gathered as justified by the decision to be made. The Dam Safety Modification study will use the USACE dam safety risk assessment and evaluation tools which provide results of increased robustness of and confidence in the risk assessment over the Issue Evaluation Study due to an increase in the level of confidence in the input data used in the study. The primary purposes of the Dam Safety Modification study are the determination or update of the baseline risk estimate; identification, evaluation, justification, and recommendation of long-term risk reduction remedial measures; and the estimation of the residual risk of the remediated project. The risk assessment shall be updated after implementation of the risk reduction remedial measures and evaluated to determine if the risk reduction objectives were achieved.

3.5 Risk Reporting and Data Management. The following will be tracked and reported on per guidance in Appendix G using the Dam Safety Program Management Tools (DSPMT).

3.5.1 SPRA ratings and findings,

3.5.2 Current DSAC Classification,

3.5.3 Listing of dam safety issues,

3.5.4 Residual risk of current conditions and confidence of the risk estimate (range of risk),

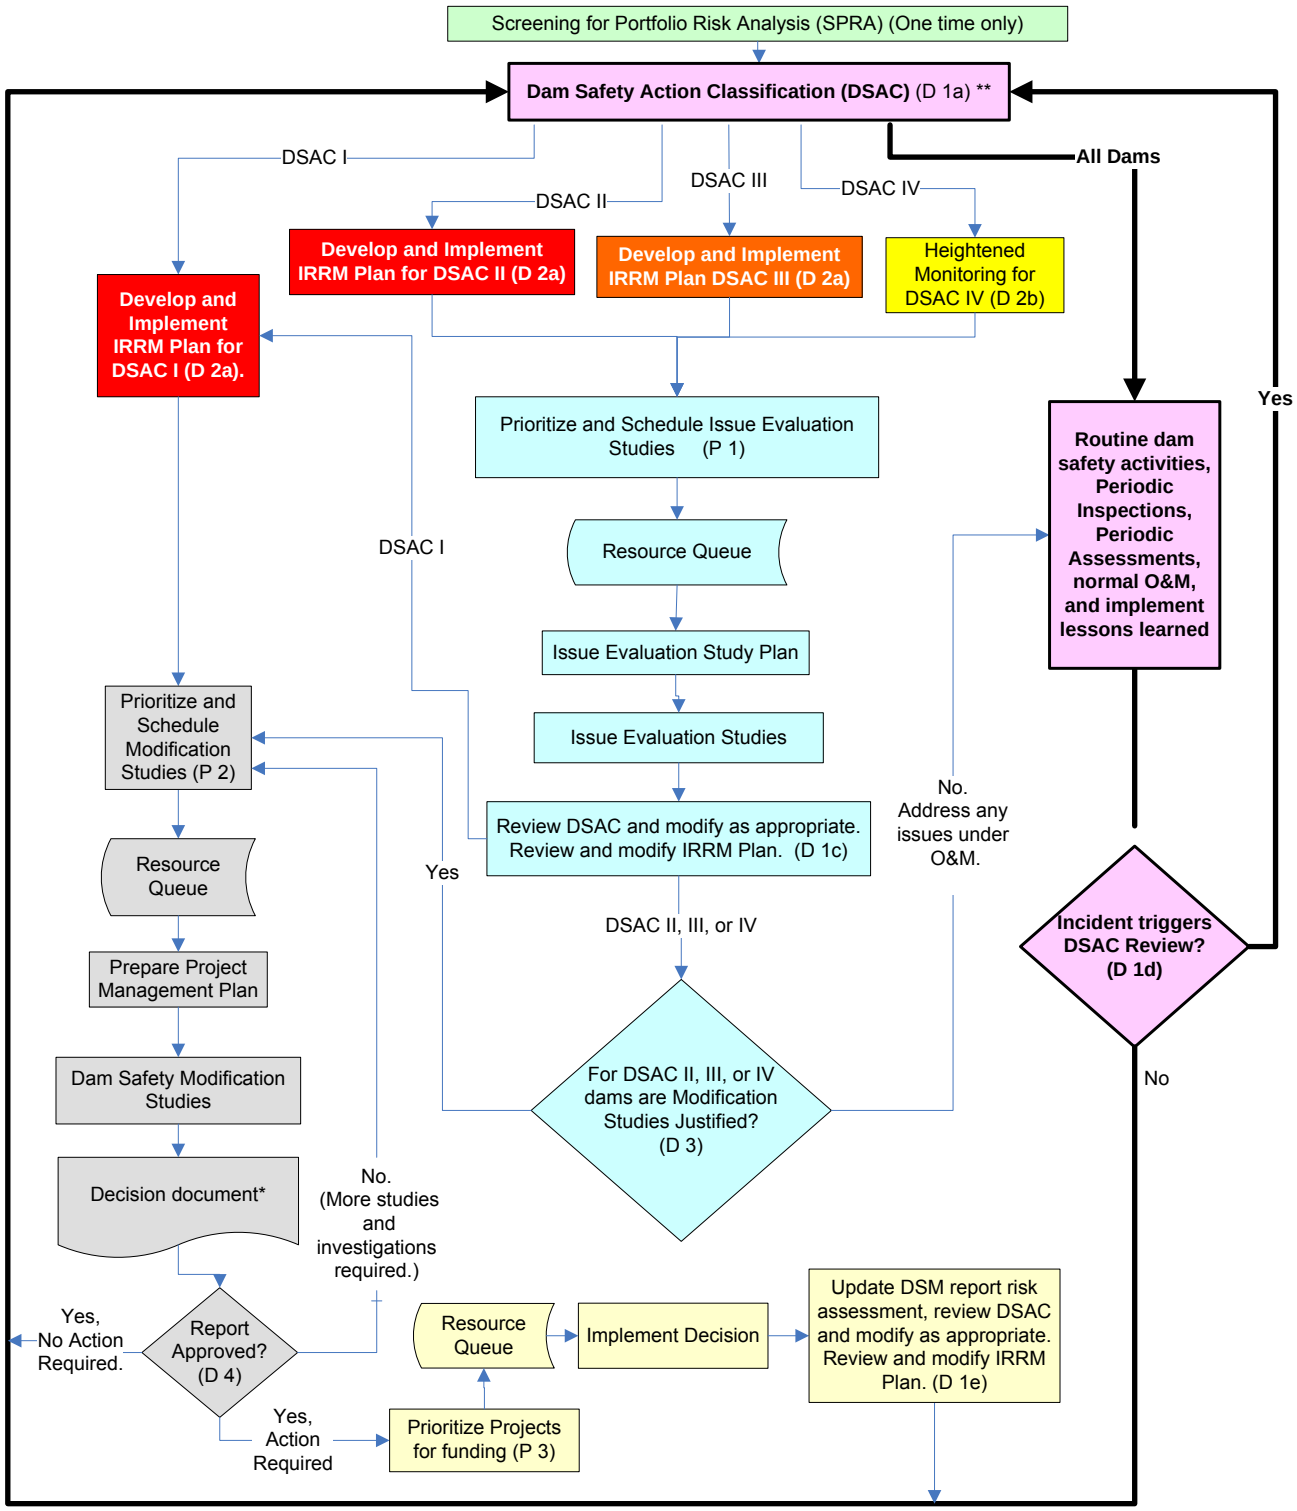
3.5.5 Previous reports and summary of recommendations,

3.5.6 Current IRRM,

3.5.7 Findings of the most recent Potential Failure Mode Analysis,

3.5.8 Findings of last PA and PI,

3.5.9 Results of the essential agency guidelines (Appendix E) evaluation,



3.5.10 Consequences - list estimated consequences related to the identified potential failure modes,

3.5.11 Issue Evaluation Study results, recommendations and final decisions, and

3.5.12 Dam Safety Modification study results, recommendation, and final decisions.

3.6 Water Storage and Risk Reduction Measures. Dam safety must be on the critical path of all decisions regarding water supply storage in USACE reservoirs. When water supply is requested by non-Federal customers, USACE decision makers at all levels must fully consider the condition of the dam, DSAC of the dam, associated risks, and their impacts on inspection, operation and maintenance of the project. While public safety is paramount, the benefits of providing safe and reliable water supply storage to non-Federal customers also must be considered. A reallocation that would require raising the conservation pool is not permitted while a project is classified DSAC I, II, or III. (See EC 1165-2-210 for further guidance, Reference A.6)

Figure 3.1 -- Corps of Engineers Dam Safety Portfolio Risk Management Process

Decision Points are label as (D 1a), Prioritization Points are labeled as (P 1), and the details for each point is explained in Chapter 3.
*** Independent External Peer Review requirements are to be addressed per guidance in the Dam Safety Modification chapter.**
**** Regardless of DSAC classification, dams with insignificant or no consequences should they fail are considered exceptions; will be so tagged, and are exempt from the dam safety portfolio management process depicted here in Figure 3.1.**

Table 3.1 – USACE Dam Safety Action Classification Table*			
Dam Safety Action Class		**Characteristics of this class**	**Actions for dams in this class**
I **URGENT AND COMPELLING** (Unsafe)		**CRITICALLY NEAR FAILURE** Progression toward failure is confirmed to be taking place under normal operations. Almost certain to fail under normal operations from immediately to within a few years without intervention. **OR EXTREMELY HIGH RISK** Combination of life or economic consequences with probability of failure is extremely high.	Take immediate action to avoid failure. Implement interim risk reduction measures, including operational restrictions, ensure that emergency action plan is current, and functionally tested for initiating event. Conduct heightened monitoring and evaluation. Expedite investigations to support justification for remediation using all resources and funding necessary. Initiate intensive management and situation reports.
II **URGENT** (Unsafe or Potentially Unsafe)		**FAILURE INITIATION FORESEEN** For confirmed (unsafe) and unconfirmed (potentially unsafe) dam safety issues, failure could begin during normal operations or be initiated as the consequence of an event. The likelihood of failure from one of these occurrences, prior to remediation, is too high to assure public safety. **OR VERY HIGH RISK** The combination of life or economic consequences with probability of failure is very high.	Implement interim risk reduction measures, including operational restrictions as justified, and ensure that emergency action plan is current, and functionally tested for initiating event. Conduct heightened monitoring and evaluation. Expedite confirmation of classification. Give very high priority for investigations to support justification for remediation.
III **HIGH PRIORITY** (Conditionally Unsafe)		**SIGNIFICANTLY INADEQUATE OR MODERATE TO HIGH RISK** For confirmed and unconfirmed dam safety issues, the combination of life, economic, or environmental consequences with probability of failure is moderate to high.	Implement interim risk reduction measures, including operational restrictions as justified, ensure that emergency action plan is current, and functionally tested for initiating event. Conduct heightened monitoring and evaluation. Prioritize for investigations to support justification for remediation considering consequences and other factors.
IV **PRIORITY** (Marginally Safe)		**INADEQUATE WITH LOW RISK** For confirmed and unconfirmed dam safety issues, the combination of life, economic, or environmental consequences with probability of failure is low and may not meet all essential USACE guidelines.	Conduct elevated monitoring and evaluation. Give normal priority to investigations to validate classification, but no plan for risk reduction measures at this time.
V **NORMAL** (Adequately Safe)		**ADEQUATELY SAFE** Dam is considered adequately safe, meeting all essential USACE guidelines with no unconfirmed dam safety issues, **AND RESIDUAL RISK IS CONSIDERED TOLERABLE**.	Continue routine dam safety activities, normal operation, and maintenance.

* At any time for specific events a dam, from any action class, can become an emergency requiring activation of the emergency plan

Table 3.2 – Primary and Secondary Use of Risk Assessment Outcomes

Use of the Outcomes from Risk Assessment	Screening	Interim Risk Reduction Measures	Periodic Assessment	Issue Evaluation Study	Modification Study
Identify DSAC I & II with low chance of missing any such dams	P				
Preliminary classification of DSAC III - IV	P				
IRRM Decisions including justification		P	s	s	s
DSAC Confirmation or Reclassification			P	s	s
Initial Portfolio Input for quantitative risk reporting			P	s	s
Portfolio Update			P	s	s
Identify all potential failure modes		s	P	s	P
Develop baseline risk estimate			P	s	P

CHAPTER 4

Management of Corps of Engineers Dam Safety Program

4.1 General. The Corps of Engineers maintains a three-level decentralized organization, HQUSACE, MSC (Regional) and district. Each level shall be staffed with qualified personnel in areas of design, construction, inspection and operations of dams and appurtenant structures, with appropriate training and experience in dam safety risk assessment, risk management, and risk communications. Each organizational level shall have a Dam Safety Officer (DSO) with supporting organization as outlined in this chapter. The Corps of Engineers utilizes risk-informed procedures to aid in the prioritization of dam safety deficiency corrections on a nation-wide basis with budgeting for dam safety studies and modifications managed at the HQUSACE level. National oversight is furnished by the Dam Safety Steering Committee and the Senior Oversight Group, which are further described herein. Prioritization of all risk assessments, studies and remediation are managed on behalf of HQUSACE by the Risk Management Center (RMC) with oversight by the Senior Oversight Group and Special Assistant for Dam Safety. Routine day-to-day operation, maintenance and safety evaluations of dams shall remain the primary responsibility of the district command. Periodic assessments of dams are accomplished with assistance from regional and national risk and reliability cadres and the RMC.

4.2 Overall Responsibility for Dam Safety Program. The Commanders at each level of the Corps of Engineers have the ultimate responsibility for dam safety within their commands. Each District Commander having responsibility for dams shall ensure that the organization has a dam safety program which complies with Corps of Engineers policy and criteria, assuring compliance with the “Federal Guidelines for Dam Safety” (reference A.71). Commanders exercise this responsibility through officially designated Dam Safety Officers at each level. Although the DSO is located in the technical element of each organizational level, dam safety crosses all business lines and office elements, and the DSO must coordinate dam safety issues and activities with the leaders of those business lines and office elements as they manage the dam safety activities in their areas of responsibility. This includes coordination between the district office and the project field offices (that serve as the first line of defense for dam safety) concerning such issues as emergency action plans, dam safety training, and control of project documentation (discussed in subsequent chapters as well as ER 1130-2-530 (reference A.63)).

4.2.1 For the Corps of Engineers Dam Safety program to be fully successful, it is imperative that technically and managerially qualified personnel who are passionate advocates of dam safety be in place at every key level of the organization. This is even more vital for a Dam Safety Officer because of the implications that their decisions can have on life safety. Their decision-making must be based solely on the best technical approach which protects life and property and cannot be clouded by political considerations. Technical capability/experience alone, while vitally important, does not assure that a person is qualified to function as a Dam Safety Officer. That person must

also possess the desire to be an advocate for the program, possess excellent communications skills, and be capable of sound decision-making under pressure. If any of these is lacking, then the person is not fully qualified even if they are extremely qualified technically.

4.2.2 For these reasons, all leaders who appoint Dam Safety Officers at the HQ, MSC, and District shall thoroughly review and verify the qualifications and suitability for a person to function in this key role. Paragraph 4.7 provides the procedures for selecting and appointing a DSO.

4.2.3 If the highest ranking technical individual in the command lacks a particular skill set (or needs additional development in an area) in order to meet the DSO qualifications, it is the responsibility of the leader with appointment responsibilities to put a developmental plan in place which will assure the full skill set is achieved within a reasonable (12 to 18 months) time frame. This developmental plan might include formal training coursework, conferences, mentor relationships with other Dam Safety Officers, and short-term assignments in districts where key dam safety decisions are being made.

4.3 Headquarters, US Army Corps of Engineers.

4.3.1 Organization. The Corps of Engineers Dam Safety Officer (DSO) is appointed by the Chief of Engineers based upon qualifications and is typically the Senior Executive Service (SES) member in charge of the Engineering and Construction Community of Practice. A Special Assistant for Dam Safety and the Corps Dam Safety Program Manager support the Corps DSO. The Corps of Engineers Dam Safety Steering Committee (DSSC) and the HQUSACE Dam Safety Committee provide additional advice and support to the Corps DSO concerning the program. The Corps Dam Safety Committee includes the Senior Oversight Group (SOG), Corps DSO, the National Inventory of Dams (NID) Program Manager, and other members with extensive knowledge and expertise in the programming, planning, design, construction, operations, and maintenance of dams. Other individuals from the various communities of practice within the Corps of Engineers may be included as members of the committee.

4.3.2 Responsibilities and Qualifications. The roles, responsibilities, and qualifications presented below are based on “Dam Safety Officer Roles, Responsibilities, Qualifications, and Professional Registration Requirements” (reference A.79).

4.3.2.1 Corps of Engineers Dam Safety Officer: The Corps (DSO) shall be a registered professional engineer with civil engineering background and with management abilities and be competent in the areas related to the design, construction, operation, maintenance, inspection or evaluation of dams and understand adverse dam incidents and the potential causes and consequences of dam failure. As Corps DSO, this individual is responsible directly to the Chief of Engineers for all dam safety

activities and shall be appointed by written order of the Chief of Engineers. The Corps DSO coordinates dam safety activities with the various elements of the Directorate of Civil Works and informs the Director concerning the condition of Corps dams. The Corps DSO is responsible for ensuring that the Corps of Engineers maintains a proactive dam safety program, implementing all practices and procedures outlined in the "Federal Guidelines for Dam Safety" (reference A.71). The Corps DSO is responsible for establishing policy and technical criteria for dam safety, and prioritizing dam safety related work. The Corps DSO or designated representative(s) shall represent the Department of Defense on the National Dam Safety Review Board (NDSRB) and Interagency Committee on Dam Safety (ICODS). The Corps DSO ensures that programs to implement dam safety needs and to monitor the activities at the various levels of the Corps are established. The Corps DSO serves as chair of the Corps Dam Safety Committee. The Corps DSO shall assess the Corps dam safety activities utilizing the best available techniques and programs, and periodically report to the Director of Civil Works and Chief of Engineers.

4.3.2.2 Special Assistant for Dam and Levee Safety. The Special Assistant acts for the Corps DSO in the execution of daily program activities and serves as Chairman of the Corps of Engineers DSSC and the SOG. The Special Assistant shall be a registered professional engineer with civil engineering background and with management abilities, be competent in the areas related to the design, construction, operation, maintenance, inspection or evaluation of dams and understand adverse dam incidents and the potential causes and consequences of dam failure. The Special Assistant works for and reports directly to the Corps DSO. The director of the RMC shall report directly to the Special Assistant. The Special Assistant represents the Corps DSO in the development of the budget submission, working with the appropriate Business Line Managers to ensure that dam safety priorities are addressed. The Special Assistant serves as the Department of Defense and/or Corps of Engineers representative on various national teams as directed by the Corps DSO.

4.3.2.3 Corps Dam Safety Program Manager. The Corps Dam Safety Program Manager (DSPM) shall be a registered professional engineer with civil engineering background (or registered professional geologist as described in paragraph 4.6) and with management abilities and have knowledge and experience in the design, construction, operation, maintenance, inspection, or evaluation of dams. The DSPM conducts the daily activities of the overall dam safety program. The DSPM coordinates the HQ review of dam safety reports and prepares Corps-wide dam safety budget submissions in coordination with the DSSC and the RMC, and works in close coordination with the Special Assistant for Dam Safety. The DSPM serves as the Department of Defense and/or Corps of Engineers representative on various national teams as directed by the Corps DSO or the Special Assistant. The Corps DSPM shall maintain an updated membership list of the Corps Dam Safety Committee, the Corps of Engineers DSSC, the SOG, and all USACE DSOs and DSPMs.

4.3.2.4 Risk Management Center: The Corps of Engineers is currently transitioning to risk-informed dam safety program management to more effectively evaluate, prioritize

and justify dam safety decision making. In order to realize the full benefits of risk-informed program management, the RMC has been established to provide technical expertise and advisory services to assist in managing and facilitating the USACE-wide dam safety program. The RMC is a support organization, partially project funded, and located within the Institute of Water Resources (IWR). The director of the RMC reports through the IWR Director to the Director of Civil Works. The RMC has close ties to the Chief of Engineering and Construction and to the Special Assistant for Dam Safety. The RMC assists the Special Assistant in implementation of dam safety policy using a combination of centralized staff as well as other national, regional, and district resources.

4.3.2.4.1 The RMC Director shall be a registered professional engineer with civil engineering background and with management abilities, be competent in the areas related to the design, construction, or evaluation of dams and understand adverse dam incidents and the potential causes and consequences of dam failure. The director shall have knowledge of risk management concepts and implementation.

4.3.2.4.2 Specific functions performed by the RMC in support of HQUSACE dam safety program management:

4.3.2.4.2.1 Maintains the 10-year plan for Periodic Assessments and Inspections of dams and pertinent structures in coordination with the MSC DSPM's.

4.3.2.4.2.2 Manages the resource queues (see the Dam Safety Portfolio Risk Management Process Chart, figure 3.1).

4.3.2.4.2.3 Supports the Agency Technical Review (ATR) and Independent External Peer Review (IEPR) (EC 1165-2-209) (Reference A.5) process, as applicable, for Dam Safety Modification Reports. The RMC shall be the Review Management Organization (RMO) for Dam Safety Modification Reports and perform the RMO functions required in EC 1165-2-209 (reference A.5). The RMC may be consulted for the names of qualified individuals who have worked with the national risk cadres and are experienced in the needed area to serve on ATR teams. The RMC shall manage the IEPR process for all dam safety modification reports.

4.3.2.4.2.4 Supports the Corps DSPM in the development of annual budget requests. The RMC communicates directly with districts and MSCs on program planning, priorities, funding and implementation. It provides workload input/commitments to resource providers regarding the future year program.

4.3.2.4.2.5 Plans and evaluates dam safety-related risk activities for all phases of the life-cycle of a project.

4.3.2.4.2.6 Manages the documentation, maintenance and publication of the Corps Dam Safety Portfolio Risk Rankings and DSAC.

4.3.2.4.2.7 Integrates dam safety portfolio risk management activities with other asset management activities.

4.3.2.4.2.8 Represents Dam Safety on the Civil Works Research and Development team.

4.3.2.4.2.9 Maintains dam safety standard engineering technology (SET) programs, and automated information systems (AIS) to include reviewing usage by various districts of the programs within SET. Reviews requests for additions to and deletions from SET and makes recommendations to the SOG.

4.3.2.4.2.10 Performs metrics roll up and interpretation of Corps-wide Dam Safety Program Performance Measures (DSPPM) and the dam safety scorecard (Appendix G) using Dam Safety Program Management Tools (DSPMT) and other dam safety AIS tools.

4.3.2.4.2.11 Assists DOD member participation on the National Dam Safety Review Board (NDSRB) and the Interagency Committee on Dam Safety (ICODS), including nominating individuals for various tasks and work groups.

4.3.2.4.2.12 Provides an individual to participate as a member of the Senior Oversight Group, Dam Safety Steering Committee, and other Ad Hoc Groups as deemed necessary.

4.3.2.4.2.13 Manages national level external peer review panels and their reports for DSAC I dams.

4.3.2.4.2.14 Coordinates special Working Groups in the Risk Management Center such as the Methodology (interim) and Policy and Procedures Work Groups (interim). It coordinates the work between RMC and Regional Cadres to include scheduling and budgeting. Other activities include assisting Dam Safety policy development and guiding Dam Safety Risk and Reliability Training Management with RA and RA facilitation. Maintains updated membership list of the cadres and other national teams.

4.3.2.5 Dam Safety Steering Committee (DSSC). The DSSC is a committee charged with facilitating and promoting dam safety as a fundamental USACE mission in all levels of the organization, promoting dam safety career development, disseminating pertinent information throughout the Corps, and reviewing and evaluating policy, technical criteria and practices, administrative procedures, and regulatory functions to support the dam safety program. The DSSC shall also review experience and qualifications of dam safety staffing at all levels within the Corps to assess competency, review MSC funding requirements for achieving program requirements, and make recommendations for future research and development in areas related to dam safety. The team shall meet as required, and shall provide advice and information to the Special Assistant for Dam and Levee Safety.

4.3.2.5.1 The DSSC shall be composed of the following members: Special Assistant for Dam Safety (Lead), Corps DSPM, one member each from HQUSACE Operations, Planning, and Program Integration Division (the Corps Operations, Planning, and Program Integration Division Chiefs may designate individuals from one of the MSCs to represent their community of practice in lieu of a member of their staff), each MSC DSPM, one ERDC individual appointed by the ERDC Director, a representative from the RMC, and four (4) district representatives with experience in the safety of dams who shall be nominated by the DSSC as at-large members with final selection by the Corps DSO. At least one of the district representatives shall be from an operating element, one should be a DSPM and one should be a DSO. Public Affairs Office (PAO), Emergency Management, and Homeland Security Office representatives should be invited to the DSSC meetings. Additional information on the DSSC is provided in Appendix J.

4.3.2.6 The Senior Oversight Group (SOG) generally consists of the following members: Special Assistant for Dam Safety (Chair); CoP & Regional Representatives to include Geotechnical and Materials CoP Leader, Structural CoP Leader, Hydraulics and Hydrologic CoP Leader, Planning CoP Leader, and Construction CoP Leader; Regional representatives determined by Special Assistant for Dam Safety; Corps Business Line & Program Representatives to include DSPM, Flood Damage Reduction, Navigation, Programs, and Director, Risk Management Center; and any other Representatives determined by the Special Assistant for Dam Safety. A current list of members and charter will be posted on the USACE Technical Excellence Network (TEN). The Corps Dam Safety Program Manager shall serve as recording secretary. The SOG shall elect a Vice Chair.

4.3.2.6.1 The SOG will review Dam Safety Action Classifications (DSAC), dam safety risk assessment reports prepared by the RA cadres and other decision documents, confirm dam safety work priorities based on portfolio risk findings, and make recommendations on dam safety modifications to the Special Assistant for Dam Safety and the Corps DSO.

4.3.2.6.2 The Special Assistant may assign additional ad hoc members to act as reviewers for the SOG for any decision documents as required. These ad hoc members will meet as necessary to accomplish these reviews in a timely fashion to prevent delays in the execution of risk reduction measures.

4.3.2.7 The Modeling, Mapping, and Consequences (MMC) Production Center supports both the USACE Dam Safety and Critical Infrastructure Protection & Resilience (CIPR) Programs. In support of HQUSACE management of the dam safety program, the MMC performs hydraulic modeling, mapping, and consequences analysis for USACE dams in support of the Dam Safety and CIPR programs. The MMC is led by a district with a core staff that is supplemented by a virtual staff of Hydraulic Engineers, Economist, and GIS professionals from across USACE. The MMC leverages H&H modeling, consequences analysis, and GIS mapping capabilities/resources via close coordination with USACE RMC to accomplish national mapping, hydraulic analysis, and

consequences requirements for the Dam Safety and CIPR Programs. The following are the major initiatives for the MMC: Develop consistent and scalable hydraulic models and consequence data for USACE dams, develop consistent mapping for Emergency Action Plans (EAP), and develop standards for GIS, consequence Analysis, and, modeling and mapping. The MMC is located within the Vicksburg District supplemented by a USACE wide virtual staff. The MMC Program Manager receives guidance from the MMC Steering Committee.

4.3.2.7.1 The Modeling, Mapping, and Consequence Production Center (MMC) Steering Committee is charged with providing oversight and guidance to the MMC program manager. The committee reviews and interprets policy, technical criteria and best practices, administrative procedures, and performs other functions as required to support the MMC mission. The committee shall also review experience and qualifications to assess agency competency in the areas of dam failure modeling, inundation mapping, and consequence estimating. The committee shall provide input to the scope, cost, schedule, and priority of MMC activities including an overall review of resource requirements. The committee shall meet as required and shall provide advice and information to the Risk Management Center Director.

4.3.2.7.2 As a minimum, the MMC steering committee shall be composed of the following members: Special Assistant for Dam Safety, HH&C CoP Lead, Planning CoP Lead, GIS CoP Lead, CIPR program manager, RMC Director (committee chair), and MMC program manager. Committee members may delegate membership to individuals within their organization or CoP in accordance with the committee charter.

4.4 Major Subordinate Commands (MSC) (Regional Headquarters).

4.4.1 Organization and Qualifications. The roles, responsibilities, and qualifications presented below are based on “Dam Safety Officer Roles, Responsibilities, Qualifications, and Professional Registration Requirements” (reference A.79).

4.4.1.1 MSC Dam Safety Officer (DSO). The MSC DSO shall be a registered professional engineer with civil engineering background and with management abilities and be competent in the areas related to the design, construction, operation, maintenance, inspection, or evaluation of dams and understand adverse dam incidents and the potential causes and consequences of dam failure. The MSC DSO should be the SES or MSC technical lead who is responsible for the engineering elements of the organization. The Commander shall ensure the DSO meets the technical qualifications and experience. The MSC DSO shall be appointed by written order of the MSC Commander following the process identified in paragraph 4.7. A copy of the appointment order for each DSO shall be forwarded to the Corps DSO. The DSO shall serve as the Chair of the MSC Dam Safety Committee.

4.4.1.2 MSC Dam Safety Committee. The MSC Dam Safety Committee shall include the DSO and DSPM plus additional members as required. The members should include the various technical engineering disciplines as well as Operations,

Water Management, and Programs from within the MSC headquarters. Other disciplines and areas of expertise, e.g., Security, Public Affairs, Construction, Emergency Management, Planning, and Office of Counsel, may be represented, as required by the DSO or Commander. The MSC Dam Safety Committee should meet at least annually and preferably twice a year.

4.4.1.3 MSC Dam Safety Program Manager. The MSC Dam Safety Program Manager shall be appointed by the MSC DSO. The DSPM shall be a registered professional engineer with civil engineering background (or registered professional geologist as described in paragraph 4.6) and with management abilities and be competent in the areas of design, construction, operation, maintenance, inspection or evaluation of dams. The DSPM conducts the daily activities for the MSC dam safety program, coordinates the review of dam safety reports, and provides support to districts within the MSC.. The DSPM works with the programs budget managers to ensure that dam safety requirements are included and properly prioritized in budget submissions. The DSPM serves on various national teams as requested by the Corps DSO and on the DSSC. The DSPM shall maintain an updated membership list of the MSC Dam Safety Committee. The MSC DSPM shall report directly to the MSC DSO on dam safety matters.

4.4.2 Responsibilities. The MSC DSO is responsible for quality assurance, coordination, and implementation of the MSC dam safety program. In this capacity the MSC DSO must establish procedures to ensure that the MSC DSO is fully advised on all dam safety issues. Quality assurance responsibilities include:

4.4.2.1 Ensuring that the organization is staffed with qualified personnel for program implementation and to meet program requirements.

4.4.2.2 Establishing dam safety related work priorities and ensuring that these priorities are addressed during budget development.

4.4.2.3 Ensuring that an appropriate technical review is conducted of the inspection, evaluation, and design for all features of dam safety projects.

4.4.2.4 Ensuring, in technically complex cases, that the project development team includes members from the MSC and RMC starting early in the process to ensure that the analytical methods and processes used by the district comply with policy and criteria.

4.4.2.5 Ensuring that adequate performance monitoring and evaluations of all dams are conducted and documented. Participating in periodic inspections and field visits to ensure that the district programs are conducted in accordance with the district quality control plans and requirements of this regulation. Reviewing and approving periodic inspection reports in accordance with Chapter 11 of this regulation.

4.4.2.6 Ensuring that Emergency Action Plans are maintained and regularly updated.

4.4.2.7 Ensure districts establish and execute a public awareness program and coordinate with State and local agencies as required.

4.4.2.8 Ensuring that adequate dam safety training and dam safety exercises are being conducted.

4.4.2.9 Monitoring the accuracy of data that are submitted for the inventory of Corps dams and DSPMT.

4.4.2.10 Monitoring and participating in district dam safety exercises.

4.4.2.11 Conducting quality assurance activities for all features of civil works dam projects, including review of district dam safety related plans.

4.4.2.12 Perform reviews and approve Interim Risk Reduction Measures Plans and related decision documents and coordinate results with HQ and the SOG for consistency.

4.4.2.13 Monitoring the performance of district dam safety programs including DSPMT, upward reporting, and submitting data to HQ for NID and biennial reports to Congress.

4.4.3 Coordination with District Commands. District DSOs and DSPMs should be invited to MSC Dam Safety Committee meetings for interaction on regional dam safety issues. The MSC Dam Safety Committee should periodically meet at a district or project location. A representative from the MSC Dam Safety Committee should participate in district Dam Safety Committee meetings whenever possible.

4.5 District Commands.

4.5.1 Organization and Qualifications. The roles, responsibilities, and qualifications presented below are based on “Dam Safety Officer Roles, Responsibilities, Qualifications, and Professional Registration Requirements” (reference A.79).

4.5.1.1 District Dam Safety Officer (DSO). The District Dam Safety Officer (DSO) shall be a registered professional engineer with civil engineering background and with management abilities and be competent in the areas related to the design, construction, operation,, maintenance, inspection or evaluation of dams and understand adverse dam incidents and the potential causes and consequences of dam failure. The District DSO shall generally be the chief of the engineering organization. The Commander shall ensure the DSO meets the technical qualifications and experience. The District DSO shall be appointed by written order of the District Commander after completion of the process outlined in paragraph 4.7. A copy of the appointment order for each DSO shall

be forwarded to the Corps DSO and the MSC DSO. The DSO shall serve as the Chair of the District Dam Safety Committee.

4.5.1.2 District Dam Safety Committee. The District Dam Safety Committee shall include the DSO and DSPM plus additional members as required. The members should include the various technical engineering disciplines as well as Operations, Water Management, and Programs. Other disciplines and areas of expertise, e.g., Security, Public Affairs, Construction, Emergency Management, Planning, and Office of Counsel, may be represented, as required by the DSO or Commander. The District Dam Safety Committee should meet at least twice a year.

4.5.1.3 District Dam Safety Program Manager (DSPM). The District Dam Safety Program Manager (DSPM) shall be appointed in writing by the District DSO. The DSPM shall be a registered professional engineer with civil engineering background (or registered professional geologist as described in paragraph 4.6) and with management abilities and be competent in the areas of design, construction, operation, maintenance, inspection or evaluation of dams. The DSPM conducts the daily activities for the District dam safety program and coordinates the review of dam safety reports. The DSPM works with the programs budget managers to ensure that dam safety requirements are included and properly prioritized in budget submissions. The DSPM shall maintain an updated membership list of the District Dam Safety Committee. The District DSPM shall report directly to the District DSO on dam safety matters.

4.5.2 Responsibilities. The District DSO is responsible for ensuring that the dam safety program is fully implemented and documented, in accordance with the District Dam Safety Program Management Plan. The Dam Safety Committee, advisory to the DSO, should meet at least twice annually and forward meeting minutes electronically to the MSC. The districts shall notify the MSC DSPM of the date and time of upcoming committee meetings and invite the MSC to send representative(s) to the meeting. District DSO responsibilities include, but are not limited to:

4.5.2.1 Ensuring that organizational staff of qualified technical and field personnel is sufficient for program implementation.

4.5.2.2 Monitoring and evaluating the performance of all dams and appurtenant structures and recommending remedial measures when necessary. Collecting data for the NID and biennial reports to Congress. Monitoring and reporting dam safety items using the Dam Safety Program Management Tools (DSPMT). A description of the DSPMT database is given in Appendix G.

4.5.2.3 Establishing priorities for dam safety related work. The DSO, as a member of the district Corporate Board, shall defend the list of dam safety work priority items. Dam safety work items are any work items impacting the safety, operation, and structural integrity of the project. The DSPMT can be used to track priorities over time.

4.5.2.4 Ensuring that dam safety training of technical staff and project operation and maintenance personnel is conducted.

4.5.2.5 Ensuring each dam has an adequate surveillance plan, and updated and fully implemented IRRMP if applicable.

4.5.2.6 Ensuring adequate and appropriate independent technical reviews for inspection, evaluation, and design for dams and appurtenant structures are accomplished. The District DSO shall certify that all design documents and periodic inspection reports have been subjected to district quality control (DQC) reviews and that the documents and reports are technically adequate.

4.5.2.7 Ensuring that adequate exploration and testing are accomplished during design and construction of civil works water control projects.

4.5.2.8 Performing periodic assessments and inspections, other supplemental inspections, and field visits. Periodically evaluating the district dams, appurtenant structures, and other water control projects using current criteria.

4.5.2.9 Coordinating and participating with local and State dam safety officials in the inspection and evaluation of non-Federal dams, upon request.

4.5.2.10 Ensuring that dam safety products are developed in accordance with documented district Project Management Business Processes as outlined in ER 5-1-11 (reference A-35) and ER 1110-2-1150 (reference A-51). A Project Delivery Team (PDT) consists of a project manager and personnel from engineering, planning, operations, public affairs office, and others necessary to develop the project. When more than one individual from the engineering organization is on the PDT, the technical chief shall designate a "lead engineer". While not necessarily appropriate for later phases of a project when the administrative requirements significantly increase, the lead engineer should be strongly considered for assignment as the project manager during the Issue Evaluation Study phase. The lead engineer may change as the project moves through the different phases of development, however continuity is important and changes should only be made after careful consideration. Because of the complexity and life safety implications of dam safety projects it is vitally important that the district DSO ensures that qualified registered professional engineer or engineering geologist are assigned as the lead engineer. In addition, they shall also ensure that the assigned project manager possesses adequate understanding of the dam safety business prior to their assignment to the project. Communication within the PDT can be particularly challenging as it routinely involves internal district coordination as well as coordination with several vertical elements (MSC, HQ, RMC, etc…). For this reason both positions require a solid combination of technical and communication skills.

4.5.2.11 Monitoring the dam safety aspects of the district’s Water Control Management Program.

4.5.2.12 Monitoring and reporting any evidence of operational restrictions or distress, including earthquake effects, of dams and appurtenant structures.

4.5.2.13 Ensuring that each dam owned by the district has an up-to-date Emergency Action Plan in accordance with Chapter 16 of this ER. Maintaining emergency notification procedures for utilization in a dam safety emergency situation and for use during dam safety exercises. Ensuring that annual coordination and review is accomplished, including review of emergency notification procedures. Emergency Action Plans should be distributed to and coordinated with all affected local agencies to use as a basis for preparing their evacuation plans. Ensuring emergency exercises are conducted.

4.5.2.14 Establishing dam safety public awareness programs and coordinating them with local interests.

4.5.2.15 Maintaining awareness of security related activities, issues, and initiatives at dams and related structures. Ensuring that the security program and the dam safety program activities and initiatives are coordinated.

4.5.2.16 Monitoring ongoing planning, design, and construction of project modifications for dam safety for adequate funding, and ensuring that they are executed in accordance with applicable regulations.

4.5.2.17 Coordinating with local and State dam safety officials concerning their review requirements for projects initiating the design phase.

4.5.2.18 Reviewing proposed design changes to district water control projects under construction and providing dam safety input at design change meetings.

4.5.2.19 Ensuring that the district has an up-to-date Dam Safety Program Management Plan.

4.5.2.20 Ensuring that each dam safety related report or design has a Quality Control Plan and that the final product is certified with a Quality Control Certificate upon completion.

4.5.2.21 Developing, reviewing and approving IRRMP as described in Chapter 7.

4.5.2.22 Ensure structural and operational modifications to Corps-owned dam projects do not diminish factors of safety or limit the ability to make flood releases.

4.6 Professional Registration. Dam Safety Officers, Dam Safety Program Managers, and various other positions providing final approval of engineering products and services to ensure the protection of life, property and the environment, are required by ER 690-1-1212 (reference A.41) to be registered professionally. It is intended and desirable that the DSPM at every level be a registered professional engineer with civil

engineering background; however, the DSO may approve the selection of a highly qualified registered professional geologist as the DSPM when filling the position. Persons holding a Dam Safety Program Manager position without appropriate professional registration at the time this regulation takes effect may continue in the position until they move to another position or retire.

4.7 Dam Safety Officer Selection Process. An individual being considered for appointment as a DSO must meet the qualifications listed in paragraph 4.3.2.1, 4.4.1.1, or 4.5.1.1. The individual should generally be the highest qualified person in the technical chain meeting the qualifications.

4.7.1 Process for District Dam Safety Officer. The District Commander should forward the name and qualifications of the individual that is being considered for the District DSO to the MSC DSO for review and comments. The individual should be in a position not lower than a branch chief within the engineering organization.

4.7.1.1 The MSC DSO will review the recommendation, request comments from the other District DSOs within the region, consolidate comments, and furnish a recommendation to the District Commander.

4.7.1.2 If no one at the District level is qualified, the District Commander and the MSC DSO will coordinate the assignment of the DSO duties to another District DSO on an interim basis.

4.7.1.3 The District Commander shall develop a plan for filling position at the District level in accordance with paragraph 4.2.3. This plan could include training, mentoring, or recruitment from outside the district. Progress on this plan will be reported to the MSC DSO at least twice annually.

4.7.2 Process for Division (MSC) Dam Safety Officer. The MSC Commander should forward the name and qualifications of the individual that is being considered for the MSC DSO to the Corps DSO at HQUSACE for review and comments. The individual should be in a position not lower than the chief of the technical directorate (or GS-15 level).

4.7.2.1 The Corps DSO will review the recommendation, request comments from the other MSC DSOs across the Corps, consolidate comments, and furnish a recommendation to the MSC Commander.

4.7.2.2 If no one at the MSC level is qualified, the MSC Commander and the Corps DSO will coordinate the assignment of the DSO duties to another MSC DSO or a District DSO within the region on an interim basis.

4.7.2.3 The MSC Commander will develop a plan for filling position at the MSC level in accordance with paragraph 4.2.3. This plan could include training, mentoring, or

recruitment from outside the MSC. Progress on this plan will be reported to the Corps DSO at least twice annually.

4.7.3 Process for Designation of Corps (HQUSACE) Dam Safety Officer. The SOG, with input from MSC DSO's, will review the qualifications of candidates at HQUSACE and furnish a recommendation through the Special Assistant for Dam Safety to the Chief of Engineers. The individual should be in a position not lower than GS-15 level.

4.7.3.1 If no one at HQUSACE is qualified, the Chief of Engineers and the SOG Chair shall coordinate the assignment of the Corps DSO duties to an MSC DSO on an interim basis.

4.7.3.2 The SOG in coordination with the Chief of Engineers will develop a plan for filling position at HQUSACE in accordance with paragraph 4.2.3. This plan could include training, mentoring, or recruitment from outside HQUSACE. Progress on this plan will be reported to the Chief of Engineers by the SOG at least twice annually.

4.7.4 An example of a Dam Safety Officer Appointment order is provided in Figure 4.1. This format may also be used to appoint interim or temporary DSO's.

REPLY TO
ATTENTION OF
CECG

SEP 0 9 2009

MEMORANDUM FOR Chief, Engineering and Construction, ATTN: Mr. James C. Dalton, P.E.

SUBJECT: Appointment of Dam Safety Officer

1. Effective 1 October 2009, you are appointed as the U.S. Army Corps of Engineers Dam Safety Officer (DSO) in accordance with the Federal Guidelines for Dam Safety (FEMA 93).

2. As DSO you will report directly to the Chief of Engineers on Dam Safety matters. The duties of the DSO are as published in the following guidance.

a. Federal Guidelines for Dam Safety, FEMA 93, June 1979

b. ER 1110-2-1155, Dam Safety - Organization, Responsibilities, and Activities, 31 July 1992

3. This appointment is effective until rescinded.

R. L. VAN ANTWERP
Lieutenant General, USA
Commanding

CF: Mr. Steven L. Stockton

CHAPTER 5

Tolerable Risk Guidelines

5.1 Introduction.

5.1.1 The Role of Tolerable Risk Guidelines in Risk Assessment and Risk Management. Tolerable risk guidelines are used in risk management to guide the process of examining and judging the significance of estimated risks obtained using risk assessment. The outcomes of risk assessment are inputs, along with other considerations, to the risk management decision process. Tolerable risk guidelines should not be used alone to prescribe decisions on “How safe is safe enough?" Meeting or achieving the tolerable risk guidelines is the goal for all risk reduction measures including permanent and interim measures. The available options for IRRM may be limited by time, available funding, and potential negative effects on public health and safety due to the IRRM. (The loss of project benefits should not override the need to reduce risk to public safety.)

5.1.2 Development of Tolerable Risk Guidelines for The Corps of Engineers. USACE is working with the Bureau of Reclamation (Reclamation) and the Federal Energy Regulatory Commission (FERC), to craft common risk management guidelines. Reclamation had been using “Guidelines for Achieving Public Protection in Dam Safety Decision making” (reference A.100), which were originally issued as interim guidance in 1997 and subsequently in final form in 2003. Guidelines are also being used in other countries, such as the Australian National Committee on Large Dams (ANCOLD) - Guidelines on Risk Assessment (2003) (reference A.80). Although these guidelines have some fundamental common characteristics, there are some subtle and important differences.

5.1.3 Continued Development of Guidelines. As USACE works with Reclamation and FERC to achieve a common risk management framework and guidelines, USACE will use an adaptation of the 2003 Reclamation public protection guidelines and the risk evaluation guidelines published by Australian National Committee On Larger Dams (ANCOLD) in 2003 (reference A.80) and some adaptations of the ANCOLD guidance implemented by the New South Wales Government Dam Safety Committee (NSW DSC) Risk Management Policy Framework for Dam Safety, 2006 (reference A.106).

5.1.4 Definition of an “Adequately Safe” Dam. USACE will use the concept that a dam is considered adequately safe (DSAC Class V) when residual risk is considered tolerable and it meets all essential USACE guidelines with no dam safety issues.

5.2 Background on Tolerable Risk Guidelines.

5.2.1 Definition of Tolerable Risk. Tolerable risks are:

5.2.1.1 Risks that society is willing to live with so as to secure certain benefits;

5.2.1.2 Risks that society does not regard as negligible (broadly acceptable) or something it might ignore;

5.2.1.3 Risks that society is confident are being properly managed by the owner; and

5.2.1.4 Risks that the owner keeps under review and reduces still further if and as practicable (Adapted from HSE, 2001) (reference A.105).

5.2.2 Definition of Broadly Acceptable Risk. “Broadly acceptable risk” is contrasted with tolerable risk. "Risks falling into this region are generally regarded as insignificant and adequately controlled. The levels of risk characterising this region are comparable to those that people regard as insignificant or trivial in their daily lives. They are typical of the risk from activities that are inherently not very hazardous or from hazardous activities that can be, and are, readily controlled to produce very low risks" (HSE, 2001) (reference A.105). By the nature of the hazard that dams pose it is inappropriate to attempt to manage them as a broadly acceptable risk and therefore the concept of the broadly acceptable risk level or limit does not apply to dams.

5.2.3 Definition of Tolerable Risk Range. Figure 5.1 shows how in general tolerable risk is a range between unacceptable, where the risk cannot be justified except in extraordinary circumstance, and broadly acceptable, where the risk is regarded as negligible (Adapted from HSE, 2001) (reference A.105). This figure illustrates the point at which the residual risk for a specific dam is tolerable within the general range of tolerability as defined by meeting the as-low-as-reasonably-practicable (ALARP) considerations.

5.2.4 Equity and Efficiency.

5.2.4.1 Two fundamental principles, from which tolerability of risk guidelines are derived, are described as follows in ICOLD (2005) (reference A.101):

5.2.4.1.1 Equity. The right of individuals and society to be protected, and the right that the interests of all are treated with fairness, with the goal of placing all members of society on an essentially equal footing in terms of levels of risk that they face; and

5.2.4.1.2 Efficiency. Efficiency is the need for society to distribute and use available resources so as to achieve the greatest benefit.

5.2.4.2 Conflict Between Equity and Efficiency. There can be conflict in achieving equity and efficiency. Achieving equity justifies the establishment of maximum tolerable risk limits for individual and societal risk. Efficiency is defined by the risk level where marginal benefits equal or exceed the marginal cost. Equity requires that a tolerable risk limit should be met regardless of the lack of economic justification or the magnitude of the cost. Equity implies the need for this limit even if efficiency does not support reducing risks to meet the maximum tolerable risk limit. There is, therefore, a need to

obtain an appropriate balance between equity and efficiency in the development of tolerable risk guidelines. In general, society is more averse to risks if multiple fatalities were to occur from a single event and hence impact on society as a whole, creating a socio-political response. In contrast, society tends to be less averse to risks that result from many individual small loss accidents involving only one or two fatalities, even if the total loss from the sum of all of the small loss accidents is larger than that from the single large loss accident. This leads to the notion that tolerable risk should consider both societal and individual risks as an integral part of the framework for managing risks.

5.2.5 “As-Low-As-Reasonably-Practicable”. The “as-low-as-reasonably-practicable” (ALARP) considerations provide a way to address efficiency aspects in both individual and societal tolerable risk guidelines. The ALARP considerations apply below the tolerable risk limit of Figure 5.1. The concept for the use of ALARP considerations is that risks lower than the tolerable risk limit are tolerable only if further risk reduction is impracticable or if the cost is grossly disproportional to the risk reduction. The related concept of disproportionality is related to the legal obligation of the owner of a hazard to protect life and property from the risks associated with a hazard. ALARP only has meaning in evaluating risk reduction measures: it cannot be applied to an existing risk without considering the options to reduce that risk. ALARP is an explicit consideration under ANCOLD (2003) (reference A.80) and NSW DSC (2006) (reference A.106) tolerable risk guidelines. Determining that ALARP is satisfied is ultimately a matter of judgment. In making a judgment on whether risks are ALARP, the following factors should be taken into account (adapted from NSW DSC, 2006) (reference A.106):

5.2.5.1 The level of risk in relation to the tolerable risk limit and the broadly acceptable risk level (not applicable to dams);

5.2.5.2 The disproportion between the sacrifice (money, time, trouble and effort) in implementing the risk reduction measures and the subsequent risk reduction achieved;

5.2.5.3 The cost-effectiveness of the risk reduction measures;

5.2.5.4 Any relevant recognized good practice; and

5.2.5.5. Societal concerns as revealed by consultation with the community and other stakeholders.

5.3 USACE Tolerable Risk Guidelines.

5.3.1 Risk Measurement. Four risk measures will be evaluated under the USACE tolerable risk guidelines:

5.3.1.1 Annual probability of failure

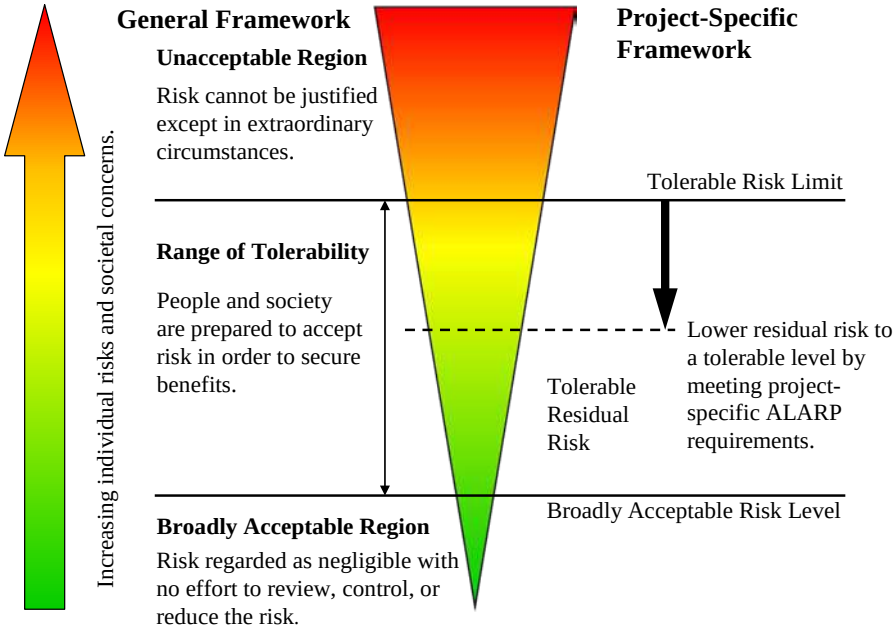

Figure 5.1 - Generalized and Project Specific Tolerability of Risk Framework (Adapted from HSE, 2001) (Reference A.105)

5.3.1.2 Life safety risk

5.3.1.3 Economic risk

5.3.1.4 Environment and other non-monetary risk

5.3.2 Additional Considerations. In addition to the tolerable risk limit guidelines, the ALARP considerations will be applied to determine when the risk is considered to be tolerable. All of these measures together will be considered when evaluating a dam and making risk management decisions; but life safety risk and the annual probability of failure will be given preference, with economic and environmental risk being given due consideration. For those projects where there is very low or no life safety risk, economic consequences and annual probability of failure will be the primary considerations along with environmental risk in making risk management decisions.

5.3.3 Incremental Consequences. In applying these tolerable risk guidelines, the incremental consequences will be considered. Incremental consequences are defined as follows:

Incremental consequences	=	Consequences associated with the estimated performance of the project with *failure*	-	Consequence associated with the estimated performance of the project *without failure*

5.3.3.1 This definition, when applied to flood-induced failure, is illustrated in Figure 5.2 and distinguishes between the following:

5.3.3.1.1 The structural design capacity, which is the maximum loading condition that the project was planned to withstand (original design loads), although the project may fail at a lesser loading condition; and

5.3.3.1.2 The flood regulation design capacity, which is the maximum loading condition above which the project no longer provides any flood damage reduction benefits, defined as a reduction in flood levels in the area protected by the project at loading levels below the structural design capacity.

5.3.3.2 Figure 5.2 also distinguishes between the following:

5.3.3.2.1 The planned or intended condition, for which failure does not occur until the loading level exceeds the structural design capacity (vertical line shading); and

5.3.3.2.2 The condition that failure may occur at loading levels less than the structural design capacity (diagonal line shading).

5.3.3.3 Incremental consequences for other initiating events such as seepage and seismic-induced dam failure are the differences due to the event with and without dam failure.

5.3.4 Annual Probability of Failure Guideline.

5.3.4.1 Annual probability of failure will be evaluated based on Reclamation’s value for its annual probability of failure (APF) Public Protection Guideline applied to the total estimated annual probability of failure from all failure modes associated with all loading or initiating event types. For a detailed discussion on the Reclamation's process see Appendix K. Although only the total annual probability of failure is to be evaluated against this guideline, it is important that the contributions to the total APF from the individual failure modes, loading types, loading ranges, exposure scenarios, etc, are analyzed. The analysis and evaluation of the individual failure modes can lead to an improved understanding of the failure modes that affect the total annual probability of failure. It can also provide insights that can lead to the identification of both structural and non-structural risk reduction measures, including interim measures.
.

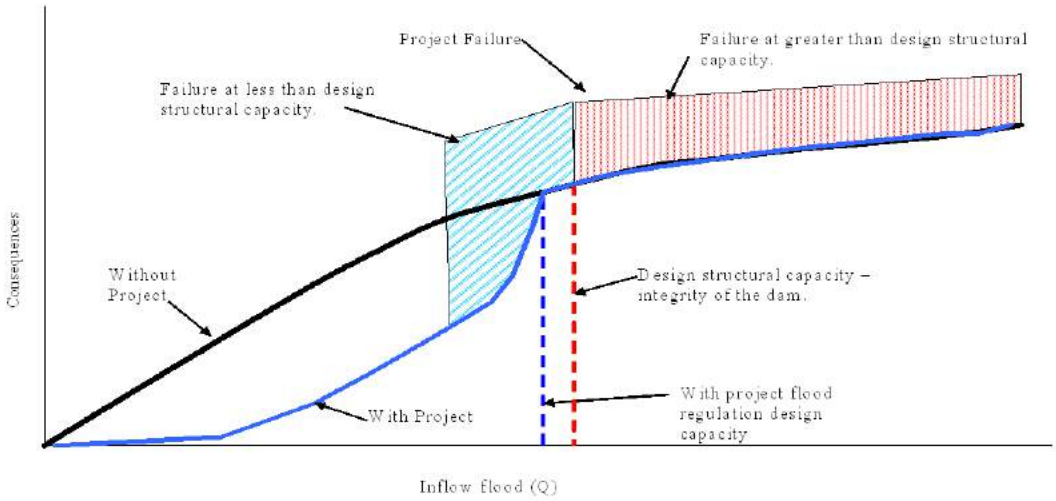

Figure 5.2 – Abstract Illustration of Incremental Consequences for Flood Induced Dam Failure

5.3.4.2 The policy for the estimated APF under USACE tolerable risk guidelines is:

5.3.4.2.1 APF > 1 in 10,000 (0.0001) Per Year. Annual probability of failure in this range is unacceptable except in exceptional circumstances. Reclamation states, "The justification to implement risk reduction actions increases as the estimates become greater than 0.0001 per year. Actions considered reasonable and prudent should be considered for implementation when the annual probability of failure estimate is in this range" (Reclamation 2003) (Reference A.100).

5.3.4.2.2 APF < 1 in 10,000 (0.0001) Per Year. Annual probability of failure in this range will be considered tolerable provided the other tolerable risk guidelines are met. Reclamation states, "The justification to implement risk reduction actions diminishes as the estimates become smaller than 0.0001 per year. Risk reduction action costs, uncertainties in the risk estimates, scope of consequences, operational and other water resources management issues play an increased role in decision-making. Actions considered reasonable and prudent should be considered for implementation when the annual probability of failure is in this range" (Reclamation 2003) (Reference A.100).

5.3.4.3 This guideline is illustrated in Figure 5.3 as the horizontal dashed line at 1×10^{-4} per year.

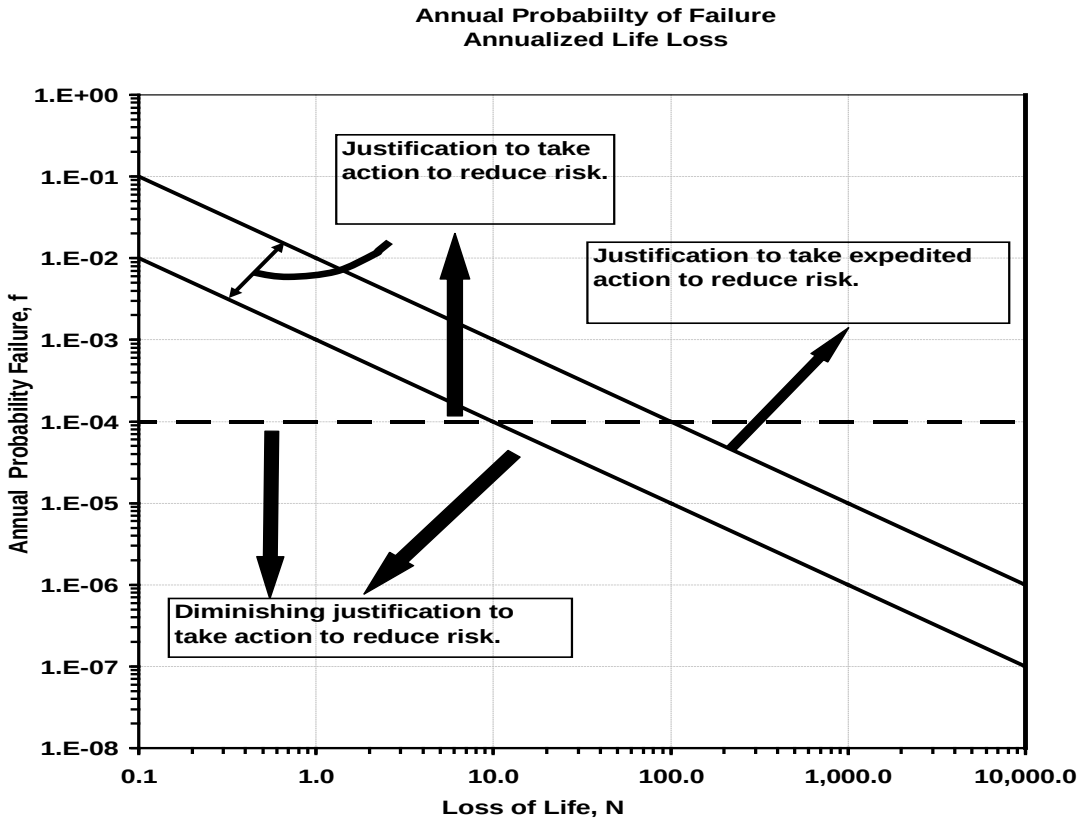

Figure 5.3 – f-N Chart for Displaying Annual Probability of Failure and Annualized Life Loss

5.3.5. Life Safety Risk Guidelines.

5.3.5.1 Life Safety Risk Guidelines. Three types of life safety risk guidelines will be used under the USACE tolerable risk guidelines.

5.3.5.1.1 Individual incremental life safety risk using probability of life loss

5.3.5.1.2 Societal incremental life safety risk expressed in two different ways –

5.3.5.1.2.1 Probability distribution of potential life loss (F-N chart as discussed in the section on *Probability Distribution of Potential Life Loss)*

5.3.5.1.2.2 Annualized Life Loss (ALL)

5.3.5.2 Evaluation of Total Life Safety Risk. As with APF, it is the total life safety risk that is to be evaluated against the life safety guidelines. However, it is important

that the contributions to the total from all individual failure modes, loading types, loading ranges, exposure conditions, subpopulations at risk, etc, are analyzed. This analysis can lead to an improved understanding of the failure modes and the exposure conditions that affect the total life safety risk. It can also provide insights that can lead to the identification of both structural and non-structural risk reduction measures, including interim measures.

5.3.5.3 Individual Incremental Life Safety Tolerable Risk Guideline. The individual risk is represented by the probability of life loss for the identifiable person or group by location that is most at risk. This is combined over all modes of failure with due regard for non-mutually exclusive failure modes, for the purpose of tolerable risk evaluation.

5.3.5.3.1 Existing Dams. For existing dams, the individual risk to the identifiable person or group by location, that is most at risk, should be less than a limit value of 1 in 10,000 per year, except in exceptional circumstances. This follows the ANCOLD (2003) (reference A.80) individual life safety risk guideline. The individual life risk is computed from all failure modes associated with all loading or initiating events, with due regard for non-mutually exclusive failure modes (Figure 5.4.a).

5.3.5.3.2 New Dams and Major Modifications. For new dams or major modifications under Section 216 (reference A.94)[1], the individual risk to the person or group, which is most at risk, should be less than a limit value of 1 in 100,000 per year, except in exceptional circumstances, following the ANCOLD (2003) (reference A.80) individual life safety risk guideline (Figure 5.5.a). Application of the new dam tolerable risk guidelines for major modifications will be decided on an individual project basis in coordination with HQUSACE.

5.3.5.3.3 All Dams. For existing dams, new dams, or Section 216 modifications (reference A.94), individual risks are to be lower than the limit values to an extent determined in accordance with the ALARP considerations. NWS DSC (2006) states that if individual risk is below 1 in 1,000,000 per annum there is no need to pursue further risk reduction. However, it is USACE policy to consider ALARP below 1 in 1,000,000 per annum although it is unlikely to justify further risk reduction.

5.3.5.3.4 Multiple Dams. Individual risk should be checked below the main and each auxiliary dam to verify that the person or group, which is most at risk, is provided a level of protection that satisfies this individual incremental life safety tolerable risk guideline.

5.3.5.3.5 Probability of Individual Life Loss and Probability of Failure. The probability of individual life loss, which is used in the evaluation of individual incremental life safety risk, is not necessarily the same as the probability of failure that is used in the evaluation of the APF guideline, which is described in Section 5.3.4. The probability of life loss is based on the probability of failure, a consideration of exposure factors to

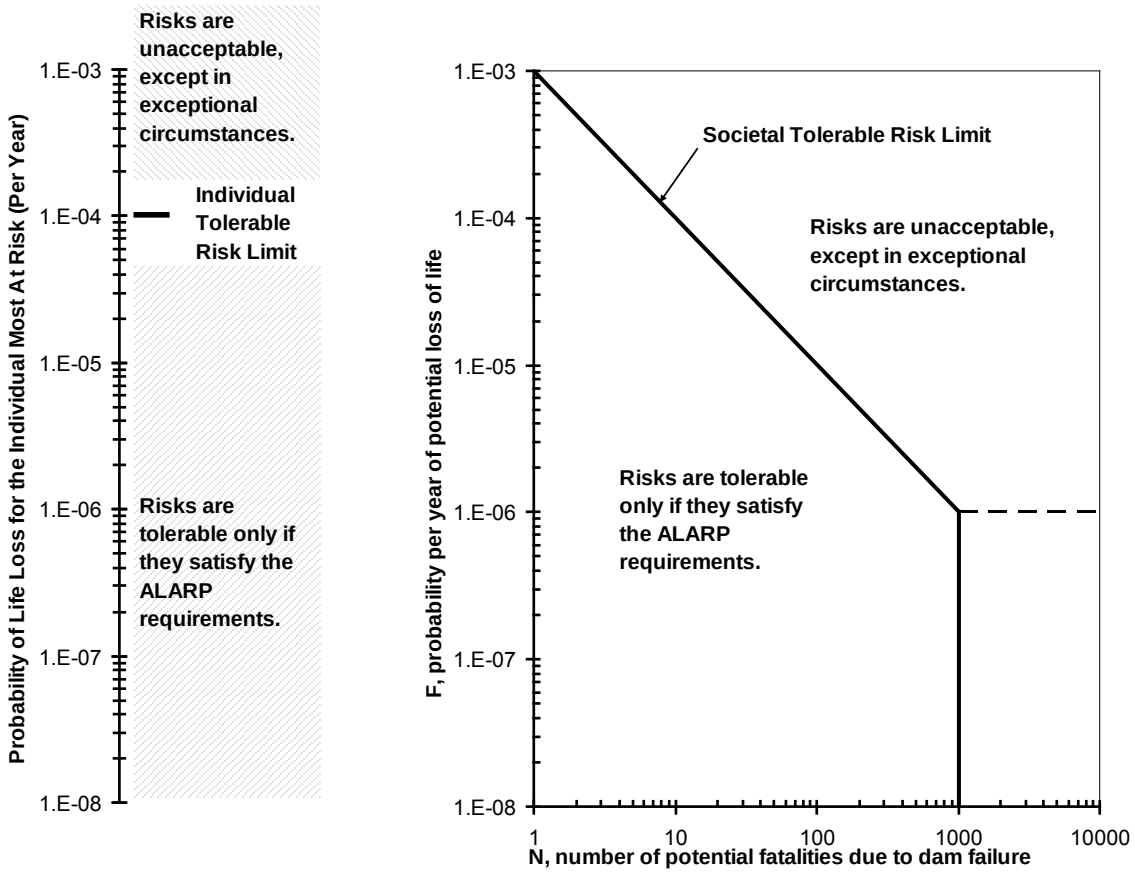
[1] A Section 216 study addresses major modification of a dam that changes authorized purposes of that dam.

characterize the day-night, seasonal, or other exposure scenarios, and the conditional probability of life loss given exposure to the dam failure flood. The level of detail that is appropriate for characterizing exposure factors should be "decision driven."

5.3.5.4 Probability Distribution of Potential Life Loss. The societal risk is represented by a distribution of the estimated annual probability of potential life loss from dam failure for all loading types and conditions and all failure modes and all population exposure scenarios. This is displayed as an F-N chart which is a plot of the annual probability of exceedance (greater than or equal to) of potential life loss (F) vs. incremental potential loss of life (N)[2] due to failure compared to the no failure condition. Thus, the F-N chart displays the estimated probability distribution of life loss for a reservoir encompassing all failure modes and all population exposure scenarios for a particular dam.

5.3.5.4.1 Existing Dams. For existing dams, the societal risk should be less than the tolerable risk limit line shown in Figure 5.4.b, except in exceptional circumstances, following an adaptation of the ANCOLD (2003) (reference A.80) and NSW (2006) (Reference A.106) societal life safety risk guideline.

5.3.5.4.2 New Dams and Major Modifications. For new dams or major modifications under Section 216 (reference A.94), the societal risk should be less than the tolerable risk limit line shown in Figure 5.5.b, except in exceptional circumstances, following an adaptation of the ANCOLD (2003) (reference A.80) and NSW (2006) (Reference A.106) societal life safety risk guideline. Application of the new dam tolerable risk guidelines for major modifications will be decided on an individual project basis in coordination with HQUSACE.

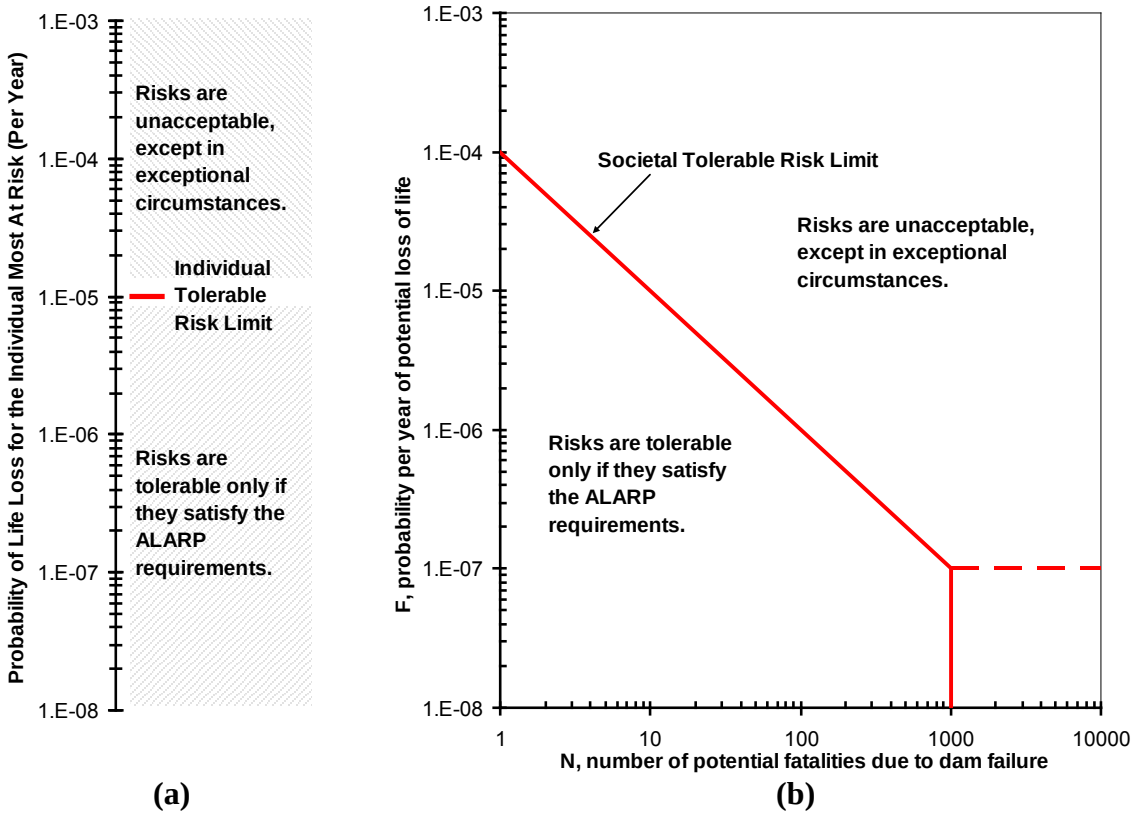


5.3.5.4.3 All Dams. For existing dams, new dams, or major modifications under Section 216 (reference A.94), societal risk are to be lower than the tolerable risk limit lines to an extent determined in accordance with the ALARP considerations.

5.3.5.4.4 Dams with Unacceptable Level of Risk. Dams with failure risks that plot above a tolerable risk limit on an F-N chart are considered to have an unacceptable level of risk. As with the individual tolerable risk limit, risks should be reduced to the tolerable risk limit regardless of cost considerations and then further until ALARP is satisfied, except in exceptional circumstances.

5.3.5.4.5 Special Evaluation of the Tolerability of Risk. If incremental life loss is estimated to exceed 1,000 lives or is above the minus 1 sloping limit line the evaluation of the tolerability of risk shall be based on an official review of the benefits and risks as described in the "Except in Exceptional Circumstances" section (paragraph5.3.6).

[2] In probability textbooks a cumulative (probability) distribution function (CDF) is defined to have probability "less than or equal to" on the vertical axis and a complementary cumulative (probability) distribution function (CCDF) is defined to have probability "greater than" on the vertical axis. Although similar to a CCDF, an F-N chart is subtly, but in some cases importantly, different because it has probability "greater than or equal to" on the vertical axis rather than "greater than" as in the CCDF.



5.3.6 Except in Exceptional Circumstances. The qualifier “except in exceptional circumstances” refers to a situation in which government, acting on behalf of society, may determine that risks exceeding the tolerable risk limits may be tolerated based on special benefits that “the dam brings to society at large”. "The justification for tolerating

Figures 5.4.a – Individual Risk Guidelines for Existing Dams
and 5.4.b – Societal Risk Guidelines for Existing Dams

such high risks is the wider interests of society. Risks, which would normally be unacceptable, can be tolerated on account of the special benefits, which the dam brings to society." (ANCOLD, October 2003) (reference A.80). This is an example of the conflict between the fundamental principles of equity and efficiency. Specifically, the maximum risk level that satisfies equity considerations can be at the expense of reducing efficiency. The equity consideration might be relaxed because of special benefits are deemed to outweigh the increased residual risk. This exception might be made where the residual potential life loss and economic consequences are large, but where the probability of failure is very low and state of the practice risk reduction measures have been implemented. For dams in this area on Figures 5.4.b and 5.5.b USACE will look critically at the confidence in the estimate of the risk. Full compliance

with essential guidelines will be expected. The adequacy of potential failure modes analysis and risk assessment will be carefully examined. The USACE is to demonstrate that risks are ALARP. HQUSACE would reach a decision based on the merits of the case.

Figures 5.5.a – Individual Risk Guideline for New Dams and Major Modification Under Section 216
and 5.5.b -- Societal Risk Guideline for New Dams and Major Modification Under Section 216

5.3.7 Annualized Incremental Life Loss (ALL) Public Protection Guideline. Annualized Life Loss (ALL) guideline is the expected value (average annual) of incremental potential life loss resulting from dam failure as shown in the f-N chart.

5.3.7.1 Annualized Incremental Societal Life Loss. Annualized incremental societal life loss will be evaluated based on the limit values as shown in the ALL guideline (Figure 5.3). This should be applied to the total estimated annualized incremental life loss from all failure modes associated with all loading or initiating event types and considering all exposure conditions associated with life loss.

5.3.7.2 Policy for Estimating ALL. The policy for the estimated ALL under the USACE tolerable risk guidelines is:

5.3.7.2.1 ALL > 0.01 Lives/Year. ALL risk in this range is unacceptable except in exceptional circumstances and is reason for urgent actions to reduce risk. Reclamation states, "… there is justification for taking expedited action to reduce risk." This is represented by the upper minus 1 sloping line in Figure 5.3 (Reclamation 2003) (reference A.100).

5.3.7.2.2 ALL Between 0.01 and 0.001 Lives/Year. ALL risk in this range is unacceptable except in exceptional circumstances and is reason for actions taken to reduce risk. Reclamation states, "…there is justification for taking action to reduce risk." This is represented by the area between the two minus 1 sloping lines in Figure 5.3 (Reclamation 2003) (reference A.100).

5.3.7.2.3 ALL < 0.001 Lives/Year. ALL risk in this range may be considered tolerable provided the other tolerable risk guidelines are met. Reclamation states, "The justification to implement risk reduction actions or conduct additional studies diminishes as estimated risks become smaller than 0.001 lives/year. Risk reduction action costs, uncertainties in the risk estimates, scope of consequences, operational and other water resources management issues play an increased role in decision making. Actions considered reasonable and prudent should be considered for implementation when the risk is in this range" (Reclamation 2003) (reference A.100).

5.3.8 As-Low-As-Reasonably-Practicable Considerations.

5.3.8.1 The ANCOLD (2003) (reference A.80) individual and societal risk guidelines include an important consideration that the risk is to be lower than the limit values to an extent determined in accordance with the ALARP considerations. Reclamation's Public Protection Guidelines do not specifically address ALARP. The ANCOLD (2003) (reference A.80) guidelines provide some overall guidance on evaluating whether risks have been reduced to ALARP. Determination is both qualitative and quantitative in nature.

5.3.8.2 In making a judgment on whether risks are ALARP, the USACE shall take the following into account: the level of risk in relation to the tolerable risk limit and the broadly acceptable risk level (not applicable to dams); the disproportion between the sacrifice (money, time, trouble and effort) in implementing the risk reduction measures and the subsequent risk reduction achieved; the cost-effectiveness of the risk reduction measures; compliance with essential USACE guidelines; and societal concerns as revealed by consultation with the community and other stakeholders. The specific ALARP considerations to be used by the USACE are listed, with commentary, below.

5.3.8.2.1 The level of risk in relation to the tolerable risk limit. When the estimated life safety risk has been reduced to the tolerable risk limit the ALARP consideration leads to the question, "How far below that limit is the level of risk to be reduced?" The

further below the tolerable risk limit the weaker the ALARP justification for further risk reductions.

5.3.8.2.2 The cost-effectiveness of the risk reduction measures.

5.3.8.2.3 The disproportion between the sacrifice (money, time, trouble and effort) in implementing the risk reduction measures and the subsequent risk reduction achieved.

5.3.8.2.3.1 Disproportionality is used as a justification to reduce the risk below the tolerable risk limit. The disproportion between the sacrifice (money, time, trouble and effort) in implementing the risk reduction measures and the subsequent risk reduction achieved is to be evaluated using the disproportionality between the sacrifice and the risk reduction achieved. This entails the use of the following two measures: 1) a cost effectiveness measure called, the "cost-to-save-a-statistical-life" (CSSL); and 2) a "willingness-to-pay-to-prevent-a-statistical-fatality" (WTP), commonly referred by the Office of Management and Budget (OMB 2003) and other federal agencies as the "value-of-statistical-life" (VSL). VSL is used by OMB, the United States Department of Transportation (USDOT) (references A.110 and A.111), and other federal agencies to evaluate the case for regulating risk or investing in life-saving risk reduction measures. The risk measure for disproportionality is the ratio of the CSSL divided by WTP. The quantitative ANCOLD (2003) (reference A.80) guidance is based on estimating the incremental CSSL for any risk reduction options that could reduce the risk below the limit values, starting at or below the limit values, and assigning a “strength of ALARP justification” to proceed with the risk reduction measure based on the magnitude of the estimated CSSL. This approach has it roots in work by the Health Safety Executive, United Kingdom (HSE 2001) (reference A.105) and by Bowles and Anderson (2003) (Reference A.85). CSSL calculations are shown in Appendix L.

5.3.8.2.3.2 The ANCOLD approach has been adapted for application to USACE dams as represented in Tables 5.1 and 5.2 that show the disproportionality ratio of the CSSL to the WTP.

$$\text{Disproportionality ratio} = \text{CSSL} / \text{WTP}$$

5.3.8.2.3.3 The value to use for WTP in USACE dam safety risk assessments will be the current value used by USDOT. As of January 2009 USDOT (2008) uses a value for WTP of US$5.8M with a standard deviation of US$2.6M or a range of US$3.2M - US$8.4M, which is equivalent to a range of plus and minus one standard deviation. (Reference A.110 and A.111)

5.3.8.2.3.4 The disproportionality ratios in Tables 5.1 and 5.2[3] have been calculated from the ANCOLD CSSL values using a WTP of $5M/statistical fatality prevented. The

[3] Tables 5.1 and 5.2 refer to the tolerable risk limit and broadly acceptable region, respectively. Based on their original use by HSE, the tolerable risk limit for individual risk may be considered to be 1 in 10,000 per year and the broadly acceptable limit may be considered to be 1 in 1,000,000 per year. However, the concept of broadly acceptable risk does not apply to dams as discussed elsewhere in this paper.

disproportionality ratio will be calculated, as described in the next paragraph, for each risk reduction alternative and compared with the ANCOLD values below for illustrative purposes.

5.3.8.2.4 Compliance with Essential USACE Guidelines. The dam will be evaluated on its ability to meet essential USACE guidelines. The USACE essential guidelines list will be developed from the published and draft design criteria documented in the USACE engineering regulations and engineering manuals. The evaluation will be

presented as pass, apparent pass, apparent no pass, or no pass tabulation with a detailed evaluation for apparent pass, apparent no pass, or no pass ratings.

5.3.8.2.5 Societal concerns as revealed by consultation with the community and other stakeholders. Societal concerns in terms of community expectations are to be identified, documented, and resolved in a public meeting and comment process modeled after similar procedures already established by USACE.

5.3.9 Economic Consequences.

5.3.9.1 Economic considerations to help inform risk management decisions include both the direct losses of the failure of a dam and other economic impacts on the regional or national economy. Part of the direct losses is the damage to property located downstream from the dam due to the failure. Items in this category include those commonly computed for the National Economic Development (NED) account in any USACE flood risk management study (USACE 2000). These include damage to

private and public buildings, contents of buildings, vehicles, public infrastructure such as roads and bridges, public utility infrastructure, agricultural crops, agricultural capital, and erosion losses to land. Direct losses also include the value from the loss in services provided by the dam such as hydropower (incremental cost to replace lost power), water supply, flood damage reduction, navigation (incremental cost for alternate transportation - if available), and recreation. Another category of NED values is the emergency response for evacuation and rescue and the additional travel costs associated with closures of roads and bridges. The sudden loss of pool due to a dam failure could result in losses to property and infrastructure within the pool area. The NED value of these losses should be included in computing direct economic loss due to dam failure. (NOTE: one potential direct loss is the cost of repairing the damage to the dam. This is a complicated issue and to some degree depends on the extent of damage to the dam. If the dam can be repaired, these repair costs could be counted as an economic cost. In the case of catastrophic failure, these rebuilding costs should not be included in the direct costs, as the decision to rebuild the dam depends on the post-failure benefits which would be a separate analysis.)

5.3.9.2 These direct economic losses can be compared to costs of any dam modification to display a measure of the economic efficiency of the modification. Additionally, these direct economic losses are used to net against the cost of remediation measures in the calculation of CSSL.

5.3.9.3 Indirect economic impacts are those associated with the destruction of property and the displacement of people due to the failure. The destruction due to the failure flood can have significant impacts on the local and regional economy as businesses at least temporarily close resulting in loss of employment and income. Similarly, economic activity linked to the services provided by the dam will also have consequences. These would include economic impacts on business that provide goods and services for the recreation activities associated with the reservoir. All these indirect losses then have ripple or multiplier effects in the rest of the regional and national economy due to the resulting reduction in spending on goods and services in the region. In this way, a dam failure can have widespread economic losses throughout the region. These losses are the increment to flood losses above those that would have occurred had the dam not failed.

5.3.10 Environment and Other Non-Monetary Consequences.

5.3.10.1 A dam failure has both direct and indirect consequences that cannot be measured in monetary terms. These stem from the impacts of the dam failure flood and loss of pool on environmental, cultural, and historic resources. In most cases, the assessment of the impacts of dam failure will be the reporting of area and type of habitat impacted, habitat of threatened and endangered species impacted, number and type of historic sites impacted, and the number and type of culturally significance areas impacted.

5.3.10.2 An additional indirect non-monetary consequence could be the exposure of people and the ecosystem to hazardous and toxic material released from landfills, warehouses, and other facilities. An estimate of the locations and quantities should be compiled identifying where significant quantities are concentrated. A potential additional source of hazardous and toxic material is the sediment accumulated behind the dam. Identifying and enumerating these indirect hazards could be important enough to require additional risk assessments including estimating additional fatalities due to exposure to theses hazards. Although these non-monetary consequences may not provide the sole basis for risk reduction, they can provide additional risk information for decision making. They can also be used to identify risks to be managed separately from dam modifications.

5.3.10.3 Intangible consequences are those that have no directly observable physical dimensions but exist in the minds, individually and collectively, of those affected. Such consequences are real and can support decisions. Intangible consequences identified in ANCOLD (2003) (reference A.80) include such things as:

5.3.10.3.1 The grief and loss suffered by relatives and friends of those who die;

5.3.10.3.2 The impact of multiple deaths on the psyche of the community in which they lived;

5.3.10.3.3 The stress involved in arranging alternative accommodations and income;

5.3.10.3.4 The sense of loss by those who enjoyed the natural landscape destroyed; and

5.3.10.3.5 The fear of lost status and reputation of the dam owning organization and its technical staff.

5.3.10.4 The effect of these intangible consequences can be observed more tangibly in terms of increased mental health expenditures and increased suicides.

5.4 Considerations in Risk Estimation for Risk Assessment and Risk Evaluation.

5.4.1 Assessing Ability to Reduce Uncertainty. The quantification of risk estimates is dependent on data and analysis regarding the design, construction, and current condition of a dam, as well as the identified loads to which the dam could be subjected to over its operating life. When making a decision regarding future actions, one should consider the risk estimates, the issues most influencing the risks, the sensitivity of the risks to particular inputs, the cost of additional actions, and the potential for reducing uncertainty. Uncertainty may be reduced by performing additional actions such as collecting more data, by performing more analysis, or by performing a more detailed analysis of the risks. However, there are occasions when additional efforts may not result in significant reduction in uncertainty. It is important to recognize when this is the

case and consider the anticipated value of the additional efforts to reduce uncertainty as a factor in selecting a course of action.

5.4.2 Risk Estimate Ranges (range of means) Straddling the Guidelines. When significant uncertainties or assumptions related to a lack of data or interpretations of data result in a range of risk estimates, the results may straddle the guideline values with portions of the risk estimates range portrayed both above and below the guidelines. In these cases, it is important for decision-makers to assess the portion of the risk estimate range that exceeds the guidelines to determine if it is significant enough to warrant further action or studies. The entire range should be used to assess the need for future actions as well as an aid in setting the priority for initiating the actions. If the range extends into the zone that justifies expedited risk reduction, studies to better define the risk should be the minimum response of the agency.

5.4.3 Risk Estimate With and Without Intervention. All risk estimates must give due consideration for intervention. The risk estimates for with and without intervention scenarios will be plotted on the tolerable risk guidelines. Further guidance is provided in Chapter 18 - Risk Assessment Methodology.

5.5 Example Presentations of USACE Tolerable Risk Guidelines. An example set of f-N data points are used in the figures below. Figure 5.6 illustrates the plotting of data using the annual probability of failure and ALL guidelines on the f-N chart. In addition the expected life loss is plotted versus sum of the APF for all failure modes and exposure scenarios are shown as a single data point on the chart. Figure 5.7 illustrates plotting the same f-N data pairs on the societal risk guideline F-N or probability distribution chart.

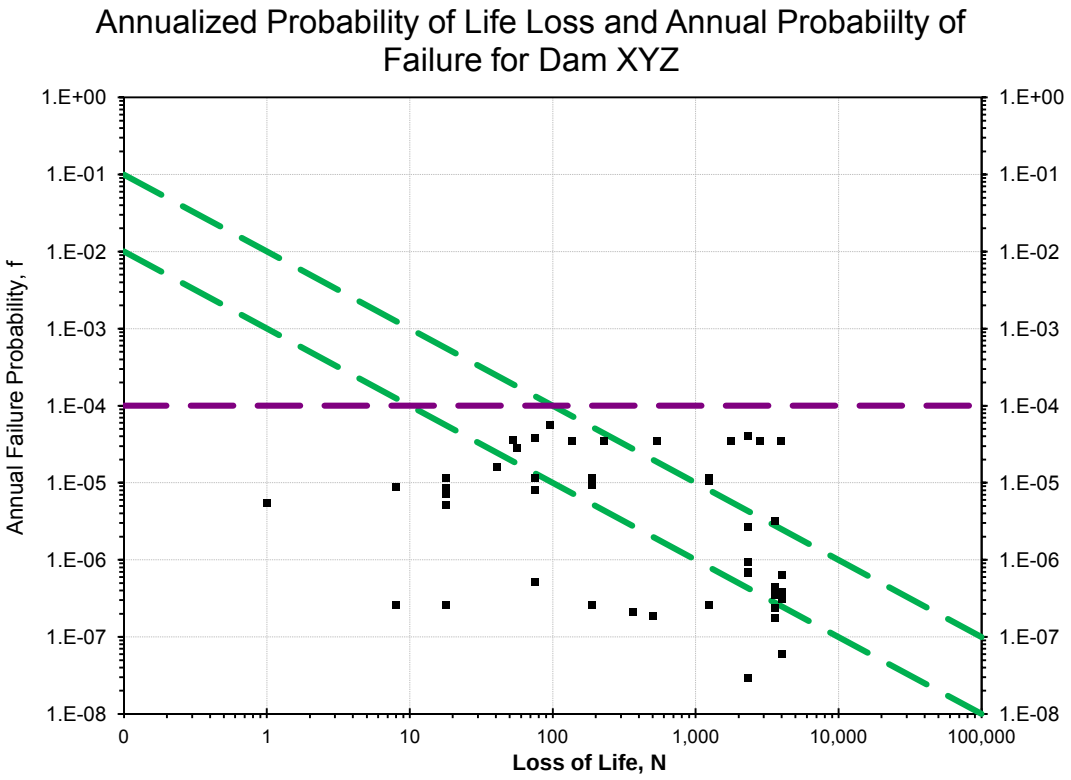

Figure 5.6 – Plot of f-N Data Pairs for Individual Failure Modes and Exposure Scenarios on the Annualized Life Loss and Annual Probability of Failure Tolerable Risk Guidelines Format

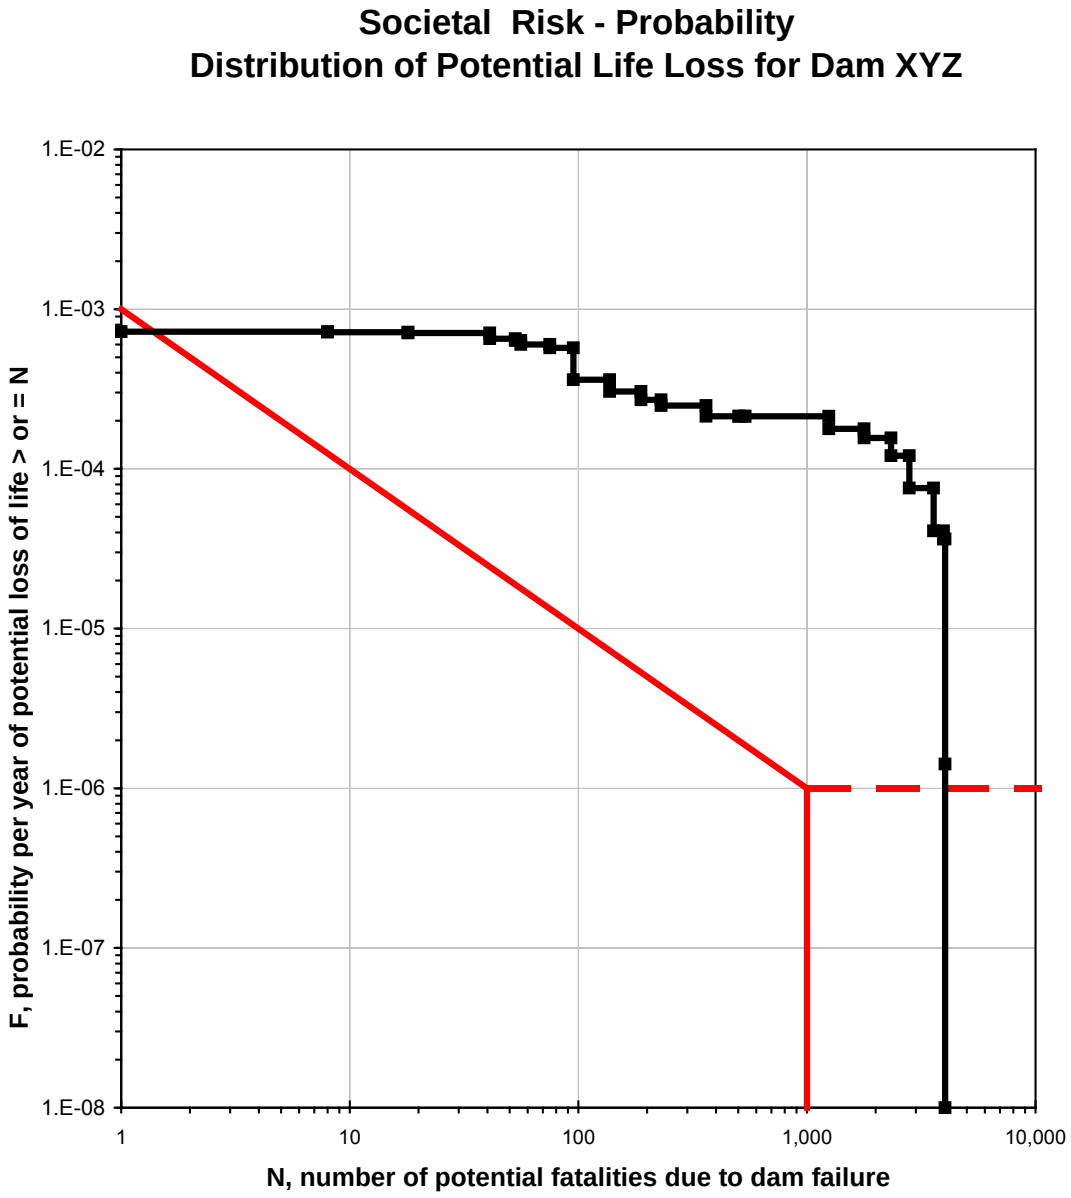

Figure 5.7 – Example Illustrating the Plotting of the Same f-N Data Pairs for Individual Failure Modes and Exposure Scenarios in a Probability Distribution of Potential Life Loss f-N Chart

CHAPTER 6

Dam Safety Risk Management Prioritization

6.1 Purpose. This chapter provides guidance for the prioritization processes at the three primary prioritization queues in USACE Dam Safety Portfolio Risk Management Process shown in Figure 3.1. Each queue contains a subset of USACE dams that are waiting for funding to proceed to the next step in the Portfolio Risk Management Process. The queues are:

6.1.1 Prioritization of Issue Evaluation Studies (P1);

6.1.2 Prioritization of Dam Safety Modification Studies (P2); and

6.1.3 Prioritization of approved remediation projects awaiting engineering design and construction funding (P3).

6.2 Organizational Roles and Responsibilities in the Prioritization Process. The Dam Safety Risk Management Center, in coordination with the Senior Oversight Group (SOG), will assist the HQUSACE dam safety officer with the prioritization of Issue Evaluation Studies (IES) and Dam Safety Modification Studies (DSM), and the implementation of Risk Reduction action queues. The ultimate goal is to prioritize the national inventory, manage risks across the entire portfolio of structures, and reduce the overall portfolio risk as quickly as possible. The decision on priorities in these queues will be risk informed and done at the national level.

6.3 General Philosophy on Prioritization.

6.3.1 Clearance of Queues. While the intent is that the dams in the queues are eventually cleared in the priority order assigned, a more urgent issue may arise due to new information such as a dam safety incident or a significant change in that state of the art. This new information may introduce a dam into the queue and move it ahead of other dams in the queue. Thus, prioritization within the queues will be an iterative process with changes in priority being affected by other dams in the queue and the availability of new information.

6.3.2 DSAC Class, Priority, and Urgency.

6.3.2.1 DSAC I dams have been determined to have a confirmed urgent and compelling issue that requires taking immediate and expedited actions to reduce and manage the risk. Therefore, DSAC I dams will automatically be given first priority for DSM studies and will not require an issue evaluation study.

6.3.2.2 Dams will be prioritized within their DSAC class. For example not all DSAC II dams have the same priority.

6.3.2.3 Priority and urgency are different but should be compatible, thus higher priority dams are normally associated with the more urgent DSAC class dams.

6.3.2.4 With the exception of DSAC I dams, prioritization decisions for Issue Evaluation Studies (P1) and Dam Safety Modification Studies (P2) can have a significant impact on the speed and efficiency of risk reduction for the overall portfolio of USACE dams. Therefore, there may be times when a lower risk dam will be funded ahead of a dam with higher risk when it is demonstrated that this action will be a more effective and expeditious in reducing the overall portfolio risk.

6.3.3 Quantitative and Qualitative Factors. Significant weight will be given to the quantitative tolerable risk guidelines, but other non-quantitative considerations, including ALARP, will also be used to provide a more complete basis for prioritization of the queues.

6.3.3.1 Quantitative Factors.

6.3.3.1.1 The level of risk in relation to the tolerable risk limit. The greater the estimated annual probability of failure and the further the estimated life risk is above the tolerable risk limit the greater the urgency to act. The more cost-effective a risk management plan is in reducing the annual probability of failure and the life safety risk below the tolerable limit, the greater the justification to select that plan;

6.3.3.1.2 The disproportion between the sacrifice (money, time, trouble and effort) in implementing the risk reduction measures and the subsequent risk reduction achieved (the lower the ratio for a given measure that reduces the life safety risk below tolerable risk limits the greater justification to implement those risk reduction measures);

6.3.3.1.3 The cost-effectiveness of the risk reduction; (the project with lower overall cost for the same level of risk reduction would be given higher priority);

6.3.3.1.4 Net benefits achieved;

6.3.3.1.5 Any relevant recognized good practice (essential USACE guidelines) (risk reduction measures that satisfy all essential USACE guidelines would be given more weight than those that do not).

6.3.3.1.6 The magnitude or severity of the economic and environmental impacts.

6.3.3.2 Non-Monetary Considerations.

6.3.3.2.1 Societal concerns as revealed by consultation with the community and other stakeholders.

6.3.3.2.2 Impacts on any facilities critical to national security and well being,

6.3.3.2.3 The magnitude of impact on community, regional, or national well being.

6.3.3.3 For more detail, see the following sections of Chapter 5 - 'Economic Consequences' (5.3.9) and 'Environment and Other Non-Monetary Consequences' (5.3.10).

6.4 Prioritization Queues and Related Issues.

6.4.1 Issue Evaluation Studies Queue (P1).

6.4.1.1 Within the Issue Evaluation study queue are those projects awaiting approval to begin the Issue Evaluation study (Phase 1 IES) as well as those projects awaiting approval for an additional Phase 2 IES effort where supplemental information and study is needed for confirmation of issue(s) that have arisen from the Phase 1 Issue Evaluation Study. For some dams, no Phase 2 study will be needed and for others it is possible that more than one Phase 2 study may be needed. All of these studies will be prioritized for approval and funding based on the information obtained from risk assessments and tolerable risk limits evaluations performed as part of overall dam safety portfolio risk management process.

6.4.1.2 At any time during an Issue Evaluation study, if evidence is obtained that justifies an ‘urgent and compelling’ need for action, the dam should be promptly recommended for reclassification as a DSAC I and moved to the expedited process that is associated with a DSAC I dam.(See Figure 3.1)

6.4.1.3 Phase 1 IES are based on existing available information except for estimating consequences. Since the basis for continuing IES into Phase 2 is that dam safety issues are not confirmed with adequate confidence, it may be useful to perform sensitivity or bounding analysis on the risk analysis to explore the range of uncertainty in risk estimates and the comparison to the tolerable risk guidelines. The resulting range of risk estimate and associated risk evaluations may be useful in assigning priority to Phase 2 IES.

6.4.1.4 Information that shall be considered, if available, for use in prioritizing dams for IES includes:

6.4.1.4.1 Information developed in the Screening Portfolio Risk Analysis (SPRA);

6.4.1.4.2 Information from a Periodic Assessment (PA);

6.4.1.4.3 Evaluations performed as part of recommending Interim Risk Reduction Measures, and;

6.4.1.4.4 Evaluations against tolerable risk guidelines and USACE essential guidelines, inspection records, previous studies for prior project remediation, project

engineering documents prepared during design and construction, and other studies as may have been performed.

6.4.1.5 See Table 6.1 for a summary of P1 prioritization factors.

6.4.2 Dam Safety Modification Studies Queue (P2). Dam Safety Modification Studies (DSM) will be performed for all dams that do not satisfy the tolerable risk limits as determined by the issue evaluation study, unless the dam has been classified as a DSAC I dam. In general DSAC I dams, except those with low life risk, are given the highest priority for starting the DSM studies. DSAC I dams are prioritized based on available data such as the SPRA report, incident report, the External Peer Review report, and periodic assessment report (if available). DSM studies for the DSAC II, III and IV dams are prioritized based on information available from Issue Evaluation studies and periodic assessments. See Table 6.1 for a summary of P2 prioritization factors.

6.4.3 Prioritize Approved Projects for Funding Queue (P3). Approved dam safety risk reduction actions from the DSM studies are prioritized for Construction funding. The ultimate decision to fund implementation of the DSM study recommendation shall be based on the results of the DSM studies and the priorities of the USACE DSO considering all approved DSM reports. The decision on construction priority will be risk informed based on the magnitude and relative importance of the life, economic, and environmental risks and the cost-effectiveness of the proposed risk reduction measures for each dam in relationship to other dams of the same DSAC class. Estimates of the reduction in annual probability of failure, reduction in the estimated life safety risk, evaluations of risk reduction measures against tolerable risk guidelines, disproportionality ratio for the recommended risk reduction alternatives, and the cost effectiveness of risk reduction alternatives will be available from the DSM report. Staged risk reduction alternatives should be developed in DSM studies, where appropriate and practicable. These staged risk reduction alternatives will be used to assist the prioritization. See Table 6.1 for a summary of P3 prioritization factors. When funding is provided to implement the approved DSM report recommendations, the district will commence pre-construction engineering and design (PED) and construction once design is completed.

Table 6.1 Prioritization Factors

Prioritization Queue	What is being prioritized?	Prioritization Factors	RA and other information available for Prioritization
P1) Issue Evaluation Studies (IES)	Phase 1 IES to confirm a dam safety issue exists that warrants a DSM study	DSAC class SPRA evaluations and ratings if no PA or IRRM PFMA or risk assessment is available. From a PA use the APF for individual failure modes and total APF of all failure modes, individual life risk, and the societal life risk for the credible PFMs. Critical infrastructure, economic and environmental aspects of the estimated consequences and risk. Recommendations from the RA team	SPRA or PA, and IRRM plan. Possibly a PFMA performed in support of the IRRM plan.
	Phase 2 IES to confirm a dam safety issue exists that warrants a DSM study for any issues for which insufficient confidence exists after a Phase 1 IES or previous Phase 2 IES	DSAC class For the issue(s) being evaluated: the APF, individual life safety risk, and the societal life safety risk for the credible PFMs. Sensitivity analysis to identify the effect of current uncertainty on DSAC and risk evaluations. Critical infrastructure, economic and environmental aspects of the estimated consequences and risk. Recommendations from the RA team	Phase I IES risk assessment

Prioritization Queue	What is being prioritized?	Prioritization Factors	RA and other information available for Prioritization
P2) Dam Safety Modification (DSM) studies	Studies and other work required to support completion of a DSM report	DSAC class From the IES or PA report use the APF for individual failure modes and total APF of all failure modes, individual life safety risk, and the societal life safety risk for the credible PFMs. Consideration of the range of uncertainty in baseline risk estimates. Critical infrastructure, economic and environmental aspects of the estimated consequences and risk. Recommendations from the RA team	IES report PA risk assessment (if done) For a DSAC I dam - SPRA report, incident report, and other available information.
P3) Risk Reduction Projects	Funding of design and implementation of risk reduction measures	DSAC class Total and individual PFM estimated baseline risk showing APF, individual life safety risk, and societal life safety risk Magnitude of the reduction in and the residual total and individual PFM risk showing APF, individual life safety risk, and societal life safety risk Cost-effectiveness as measured by the Cost of a Statistical Life Saved. Disproportionality ratio Benefit cost ratio (BCR) Critical infrastructure, economic and environmental aspects of the estimated consequences and risk.	DSM study report

CHAPTER 7

Interim Risk Reduction Measures for Dam Safety

7.1 Purpose. This chapter provides guidance and procedures for developing and implementing Interim Risk Reduction Measures required for all DSAC I, II, and III dams based upon the USACE Dam Safety Action Classification Table 3.1 of Chapter 3, except for those dams as noted in paragraph 3.3.1 and referenced in Figure 3.1. Interim Risk Reduction Measures (IRRM) are developed, prepared, and implemented, to reduce the probability and consequences of catastrophic failure to the maximum extent that is reasonably practicable while long term remedial measures are pursued.

7.2 Principles for Implementing Interim Risk Reduction Measures at High Risk Dams.

7.2.1 Execution of Project Purposes. USACE executes its project purposes guided by its commitment and responsibility to public safety. In this context, it is not appropriate to refer to balancing or trading off public safety with other project benefits. Instead, it is after public safety principles are met that other purposes can be considered. Dam Safety Officers are the designated advisors and advocates for life safety decisions.

7.2.2 Do No Harm. The principle of ‘Do no harm’ should underpin all actions intended to reduce dam safety risk. Applying this principle will ensure that proposed IRRM implementation would not result in the dam safety being compromised at any point in time or during IRRM implementation.

7.2.3 Risk-Informed Decisions. Decisions should be risk-informed, not risk-based. Risk-informed decisions integrate traditional engineering analyses with numerical estimations of risk through the critical experience-based engineering judgment. We no longer refer to risk-based decisions because of the inappropriate implication that life safety decisions can be reduced to simple, numerical solutions.

7.2.4 Congressional Authorizations. USACE projects provide specific Congressional authorizations and legal responsibilities that often cover a broad array of purposes and objectives. The public safety responsibility is critical to informing how we implement these statutory responsibilities and requires USACE to assure projects are adequately safe from catastrophic failure has specific public safety responsibility, when a project has known safety issues, to take appropriate interim risk reduction measures including reservoir releases USACE statutory responsibilities require operation of dams in a manner that reduces the project's probabilities of failure when there are known issues with the integrity of the project.

7.2.5 Flood Risk Management. We manage risks of flood waters, we do not control them. Our projects do not have unlimited operational capacity to control extreme floods. Our outlet works have limited capacity to release flows in a controlled manner, and thus all properly designed projects have a capacity above which the inflow is passed through

without attenuation. These are very large releases that may cause damage downstream of the dam but not to a greater degree than would have occurred under pre-project conditions. Decision makers must understand these limitations and operational constraints.

7.2.6 Unique Projects Over Time. All projects have unique geographic, physical, social, and economic aspects that are subject to dynamics over time. Decision making within Interim Risk Reduction Measure Plans should consider these complexities and be modified as required over time.

7.2.7 Loss of Life Versus Economic Damages. The operations of a high risk (unsafe or conditionally unsafe) dam during flood conditions can create a conflict between the potential for loss of life and economic damages resulting from an uncontrolled release due to failure and associated economic damages resulting from operational release to prevent failure. Operational releases can be accompanied with planning, advanced warnings, and evacuations with the goal of avoiding loss of life. Economic impacts may be incurred and options for mitigating these impacts can be explored. The advanced planning and execution of mitigating measures is usually more effective with planned, controlled release of the pool than with the case of unplanned, uncontrolled release resulting from failure of the project.

7.2.8 Interim Risk Reduction Measure Plan. The Interim Risk Reduction Measure (IRRM) Plan, including changes to the supporting Water Control Plan, is the key document that frames operational decision making for DSAC I, II, and III dams. This plan establishes the specific threshold events, decision points, and actions required. The IRRM Plan should recognize the need for two primary water control management objectives.

7.2.8.1 A recommended safe operating reservoir level that is maintained for the vast majority of time through non damaging releases to restore the reservoir to restricted level as quickly as reasonable.

7.2.8.2 A plan for which emergency measures such as rapid reservoir drawdown and recommendations on evacuation of the reservoir storage must occur.

7.2.8.3 This approach to water control management recognizes that pool restrictions established for safety purposes cannot and should not be viewed as “must meet” requirements in all flood events, but that there does come a point when emergency measures are necessary.

7.2.9 Centrally Led – Decentrally Executed Program. In the centrally led and decentrally executed USACE Dam Safety Program, responsibilities and decision making for Interim Risk Reduction Measures are vertically distributed.

7.2.9.1 Districts. Develop IRRM Plans, coordinate plans, and execute all plans.

7.2.9.2 Divisions. Coordinate, review, and approve plans for DSAC I, II and III dams. In particular, divisions are critical in assuring system and watershed issues are considered and coordinated.

7.2.9.3 HQS. Establishes, in consultation with the RMC, the DSAC class for all dams, reviews and concurs on IRRM Plans for DSAC class I and II dams, and aligns investment strategies for all unsafe dams.

7.2.10 Risk Communications. Familiarity with IRRM Plan is the key to effective risk communications. It is important that managers and leaders discuss issues consistently and openly with affected stakeholders.

7.3 General. IRRMs shall be established for DSAC I, II and III dams. The DSAC Table (Table 3.1) provides the characteristics and actions for each DSAC, including preparation of an Interim Risk Reduction Measures Plan (IRRMP), considerations for preparation of the plan, and example interim measures. All dams are unique and have specific vulnerabilities and potential failure modes that require expert judgment in the development of the IRRM plans. Interim Risk Reduction Measures are a temporary approach to reduce Dam Safety risks while long-term solutions are being pursued. However, they should not (unless otherwise approved) take the place of long-term approaches. Guidelines for determining if the planned interim risk reduction measure is an interim or a more permanent measure are explained in Section 7.8. In establishing IRRM, the prevention of loss of life is the first and foremost objective, followed by prevention of catastrophic economic or environmental losses. The process of identifying and evaluating IRRM shall be conducted as expeditiously as possible and shall be a collaborative effort between all district elements as well as technical experts within the MSC, RMC, and HQUSACE. The dialogue and coordination between district technical elements, Operations, and Programs is particularly important. After initial assessment within USACE, early involvement with the project stakeholders (e.g., project sponsors, project beneficiaries, local emergency response agencies, power marketing agencies, etc.) will be established with the goal of coordinating support for the IRRM. The public trust must be established through frequent and early interaction and maintained through an effective Communication Plan. A risk assessment may be required as part of the IRRM plan to justify significant restrictions in project storage and release regulation schedules. Pool restrictions should not be held up or delayed waiting for this risk assessment.

7.4 Funding for IRRMP and IRRM. Funding for IRRMP preparation for DSAC I, DSAC II and DSAC III dams is from the O&M account (or the Maintenance portion of the MR&T account). Funding for IRRMP implementation for DSAC I, DSAC II and DSAC III dams is from the O&M account. Studies and planning leading to a Dam Safety Modification Report are funded from the Construction account as part of the Dam Safety Assurance and Seepage/Stability Correction Program. For example, Program funds can be used for inundation maps since that will provide information to advance the Dam Safety Modification study. Design and implementation of permanent risk reduction measures described in the Dam Safety Modification Report are funded from the Construction

account, beginning with the Dam Safety Assurance and Seepage/Stability Correction Program until line-item Construction funds become available. For the O&M account, the work category code (WCC) for IRRMP and IRRM is 61130 for navigation, 61230 for flood damage reduction, and 61630 for joint activities. While these budgeted items will be fully coordinated with program management and operations funding personnel, it is the job of the technical team to make sound, reasonable recommendations on the correct IRRMs and implementation schedules without making compromises due to perceived funding shortfalls. While funding challenges are often a reality, dealing with them is a secondary action that comes only after reaching agreement on the right technical course of action. For the Construction account, use category class subclass code (CCS) 240, 540, or 640 based on the type project. Construction funds will not be used for maintenance repairs, IRRMP, or IRRM. O&M funds will not be used for the Dam Safety Modification study or implementation. The Mapping, Modeling, and Consequence Production Center (MMC) has overall responsibility for developing dam failure, inundation mapping, and consequence models for USACE dams in support of the IRRMP. Districts must seek O&M funds, through the budget process and/or reprogramming, for IRRMP and IRRM. HQUSACE will seek Construction funds for the Dam Safety Assurance and Seepage/Stability Correction Program and will allocate Program funds among projects for Issue Evaluation Studies and Dam Safety Modification work.

7.5 Interim Risk Reduction Measures Plan (IRRMP). Districts with DSAC I, II, and III dams shall develop and submit to the MSC Dam Safety Officer (MSC DSO an IRRMP outlining the proposed risk reduction measures for approval. IRRMP's for DSAC I dams shall be submitted within a 60-day period after being designated as DSAC I , or within 90 days after being designated as a DSAC II, or within 120 days after being designated as a DSAC III. Prior to submission of the IRRMP, the plan shall be subjected to a district Quality Control Review (DQC) with Regional Technical Specialists, or other appropriate specialists. NEPA coordination should be started early in the IRRMP process and be continued to avoid later problems (See Appendix M). Stakeholders should also be engaged in developing the plan to the extent possible. Submission of the IRRMP shall include a formal briefing to the HQ DSO for DSAC I, II and III dams if requested. The IRRMP should as a minimum include the following:

7.5.1 Overall project description, brief construction history, operational history, and purposes.

7.5.2 Overview of identified potential failure modes.

7.5.3 General consequences associated with each identified potential failure mode.

7.5.4 Structural and nonstructural IRRM alternatives considered to reduce the probability of failure and/or consequences associated with the failure modes (reservoir pool restrictions, modification of reservoir regulation plan and updating of EAPs must always be included as an option that is addressed).

7.5.5 General discussion of predicted reduction in the probability of failure and associated consequences, impact on project purposes, environmental impacts, and economic impact to region associated with potential IRRM, both positive and negative.

7.5.6 Recommendations and risk informed justification for IRRM to be implemented.

7.5.7 Schedules and costs to the USACE and others for implementation of IRRM recommendations.

7.5.8 If necessary, proposed cost and schedules for conducting a risk assessment to estimate the benefits and costs for incremental evaluation of IRRM. Risk may justify significant restrictions in project storage and release schedules. Pool restrictions should not be held up or delayed waiting for this risk assessment.

7.5.9 DQC comments and comment resolutions.

7.5.10 Hyperlink to electronic version of current EAP which reflects site specific risks, and which includes emergency exercises for DSAC I, II, and III dams conducted in manners that are appropriate for the risk involved (See paragraph 7.6 for more information on the appropriate level of emergency response exercise).

7.5.11 Communication Plan (Internal and External).

7.6 EAP and Emergency Exercises. The frequency of emergency exercises should correspond directly to the Dam Safety Action Classification (DSAC) rating and hazard potential of the project. The completion of these exercises should be incorporated into the official Interim Risk Reduction Measures Plan for the project if applicable. Refer to Chapter 16 for guidance on the appropriate type and frequency of exercises.

7.7 Decision Process for USACE Dam Safety Interim Risk Reduction Actions. The decision process associated with Dam Safety-related actions will depend on the nature of the action under consideration, the consequences of the action in both the short and long term, and the potential for national and international interest and attention. The decisions will be made based on life safety first, economic risk second, and other considerations last.

7.7.1 Long-term life-safety tolerable risk guidelines should be met by IRRMs wherever available non-structural and appropriate structural options exist to do so. Because life safety is paramount, this implies that the economic and other impacts of IRRMs will not influence meeting long-term life-safety tolerable risk guidelines except in exceptional circumstances. The life safety tolerable risk guideline is intended to influence only the speed with which IRRMs are developed and implemented and not to be a lower level of public safety for short- and medium-term exposure to dam safety risks. See Chapter 5 for more information on tolerable risk guidelines.

7.7.2 Fundamentally, decisions within USACE are the responsibility of the district Commander. Technical decisions related to Dam Safety are generally delegated to the district Dam Safety Officer (DSO). IRRMP and associated decisions require MSC approval and require HQ USACE concurrence; and there are certain USACE actions that are executed by warranted officials, such as procurement, that function outside the usual Commander's chain.

7.7.3 In the Dam Safety area, the principal team members involved in the decision process are the district Dam Safety Officer and Dam Safety Program Manager, the MSC Dam Safety Officer and Dam Safety Program Manager, and at the HQ USACE level, the USACE Dam Safety Officer, the Special Assistant for Dam Safety, and the Dam Safety Program Manager (DSPM). These principals inform and at times execute decisions on behalf of the Commanders in whom the decision authority is vested.

7.7.4 For non-controversial Dam Safety-related actions, following routine review within the local district, MSC, and Headquarters Dam Safety staff, the decision by the district Dam Safety Officer, acting on behalf of the Commander, would be expected. As the level of controversy and potential consequences and attention escalates, a more thorough review would progressively include Commanders at the District, MSC, and HQ USACE levels, perhaps informed by outside experts, and engaging Public Affairs officers. The decision may then be retained by the district Commander and in the case of highly significant dam safety problems, the MSC Commander. While the decision authority lies with the Commanders, the process leading to the final choice for action is informed by technical, policy, and management staff at the district, MSC, and HQ USACE levels.

7.7.5 Table 7.1 depicts a summary of the principal participants in the decisions involving IRRMP formulating, informing and reviewing, and final solution selection and implementation. An electronic copy of the IRRMP (review copy) shall be uploaded to the Risk Management Center's centralized data repository at the time of review copy submittal. A copy of the final IRRMP reflecting all updates and revisions required from the review process shall be uploaded after IRRMP approval.

Table 7.1
Decision Levels for Interim Risk Reduction Actions

DSAC	District	MSC	HQ USACE
I, II, and III (including significant changes)	Formulate, recommend, and implement	Concurrent Review Followed by MSC Approval	
I and II (Annual Review)	Annual Review and update required.	Annual Review	No action required.

7.7.6 An annual review of all DSAC I and II IRRMP's is required unless some event occurs that would trigger an earlier review, e.g., rise in piezometers readings, completion of a remediation phase, etc.

7.7.7 A standard IRRMP review checklist is provided in Appendix N to assist developers and reviewers in the completion of approvable plans.

7.8 Interim Risk Reduction Measures (IRRM).

7.8.1 Types of IRRM that should be considered include, but are not limited to, the items listed below. Practical options will vary from dam to dam, and therefore a creative effort may be needed to identify the options that exist for a specific project. The imperative objective is to reduce the probability of catastrophic failure and associated consequences to the maximum extent reasonably practicable while long-term remedial measures are pursued. IRRMP must be developed on an aggressive timeline to reduce the probability of failure or potential for loss of life once a major dam safety issue is identified. IRRMPs are mandatory for DSAC I, II, and III dams. IRRMP development timeline guidance outlining development, review, and implementation requirements is detailed in Table M.1 in Appendix M. Seepage and internal erosion have been identified as the primary failure mode governing risk for the USACE' dam inventory. Seepage and internal erosion can be a lengthy failure continuum (progressive failure) which may lead to catastrophic loss of pool with little or no warning. An example of a seepage failure development continuum is shown in Figure O.1 in Appendix O. As such, expert judgment is required to match IRRM with the identified potential failure modes, geology, dam design and loading, and determination of where the dam is on a failure line continuum.

7.8.2 Interim risk reduction measures are not intended to be the process for permanently remediating dam safety concerns. The following principles (and associated questions) can be used to determine if a proposed interim risk reduction measure is appropriate.

7.8.2.1 Timely. Will the measure be implemented in a timely manner to reduce risk? Taking several years to implement a measure may mean it is not an interim risk reduction measure. Efforts that require significant investment in time and money for studies and investigations should most likely be included in the Dam Safety Modification Study as a potential alternative.

7.8.2.2 Cost. Is the cost of the measure within budgetary threshold for major maintenance or O&M as outlined in the current budget EC? Measures exceeding the threshold for major rehabilitation modifications are generally not appropriate for interim risk reduction measures.

7.8.2.3 No New Risk. Does the measure increase the overall risk from the dam to the downstream public? This may be a concern for measures that involve changes to

the current approved water control plan and may require a risk estimate to be developed to adequately assess the proposed changes.

7.8.2.4 Emergency Actions. An action done during a response to a dam safety emergency is not an interim risk reduction measure.

7.8.3 Examples of non-structural Interim Risk Reduction Measures.

7.8.3.1 Reservoir pool restrictions or change in water control plan the district should begin immediate action to update the water control plan to reflect the operational change or pool restriction.

7.8.3.1.1 Guidance is provided in ER 1110-2-240, Water Control Management (Reference A.49) for water control plan deviations and updates. In the interim a deviation from the current water control plan should be implemented until the water control plan is updated to reflect the operational change or pool restriction. Regulation plan changes must be documented, and formal deviation requests from the Water Control Plan must be approved by the MSC.

7.8.3.1.2 Annual command level reviews of IRRM implementation are required for DSAC I, II, and III dams and revision to the IRRM plan are to be made as necessary. These reviews should also include review of the communication plans with stakeholder engagement and public involvement plans.

7.8.3.2 Pre-position emergency contracts for rapid supply of other needed items/equipment.

7.8.3.3 Stockpiling emergency materials, e.g., rock, sand, sand bags, emergency bulkheads, or other operating equipment, etc.

7.8.3.4 Use of other reservoirs in the system may be required to mitigate the impact of regulation schedule changes. If the change in regulation schedule is required for other dams in the system, then a regulation deviation for those dams would be required as well.

7.8.3.5 Improved and/or increased inspection and monitoring to detect evidence of worsening conditions to provide an earlier warning to the public for evacuation.

7.8.3.6 Update the Emergency Action Plan and the inundation mapping to include project-specific failure mode(s). The NWS must be included in the EAP to take advantage of their television/radio announcement and stream forecasting capabilities. The Modeling, Mapping, and Consequence Production Center (MMC) has overall responsibility for developing dam failure, inundation mapping, and consequence models for USACE dams in support of the EAP.

7.8.3.7 Explicit procedures, communications systems, and training of appropriately skilled team members for prompt and effective emergency response by the USACE in the event of the detection of worsening or catastrophic conditions. Refer to Chapter 16 for guidance on the appropriate type and frequency of exercises.

7.8.3.8 Conduct appropriate emergency exercises that plan for a range of failure scenarios (including the combined effects of multiple failure modes and different timing of detection) to improve warning and evacuation times.

7.8.3.9 Coordination with local interests and Federal and non-Federal agencies, including the National Weather Service (NWS) and local Emergency Management Agencies (EMA), with a focus on the specific failure mode(s) and the effectiveness of response including appropriate response exercises.

7.8.3.10 Identify instrumentation/monitoring “trigger” or threshold pools that would initiate more urgent monitoring or emergency response. In addition, threshold values should be established for instrument readings where possible.

7.8.3.11 Installation of early warning systems to increase evacuation percentage and time.

7.8.3.12 Preventive maintenance and repairs such as cleaning drains and improving spillway gate reliability where non-functioning components would exacerbate the existing conditions in an emergency.

7.8.3.13 Acquisition of real estate (if possible) that would preclude damages and potential loss of life from a potential dam failure or other IRRM.

7.8.4 Examples of Structural Interim Risk Reduction Measures (Some Can be Incorporated in Long Term Remedial Measures).

7.8.4.1 Isolate problem area (e.g., cofferdam around problem monolith(s) or other project feature).

7.8.4.2 Improve seepage collection system.

7.8.4.3 Lower the spillway crest to aid in prevention of failure (A consequence estimate may be warranted to ensure overall risk is not increased by this measure).

7.8.4.4 Increase spillway capacity/construct another spillway. (A consequence estimate may be warranted to ensure overall risk is not increased by this measure).

7.8.4.5 Breach/lower saddle dams along the reservoir perimeter. (A consequence estimate may be warranted to ensure overall risk is not increased by this measure).

7.8.4.6 Strengthen weak areas (e.g., upstream or downstream blanket to cut off/slow seepage; install tie-backs/anchors; and install additional buttresses).

7.8.4.7 Construct a downstream dike to reduce head differential.

7.8.4.8 Construct stability berm.

7.8.4.9 Increase dam height. (A consequence estimate may be warranted to ensure overall risk is not increased by this measure).

7.8.4.10 Modify outlet discharge capability such as by installing temporary siphon(s).

7.8.4.11 Increase erosion protection where necessary.

7.8.4.12 Protect downstream critical facilities (e.g., medical and emergency services).

7.8.4.13 Construct shallow cutoff trench to slow seepage.

7.8.4.14 Target grout program specifically for suspected problem area(s) to slow seepage.

7.8.4.15 Remove significant flow restrictions (downstream bridge conditions may restrict maximum discharge from the outlet works. Upstream bridges or small dams may restrict flow caused by debris buildup that could result in a large release).

7.8.5 Contrasting Interim Measures with Permanent Measures. The above examples of IRRMs are a good guide for how interim measures differ from permanent measures; however, there are always situations for which judgment must be used in determining what measures are appropriate. Following are principles for making such distinctions:

7.8.5.1 Interim measures should not induce additional risks beyond what the dam safety deficiency present;

7.8.5.2 Interim measures should be timely (i.e. implemented within 6 months or less);

7.8.5.3 Some interim measures – whether structural or non-structural - may become permanent based on the recommendations of an Issue Evaluation Study or Modification Report;

7.8.5.4 Interim measures are funded out of the operations and maintenance account and are subject to the dollar limitations for O&M described in the Major Rehabilitation guidance; and

7.8.5.5 Emergency measures may exceed the dollar and scope limitations established for the O&M account.

7.9 Evaluation Factors for IRRM. Some types of IRRM may significantly impact authorized project purposes (e.g., water supply, recreation, hydropower, etc), project beneficiaries, and others who depend indirectly on the project. Additionally, some IRRM may result in more frequent discharges from the dam and from lower pool elevations than originally designed, impacting stakeholder interests. Public safety must always be given a higher priority over all other project purposes and benefits. In evaluating and formulating IRRM, it must be kept in mind that each project has its own unique attributes that have to be addressed on a case by case basis using expert judgment. The following shall be considered and addressed:

7.9.1 Providing protection of life, property and the environment. Examples to consider are loss of life; increased sickness and disease; employment losses; business income losses; private property damage; infrastructure damage including roads and utilities; losses in social and cultural resources including community effects and historical resources; environmental losses including aquatic and riparian habitat, threatened and endangered species; and HTRW (such as flooding a Superfund site). Early and frequent NEPA coordination with IRRMP is recommended.

7.9.2 Reducing the probability of failure and consequences of uncontrolled pool releases. Increasing the confidence that any changes associated with the dam that are related to development of a failure mode will be promptly detected.

7.9.3 Increasing the confidence that emergency management agencies will be notified promptly.

7.9.4 Increasing the warning time and effectiveness of evacuation of the populations at risk.

7.9.5 Reducing the probability of the initiating loading (critical pool levels).

7.9.6 Improving the organizational capability to implement IRRM (resources, time, funding, technology, etc.).

7.9.7 Preserving the public trust.

7.9.8 Addressing stakeholder issues and impacts.

7.9.9 Understanding the degree of confidence in the scope of the problem and effectiveness of the interim solution.

7.9.10 Capability for incorporating IRRM into the permanent solutions.

7.9.11 Impacting authorized project purposes or other project benefits.

7.9.12 Maximizing cost effectiveness.

7.9.13 Minimizing social disruption and environmental impacts.

7.10 Communications Plan. A communication plan is to be submitted for review as part of the Interim Risk Reduction Measures Plan. Information about the communication plan is in Chapter 10 of this document.

7.11 Approval and Implementation of IRRMP. Approval of the IRRMP for DSAC I, II, and III dams shall be by the MSC DSO with concurrent review by HQUSACE (see Table 7.1). If significant changes are made to a previously approved IRRMP, the revised plan is to be submitted for review and approval as a new plan.

CHAPTER 8

Issue Evaluation Studies

8.1 Purpose of Issue Evaluation Studies (IES).

8.1.1 This chapter provides guidance and procedures for developing the IES report that presents the risk assessment, documentation, and justification for conducting a Dam Safety Modification study at completed USACE projects. In addition, this chapter provides guidance for completing Issue Evaluation Study plans, Issue Evaluation studies, and Issue Evaluation Study reports. Figure 8.1 is a graphical representation that shows the work flow process for Issue Evaluation Studies. Figure 8.2 shows how the Issue Evaluation Study and Periodic Assessments fit into the overall portfolio risk management process for dam safety.

8.1.2 Issue Evaluation Studies for dams rated as DSAC II, III and, IV are studies to determine the nature of a safety issue or concern, and the degree of urgency for action within the context of the entire USACE inventory of dams. The purpose of an Issue Evaluation Study (IES) is to focus on significant potential failure modes when evaluating risk, verify the current DSAC rating, guide the selection and gauge the effectiveness of interim risk reduction measures, and justify the need to pursue or not pursue Dam Safety Modification studies. Issue Evaluation Study results are used to assist dam safety officials with making risk informed decisions, and prioritize dam safety studies and investigations within the context of the entire USACE inventory of dams.

8.2 Objectives of Issue Evaluation Studies**.** The overall objective of an IES is to evaluate a dam safety issue found during an incident, inspection, or study, in relation to the USACE tolerable risk guidelines and determine if the issue justifies further actions either through interim measures, formal study, or both. The scope of the issue evaluation study is to evaluate both confirmed and unconfirmed issues related to the performance, maintenance, and operational concerns of the dam.

8.2.1 Confirmed Dam Safety Issues. Confirmed issues are those that pose a significant risk (approaching or exceeding tolerable risk limits) with a high level of confidence (due regard for uncertainty) such that additional studies and investigations are not likely to change the decision that dam safety modifications are justified. Confirmed dam safety issues are manifested or obvious issues that impact the safe operation of a dam. Examples of confirmed issues can be described as performance concerns, such as a lack of spillway capacity, or deficiencies that are demonstrated by signs of seepage and piping, known flaws or defects, component distress or malfunction, unusual settlement, unsatisfactory instrument readings, etc. that can be specifically linked to one or more potential failure modes. Confirmed dam safety issues are typically addressed in Phase I Issue Evaluation Studies, where there is sufficient performance data and documentation to prepare a risk estimate that contains minimum uncertainty and provides an adequate level of confidence that a Dam Safety Modification Study is warranted.

8.2.2 Unconfirmed Dam Safety Issues. Unconfirmed issues are issues that are judged to pose a high probability of unsatisfactory performance, but are based on data with such high uncertainty that the conclusions may be significantly influenced or changed if additional data was obtained. Examples of unconfirmed dam safety issues can be described as performance concerns where the contributing factors are unclear due to limited or outdated design documentation, or subtle changes in performance that cannot be visually inspected or obviously linked to a potential failure mode. In these cases, additional studies, investigations, and analysis may be needed to clearly identify the potential failure mode, or more accurately predict the system response probabilities of the potential failure mode causing the concern. Unconfirmed issues are typically addressed in Phase 2 Issue Evaluation Studies where additional funding and time is justified to further investigate the dam safety issue prior to finalizing the risk estimate.

8.2.3 Scope of Issue Evaluation Studies. The scope and level of rigor required for a Issue Evaluation Study will be based upon the complexity of the dam safety issue, and the ability to evaluate these issues and potential failure modes using existing data, analyses, and performance history. As the risk management process develops over time, a baseline risk estimate will be prepared for every dam in the portfolio either through a Periodic Assessment, or through other risk informed studies. For projects where a baseline risk estimate has been prepared during a previous Periodic Assessment or other risk informed study, the risk estimate should be updated to address the current issue or concern. For projects where a baseline risk estimate has not been performed, an initial risk estimate for issue evaluation will be prepared to determine if the issues of concern approach or exceed the tolerable risk limits.

8.2.4 Based on the results of an Issue Evaluation Study, the following actions can be taken:

8.2.4.1 Confirm that dam safety issues do or do not exist;

8.2.4.2 Verify or reclassify the current DSAC rating based on these findings;

8.2.4.3 Determine if a dam should be reclassified as DSAC I and thus warrants the expedited process for a DSAC I dam as shown on the left side of Figure 8.2;

8.2.4.4 Gauge the effectiveness, and guide the selection, of current and additional risk reduction measures;

8.2.4.5 Use the Issue Evaluation Study results to develop effective risk management plans, identify data deficiencies, develop study plans, and prioritize dam safety modification studies; and

8.2.4.6 Determine if there is justification (or not) to proceed to a Dam Safety Modification study.

8.3 Issue Evaluation Study Plan. The Issue Evaluation Study Plan shall include, at a minimum, the following sections:

8.3.1 Overall project description and purposes;

8.3.2 Overview of the previous findings and reason(s) for the current DSAC rating;

8.3.3 Description of the specific dam safety issues of concern, and how these dam safety issues were identified. Include narrative that explains if these issues are a result of identified defects, flaws, or unsatisfactory performance, or if these are unconfirmed dam safety issues that require additional data, analysis or site investigations to confirm the dam safety issue does or does not exist;

8.3.4 Description of the interim risk reduction measures that were implemented as a result of previous risk estimates and PFMA;

8.3.5 A listing of all PFMA reports or risk estimates that have been performed for the project to date, the names of the lead facilitator and lead risk estimator who completed these efforts, and the dates they were completed. This would include reference to prior PFMA's conducted by the district for the development of IRRMP's, Issue Evaluation studies, Periodic Assessments, etc.;

8.3.6 A description of the proposed work plan/scope of work and funding estimate for the district to complete the Issue Evaluation Study. The district will coordinated with the RMC and obtain RMC concurrence of the scope of work prior to the development of the plan. The will help the district develop the scope of work and deliverables for each IES plan. The plan should then be submitted for review and approval.

8.3.7 A listing of the proposed key district team members and disciplines who will participate in the proposed PFMA and Issue Evaluation Study, the district team lead engineer who will be responsible for preparing the issue evaluation report, and a listing of the specialties required to be part of the ATR team.

8.3.8 Phase 1 study plan examples from other USACE projects are available upon request by contacting the Risk Management Center.

8.4 Funding for Issue Evaluation Study Plans. The preparation of Issue Evaluation study plans will be funded from Dam Safety Assurance, Seepage/Stability Correction Program (“Wedge Funds”). The 5 to 7 page Issue Evaluation Study plan will be used to ensure the scope and cost of the proposed study is appropriate, and will act as the official requesting document that enters the project into the dam safety program funding queue for Issue Evaluation Studies.

8.5 Schedules for Submittal of Issue Evaluation Study Plans. Preparation of Issue Evaluation Study plans for DSAC II, III, & IV dams shall begin when the project receives a priority rating and the district is notified by the RMC/HQUSACE to proceed with

preparation of the IES Study plan. The plan study plan shall be submitted to the MSC DSO within 60 days after such notification.

8.6 Approval Authority. Issue Evaluation Study Plans for Phase 1 and addendums to Phase 1 plans for Phase 2 studies shall be prepared by the district and approved by the district's dam safety officer. The study plan will contain a District Quality Control plan as per EC 1165-2-209 (reference A.5). The need for Phase 2 studies will be determined by the vertical team based on findings documented in the IES draft report. The execution strategy for incremental Phase 2 efforts must be formulated during a collaborative meeting between the risk assessment cadre and district to assure that the district obtains the information required to complete the risk estimate with the minimal expenditure of time and resources. Due to the complexity of work efforts and funding required for Phase 2 efforts, Phase 2 work scope must be approved by the Risk Management Center, and the funding request will require budgetary approval for Wedge Funds from the HQUSACE Dam Safety Program Manager. Table 8.1 depicts a summary of the principal participants in the decisions involving the development, review, and approval of study plans.

Table 8.1 Issue Evaluation Study Plan - Review & Approval Requirements

</table>

8.7 Submittal Requirements. Issue Evaluation Study plans shall be submitted electronically to the MSC DSO, HQ USACE DSPM, and the Dam Safety Risk Management Center. An electronic copy of the study plan (review copy) shall be uploaded to the Risk Management Center's centralized data repository site (RADS II) at the time of hard copy submittal. A copy of the final study plan reflecting all updates and revisions shall be uploaded after approval.

8.8 Issue Evaluation Studies - Phase 1.

8.8.1 Risk Estimates. Risk estimates in support of the Issue Evaluation Studies (IES) are conducted to determine if the total project risk approaches or exceeds the Corp's tolerable risk limits, and if Dam Safety Modification (DSM) studies are justified. Phase 1 efforts utilize existing data and information. The risk estimate resulting from an issue evaluation study is used to verify or reclassify the current DSAC, guide the selection and gauge the effectiveness of interim risk reduction measure requirements, and provide information to support prioritization of Dam Safety Modification Studies from a national portfolio level.

8.8.2 Scope of Risk Estimates. The scope of the risk estimate must be more rigorous than the level of detail executed in SPRA estimates, may be more or less rigorous than a Periodic Assessment, and is intended to achieve a defensible, risk informed justification for initiating Dam Safety Modification Studies. Typically, risk estimates for confirmed issues can be established with existing data and performance history because the physical manifestations are visual and measurable. Unconfirmed issues may require the collection of additional data if the missing data required to assess performance is not available or cannot be linked to a specific failure mode or observation.

8.8.3 Data for Risk Estimates. For dams with no baseline risk estimate (see Chapter 3) the IES risk estimate should be conducted using existing data and should include as many significant failure modes as are necessary to determine that the estimated risk justifies going on to a DSM study. For dams where a previous risk estimate has been calculated from a Periodic Assessment or other dam safety study, the potential failure modes should be reviewed, and the risk estimate should be updated based on any changes in condition or new information that may have become available since the last risk estimate was performed.

8.8.4 Finding of Urgent and Compelling. At anytime during the conduct of an Issue Evaluation Study, if a finding of major concern or evidence is identified requiring an ‘urgent and compelling’ need for action, such as if the dam is judged to be in the failure continuum, the project should immediately be moved to the expedited process as outlined in Chapter 9, Dam Safety Modification Studies and Documentation.

8.8.5 Minimum Phase 1 Study Tasks. As a minimum, the following tasks must be performed to develop a risk estimate for Phase 1 Issue Evaluation Studies:

8.8.5.1 Perform a facilitated Potential Failure Mode Analysis.

8.8.5.2 Evaluate potential failure modes, using existing information and data, based on the collective knowledge and expertise of the facilitator, risk assessment cadres, regional technical specialists, district dam safety engineers, and the project staff. Potential failure modes that cannot be confirmed without additional analysis or investigations should be identified and documented.

8.8.5.3 For all potential failure modes that pose significant risk to the project, identify the initiators, the failure progression mechanisms, and the resulting impacts.

8.8.5.4 Estimate load-frequency and load-response probabilities for a full range of pools using the best available methodology and risk tools

8.8.5.5 Utilize consequence estimates provided by the Modeling, Mapping, and Consequence Production Center (MMC).

8.8.5.6 Prepare a risk estimate for issue evaluation (that typically addresses four or five significant failure modes), and determine if the issues of concern approach or exceed the tolerable risk limits.

8.8.6 Dam Safety Risk Assessment Tools. Corps of Engineers Dam Safety Risk Assessment Tools along with Expert Elicitation can be used to calculate load-frequency and load-response probabilities for all potential failure modes included in the risk estimate. The Risk Management Center will provide guidance on selection of the most appropriate risk estimating tools and methodologies to be employed, prior to the start of the Issue Evaluation Study.

8.9 Issue Evaluation Studies - Phase 2.

8.9.1 Additional Study. When existing data and design documentation is either unavailable or insufficient to reduce the uncertainties in the computation of load-response probabilities and resulting risk estimate, parametric (sensitivity) studies should be conducted to determine what influence the data has on the load-response probabilities and resulting risk computations. The need for additional information, studies and investigations to resolve uncertainty should be determined after the parametric studies are completed and insight is gained as to what improvements in the confidence of the risk estimate can be gained from the additional expenditure of time and resources.

8.9.2 Phase 2 Justifications. Phase 2 efforts should be considered when there is a lack of confidence in the ability to make a decision regarding whether to proceed to a DSM study. Phase 2 studies are justified when it can be clearly demonstrated that additional reductions in uncertainty or a greater level of confidence can be achieved in the IES risk estimate from the additional time, resources, investigations, and analyses that are proposed. Phase 2 efforts will be incrementally funded to support increasing levels of rigor until the uncertainties are sufficiently minimized. Figure 8.2 of the Issue Evaluation Study process shows the incremental approach and decision making process as the levels of rigor are increased.

8.9.3 Study Plan Addendums. Study plan addendums for Phase 2 efforts shall be prepared and submitted to the Risk Management Center if issues require further analysis or field investigations that are beyond the scope of completing a Phase 1 study. A parametric study should clearly show the likelihood of better defining an issue,

and determine if it is a problem or not, with a high degree of confidence or certainty with the additional studies, analyses, and investigation efforts. The addendum should clearly summarize the following information:

8.9.3.1 Results from the risk estimate performed during the initial Issue Evaluation Study.

8.9.3.2 A detailed description of specific uncertainties in the existing data, analyses, and site conditions, that appears to be major risk drivers in the initial risk estimate.

8.9.3.3 A detailed description of proposed studies, analysis, and investigations that are required to reduce uncertainty or investigate the unconfirmed issues.

8.9.3.4 A description of how these additional work efforts will reduce uncertainty or confirm a hidden flaw or defect.

8.9.3.5 A detailed description of how these efforts will be phased, and how the results of these studies will be incrementally assessed prior to advancing to the next phase of study.

8.9.3.6 Results of sensitivity analysis or other appropriate uncertainty analysis methods to explicitly show how the uncertainty influences the risk estimate.

8.9.3.7 The estimated cost and schedule duration to complete these more detailed studies.

8.10 Use of Tolerable Risk Guidelines.

8.10.1 The results of the risk estimate in an Issue Evaluation Study will assist the vertical team in determining what additional actions are justified and the urgency of such actions.

8.10.2 Projects with an approved Issue Evaluation Study that concludes that the estimated risk exceeds the USACE tolerable risk limits will undergo a DSAC review and be recommended for a Dam Safety Modification study. The project will be prioritized, scheduled, and moved into the resource queue for funding.

8.10.3 If the Issue Evaluation Study concludes that the risk estimate is significantly below the tolerable risk limits, the study should recommend that an evaluation of the tolerability of the residual risk and compliance with Essential Agency Guidelines be conducted accordance with Chapter 5. The DSAC reclassification will then be reviewed.

8.10.4 Prioritization of projects for Dam Safety Modification Studies will be based on the following three criteria as well as additional criteria listed in Chapter 6, Dam Safety Risk Management Prioritization:

8.10.4.1 The total annual probability of all failure modes;

8.10.4.2 The incremental risk estimate above the limit line for life safety; and

8.10.4.3 The total annualized (mean) risk estimates for life safety for all failure modes.

8.11 Issue Evaluation Study Documentation.

8.11.1 Objective. The document for this phase of the dam safety portfolio risk management process shall be called Issue Evaluation Study report. The IES report will be used to present information that confirms the dam safety issues and support the need for a dam safety modification study (DSM), or states the case to revise the current DSAC rating. Therefore the dam safety issue or issues must be clearly defined and supported by the related risk estimate. In the event that a Dam Safety Modification study is not justified, or a determination is made at any point during the study that the issues can be remediated under the major rehabilitation threshold funding cap , the Issue Evaluation Study is stopped and documented, and project is assigned to the routine O&M processes as defined in Figure 3.1. At the minimum a potential failure mode analysis will be conducted. The IES document shall include information that provides the rationale for the decisions presented in the report and shows how this dam does or does not comply with the tolerable risk guidelines, and describes the recommended plan and why it is justified.

8.11.2 Organization and Scope. The IES report shall consist of two separate documents, the Issue Evaluation Study Summary of Findings (IESSF) report, and the IES Report. These documents shall be prepared in a standardized modular format to allow for relative ease of assembly and updating. This approach allows for the district to provide concise and consistent reports to the MSC, RMC, SOG, and HQ and allows for studies to be easily prioritized on a national level. This will also support rapid reevaluation of a project if adverse incidents occur or criteria changes at a later date that would warrant review of the risk estimate and the priority given the dam.

8.11.2.1 The IESSF for an Issue Evaluation Study is intended to be a stand-alone component of the IES report that provides information to senior USACE officials to make dam safety decisions. The IESSF for an Issue Evaluation Study is an internal working document and not intended for public release.

8.11.2.2 The IESSF for an Issue Evaluation Study concisely summarizes the following: The USACE dam safety program; the history and status of safety issues and actions for the subject dam; the recommended actions and supporting facts; the outcomes from analysis and assessment; and the degree of confidence in the basis for the recommendations. The document will be ten to fifteen pages, well formed and will comprise text, tables, diagrams, and photos.

8.11.2.3 The Issue Evaluation Study shall contain all background data, risk computations, findings, conclusions, and recommendations, and supporting documentation. It will act as the technical reference and supporting document for the IESSF Report.

8.11.2.4 The format and content of these two complimentary IES Report documents are detailed in Appendix P.

8.12 Roles and Responsibilities.

8.12.1 Risk Management Center (RMC). The Risk Management Center will provide support to the HQUSACE DSO and the Senior Oversight Group (SOG) for the formulation of dam safety policy, actions, and budgets, for risk informed management of USACE national portfolio of dams. The RMC will coordinate with the SOG, MSC, and district offices to prioritize the Issue Evaluation and Dam Safety Modification Studies from a national perspective. The RMC will schedule and budget all centralized resources needed for the execution of Issue Evaluation Studies based on the SOG's prioritization and assign facilitators and regional cadre members to perform the PFMA and risk estimate. The Risk Management Center will also assign a separate risk assessment cadre to assist with the agency technical review requirements. Risk assessment cadre members shall not be assigned to work on projects that are located within the boundaries of their home district.

8.12.2. Risk Assessment Cadre. A risk assessment cadre and an approved PFMA facilitator, with support from the district, will be responsible for conducting the potential failure mode analysis and performing the risk estimate. The regional cadre will provide the district with recommendations on implementing or revising Interim Risk Reduction Measures, provide recommendations for Phase 2 studies when warranted, and collaborate with the district staff concerning the scope of the recommended phase 2 work efforts. The Risk Assessment Cadre will also provide limited consulting services to the district during formulation of the Risk Management Plan, and during preparation of the IES report. The risk assessment cadre will also perform a quality control review of the final IES and companion IESSF report prior to the agency technical review.

8.12.3 District. The district is responsible for the overall management and execution of Issue Evaluation Studies. This includes formation and management of an Issue Evaluation Study Product Delivery Team as directed in ER 5-1-11 (reference A.35). The PDT will coordinate the development of the IES plan scope of work with the RMC; prepare and submit the Issue Evaluation Study plans; collect, compile, and present project data in support of the PFMA and risk assessment; support the risk assessment cadre during the PFMA, the risk estimate; conduct additional investigations required to reduce uncertainty; conduct parametric studies required to support development of additional IRRM; funds requests addendums; and schedule the various work efforts required to complete the Issue Evaluation Study. The districts are also encouraged to utilize the PFMA and risk estimate work efforts conducted by the risk assessment cadres as risk management training opportunities for additional members

of their technical staff who are not specifically assigned to the Issue Evaluation Study PDT. The makeup of the PDT is critical to the expeditious accomplishment of the IES. The PDT will have one or more engineer members, one of which will be designated as the team's 'lead engineer' in ER 1110-2-1150 (reference A.51). Care should be taken that the appointed 'lead engineer' has the experience and qualification to perform as the coordinator of engineering activities and serve as the single-point-of contact within the PDT on engineering technical matters for the IES.

8.12.4 Agency Technical Review. The Risk Management Center is responsible for coordinating and managing agency technical review of the IES reports in accordance with EC 1165-2-209 (reference A.5).

8.13 Funding. Issue Evaluation Studies will be funded by HQUSACE from the Dam Safety Assurance and Seepage/Stability Correction Program ("Wedge") funds. Projects will be prioritized and funded based on the prioritization policies outlined in Chapter 6.

8.14 Schedule. The schedule for completion of an Issue Evaluation Study is dependent on the complexity and urgency of the project being studied, and its position in the national funding priority queue. Once funding is received, work should be accomplished in accordance with the schedule presented in the Issue Evaluation Study plan. Phase 1 Issue Evaluation Studies should be completed within 6 months from receipt of funds. For projects where Phase 1 efforts find that a Phase 2 study is justified, the study should be executed in accordance with the approved study plan addendum for the Phase 2 efforts.

8.15 Decision Process; Submittal, Review, and Approvals of IES.

8.15.1 Decision Process. The decision process: submittal, review and approvals of IES involve both sequential and concurrent actions by a number of participants. This process includes: the PDT; the district, MSC and RMC; ATR team; and HQUSACE. It is therefore imperative that the vertical teaming efforts are proactive and well coordinated to assure collaboration of the report findings, conclusions, and recommendations, and that there is consensus at all levels of the organization with the recommended path forward. The dam safety program will follow the policy review process described in EC 1165-2-209, Civil Works Review Policy. The RMC will be the review management office for the ATR, and the RMC must certify that the risk assessment was completed in accordance with the USACE current guidelines and best risk management practices. A Quality Control and Consistency (QCC) review will be conducted including the district, MSC, and RMC. The district and the risk assessment cadre present the IES risk assessment, IES findings, conclusions, and recommendations for review. After resolution of QCC review comments, the MSC and HQUSACE will complete quality assurance and policy compliance review. Then the district will present the report findings and recommendations to the Senior Oversight Group (SOG). Once any SOG comments are resolved the district DSO, MSC DSO, and the SOG Chair will sign a joint memorandum approving the findings and recommendations of the IES report. By

formal memorandum the SOG Chair will notify the USACE DSO and the MSC commander that the IES report is approved. (See Figure 8.3)

8.15.2 Table 8.2 depicts a summary of the principal participants in the decisions involving approval of Issue Evaluation Studies.

Table 8.2 Issue Evaluation Study Report - Review and Approval

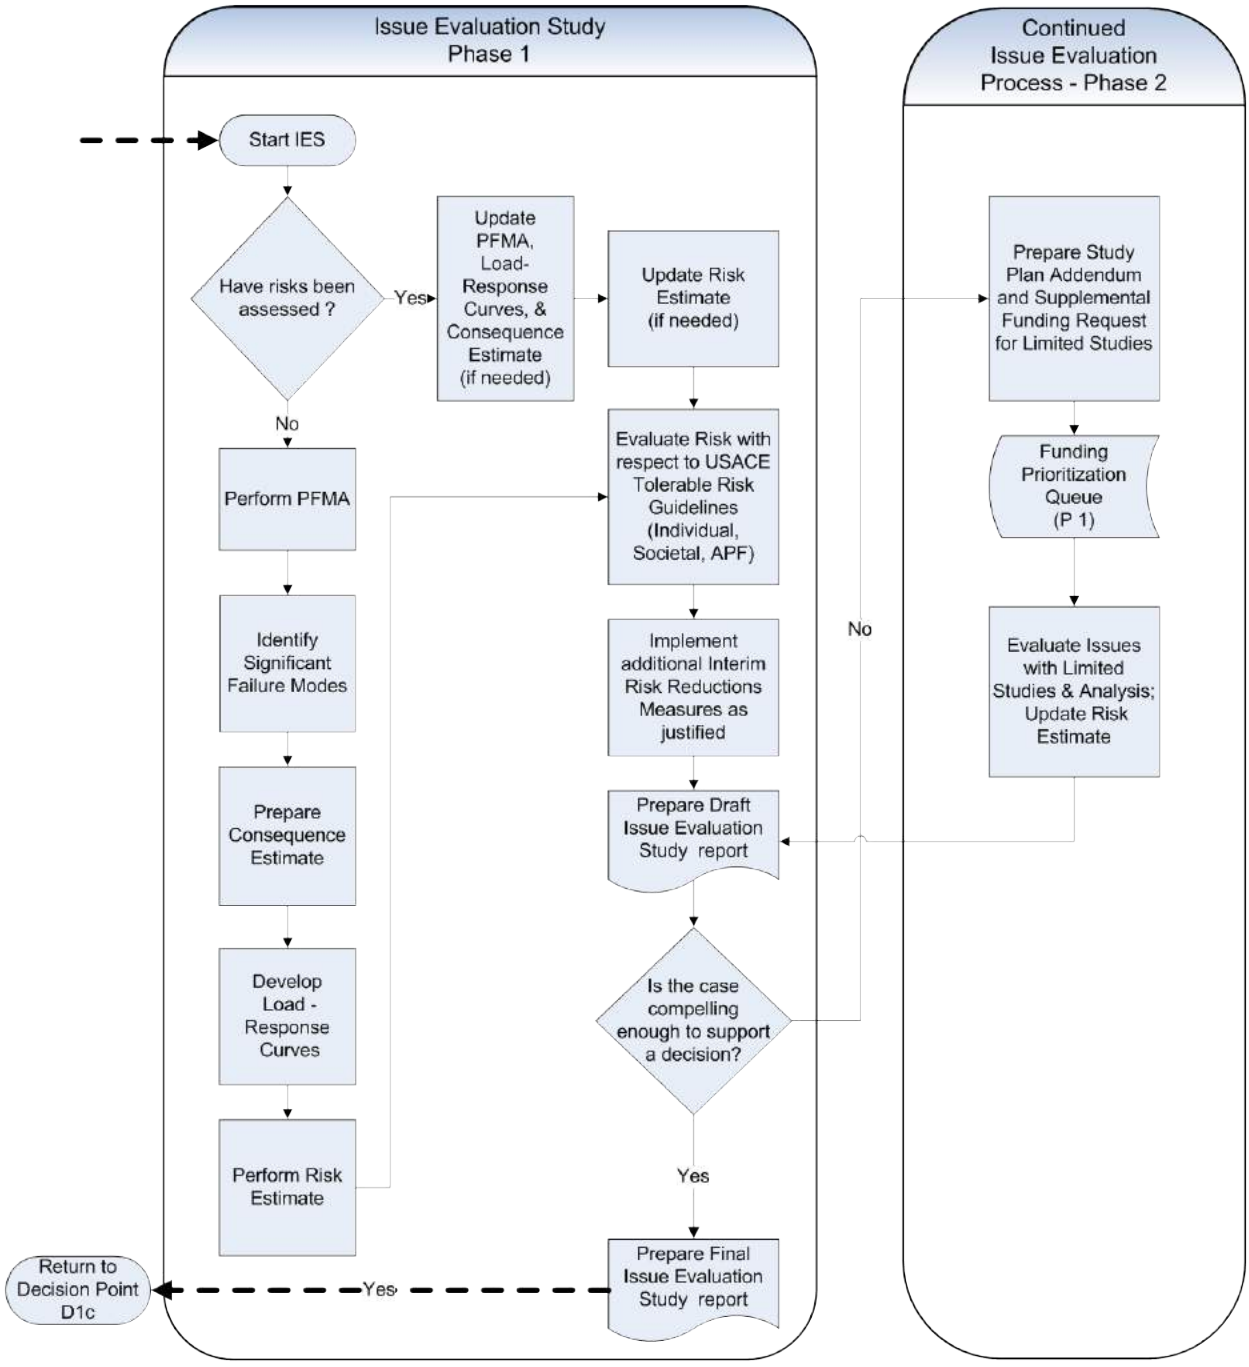
Study Phase	For DSAC II, III, & IV	District	MSC	RMC	HQUSACE DSO
Issue Evaluation Study Report	Includes: Report, Appendices, to include Risk Estimate	ATR w/Risk Assessment Cadre Cert Joint Approval by DSO	Quality Assurance Review Joint Approval by DSO	QCC Risk Cadre Review & Approval of Risk Estimate Concurrence with Recommendations	Policy & Compliance Review Joint Approval by SOG Chairman

8.15.3. Report submittal requirements are as follows:

Review Center	Number of Paper Copies	Number of CD-R Copies
MSC DSO	1	2
HQ USACE DSPM	1	2
Risk Management Center	1	3

An electronic copy of the IES report (review copy) shall be uploaded to the Risk Management Center's centralized data repository (RADS II) at the time of hard copy submittal. A copy of the final IES Report reflecting all updates and revisions required from the review process shall be uploaded after report approval.

8.15.4 Following joint approval of the Issue Evaluation Study, the RMC, MSC, and district will be notified, and the project will be placed in the national priority queue for Dam Safety Modification study funds.



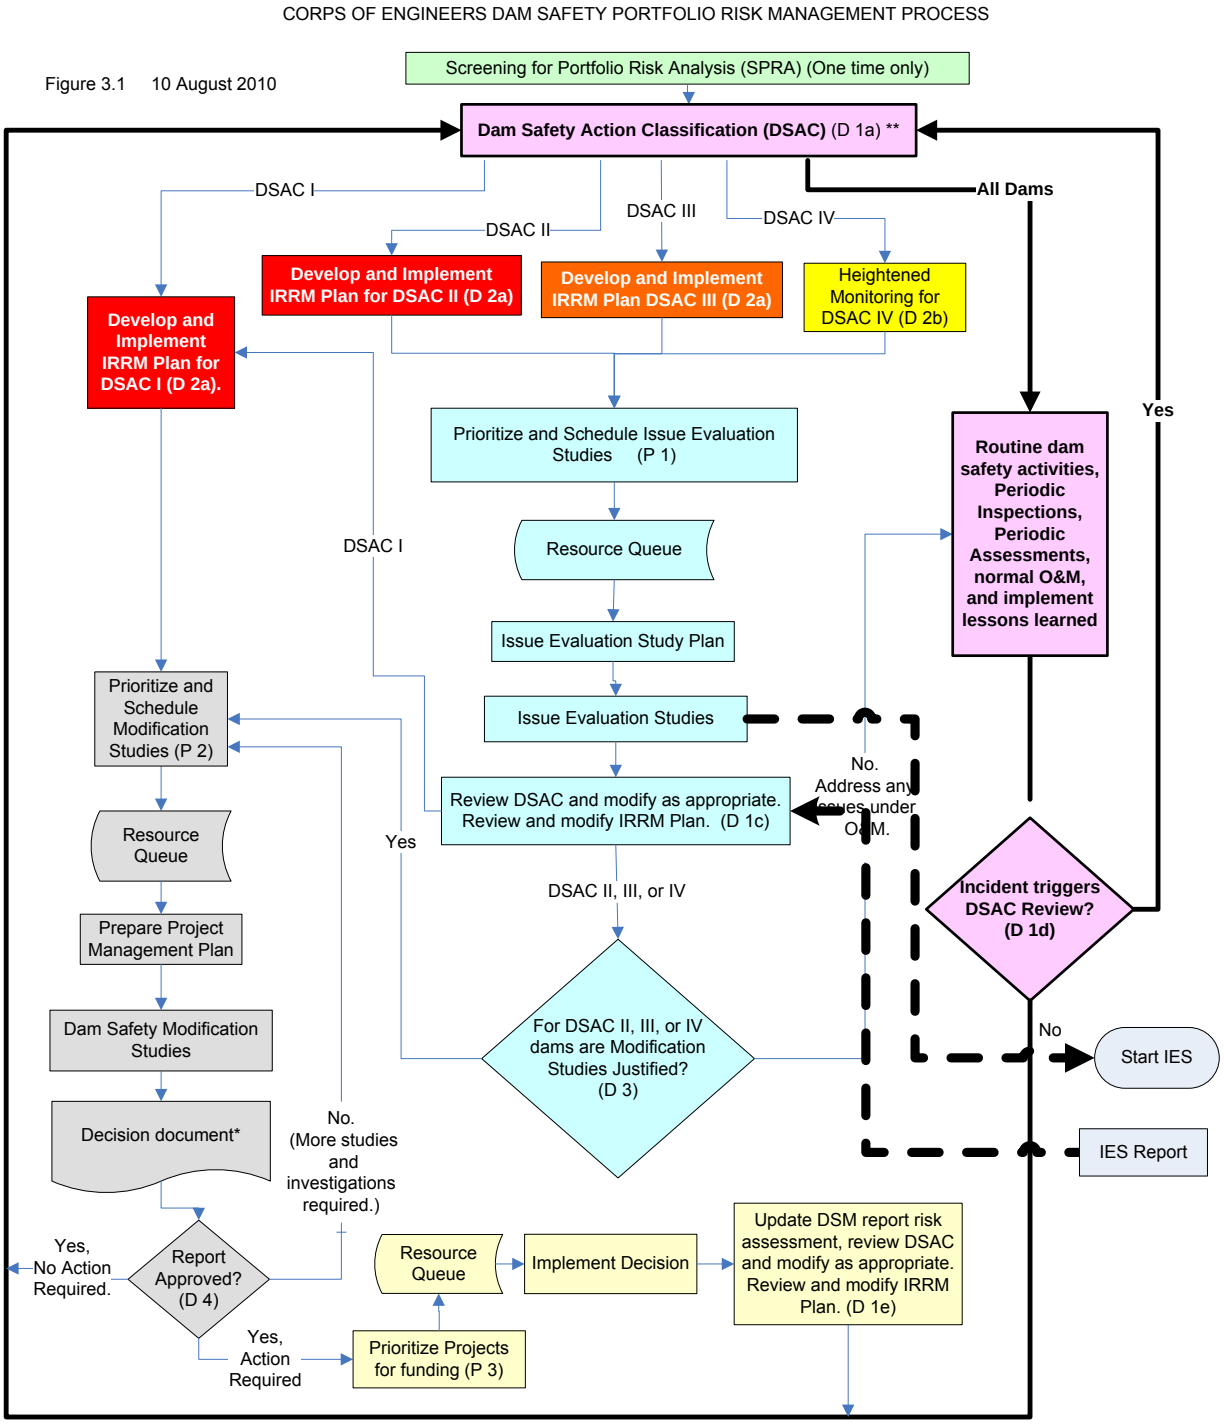


Figure 8.1 - Graphical Representation that Shows the Work Flow Process for Issue Evaluation Studies

Decision Points are label as (D 1a), Prioritization Points are labeled as (P 1), and the details for each point is explained in Chapter 3.
*** Independent External Peer Review requirements are to be addressed per guidance in the Dam Safety Modification chapter.**
**** Regardless of DSAC classification, dams with insignificant or no consequences should they fail are considered exceptions; will be so tagged, and are exempt from the dam safety portfolio management process depicted here in Figure 3.1.**

Figure 8.2 - How the Issue Evaluation Study Fits Into the Overall Portfolio Risk Management Process

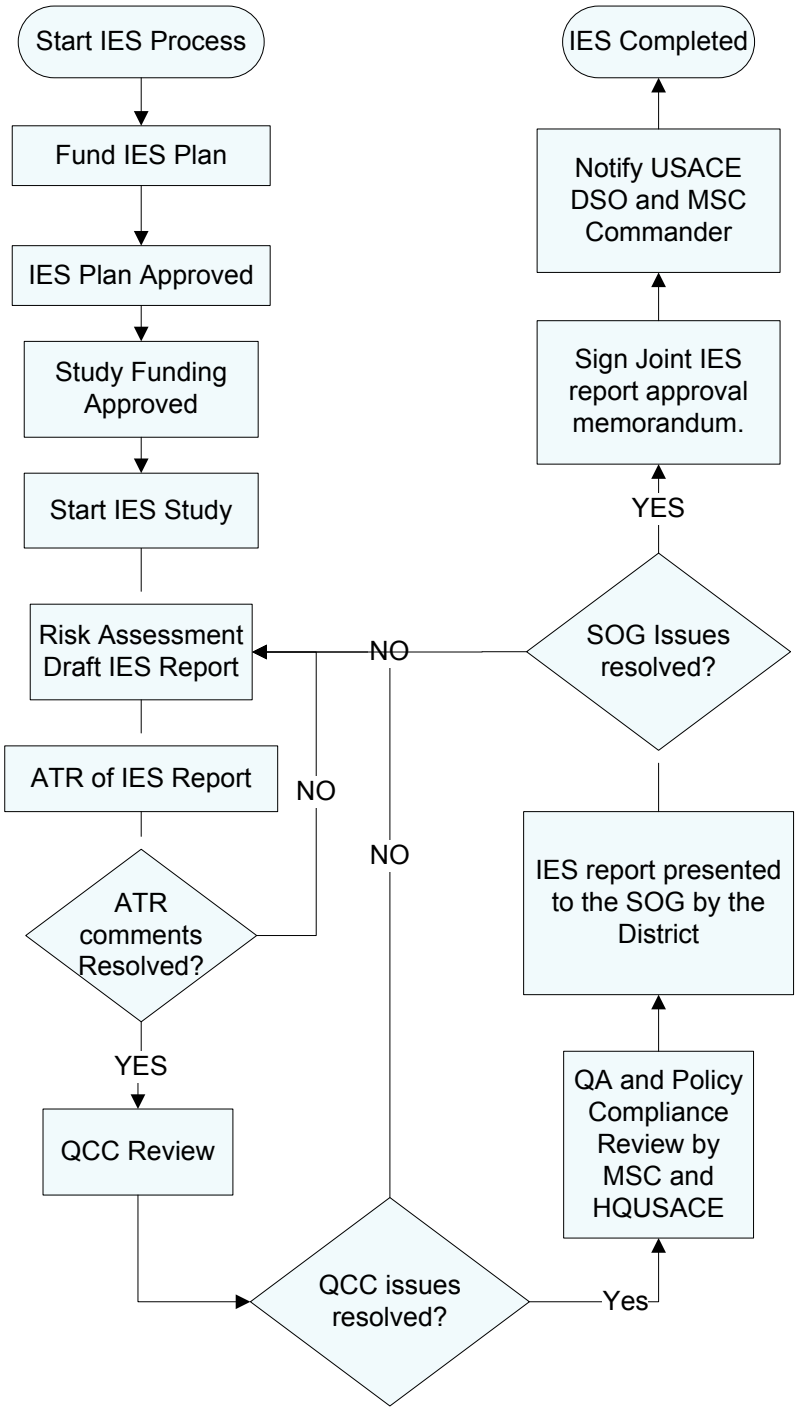

Figure 8.3 – Flowchart of the IES Decision, Review, and Approval Process

CHAPTER 9

Dam Safety Modification Studies and Documentation

9.1 Purpose. This chapter provides guidance and procedures for developing the dam safety modification report that presents the investigation, documentation, and justification of modifications for dam safety at completed USACE projects. This chapter provides a description of the requirements to obtain approval to modify a dam to address the risks associated with a dam safety issue(s) and to meet USACE tolerable risk guidelines. A dam safety issue is any condition at a dam that results in unacceptable life safety, economic, and environmental risks posed by the failure of the dam (See Glossary for definition of dam failure). A single type of decision document – Dam Safety Modification (DSM) report – will be used for all dam safety modification projects not requiring additional authorization by Congress. The DSM report shall be prepared for any Dam Safety Action Classification (DSAC) Class I, II, III, and IV dams upon the approval of the Dam Safety Senior Oversight Group (SOG) in accordance with national priorities. Figure 3.1, Corps of Engineers Dam Safety Portfolio Risk Management Process, depicts the process by which dams can be identified, approved, and prioritized for a Dam Safety Modification study. Figure 9.1 presents the DSM study, review, decision and approval process flowchart. The DSM report shall include a risk assessment for all potential failure modes (PFM) that have been determined to contribute to significant risk for that dam. The report must also document additional efforts (if any) to further define the dam safety issue. The risk assessment in support of the Dam Safety Modification study shall address the life safety, economic, and environmental consequences associated with the identified significant failure modes. The goal of the risk management alternatives, including potential staged implementation options, is to achieve the tolerable risk guidelines presented in Chapter 5. The report format and additional technical guidance is contained in Appendix Q.

9.2 Change from Previous Guidance. The Dam Safety Modification study process described in this chapter replaces the Major Rehabilitation Evaluation report for Dam Safety and the Dam Safety Assurance Evaluation reports described in previous regulations (ER 1110-2-1155, “Dam Safety Assurance Program” (reference A.52); and ER 1130-2-500, “Project Operations - Partners and Support (Work Management Policies)” (reference A.62). Note - for projects with currently approved Dam Safety Assurance reports or major rehabilitation reports a DSM report will not be required.

9.3 Eligibility. This guidance encompasses all structural and non-structural project modifications to address dam safety issues. Potential operational failures, identified by the DSM risk assessment, such as the failure of operating equipment not directly impacting dam safety, will generally not be addressed with a DSM Report. Those actions should follow normal O&M or major rehabilitation paths for funding. Only projects that have received approval as a national priority project by the USACE SOG, based on an assessment of risk, shall be funded to go through the DSM study process. The decision to modify a dam should be based upon the magnitude of existing life, economic, and environmental risks; the effectiveness of the proposed alternatives to

reduce the risk to tolerable levels, and meeting essential USACE guidelines. Funding for preparation of the report and implementation of the action(s) is addressed in a following paragraph.

9.3.1 Eligibility Requirements.

9.3.1.1 In order to qualify, the modifications must be within the Chief of Engineers' discretionary authority to operate and maintain the dam. Guidance that will assist in making this determination is contained in ER 1110-2-240 “Water Control Management” dated 8 October 1982. Essentially, the requirement is that the proposed modification must not significantly impact the congressionally authorized purposes. Further guidance is provided in ER 1105-2-100, Appendix E, Section 57 ‘Other Authorities’, paragraph d. ‘Reallocation of Storage.’

9.3.1.2 At such time during execution of the DSM study that it is determined that the likely recommended alternative will significantly impact authorized purposes, the study process should transition to “Additional Authorization” as described in paragraph 9.3.2 below. A DSM report will be used to approve projects to be funded with Construction appropriation funding. A DSM study is not required for major maintenance work under the Operation and Maintenance appropriation (generally items costing less than the current cap for major maintenance in the budget EC and that can be completed in one construction season). Once a DSM report is prepared and approved, budget justification and other supporting data will be prepared in accordance with directions from the USACE DSO in coordination with the business line managers.

9.3.2 Additional Authorization. Project modifications that require additional authorization should be studied under the authority of Section 216 of the Rivers and Harbors Act of 1970 (reference A.94), following the guidance in Chapter 2 of ER 1105-2-100 (reference A.42).

9.4 DSM Study Objectives. The objective of a dam safety modification study is to identify and recommend an alternative risk management plan that supports the expeditious and cost effective reduction of risk within the overall USACE portfolio of dams. Recommended risk management alternatives are to be technically feasible and acceptable following current best practices, comply with applicable laws, and satisfy applicable tolerable risk and essential USACE guidelines for remediation of existing dams. The risk associated with each failure mode being addressed by a risk management alternative must be reduced to a level that satisfies the tolerable risk guidelines in Chapter 5 on an individual failure mode basis, including considerations for ALARP. The intent is to achieve a complete remediation of those individual failure mode(s) being addressed by the plan to support the ultimate goal of having an adequately safe dam where the dam meets essential USACE guidelines and the total residual risk for the dam is considered tolerable (DSAC V). Each alternative risk management plan must be formulated to support effective and efficient risk reduction within the USACE portfolio of dams which may require a staged implementation

approach. The principle of “Do No Harm” (see paragraph 1.10.2.) must be respected in development of the risk management plan.

9.4.1 DSAC I and II Dams.

9.4.1.1 The DSM report for DSAC I and II dams will support expedited risk reduction for urgent dam safety issues. The objective is to identify and recommend an alternative risk management plan that addresses all failure modes that contribute to the DSAC I or II classification such that the failure modes being addressed would be completely remediated and the dam would be reclassified after implementation of the plan.

9.4.1.2 The DSM study for DSAC I and II dams will focus on those individual failure mode(s) that collectively contribute to the DSAC I or II classification. Other significant failure modes should be included in the study if they can be expeditiously and cost effectively addressed at the same time without impacting the schedule for completion of the study and the timeframe for implementation of the alternative risk management plan. All significant failure modes still need to be identified during the PFMA and quantified for the baseline risk estimate even though they may not be addressed by an alternative risk management plan. Resources allocated to the evaluation of failure modes that will not be part of an alternative risk management plan should be kept to a minimum relying primarily on existing information.

9.4.1.3 After implementation of the alternative risk management plan, the dam will be reclassified and inserted back into the portfolio risk management process at the appropriate location for national prioritization of any remaining dam safety issues.

9.4.2 DSAC III and IV. The DSM report for DSAC III and IV dams will support risk reduction for priority dam safety issues. The objective is to identify and recommend an alternative risk management plan that addresses all failure modes that contribute to the DSAC III or IV classification such that the failure modes being addressed would be completely remediated and the dam would be reclassified after implementation of the plan. All significant failure modes need to be identified during the PFMA, quantified for the baseline risk estimate, and addressed by the alternative risk management plan. The intent is to achieve a complete remediation of those individual failure mode(s) being addressed by the plan to support the ultimate goal of having an adequately safe dam (DSAC V).

9.5 Basic Approach and Principles for Execution of a DSM Study.

9.5.1 DSM studies will be undertaken following the six step framework of civil works planning presented in ER 1105-2-100 "Planning Guidance Notebook" (reference A.42) as adapted herein for addressing dam safety issues.

9.5.1.1 Identify dam safety issues and opportunities;

9.5.1.2 Estimate baseline risk condition;

9.5.1.3 Formulate alternative risk management plans;

9.5.1.4 Evaluate alternative risk management plans;

9.5.1.5 Compare alternative risk management plans; and

9.5.1.6 Select a risk management plan.

9.5.1.7 A description of each step is presented in subsequent paragraphs. USACE dam safety decision making is generally based on the accomplishment and documentation of all of these steps. It is important to stress the iterative nature of this process, and the need to tailor the scope and detail of the study to the specific dam and its suspected safety issue, and its evidenced urgency for action. As more information is acquired and developed, it may be necessary to reiterate some of the previous steps. The six steps, though presented and discussed in a sequential manner for ease of understanding, usually occur iteratively and sometimes concurrently. Iterations of steps are conducted as necessary to formulate efficient, effective, complete and acceptable plans. The results of and data from previous interim risk reduction measures (IRRM) studies, Issue Evaluation studies (IES), and periodic assessments (PA) completed under Chapters 7, 8, and 11 shall form the beginnings of the DSM study.

9.5.1.8. Environmental Compliance. DSM studies and modifications should be in compliance with all applicable Federal environmental statutes and regulations and with applicable State laws and regulations where the Federal government has clearly waived sovereign immunity. The National Environmental Policy Act (NEPA) requires Federal agencies, including the USACE, to comply with a process that includes the inventory and assessment of the environmental resources within the study area. NEPA also requires the evaluation and comparison of alternatives to determine the impacts to those ecological, cultural, and aesthetic resources identified and investigated. Involvement by resource agencies and the general public during the study process is also required. USACE NEPA guidance can be found in ER 200-2-2. The NEPA process will be integrated with the USACE six step planning process. This should also include all measures required for compliance with other applicable environmental statutes, such as the Endangered Species Act, the Clean Air Act, the Clean Water Act, the Fish and Wildlife Coordination Act, and the Historic Preservation Act, among others. (See ER 1105-2-100, Appendix C for compliance requirements.) This integration is intended to reduce process overlap and duplication. The integrated process will help assure that well-defined study conditions and well-researched, thorough assessments of the environmental, social, and economic resources affected by the proposed dam safety activity are incorporated into dam safety decisions.

9.5.2 Identify Dam safety issues and opportunities (Step 1). Dam safety issues and opportunities statements will be framed in terms of the USACE dam safety program objectives, identified dam safety issues (significant potential failure modes), and tolerable risk and essential USACE engineering guidelines. Issues and opportunities

should be defined in a manner that does not preclude the consideration of all potential alternatives to resolve the dam safety issues. Problems and opportunities statements will generally encompass just current conditions, but in some instances, may need to encompass future conditions (changes in consequences, on-going changes in site, downstream, and reservoir pool terrain conditions, etc.) as well if they are expected to be significantly different from the current conditions and thus be relevant to 'fix' decisions and risk characterization. Thus, they can be, and usually are, re-evaluated and modified in subsequent steps and iterations of the DSM study process.

9.5.2.1 Properly defined statements of dam safety issues and opportunities will reflect the priorities and preferences of the Federal Government, the non-Federal sponsors and other groups participating in the DSM study process; thus active participation of all stakeholders in this process is strongly recommended. Proper identification of dam safety issues and opportunities (risk management measures) are the foundation for scoping the DSM study process.

9.5.2.2 Once the dam safety issues and opportunities are properly defined, the next task is to define the DSM study risk reduction objectives and the constraints that will guide efforts to resolve these safety issues and achieve these opportunities. Dam safety risk reduction objectives are statements that describe the desired results of the DSM study process by resolving the dam safety issues and taking advantage of the opportunities identified. Objectives must be clearly defined based on tolerable risk guidelines and essential USACE guidelines.

9.5.2.3 Constraints are restrictions that limit the DSM study process. Constraints are unique to each DSM study. Some general types of constraints that need to be considered are resource constraints and legal and policy constraints. It is also essential that the team focus on practical and realistic plans so that quick and efficient evaluation may occur. Resource constraints are those associated with limits on knowledge, expertise, experience, ability, data, information, money and time. Legal and policy constraints are those defined by law, USACE policy and guidance. Plans should be formulated to meet the DSM study risk reduction objectives and to avoid violating the constraints. Thus, a clear definition of risk reduction objectives and constraints is essential to the success of the DSM study process.

9.5.3 Estimate Baseline risk condition (Step 2). A quantitative and qualitative description is made, for both current and, in selected instances, future risk conditions that become the baseline conditions. A vital activity during this step is to identify all key assumptions and sources of uncertainty in defining this baseline risk condition. These activities would include the potential failure mode analysis (PFMA) and detailed risk assessment of current and where important, future, without modification, conditions. Existing conditions are those at the time the study is conducted and most often constitute the baseline risk condition. The baseline risk condition provides the basis from which alternative plans are formulated and their impacts are assessed. Since impact assessment is the basis for plan evaluation, comparison and selection, clear definition and full documentation of the baseline condition are essential. Consequence

analysis will consider existing and future population at risk and threatened population for fatality estimates. All dam safety issues (significant failure modes) will undergo a risk assessment to determine the baseline risk and for each subsequent risk reduction alternative. Each potential failure mode must be shown to lead to a plausible failure of the dam. These steps are accomplished with the risk assessment that establishes the baseline risk estimate on a without IRRM condition. Permanent structural IRRM and permanent changes to the water control manual are to be included in the baseline risk condition.

9.5.4 Formulating alternative risk management plans (Step 3). Alternative risk management plans shall be formulated to identify specific ways to achieve dam safety objectives within constraints, so as to resolve the dam safety issues and realize the opportunities that were identified in step 1. A risk management alternative plan consists of a system of structural and/or nonstructural measures, strategies, or programs formulated to meet, fully or partially, the identified DSM study risk reduction objectives subject to the constraints. At least one proposed risk management alternative must be shown to reduce the risk to the levels defined in the tolerable risk guidelines (Chapter 5). A risk management measure is a feature or an activity that can be implemented at a specific geographic site to address one or more objectives. Risk management measures are the building blocks of alternative plans and are categorized as structural and nonstructural. An alternative plan is a set of one or more risk management measures functioning together to address one or more objectives. A range of alternative plans shall be identified at the beginning of the study process and screened and refined in subsequent iterations throughout the study process. However, additional alternative plans may be identified at any time during the process. Plans should be in compliance with existing statutes, administrative regulations, and common law. Alternative plans shall not be limited to those USACE could implement directly under current authorities. Plans that could be implemented under the authorities of other Federal agencies, State and local entities and non-government interest should also be considered.

9.5.4.1 The first phase in the plan formulation process is the identification of dam safety risk management measures that could be implemented, giving consideration to structural and non-structural measures, for individual significant failure modes. The second phase is the formulation of alternative risk management plans by combining the risk management measures as appropriate for multiple significant failure modes. Alternative risk management plans should be significantly differentiated from each other. As a general rule alternatives must be formulated to contribute to achieving the tolerable risk and essential USACE engineering guidelines, and reflect the ALARP considerations.

9.5.4.1.1 Required alternatives are:

9.5.4.1.1.1 No action alternative (current condition baseline risk);

9.5.4.1.1.2 Meeting risk reduction objectives for the DSAC class of the dam (Refer to Section 9.4);

9.5.4.1.1.3 Achieving only tolerable risk limit for life safety;

9.5.4.1.1.4 Make IRRM permanent,

9.5.4.1.1.5 Remove structure, and

9.5.4.1.1.6 Replace structure.

9.5.4.1.2 Each alternative risk management plan shall be formulated in consideration of four criteria described in the Principles and Guidelines (P&G): completeness, efficiency, effectiveness, and acceptability.

9.5.4.1.2.1 Completeness is the extent to which an alternative risk management plan provides and accounts for all necessary investments or other actions to ensure the realization of the DSM study risk management objectives, including actions by other Federal and non-Federal entities.

9.5.4.1.2.2 Efficiency is the extent to which an alternative risk management plan is the most cost effective means of achieving the objectives.

9.5.4.1.2.3 Effectiveness is the extent to which an alternative risk management plan contributes to achieving the objectives.

9.5.4.1.2.4 Acceptability is the extent to which an alternative risk management plan is acceptable in terms of applicable laws, regulations and public policies.

9.5.4.1.2.5 Appropriate mitigation of adverse effects shall be an integral component of each alternative risk management plan.

9.5.4.2 Non-structural measures shall be considered as means for addressing dam safety issues and opportunities. Non-structural measures may be combined with structural measures to produce a risk management plan or considered as a stand-alone alternative. Non-structural measures shall receive equal consideration in the alternative development process to structural risk management measures.

9.5.5 Evaluating alternative risk management plans (Step 4). The evaluation of effects is a comparison of the with-risk reduction condition to the without IRRM condition (baseline condition) for each risk management alternative. This necessitates risk assessment be performed for all alternatives. Considering the IRRM as an alternative for permanent implementation should be considered in the formulation process.

9.5.5.1 Evaluation consists of four general tasks.

9.5.5.1.1 The first task is to determine the most likely condition expected under each alternative risk management plan. Each with-risk reduction condition will describe the same critical variables included in the baseline condition developed in step 2 (risk

evaluation factors of annual probability of failure, life safety and economic and environmental consequences, and costs and benefits). Criteria to evaluate the alternative plans include all significant resources, outputs and plan effects. They also include contributions to the dam safety risk management objectives, compliance with environmental protection requirements, the P&G's four evaluation criteria (completeness, effectiveness, efficiency and acceptability) and comparison with tolerable risk and essential engineering guidelines.

9.5.5.1.2 The second task is to compare each with-risk reduction condition to the baseline condition and document the differences between the two.

9.5.5.1.3 The third task is to characterize the beneficial and adverse effects by magnitude, location, timing and duration. Beneficial and adverse effects of each plan must be compared. Special care shall be taken to insure that the plan will not result in the risks being increased by the plan instead of lowered. These include monetary and non-monetary benefits and costs. Identification and documentation of tradeoffs will be required to support the final recommendation. The effects include those identified during the evaluation phase and any other significant effects identified in step 5. The comparison step can be defined as a reiteration of the evaluation step, with the exception that in this step each plan (including the no action plan) is compared against each other and not against the without-project condition. The output of the comparison step shall be a ranking of plans.

9.5.5.1.4 The fourth task identifies the plans that will be further considered, dropped or reformulated in the DSM study process. A plan will be further considered based on a comparison of the adverse and beneficial effects and the extent that the plan achieves the tolerable risk guidelines and essential USACE guidelines.

9.5.5.2 Steps in the procedures may be abbreviated by reducing the extent of the analysis and amount of data collected where greater accuracy or detail is clearly not justified by the cost of the plan components being analyzed. The steps abbreviated and the reason for abbreviation shall be documented in the study reports.

9.5.6 Comparing alternative risk management plans (Step 5). In this step, plans (including the no permanent risk reduction action plan) are compared against each other, with emphasis on the outputs and effects that will have the most influence in the decision making process, e.g. annual probability of failure, life safety tolerable risk guidelines, ALARP considerations, and essential USACE guidelines. A comparison of the outputs of the various plans must be made. The no action plan is to be based on a without IRRM condition. Beneficial and adverse effects of each plan must be compared. The comparison step can be defined as a reiteration of the evaluation step, with the exception that in this step each plan (including the no permanent risk reduction action plan) is compared against each other and not against the baseline condition. The output of the comparison step shall be a ranking of plans.

9.5.7 Selecting a risk management plan (Step 6). A single risk management plan will be selected for recommendation from among all alternative plans that have been considered, including the no action plan. The criteria for selecting the recommended risk management plan will generally be based on the ranking resulting from the comparisons of plans described in 9.5.5. The primary evaluation factors of tolerable risk guidelines, ALARP considerations, and essential USACE guidelines form the basis for plan selection. Beneficial and adverse effects of each plan must be compared. Other considerations, such as economic and environmental, might be used in selecting a risk management plan must be fully documented and justified. The DSM study risk assessment shall be updated after implementation of the risk reduction remedial measures and evaluated to determine if the risk reduction objectives were achieved.

9.6 Dam Safety Modification Study Project Management Plan and Tasks.

9.6.1 Project Manager, Lead Engineer, Project Delivery Team, and the Project Management Plan.

9.6.1.1 The first actions under the study shall be the assignment of a project manager, a lead engineer, creation of a vertical project delivery team, and the development and completion of a project management plan (PMP) for the study per ER 5-1-11, *U.S. Army Corps of Engineers Business Process* (reference A.35) and ER 1110-2-1150, *Engineering and Design of Civil Works Projects* (reference A.51). The PDT consists of personnel from engineering, planning, operations, public affairs office, and others necessary to develop the project.

9.6.1.2. A copy of the final DSM PMP reflecting all updates and revisions required from the review process shall be uploaded after PMP approval.

9.6.2 Establish Vertical Team. Establish the vertical project delivery team (PDT) to include the appropriate level of district, MSC, Risk Management Center, and HQUSACE members.

9.6.3 Vertical team meetings.

9.6.3.1 Kickoff Meeting. The district will hold a kickoff meeting with HQUSACE, Risk Management Center, MSC and all others involved to review and obtain concurrence of the PMP prior to approval by the district dam safety officer and the start of the DSM study (See Table 9.1). Any review comments are to be provided the district within 30 days of submission of the PMP for review or the district will proceed with the submitted plan. An electronic copy of the DSM study PMP (review copy) shall be uploaded to the Risk Management Center's centralized data repository at the time of review copy submittal.

9.6.3.2 Alternative Scoping Meeting. After step 2 (Estimate baseline risk condition) a vertical team meeting shall be held to brainstorm and identify the risk management measures to be used in the development of the risk management alternatives.

Table 9.1 Dam Safety Modification Study Project Management Plan - Review & Approval				
Activity/Document	District	MSC	HQ	
			RMC*	DSO
Dam Safety Modification Study PMP	Approval of PMP by DSO	Concurrent Review (NTE 30 days)	Concurrent Review (NTE 30 days)	Concurrent Review (NTE 30 days)
Review Plan	Prepare	Review and Approve	Concurrent Review and Certify (NTE 30 days)	N/A
*Review Management Organization				

9.6.3.3 Risk Management Plan Formulation Briefing. After step 3 (Formulate alternative risk management plans) there shall be a vertical team meeting where the various alternatives will be presented and discussed. The outcome of this meeting will be agreement on those alternatives that will be carried forward to steps 4, 5, and 6, and the level of design and cost estimate for each alternative.

9.6.3.4 In-Progress Reviews. Additional in-progress review meetings are to be scheduled with the vertical team on a regular basis not to exceed six month time intervals.

9.6.4 External Consultants. In consultation with the vertical team determine if an expert advisory panel to support the DSM study effort is recommended and outline the scope of services to be provided by the board of consultants. This is not the independent external peer review discussed later in this chapter.

9.6.5 Study Schedule and Cost Estimate. Based on the study scope, a study schedule and cost estimate shall be developed. Copies of the schedule and cost estimate shall be included in the PMP and provided to the MSC and HQUSACE DSO.

9.6.6 Investigations and Studies.

9.6.6.1 Detailed field investigations and office studies shall be scoped based on the need for a full baseline risk assessment of the dam.

9.6.6.2 The DSM study must include sufficient field investigations, model studies, and other studies to ensure that all dam safety issues have been adequately defined and the data will support the identified and recommended permanent risk management

alternatives and that a supportable cost estimate can be prepared for inclusion in the DSM Report.

9.6.7 Baseline Risk Estimate. One of the first major tasks of a DSM study is to perform a baseline risk assessment to ensure that all credible potential failure modes that contribute significant risk to the total risk of the dam are evaluated and their associated risk estimated for the baseline risk estimate. All risk assessments done up to this point are to be reviewed and considered for use in this full risk assessment of the dam.

9.6.8 Product Review.

9.6.8.1 Review Plan (RP). District will prepare a review plan per EC 1165-2-209 (reference A.5). The Risk Management Center is the RMO. This plan includes all levels of review: District Quality Control (DQC), Agency Technical Review (ATR), Quality Control and Consistency (QCC) review, quality assurance and policy compliance review, SOG review, and Independent External Peer Review (IEPR). DQC and ATR will occur during key stages in the development of the particular work product as outlined in the review plan. Figure 9.1 shows the sequence for the various levels of review. If a particular level of review is not anticipated, the RP will document the risk-informed decision not to perform that level of review. Note that DSM reports that recommend the 'no action' alternative are to be reviewed in the same manner as DSM reports that recommend an action alternative.

9.6.8.2 Quality Control and Consistency Review. Quality Control and Consistency (QCC) review will be conducted including the district, MSC, and RMC. The district and the risk assessment cadre present the baseline risk assessment, risk management alternatives considered, and the recommended risk management plan for review.

9.6.8.3 SOG Review. The district presents the baseline risk assessment, risk management alternatives considered, and the recommended risk management plan to the dam safety senior oversight group prior to the IEPR.

9.6.8.4 Independent External Peer Review (IEPR). Section 2034 of WRDA 2007 (P.L. 110-114) requires an IEPR for all new projects and for all project modifications that meet the criteria listed in EC 1165-2-209 (reference A.5). This review must be completed before the DSM report is approved. EC 1165-2-209, Water Resources Policies and Authorities, Civil Works Review Policy (reference A.5), contains the current guidance for the review for all civil works products. If a Type I IEPR is not required the Type II IEPR scope will contain a comprehensive review of the DSM report in addition to the Safety Assurance Review (Section 2035 of WRDA 2007, P.L. 110-114.) The intent is not to have two separate review panels for the same dam safety project. This review will be completed within a designated time frame for all DSAC I and II dams or the project will go forward without the review being completed due to life safety concerns.

9.6.9 IRRM Plan. After completion of the DSM baseline risk estimate review the IRRM plan and update as appropriate.

9.6.10 Post Implementation Risk Assessment. The PMP shall include the task of updating the DSM study risk assessment after implementation of the risk management remedial measures. The dam shall be evaluated to determine if the risk management objectives were achieved.

9.7 Dam Safety Modification Decision Document.

9.7.1 Name of Decision Document. The decision document for this phase of the dam safety portfolio risk management process shall be called a Dam Safety Modification Report (DSM Report) and shall be approved in accordance with paragraph 9.8, before initiation of detailed design leading to the preparation of the plans and specifications.

9.7.1.1 The DSM report will include a Dam Safety Action Decision Summary (DSADS) which is intended to be an extractable, stand alone component of the DSM report that meets the information needs of senior USACE officials in making dam safety decisions. It would be a public document with unrestricted distribution, but is not designed to be a public communications document per se.

9.7.1.2 The DSM report format, detailed description of the report requirements, and additional technical guidance is contained in Appendix Q. All technical sections shall be appended to the report. The reporting requirements are the same for all projects, regardless of the type of deficiency or mode of failure. Detailed guidance for preparation of the DSADS is in Appendix R.

9.7.2 Reports for DSAC I and II Dams. When a project is placed in DSAC Class I and II, an expedited process shall be followed in the preparation of the DSM Report. This expedited process can be accomplished by the maximum use of vertical teams, concurrent ATR, and early initiation of design documentation report and plans and specifications for the first contracts. This expedited process shall not short cut any necessary investigations and analysis. Field investigations should be started early and include concurrent analysis for findings as the investigations continue. The NEPA (Reference A.37) and real estate processes (Reference A.38) shall start as early as possible. While the report must be expedited, it should still follow the format outlined in Appendix Q. During preparation of the report, extensive and more frequent communication with approving authorities is required to assure a smooth and successful expedited approval process.

9.7.3 Cost Estimate, Economic Analysis, and Total Project Cost.

9.7.3.1 Recommended Risk Management Plan Cost Estimate. An M-CACES cost estimate is required for the recommended risk management plan. Cost estimates shall include a cost risk analysis showing the uncertainty per ER 1110-2-1302, Civil Works

Cost Engineering (reference A.53). The level of detail in the cost estimate is to be that of a feasibility report in order to more accurately identify the baseline cost estimate.

9.7.3.2 Present the results of the economic cost analysis and the total project cost for the recommended risk management plan.

9.8 Submittal, Policy Compliance Review, and Approval Process.

9.8.1 Submittal. The district DSO shall submit the DSM report package including a cover letter requesting policy compliance review in preparation for approval to the MSC DSO, Risk Management Center, and HQUSACE in the number listed in Table 9.2. Two complete copies and 6 copies of the main report without appendices shall be transmitted directly by the district to the USACE DSO at HQUSACE, ATTN: CECW-CE for concurrent review. The transmittals shall include the completed review checklists as given in Appendix S - Dam Safety Modification Report Issue Checklist and Appendix T - Post-Authorization Decision Document Checklist. Once the report is transmitted, further work on the project shall be accomplished only after consultation with the MSC and the USACE DSOs and their concurrence is obtained. An electronic copy of the DSM Report (review copy) shall be uploaded to the Risk Management Center's centralized data repository at the time of hard copy submittal. A copy of the final DSM Report reflecting all updates and revisions required from the review process shall be uploaded after report approval.

Table 9.2 DSM Report Submission

Office	Number of Complete Reports (Includes Appendices) Paper Copies	Number of Main Report (No appendices) Paper Copies	Number of CD-R Copies of Full Report
MSC DSO	6	-	10
HQ USACE RIT and DSPM	2	6	8
Dam Safety Risk Management Center	2	-	8

* The HQUSACE DSO will send two copies with CDs to the MSC RIT

9.8.1.1 Modification to the Water Control Plan. If one of the alternatives recommended is a change to the water control plan, the district is to follow the normal process of submitting a formal request to the USACE chain-of-command for approval of the changes in the official water control plan after the DSM report is approved. Guidance is provided in ER 1110-2-240, Water Control Management (reference A.49).

9.8.1.2 For DSAC I and II dams, during preparation of the report, extensive and higher frequency of communication with approving authorities is required to assure a

smooth and successful approval process. An appropriate level of communications is recommended for DSAC Class III and IV projects.

9.8.2 Policy Compliance Review. The MSC and HQ will conduct agency policy compliance review. The Risk Management Center will review the risk estimate and verify that risk estimate is in compliance with the current policy for dam safety risk estimates. The Risk Management Center will review the risk management recommendations and verify the estimated risk reductions.

9.8.3 Approval of Dam Safety Modification Reports (Table 9.3).

9.8.3.1 The USACE DSO has been delegated approving authority from the Assistant Secretary of the Army (ASA) (Civil Works) and is the responsible approval official for Dam Safety Modification Reports submitted in accordance with this regulation.

9.8.3.2 The district DSO, MSC DSO, and the Chairman, HQUSACE Dam Safety Senior Oversight Group will sign the memorandum recommending approval once the review process is completed. This memorandum will state that all agency requirements, certifications, and reviews have been completed and all NEPA and ESA documentation has been satisfactorily completed.

9.8.3.3 The report will then be sent to the USACE DSO for approval. The USACE DSO will then notify the USACE commander and the MSC commander that the DSM report has been approved.

9.8.3.4. Approval-Subject-To-Comments. If the report is approved subject to resolution of specific comments, the district shall provide the MSC and HQUSACE acceptable documentation during the design phase of the project to show compliance with the comments

9.9 ASA(CW) Notification and Concurrence with Construction. The USACE DSO shall notify ASA (CW) of report approvals and the start of the design phase of the project. Two copies of the approved and final reports shall be provided to ASA (CW) for concurrence with construction and consideration of budgeting as a continuing line item under the project name in the Construction program.

9.10 Supplemental DSM Decision Documents.

9.10.1 Past experience has shown that during the design or the construction phase large changes in the scope of the modifications or increases in construction effort occur increasing the cost of risk management measures. Whenever such changes occur, for whatever reason, a supplemental to the DSM report will be prepared and processed for approval in accordance with the guidance for the decision report. The supplement will be prepared and submitted for approval when new information increases the original cost estimate by 20 per cent.

9.10.2 A supplement to the DSM study scope will be submitted for approval if additional significant failure modes are identified after the DSM report is approved or to address the failure modes that were not addressed in the original DSM report for DSAC I and II dams as per paragraph 9.4.1.

9.11 Funding of Dam Safety Modification Studies, Reports, and Construction Projects.

9.11.1 Initial Funding for the Study and Report Preparation. For dams operated and maintained by USACE, funds for preparation of DSM Reports will be made available from Dam Safety Assurance and Seepage/Stability Correction Program (WEDGE) line item in the Construction Account, except for projects on the Mississippi River and its tributaries funded by the Flood Control, Mississippi River and Tributaries (FC, MR&T) Account. Those projects will be funded from the Construction portion of the FC, MR&T Account. Districts should submit requests for Dam Safety WEDGE study funds in accordance with guidance from HQUSACE. Subject to overall budget constraints, funds should be sufficient in any one year for the study effort required for a

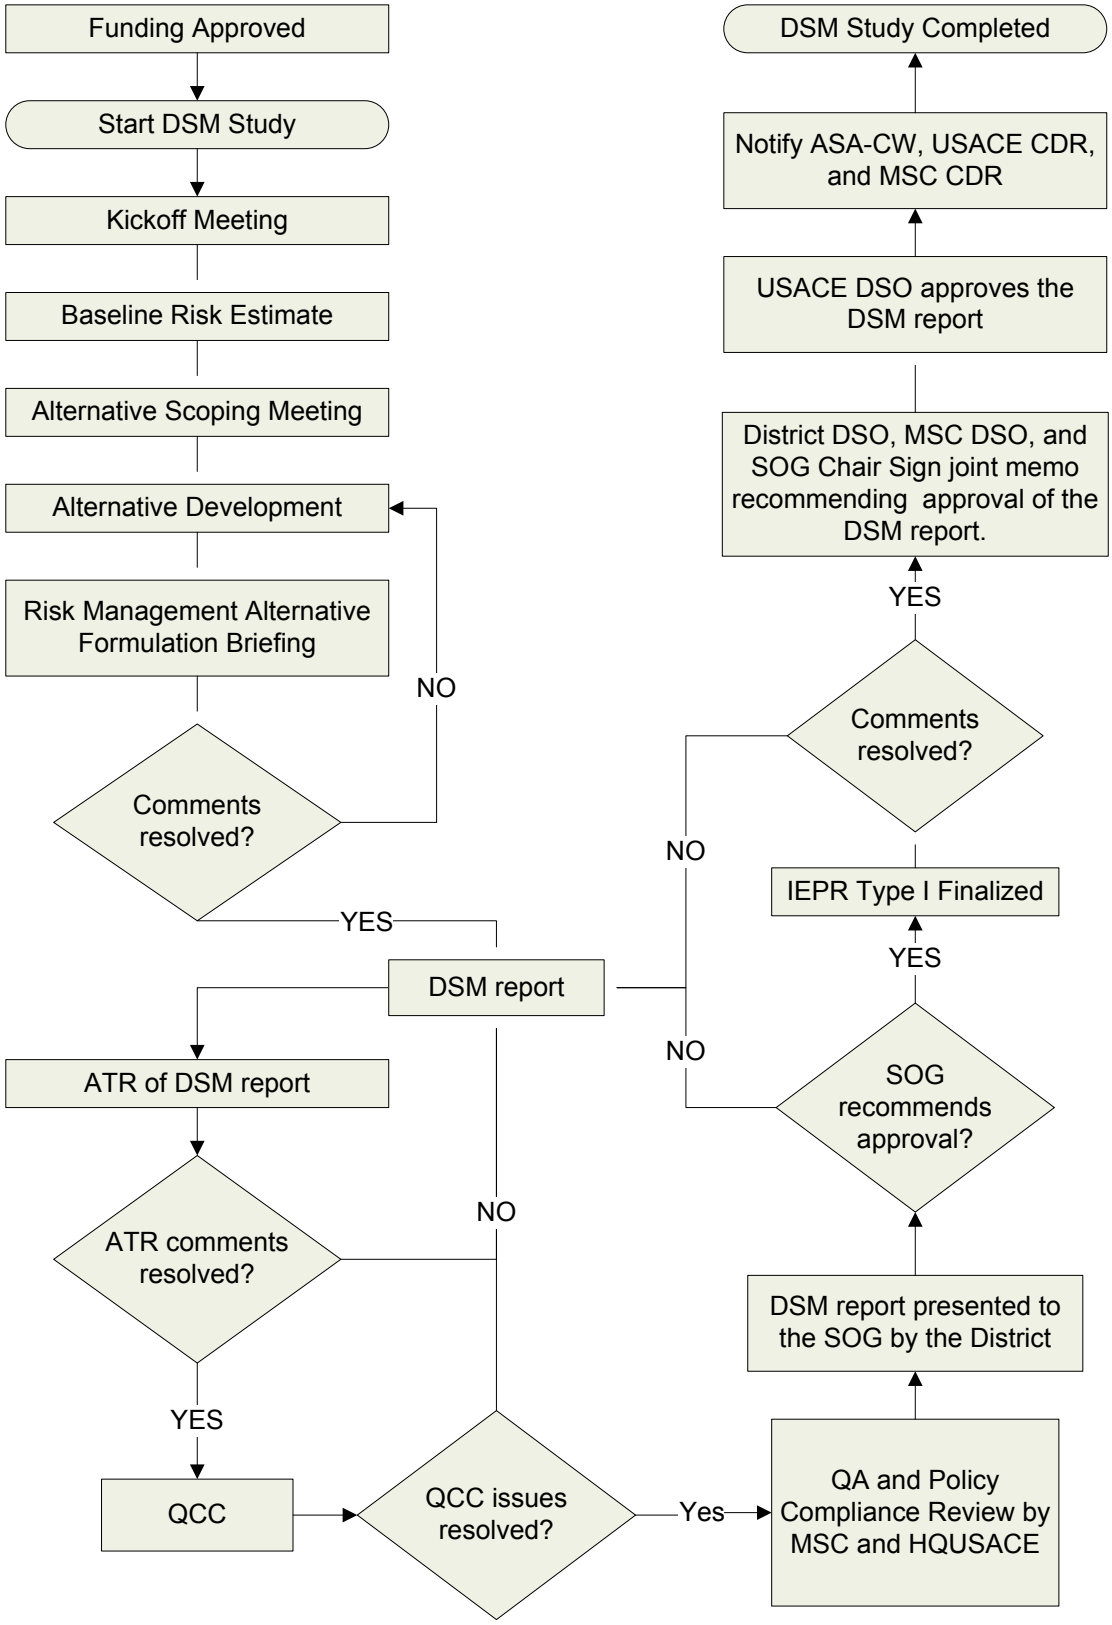

Figure 9.1 DSM Study, Review, Decision and Approval Process

newly identified problem, especially for expediting risk reduction to DSAC I dams. Additional Dam Safety WEDGE funds will be made available in future years until the report is completed or a no action required determination is made. For the definition of the Dam Safety WEDGE line item, refer to the current budget EC.

9.11.2 Funding for Engineering and Design Documents: Following DSM Report approval, the district shall request and use Dam Safety WEDGE funds to proceed with preconstruction engineering and design activities, and in some cases completion of plans and specifications and initiation of construction. The USACE DSO will consider the project's DSAC status, national priorities, and overall funding limitations when approving or disapproving the release of funds. Priority will be risk informed, based on the magnitude and relative importance of the life, economic and environmental consequences and the effectiveness of the proposed risk reduction measures for each dam in relationship to other dams of the same DSAC rating in the USACE portfolio of dams. The district shall recommend budgeting for follow on Construction funds for preconstruction engineering and design activities during the next budget cycle in accordance with guidance from HQUSACE. See chapter 6, Dam Safety Risk Management Prioritization, for further details on the prioritization guidance.

9.11.3 Funding Construction Activities: The ultimate decision to fund construction shall be based on the results of the DSM studies, the priorities of the USACE DSO considering all approved DSM reports, and overall budget priorities. The decision on construction priority will be risk informed based on the magnitude and relative importance of the life, economic and environmental consequences and the effectiveness of the proposed risk management measures. See chapter 6, Dam Safety Risk Management Prioritization, for further details on the prioritization guidance.

9.11.3.1 A district shall request funding for the construction of an approved dam safety project in accordance with current budget guidance from HQUSACE as a line item project.

9.11.3.2 When a project is ready for construction or land acquisition prior to receiving appropriations under the project name, the district DSO may request funds from the Dam Safety Assurance and Seepage/Stability Correction Program (WEDGE) line item to initiate construction; except for projects on the Mississippi River and its tributaries funded by the Mississippi River and Tributaries (MR&T) Account, in which case construction funds should be requested in the Construction portion of the MR&T Account.

9.11.3.3 Construction or land acquisition may not commence until construction funds have been specifically allocated for the required work, and a project partnership agreement (PPA) or amendment has been executed, if required. For DSAC I and some DSAC II projects, the USACE DSO may recommend to the ASA(CW) that construction commence without an approved PPA due to the risk to the public. Even if a PPA is not required, serious consideration should be given to developing one, especially for older projects, to make sure that they meet the provisions of modern day agreements.

9.11.4 Funding Minor Modifications: When the initial analysis of a dam safety deficiency indicates that the work will cost less than Major Rehabilitation funding cap (see guidance in the annual budget EC) and the work can be accomplished in one construction season, the district DSO should consider going directly to a major maintenance action. Such minor modifications for dam safety would be funded as major maintenance with Operation and Maintenance funds. If significant risk reduction can be made at high risk dams for amounts costing less than the Major Rehabilitation funding cap, districts should coordinate with the MSC and HQ dam safety program managers to determine if Operation and Maintenance funds are available.

9.12 Cost Sharing Requirements. Dam Safety Modifications shall be cost shared in accordance with the following policies.

9.12.1 Section 1203 of WRDA 1986: Section 1203, WRDA, 1986 (reference A-103) provides for special cost-sharing for modification of dams and related facilities constructed or operated by USACE. In accordance with long standing Army policy, Section 1203 cost sharing shall only apply to modifications needed to address new hydrologic or seismic data. While Section 1203 also addresses modifications related to changes in the state of the art design or construction criteria, this terminology makes it difficult to define the kinds of repairs that would be applicable, and so it is not used. Instead, any modifications that are required for safety that are not related to new hydrologic or seismic data (such as seepage and stability corrections) shall be addressed through the Major Rehabilitation program and cost shared in accordance with the provisions in effect at the time of initial project construction. The cost of dam safety modifications needed to address new hydrologic or seismic data shall be cost shared as described below. Section 1203 also may be used to modify dams built by the USACE where local interests are responsible for operation, maintainence, repair, rehabilitation, and replacement, but only if Congress directs the Secretary of the Army to do so, in law, for a specifically named project. Without specific congressional direction, in law, non-Federal sponsors remain responsible for operation, maintainence, repair, rehabilitation and replacement of these projects, as required by their authorizations and the terms of the agreements under which they were constructed by the Federal government.

9.12.1.1 In accordance with Section 1203 of WRDA 1986 (reference A-103) and the Army policy specified above, costs incurred for modifications for dam safety assurance (i.e., strictly limited to new hydrologic or seismic data) shall be recovered in accordance with provisions of the statute. Repayment of the local share of costs, except for irrigation, may be made, with interest, over a period not to exceed 30 years in accordance with provisions of subsection (a)(2) of the legislation. Costs assigned to irrigation shall be recovered by the Secretary of Interior in accordance with Public Law 98-404 (reference A-97).

9.12.1.2 Under Section 1203 and Army policy, for project modifications due to changes in hydrologic or seismic data, 15% of the cost of the modification is allocated to

the project purposes in the same percentages as the original project costs. General procedures for determining the amount of sponsor cost are outlined in the following subparagraphs. These are general procedures that will need to be tailored to fit the specifics of each individual project.

9.12.1.2.1 Projects with a Formal Cost Allocation. In this case, 15% of the cost of the modification for dam safety assurance shall be allocated among project purposes in the same percentage as the construction expenditures in joint-use facilities are allocated in the cost allocation currently in effect.

9.12.1.2.1.1 The cost allocated to each project purpose will then be shared in the same percentage as when the project was constructed, or when the purpose was added, whichever is appropriate.

9.12.1.2.1.1.1 For large reservoir projects, it is likely that the cost assigned to flood control is 100% Federal. The cost assigned to power generation is most likely 100% non-Federal (to be reimbursed by the sale of the power). Costs may have been allocated to water supply or to conservation. Costs allocated directly to water supply are 100% non-Federal costs. Where costs have been allocated to conservation, water supply users may have contracted for a portion or all of the conservation storage. In such cases, the contract will need to be modified if it does not include provisions of payment for the proposed work.

9.12.1.2.1.1.2 For illustrative purposes, assume a dam safety modification cost of $15 million, and a formal cost allocation that assigns 60% of the construction costs to hydropower, (with 45% as the hydropower joint-use construction costs); and 40% of the construction costs to flood control. Under this example, hydropower interests would have to repay $1,012,500 [($15,000,000 x 0.15) x 0.45].

9.12.1.2.1.1.3 If there was no sharing of· the initial construction costs (either cash or the value of real estate) allocated to flood risk management, all of the modification costs assigned to flood risk management would be Federal.

9.12.1.2.1.1.4 If a sponsor shared in the initial construction costs allocated to flood risk management (either cash or the value of real estate), the dam safety costs assigned to flood risk management would be shared on the same percentage basis.

9.12.1.2.1.2 In cases where storage is reallocated from flood risk management to another purpose, the sponsor for the added purpose is responsible for repaying a share of the dam safety modification costs. For example, if a contract is executed for water supply that assigned 1.5% of the joint-use cost of major replacements to a water supply sponsor, this sponsor would be required to repay $33,750 of the dam safety costs [($15,000,000 x 0.15) x 0.015].

9.12.1.2.2 Projects without a Formal Cost Allocation, but with a signed Project Partnership Agreement or Project Cooperation Agreement or Local Cooperation

Agreement: An agreement for the initial project construction may contain an allocation or assignment of costs among project purposes.

9.12.1.2.2.1 For projects with this type of agreement, 15% of the cost of the dam safety modification shall be assigned to project purposes in the same manner as costs were allocated for the agreement, and shared in the same percentage according to the terms of the agreement. The percent joint-use facilities cost should be used if available; otherwise, the assignment is based on the percent of total cost.

9.12.1.2.2.2 As before, assume a dam safety modification of $15,000,000; project agreement requiring a sponsor to provide a one-time payment of $3,000,000 (5%) toward the construction of a project with an actual initial construction cost of $60,000,000. The sponsor in this example would be required to repay $112,500 [($15,000,000 x 0.15) x 0.05].

9.12.1.2.3 Projects without a Formal Cost Allocation or a signed agreement: In most cases where there is no signed agreement, there was some sort of a letter of intent at the time of construction that indicated what items of local cooperation that non-Federal interests would provide, such as lands, easements, rights-of-way, relocations, or disposal areas (LRRED).

9.12.1.2.3.1 These projects will require a review of letters of intent or other documentation of arrangements for provision of LERRD, or of cash contributions by a sponsor at the time of project construction. If a sponsor accomplished some portion of the required work, such as relocations, or made cash contribution, the value of the work or the contribution should be converted to a percent of total initial project cost. Fifteen percent of the cost of the dam safety modification will be shared in the same percentage as the percentage of total initial project cost, computing the non-Federal share as the percent of contribution to total cost. The percentage should be computed based on actual rather than estimated cost of construction, if available.

9.12.1.2.3.2 For example, if the actual construction cost was $50,000,000, and non-Federal interests contributed LERRD's valued at $500,000, the non-Federal share of initial construction was 1%. In this case the non-Federal share of a $15 million dam safety assurance modification would be $22,500 [($15,000,000 x 0.15) x 0.01].

9.12.1.2.4 Contract for Storage. In some cases water supply storage may have been reallocated from conservation or from flood control storage. The agreement for the reallocation of storage is a contract. The terms of the contract will specify what storage capacity is provided in return for the payment amount. The contract usually defines how the amount paid by the contract holder was computed and shows the basis for the assignment of costs. The share of cost to be paid for the dam safety modification should be allocated in the same percent as the cost of joint use facilities was allocated. In such a case, the contract will need to be modified if it does not include a provision for payment of the proposed work.

9.12.2 Seepage/Stability Corrections do not qualify under Section 1203, WRDA 1986 (reference A-103). Therefore, 100% of the modifications shall be cost shared in accordance with current cost sharing policy as defined below.

9.12.2.1 Projects with a formal agreement with a non-Federal sponsor that identifies the cost sharing percentages for major rehabilitation or dam safety modifications shall be cost shared in accordance with the current agreement (contract).

9.12.2.2 Projects without a formal agreement will be cost shared at the same ratio as the original cost sharing for the project.

9.12.3 Special Cost Sharing for Navigation and Hydropower.

9.12.3.1 For navigation projects, dam safety modifications shall be cost shared by the Inland Waterways Trust fund or the Harbor Maintenance Trust Fund in accordance with WRDA 1986 as amended (reference A.99).

9.12.3.2 For hydropower dam safety modifications, costs are reimbursed, over time, by the affected Power Marketing Administration (PMA) in accordance with the joint use percentage for that particular dam.

9.12.3.3 Cost sharing for major maintenance work under the Operation and Maintenance account will be the same as cost sharing for ordinary annual operations and maintenance.

9.13 Sponsor Identification. Requirements for cost sharing sponsorship, and the identification of non-Federal sponsors shall occur very early in the study process to ensure that the non-Federal interests are willing cost share partners. Uncertainty about sponsorship and the lack of meaningful sponsor involvement in the scope and extent of dam safety repairs can cause delays to the dam safety modification work. Before initiating discussions with project sponsors on cost sharing, an interpretation on the need for sponsorship and the application of the generic guidance contained in this regulation shall be forwarded to HQUSACE, ATTN: Dam Safety Officer for information. This should occur within 60 days after the DSM is started and study funding is received.

9.13.1 Reports shall include documentation of substantive involvement and coordination with non-Federal sponsors, and expressions of their willingness to cost share in the dam safety assurance work when required

9.13.2 On projects classified as DSAC I or II, the lack of sponsor identification shall not delay completion of the report. When a sponsor cannot be identified, the district shall notify HQUSACE, ATTN: Dam Safety Officer, and request that project work continue without cost sharing due to the risk to public safety. Efforts shall continue to find the appropriate sponsor for the modification and recoup the non-Federal share of the modification cost. Extension of Interim Risk Reduction Measures, including permanent extension, shall be considered in lieu of the dam safety modification in those

cases where a non-Federal sponsor is unwilling or unable to participated as the cost share partner.

9.14 Cost Recovery. Recovery of the non-Federal share of the dam safety modification cost will be determined by the current arrangement for project cost recovery.

9.14.1 For costs that are reimbursable through the sale of power, the share of dam safety cost under Section 1203 will be reported to the power marketing administration for recovery in the same manner as major rehabilitation costs.

9.14.2 For cost sharing based on a project partnership agreement that does not have a provision for dam safety cost sharing, the agreement will need to be modified to include the dam safety costs, or a new agreement will be required.

9.14.3 Where the project cost sharing was based on a letter of intent, an agreement will be negotiated with the sponsor.

9.14.4 In the case of water supply, the existing contract may need to be modified, or a new contract signed to cover the dam safety cost sharing.

9.14.5 If no current agreement addresses repayment of this cost, the sponsor may elect to repay the cost, with interest, over a period up to 30 years in accordance with the provisions of Section 1203 (a) (2) of the Water Resources Development Act of 1986. If a sponsor is unwilling or unable to cost share the modification, the district/division will either seek authorization to terminate the project or perform the dam safety modification at 100% Federal cost and seek reimbursement from the sponsor through litigation, or extend the Interim Risk Reduction Measures until a non-Federal sponsor can be identified.

CHAPTER 10

Dam Safety Risk Communication

10.1 Purpose/Objective. This chapter provides guidance for the USACE to integrate risk communication into routine dam safety program activities, and develop communication strategies when conducting dam safety evaluations and risk reduction actions. Key points are use of the Dam Safety Action Classification System, the Dam Safety Portfolio Risk Management for the USACE portfolio of dams using the principles outlined in Chapters 2 and 3, and the importance of internal PDT communications on a "typical" dam safety project.

10.2 USACE Dam Safety Risk Communication Philosophy.

10.2.1 Risk communication is a management/leadership process and responsibility. It involves more than only the public affairs staff.

10.2.2 Risk communication is an open, honest, genuine, sincere exchange of information with affected stakeholders. It requires planning, practice and preparation. It helps USACE focus on its mission, build better relationships with stakeholders and drives better risk management decisions.

10.2.3 Communication about risk is equally important as the steps taken to determine the risks associated with a project. An informed public is safer because individuals are able to make risk-informed decisions about their personal safety. Communicating risk to the public is a shared responsibility among federal, state, local agencies and local stakeholders.

10.2.3.1 For example, USACE works closely with respective state and local emergency officials to ensure they have the information they need to fulfill their emergency management responsibilities to protect public health, safety and welfare.

10.2.3.2 Concerning the public affected by a high-risk project, information security must be balanced with information essential for individuals to make informed decisions about their safety. There are no simple solutions to communicating risk, but open and honest dialogue, along with diligent efforts at the local level, have proven successful when informing stakeholders about USACE highest risk projects.

10.2.4 USACE is responsible to protect public safety by effectively communicating risks associated with USACE-owned dams, while also protecting security interests.

10.2.5 A dam is adequately safe when it meets all essential USACE engineering guidelines and the residual risk is considered tolerable.

10.2.6 While risk communication is necessary when confirmed unsafe dam safety issues are identified, it is equally important when unconfirmed or potentially unsafe dam

safety issues are present that could have life safety, economic, or environmental consequences.

10.3 Understanding Tolerable Risks.

10.3.1 USACE operates more than 600 dams that range in age from less than 10 years old to more than 100 years old. These projects serve multiple purposes and span the range of construction methods and materials, and geographic settings, etc. USACE has a responsibility to educate internal and external stakeholders that the USACE dams are well constructed based on the state of practice and best science at that time, and have generally performed well. However, these structures do not have an indefinite life cycle and individual dams vary in their condition and risk potential. The public may falsely perceive that they are “safe” for a wide range of conditions, but the results of the USACE Screening for Portfolio Risk Analysis (SPRA) initiative conducted from 2005-2010 and risk assessments of specific dams have told us otherwise. These findings support the agency’s transition to a risk informed dam safety program and related decision making. More important to the longer term implementation of our dam safety program, however, are the lessons learned about how to continually adjust and refine the program. We are a learning organization and have recognized the need to build upon changes and improvements to the state of the practice in all aspects of flood risk management, which allows better assessment of risk and uncertainty, and therefore reduce public safety and economic risks.

10.3.2 The key to assessing safety is whether the residual risk for an individual dam is tolerable and that the dam meets essential USACE safety guidelines. An informed public better understands risk and can contribute to discussions of deciding how far to lower the risk and take on some degree of responsibility for their safety.

10.3.2.1 Tolerable Risk. ‘Tolerable’ does not mean ‘acceptable’. Tolerable refers to a willingness to live with a risk to secure certain benefits and with confidence that it is being properly managed. Tolerable risk is not regarded as negligible or something to ignore. It must, however be kept under review and reduced further if possible. For a risk to be ‘broadly acceptable’ on the other hand means that "for purposes of life or work, we are prepared to take it pretty well as it is." (HSE 1992) (Reference A.102) (See Chapter 5 of this regulation for more details).

10.3.2.2 Tolerable Risk Guidelines. Tolerable risk guidelines are used in risk management to guide the process of examining and judging the significance of estimated risks obtained using risk assessment. The outcomes of risk assessment are inputs to the risk management decision process along with other considerations. Meeting or achieving the tolerable risk guidelines is the goal for all risk reduction measures including permanent and interim measures. Reference is made to Chapters 2, 5, 6 and 8 for additional information.

10.3.3 Communication Shapes Risk-Informed Decisions. Risk communication is integral to decisions on interim and permanent risk reduction actions. Risk

communication ensures that decision makers, stakeholders, and affected publics understand potential short term and long term impacts and risks. Some may be willing to temporarily accept risks that exceed USACE tolerable risk guidelines and do not meet essential guidelines, if operating the dam serves a significant benefit or benefits. For example, the level of a reservoir operating restriction may be refined based on stakeholder and public feedback. Knowing their degree of risk allows people who feel they are not adequately protected to make individual decisions about their personal safety. This includes taking actions such as purchasing weather alert radios and developing evacuation plans.

10.4 Communication Planning. Dam safety issues must be coordinated within USACE and with the public and affected stakeholders. Examples of stakeholders requiring identification include but not limited to**,** neighboring dam owners, emergency managers, recreation partners, hydropower marketing agencies, irrigators, water supply contractors, and Dam Safety Regulating agencies.

10.4.1 Districts must clarify roles and responsibilities when organizing meetings and coordinating media events and will develop a detailed communication plan with a roles and responsibilities matrix to synchronize communication efforts.

10.4.2 Dam safety risk communication may also be required for routine project activities, such as dewatering, inspections and maintenance work, and for non-routine remediation work and responses to unusual or emergency events, such as floods or earthquakes. Because each project has different characteristics, the level of detail and methodology of communication effort should be commensurate with the overall risk posed by the project. Minimally, the communication planning team shall include the Operating Project Manager, the Dam Safety Program Manager, and the Public Affairs Officer.

10.5 Communication of the USACE Dam Safety Action Classifications.

10.5.1 In the past, the USACE dam safety program essentially recognized two categories of actions: those for dams considered safe, which comprised routine dam safety activities, normal operation and maintenance; and those for dams considered in need of remediation, for which investigations, remediation funding justification documents, and design and construction of remediation measures were additional activities. However, these two categories do not provide formal recognition of an adequate range of actions and degrees of urgency, especially for dams with significant issues or extremely high risk.

10.5.2 The USACE Dam Safety Action Classification is the framework by which USACE provides consistent and systematic guidelines for appropriate actions to address the dam safety issues and deficiencies of USACE dams. MSCs and districts may not reinterpret or redefine the Dam Safety Action Classification or project assignments. DSAC values should only be used in conducting internal communications with USACE staff. However, in coordinating with the public, the descriptions assigned

to each class (Urgent and Compelling, Urgent, High Priority, Priority and Normal), as well as the safety designations should be used, in lieu of the terms “DSAC I”, “DSAC II,” etc.

10.5.3 Appendix F provides information on the DSAC system. Appendix U includes examples of Frequently Asked Questions and Answers that may be useful in preparing for internal and external communication.

10.5.4 Risk-informed decision making, which drives action for IRRM and remediation, includes public communication about an unsafe project. Clearly communicating risks to the public is challenging, but necessary. In many cases the public perceives safety as being related only to probability of failure, regardless of consequences. We should not, however, miss the opportunity to discuss what is driving some of the risks and the very important responsibility and role the public and local governments have in managing their risks (consequence management).

10.5.5 DSAC ratings have the potential to cause concern among uninformed district staff and affected communities near the dam. Districts shall initiate notification planning shortly after receiving project specific DSAC rating. The Operating Project Manager should collaborate with the Dam Safety Program Manager, Dam Safety Officer, and the Public Affairs Officer to craft a strategy.

10.5.6 District leadership should brief district personnel prior to providing information to the public. The MSC and HQUSACE Dam Safety Officers must also be engaged for high risk, controversial, or locally sensitive issues. Leaders shall explain the situation and assure employees that appropriate details will be shared with the public. Any message to employees delivered prior to public communication should be delivered as FOUO.

10.6 DSAC I and II Communication Strategies.

10.6.1 Districts shall develop timely communication plans for DSAC I and II projects to inform key community leaders and affected stakeholders.

10.6.2 Engagement, awareness and understanding of the communication plan at all levels of district and MSC leadership are imperative to ensure adequate opportunity for full understanding of input and guidance. MSCs must also coordinate with HQUSACE to ensure consistency of key messages and strategies.

10.6.3 Districts shall not conduct external coordination prior to approval of the project specific Interim Risk Reduction Measures (IRRM) Plans, which shall include a Communication Plan unless, coordinated with the vertical team. Per Chapter 7, IRRM Plans for DSAC I and II projects are approved by the MSC Dam Safety Officer

10.7 Public Meetings and Stakeholder Involvement.

10.7.1 For security reasons, numerical risk results and aggregate lists of the Dam Safety Action classifications shall not be released to the public. Regional and project specific information may be shared with stakeholders, adjacent and potentially impacted dam owners, emergency responders and Congressional interests, designated as For Official Use Only. The HQUSACE Dam Safety Special Assistant and HQUSACE Homeland Security Office must approve release of aggregate information and FOUO reports, on a case by case basis. Release of inundation maps and information will be in accordance with Interim USACE Policy on Release of Inundation Maps, dated 10 May 2007 (reference A.77).

10.7.2 Prior to external coordination, fact sheets, press releases, and other informational products will be furnished to the MSC and HQ Public Affairs and Dam Safety Officers, applicable State Dam Safety Officials, and neighboring dam owners who may receive media inquiries.

10.7.3 It is extremely important that community leadership understands the issue when/if the public asks questions. Similarly, the district must ensure that USACE is the primary release of information to the public about its respective project dam safety risks. USACE has an obligation to educate and inform affected stakeholders about the risks associated with its projects. Withholding information because of potential embarrassment is not appropriate.

10.7.4 Dam safety is an extremely technical subject and it is important that information presented is understandable. Visual aids, such as physical models, drawings or cut-a-ways of the dam to help explain the technical issues during briefings may be particularly useful.

10.7.5 When scheduling external briefings, recommend using normal meetings/coordination opportunities, unless the project is a DSAC Class I or II dam where immediate risk reduction actions are required, such as operating restriction.

10.8 Emergency Risk Communications.

10.8.1 Local authorities, counties, and states may have plans for multiple disasters or for a specific disaster such as a dam failure. These plans provide detailed instructions for agencies and individuals for responding to emergencies and may include threat recognition, emergency action message formulation, message dissemination to authorities and the public, provisions for search and rescue, and early stages of recovery.

10.8.2 During a dam safety emergency, Reporting of Distress within USACE shall be conducted in accordance with Chapter 13. The district Dam Safety Officer shall take immediate actions to notify the USACE Dam Safety Officer, through the Chain of

Command, and mobilize a team to expediently develop a communication plan, including notifying key stakeholders and Congressional interests, and issuing press releases.

10.8.3 It is important that USACE field personnel establish relationships with downstream officials and stakeholders, and maintain accurate lists of contacts in preparation for emergency events.

10.8.4 Notification lists for emergency action plans shall be updated annually. Face-to-face interaction with the local emergency response entities is also strongly encouraged. Copies of the emergency action plans shall be furnished to appropriate emergency response agencies. Release shall be considered as FOUO. Emergency action plans and corresponding inundation mapping can be furnished to the public or media in accordance with Interim USACE Policy on Release of Inundation Maps, dated 10 May 2007 (reference A-80).

10.8.5 Preparation for real time emergency notifications can be greatly enhanced by including local officials and emergency response agencies at emergency exercises and project specific dam safety training sessions.

10.9 Internal PDT Communications. As outlined above, proper external communication of risk is a key component to ensure the success of a dam safety project. Equally important is the proper internal communication within the PDT as a project moves through its various phases (issue identification and analysis, planning, E&D, and construction). Communication within the PDT can be particularly challenging as it routinely involves internal district coordination as well as coordination with several vertical elements (MSC, HQ, RMC, stakeholders, etc…) throughout a project's life. For this reason it is vital that team members are selected who possess a solid combination of both technical and communication skills - particularly the lead engineer and project manager positions.

CHAPTER 11

Periodic Inspection, Periodic Assessment and Continuing Evaluation

11.1 Applicability and Policy. This chapter on Periodic Inspection, Periodic Assessment, and Continuing Evaluation is applicable to Civil Works structures including dams, navigation structures, and other water control facilities.

11.1.1 Periodic Inspections are recurrent engineering inspections conducted at dams and other civil works structures whose failure or partial failure could jeopardize the operational integrity of the project, endanger the lives and safety of the public or cause substantial property damage to ensure their structural stability, safety, and operational adequacy.

11.1.2 Periodic Assessments consist of a periodic inspection, a potential failure modes analysis, and a risk assessment based on existing data and a minimum development of limited consequence data.

11.2 Institutional Knowledge and Technical Expertise. It is essential that USACE maintain institutional knowledge and technical expertise in the disciplines related to dam design and dam safety, including risk assessment and forensic engineering. An important component of this knowledge is gained by conducting periodic inspections, periodic assessments and evaluations by district and MSC engineering, construction, and operations personnel. Lessons learned by multi-disciplinary assessment and inspection teams over a long period of observations and analyses can be applied to the design, construction, operation, and maintenance of existing and future projects.

11.2.1 Periodic inspections and assessments of significant and high hazard potential structures shall not be contracted. Where in-house manpower constraints exist, inspections and assessments may be augmented, in order of preference, by (1) use of trained and experienced USACE personnel from other districts, or other MSC's, on a fully reimbursable basis; or by (2) contracting for individual qualified personnel as inspection participants for highly specialized functions, such as underwater diving or camera work, or other tasks requiring special skills or equipment not readily available in the USACE.

11.2.2 It cannot be over emphasized that inspections should be done with licensed Professional Engineers present. Care must be taken to maintain in-house capability for the on-site conduct of the program and continue to keep the involved disciplines (design, construction, and operations personnel) fully integrated in project inspections and assessments. This does not imply the necessity for maintaining all technical disciplines in all districts. It may be in the best interests of the project and smaller districts to let other districts assist in the management their dam safety programs.

11.3 Inspection and Assessment Policy. Civil Works structures whose failure or partial failure could result in loss of life or major damage to permanent structures, utilities, or transportation facilities shall be periodically inspected and assessed to ensure structural stability, safety, and operational adequacy. This policy is to be accomplished using risk assessment and management tools provided by HQUSACE as follows:

11.3.1 Appropriate instrumentation programs that provide timely and accurate data for evaluations under all operating conditions shall support visual inspections and periodic assessments. During periods when a reservoir is, or is expected to be, above the maximum pool of record or above a potential "triggering" threshold level established from past performance, an appropriate team shall be dispatched to monitor and evaluate performance and verify the adequacy of flood and outlet control gates and other equipment, which facilitate downstream releases. A report of performance outlining the findings and evaluation shall be prepared and documented in a memorandum with copy furnished to the MSC for information within 14 days after the event. Evaluation reports shall provide a basis for initiating timely remedial or rehabilitation measures.

11.3.2 The operating entity of facilities constructed by USACE and turned over to others for operation and maintenance is responsible for periodic inspections after the first and second periodic inspections. USACE may conduct subsequent inspections and write a report on behalf of the Project Sponsor, provided appropriate procedural and financial reimbursement arrangements are made. Inspections shall be conducted in accordance with appropriate guidance contained in the operation and maintenance manual for the facility and in accordance with applicable portions of this regulation. In addition, any inspection responsibilities established by the Project Cooperation Agreement (PCA) shall be related to the operating entity at the time of their acceptance of the structure. Dams built by USACE and turned over to others for Operation, Maintenance, Repair, Replacement and Rehabilitation (OMRR&R) shall include in the Operation and Maintenance (O&M) manual, a requirement that USACE conducts inspections/assessments in accordance with this regulation. These inspections are to ensure design/construction quality. USACE is responsible for the first and second periodic inspections. See Policy Guidance Letter No. 39, dated 13 November 1992 (reference A.77) for USACE and sponsor responsibilities.

11.3.3 Under the authority of ER 1130-2-530 (reference A.63), USACE shall participate in inspections/assessments of a sponsor-operated and maintained structure (e.g., local flood protection project) to ensure that the structure is conforming to the requirements of the PCA, the agreed upon inspection program, and the operation and maintenance program. USACE participation in these inspections shall be funded under Inspection of Completed Works (ICW) Program.

11.3.4 In cases where ownership, operation, maintenance, or other activities at a project or its major elements are divided between USACE and other organizations, private sector (e.g., power plants), government or municipal, USACE shall inspect and/or assess using risk and reliability tools, those features of non-USACE elements

that could adversely affect the stability, safety, or operational adequacy of any USACE owned, operated, maintained, or otherwise related portion of the project, including features not constructed by the USACE.

11.3.5 Non-Federal dams located upstream or downstream of a USACE project may potentially affect the safety of a USACE project. A list of significant dams upstream or downstream and their points of contact must be prepared and maintained in the project Emergency Action Plan (EAP). When inspecting/assessing a USACE structure or project it may be appropriate to evaluate the safety of the upstream or downstream non-Federal dam(s) and to ascertain operational procedures or emergency situations that could make excessive demands on a USACE project. When failure of a neighboring non-Federal structure would cause overtopping or other major damage to USACE project, USACE shall obtain and review the current comprehensive inspection report, such as a Federal Energy Regulatory Commission (FERC) or State Dam Safety Agency report, for the non-Federal structure. If the non-Federal project has not been inspected within the last five years, USACE shall coordinate with the owner and the regulatory authority to have the dam inspected. Every effort shall be made to encourage owners of such projects to comply with the inspection requirements in the Model State Dam Safety Program (FEMA Publication 316) (reference A.73).

11.3.6 Federally owned dams (non-USACE) on a military installation might have a substantial bearing on the safety of life and endanger downstream property. USACE, on request of the installation, may inspect, and/or assess these dams on a cost reimbursable basis. Requests are to be coordinated with HQUSACE DSPM. This policy extends to non-federally owned dams on a military installation where the safety of life and Federal property are in jeopardy from probability of a failure. These inspections and assessments shall be performed and documented in the same manner as the inspections of USACE dams, except that the reports should be forwarded to the Installation Management Agency and to the owner of the dam if not owned by the installation.

11.4 Program Implementation. A periodic and comprehensive inspection and assessment schedule shall be established based on the project size, importance, and hazard/risk potential. Other inspections, including intermediate, informal, and annual inspections, may be conducted between Periodic Inspections/Assessments. MSC Dam Safety Officers are responsible for management and oversight of the periodic inspection/assessment program. District Dam Safety Officers are responsible for implementing the inspection and periodic assessment program.

11.4.1 Frequency of Inspections/Assessments. Inspections/Assessments of all water control facilities shall be conducted as outlined below:

11.4.1.1 Dams and Appurtenant Structures. All dams are included in the Dam Safety Program without regard to the hazard potential classification of the dam. The guidance for developing the interval for initial inspections and subsequent periodic inspections /assessments of dams and appurtenant structures set forth in the following

subparagraphs does not preclude other intervals as the situation or structural integrity warrants. Nor does this guidance preclude the surveillance plan for the initial filling of USACE reservoirs as prescribed by ER 1110-2-1150 (reference A.51) and chapter 17 of this regulation.

11.4.1.1.1 Initial Periodic Inspection. The first periodic inspection and evaluation of a dam shall be carried out prior to impoundment of the pool; however, if involuntary impoundment occurs before the first inspection is accomplished; the inspection shall be performed at that time. This inspection will be funded using Construction funds. The initial periodic inspection of navigation locks shall be made immediately prior to flooding of cofferdams, culverts or chambers.

11.4.1.1.2 Subsequent Periodic Inspections. A second periodic inspection for new dams shall be performed no later than one year after impoundment is initiated. The 3rd and 4th periodic inspections shall also be performed at one-year intervals. The 5th and 6th periodic inspections shall be performed at two-year intervals. Subsequent periodic inspection intervals may then be extended to a maximum of five years with a periodic assessment, which includes the periodic inspection, held at intervals not to exceed ten years, i.e., at alternating periodic inspections. Inspection intervals more frequent than indicated above shall be scheduled, if conditions warrant, as approved by the district Dam Safety Officer. The second and all subsequent regular Periodic Inspections will be funded with Operations and Maintenance funds.

11.4.1.1.3 Special Inspections. Special inspections should be performed immediately after the dam has passed unusually large floods and after the occurrence of significant earthquakes, sabotage, or other unusual events reported by operating personnel.

11.4.1.1.4 Periodic Assessments. Periodic Assessment (PA) of projects shall be conducted as determined by risk factors, but they shall not exceed a ten-year interval. Initial periodic assessments involve a greater level of effort due to the data gathering and documentation requirements. Once completed, this information will be available for future assessments, and data collected in the interim and performance history will be added to the subsequent reports. The periodic assessment will generally be accomplished in conjunction with a periodic inspection. The district will coordinate schedule and resources for initial periodic assessments with the Risk Management Center.

11.4.1.1.5 Intermediate Inspections. For projects on five-year alternating cycle of periodic inspections and periodic assessments, an intermediate inspection of all or some of the features may be scheduled, if warranted. Selection shall be based on consequences of failure, age, degree of routine observation, performance record and history of remedial measures. Intermediate inspections shall also be made of any portion of a project exposed during dewatering that could not be accomplished during the scheduled periodic inspection. Completion of dam modifications, e.g., major rehabilitations, addition of appurtenance structures, addition of hydropower, etc.,

requires a series of intermediate inspections to determine effect and performance of new work. A summary of the findings from intermediate inspections is to be included in the next periodic inspection report. Annual inspections performed by Operations personnel, in accordance with ER 1130-2-530 (reference A.63), are mandatory for all high hazard potential dams, shall include district dam safety personnel, and are considered intermediate inspections for reporting purposes. As per Federal Guidelines for Dam Safety (reference A.71), annual inspections should include a thorough field inspection of the dam and appurtenant structures, and a review of the records of inspections made at and following the last periodic inspection. If unusual conditions are observed that are outside the expertise of these inspectors, arrangements should be made for inspections to be conducted by specialists.

11.4.1.1.6 Informal Inspections. Appropriate employees at the project shall make frequent observations of the dam and appurtenant structures. The purpose is to identify and report abnormal conditions and evidence of distress in accordance with training instructions and guidance. Any unusual conditions that seem critical or dangerous shall be reported immediately as Evidence of Distress, using proper procedures and channels to the DSO, as required by Chapter 13, paragraph 13.4, of this regulation, and the Emergency Action Plan Notification Plan for the project

11.4.1.2 Other Structures. The district is responsible for establishing periodic inspection and periodic assessments intervals, for other USACE-owned and -operated water control facilities. Inspection intervals must be defined in the project Operation and Maintenance (O&M) manual using a risk informed approach and methodologies. Projects designed and constructed by the USACE, but operated and maintained by the sponsor, shall also have inspection intervals defined in the O&M manual.

11.4.1.3 Hydraulic Steel Structures (HSS). ER 1110-2-8157 (reference A.60) requires fracture critical members to be inspected every five years and that all HSS be inspected not to exceed 25 years, even if dewatering is required. Based on the baseline and/or subsequent Periodic Assessment, a frequency shorter than every five, or 25 years may be necessary. When several of the same type of HSS exists at a project, at least one of each type of HSS must be inspected as part of each periodic inspection. A different HSS should be selected for each inspection. For HSS whose failure could result in loss of life, the critical components should be subjected to at least a thorough visual examination during each inspection. Hydraulic Steel Structures include lock gates, dam spillway gates, tainter valves, flood protection gates, stop logs, bulkheads, and lifting beams used for installing other Hydraulic Steel Structures. A summary of findings and deficiencies from the HSS inspection shall be included in the next subsequent periodic inspection report.

11.4.1.4 Stilling basins. When feasible, stilling basins shall be dewatered for inspection for each periodic inspection if there have been significant releases through the stilling basin or potential damage or wear is suspected. If no significant releases through the stilling basin have occurred, or there is no suspicion of damage or wear, the schedule for dewatering may be deferred until the next periodic inspection. The district

Dam Safety Officer may require a diver inspection or hydro-acoustic survey to verify that there is no significant debris in the basin or damage to the structure. When stilling basins cannot feasibly be dewatered, except for emergency repairs, diver inspections or hydro-acoustic surveys are recommended to be performed at five-year intervals. If there is a need, due to acceleration in erosion damage, then surveys may be necessary more frequently. Changes in the operational release patterns for environmental, fish and wildlife, or other purposes may warrant more frequent inspections of the stilling basin. After there have been significant releases through the stilling basin or potential damage or wear is suspected, the stilling basin shall be dewatered for a special inspection or an underwater inspection shall be performed immediately after the event.

11.4.2 Report. A formal technical report of periodic inspections and periodic assessments shall be prepared for permanent record and for reference for needed remedial work. These reports shall be based on a detailed, systematic technical inspection, and appropriate risk assessment methodology for each structure and its individual components regarding its safety, stability, structural integrity, operational adequacy, and risk of failure. A summary of findings from intermediate inspections shall be included in an appendix. See Appendices V and W for report content and format of PI reports and PA reports, respectively, and Appendix X for details on PFMA procedures and documentation.

11.4.2.1 Inspections or routine observations indicating that the safety of a structure is in jeopardy shall be reported in accordance with Chapter 13 of this regulation.

11.4.2.2 Inspections/assessments indicating necessity for project modifications, major repairs, rehabilitation, replacement or need for further study beyond the scope of normal maintenance shall be reported to the MSC Dam Safety Officer in the memorandum transmitting the report. Reports of conditions requiring modification shall contain a statement as to whether studies shall be pursued under Operations and Maintenance Program or Dam Safety Modification Program.

11.4.2.3 The Executive Summary of the reports shall be provided electronically to HQUSACE Dam Safety Program Manager (HQ-DamSafety@usace.army.mil) and the MSC Dam Safety Program Manager within 90 days of completion of the periodic inspection, or assessment. See Appendix V of this regulation for information on preparing and submitting the Executive Summary. The Executive Summary shall also be entered into the Dam Safety Program Management Tools (DSPMT) database within 90 days.

11.4.3 Report Completion and Submittal Schedule. Two printed copies of the reports shall be submitted by the district to the MSC Dam Safety Officer within 90 days after the inspection. The district shall establish completion and tracking standards for the review of periodic inspection and periodic assessment reports (District Quality Control Review for Periodic Inspection reports and Agency Technical Review for Periodic Assessment reports.) The submission shall include all review comments and the resolution of the comments. The district Dam Safety Officer shall certify the review

and the reports prior to submittal to the MSC Dam Safety Officer. At least two printed copies shall be retained at the district and one printed copy submitted to ERDC. Reports Control Symbol (RCS) is exempt based on AR 335-15 (reference A.3). Each printed copy of the report shall also contain an electronic version of the report in the appropriate media (CD or DVD).

11.4.4 Report Approval. The MSC Dam Safety Officer is responsible for approval of all the inspection and assessment reports on dams operated and maintained by the USACE.

11.4.5 Distribution of Approved Inspection Reports.

11.4.5.1 Library Copy. Upon approval of the inspection report, one printed copy together with a copy of all correspondence bound under the front cover will be sent by the originating district directly to:

Commander, U.S. Army Engineer Research & Development Center
ATTN: Research Center Library
3909 Halls Ferry Road
Vicksburg, MS 39180-6199

11.4.5.2 District Copies. The districts shall determine the distribution of printed reports within their respective offices, to include the project site, local sponsor, military installation, and other Federal agency and/or state agency, as deemed appropriate.

11.4.6 Obligation to Others. In cases where ownership, operation, maintenance, and other activities at a project or its major elements is divided between USACE and others, information pertinent to the condition of project elements owned, operated, or maintained, or otherwise affected by others, as observed by USACE' inspection or periodic assessment teams, shall be furnished to the co-owner. The district Dam Safety Officer shall furnish this information to the FERC, when hydroelectric power projects are under the purview of the Federal Power Act (41 Stat. 1063, U.S.C. 791-823) 10 June 1920, as amended (FPA) (reference A-112). Owners and operators of such FERC licensed facilities shall be advised that the information made available by USACE shall not be presented as representing results of inspections/assessments performed for the licensee by USACE and is not a substitute for the FERC inspection under the FPA.

11.5 Instrumentation. Instrumentation shall be continually monitored and data analyzed in a timely manner by a qualified engineer between periodic inspections to detect changing conditions in the facility. Plots and written assessments and evaluations of the instrumentation data shall be included in pre-inspection/assessment packets, and in periodic inspection reports.

11.6 Responsibilities.

11.6.1 District Dam Safety Officer. The district Dam Safety Officer shall be responsible for:

11.6.1.1 Formulating the inspection/assessment plans, conducting the inspections /assessments, processing and analyzing the results of the instrument observations, evaluating the condition of the structures, recommending the schedule of the next inspection/assessment, and preparing and submitting the resulting reports.

11.6.1.2 Coordinating with the district Operations, and Programs & Project Management (PPMD) Divisions to ensure sufficient funding for inspections, assessments and remedial measures is budgeted in the Operations and Maintenance, General account**,** prioritizing recommended remedial measures as necessary using HQUSACE national risk-informed priorities for major remedial measures.

11.6.1.3 Notifying the district Commander, the MSC Dam Safety Officer, and the USACE Dam Safety Officer when allocated funding is insufficient for conducting inspections or other activities required by USACE criteria and standards and the Federal Guidelines for Dam Safety (reference A.71).

11.6.1.4 Coordinating with Operations Division personnel of scheduled inspections /assessments and requesting their assistance and participation. For projects or structures being inspected for the first time, personnel from the Construction Division shall be invited to participate. A representative(s) of the sponsor and the appropriate State Dam Safety official(s) shall also be invited to attend the inspection. If hydropower is a feature of the project, the regional FERC office and any licensee shall be invited to the inspection.

11.6.1.5 Forwarding the approved periodic reports to the district Operations Division for implementation of any routine recommendations. The Dam Safety Officer shall coordinate with PPPMD and Operations Divisions to develop schedules and any funding prioritization based on the PIs and PAs.

11.6.1.6 Ensuring the inspection team is comprised of the technical, and where appropriate professionally registered, expertise necessary to execute a thorough and technically sound inspections and assessments. Lacking district expertise, the Dam Safety Officer shall obtain assistance from HQUSACE, MSC, or other districts. HQUSACE personnel will not normally participate in inspections unless requested, or when project conditions dictate. See Appendix V for further details.

11.6.1.7 Ensuring all recommendations made in the reports are resolved. If the recommendation is related to confirmed and unconfirmed dam safety issues and interim risk reduction measures, the district DSPM will update the DSPMT.

11.6.1.8 Updating the deficiency spreadsheet module screen 4.5 of the Dam Safety Program Management Tool software and assigning the DSPMT priority code 1 through 6 to each recommendation so the assigned priority can be tracked over time. Only Confirmed and Unconfirmed Dam Safety Issues and Interim Risk Reduction Measures should be updated to the NID/DSPMT.

11.6.1.9 Performing annual program review, see paragraph 11.7.

11.6.2 District Operations Division. The district Operations Division shall be responsible for:

11.6.2.1 Performing needed maintenance, such as mowing and dewatering, to support a thorough and safe inspection, and allowing full access to critical project features.

11.6.2.2 Accompanying the inspection/assessment team and providing the field support required for the team. The project staff shall be prepared during the inspection/assessments to operate those project components whose failure to operate properly could impair the operational capability and/or usability of the structure. Where the operation of these components is vital to the safe operation of the project under emergency conditions, the components shall be operated using emergency power to ensure the inspection/assessment team that all critical project features will function under emergency conditions or in the absence of the normal source of power. Testing of the emergency power source shall require, if possible, the maximum power demand expected under emergency conditions. Additional details and requirements are described in Appendix V.

11.6.2.3 Performing required preliminary inspections, such as Gate Operability and Capability Inspections, and furnishing completed reports to the inspection team.

11.6.2.4 Acting on inspection recommendations for routine O&M in a timely manner in accordance with the deficiency classification table in Appendix V.

11.6.2.5 Completing an annual inspection of all water control projects and providing documentation of the findings and status of previous recommended actions to the district DSPM.

11.6.2.6 Annual budgeting and funding of sufficient funds for the district DSO to execute the district’s Dam Safety Program.

11.6.3 District Programs and Project Management Division. The Programs and Project Management Division shall be responsible for:

11.6.3.1 Supporting the program with proper funding and shall coordinate and cooperate with the project sponsor as needed.

11.6.3.2 Ensuring the sponsor fulfills all terms of the applicable Project Cooperative Agreement, Local Cooperative Agreement, or other agreements based on Section 221 of the Flood Control Act of 1970 (PL 91-611) (reference A.108).

11.6.3.3 Coordinating the timely correction of all noted deficiencies with the project sponsor.

11.6.4 MSC Dam Safety Officer. The MSC Dam Safety Officer shall provide quality assurance, oversight and management for this program. As a minimum, the MSC Dam Safety Officer shall:

11.6.4.1 Provide representation at the first and second post construction inspections, the inspection of high hazard potential structures, and the inspection of structures whose condition or performance has warranted more frequent attention.

11.6.4.2 Provide oversight for the monitoring of data collection, processing, and assessment using risk informed methodology.

11.6.4.3 Retain approval authority for the frequency and scope of periodic assessments, and review/approve the schedules for them. Intervals in excess of 10 years require written request and approval by USACE Dam Safety Officer.

11.6.4.4 Provide oversight and review of the regional database using DSPMT to include schedules and history of project remedial measures, unless this information is otherwise recorded in an official database.

11.7 Program Review. At the end of each fiscal year, the district Dam Safety Officer shall review and set priorities for the recommended remedial actions for the next budget submission.

11.8 Reporting Distress. Refer to Chapter 13, paragraph 13.4, of this regulation for procedures when reporting evidence of distress.

11.9 Funding. Funding for all Dam Safety activities and reports preparation shall be budgeted in the minimum funding level of the district's fiscal year budget request for project operation and maintenance. Periodic inspections are considered routine, recurring actions that are budgetable in the initial O&M increment for each project. Costs incurred by HQUSACE and MSC personnel shall not funded by the district.

11.9.1 Funding During Construction. Funding for inspections and other Dam Safety activities for a project during the period of construction shall be under Cost Code 51, Appropriation 96X3122, Construction. The term "period of construction" is defined as the period from the issuance of the solicitation for the first construction contract to the date the district Commander notifies the sponsor in writing of the government's determination that construction is complete; or, to the date the Government takes beneficial occupancy (for solely USACE-retained projects).

11.9.2 Funding During Operations. Funding for inspections and other Dam Safety activities after the project components are placed in operation shall be under Appropriation 96X3123, Operation and Maintenance, General. Funding for periodic assessments shall be included in the minimum program of the Operations and Maintenance budget submission.

This Page Left Blank

CHAPTER 12

Operations and Maintenance Activities

12.1 General. The transition from construction to operation may consist of overlapping activities. Therefore, it is very important that problems encountered during construction be adequately documented and resolved prior to the operational phase. Rigorous and continuous vigilance, checking, and inspection, for as long as the dam is operational, are necessary for dam safety, as problems may occur following many years of trouble-free operation. This is particularly true for untested flood control dams where a significant percentage of the maximum head has not occurred. Guidance on control of construction is available in EM 1110-2-1911 (reference A.16). Operations and maintenance policies for flood control operations are covered in ER 1130-2-530 (reference A.63).

12.2 Operations and Maintenance Manual. The Operations and Maintenance (O&M) manual provides guidance and instructions to project personnel for proper operation and maintenance of the facility. The O&M manual contains a narrative summary of the critical dam features including design features with safety limits, equipment operating and testing procedures, instrumentation requirements, probable failure modes, a history of problems, and how those problems could adversely affect the structure under stress. The O&M manual shall be prepared during the construction phase and shall be updated as features are added to the project, when equipment is replaced, or when changes in project operations are implemented.

12.3 Project Geotechnical and Concrete Materials Completion Report for Major USACE Projects. ER 1110-1-1901 (reference A.44) requires, as part of the permanent project record, documentation of the as-constructed geotechnical and concrete materials aspects of all major, complex and unique engineered projects constructed by USACE, including all subsequent modifications. This report, shall be identified, scheduled, and resourced in the Project Management Plan (PMP). The information and data in this document shall be presented and discussed with the sponsor/owner. The report provides, in a single document, the significant information needed by the sponsor, USACE technical staff, and other team members to become familiar with the project. The report shall facilitate accurate, timely inspections and performance evaluations, and serve as the basis for developing and implementing appropriate and effective modifications, “flood fighting” efforts, and emergency and/or remedial actions to prevent flood damage or required as a result of unanticipated conditions or unsatisfactory performance.

12.4 Instrumentation and Monitoring. All USACE dams and other water control facilities are required to have a level of instrumentation that enables proper monitoring and evaluation of the structure during the construction period and under all operating conditions. Instrumentation systems are also expected to furnish data on structural behavior for application to future designs. Each dam or other water control structure shall have instrumentation to measure hydrostatic pressure, embankment and abutment

seepage, foundation under seepage, and displacement of major elements of the structure. Strong motion accelerometers are to be installed in structures located in designated seismic regions in accordance with ER 1110-2-103 (reference A.46). After a project is operational for several years, scheduled maintenance, repair, and replacement of instrumentation shall be part of the normal plan of operation. Instrumentation shall be properly maintained or replaced, as necessary, in order to obtain accurate and timely data. Readings shall be made at scheduled frequency and shall be properly recorded and analyzed. Detailed information on instrumentation for earth and rock fill dams is given in EM 1110-2-2300 (reference A.25) and EM 1110-2-1908 (reference A.15). Information on instrumentation for concrete dams is given in EM 1110-2-2200 (reference A.23) and EM 1110-2-4300 (reference A.30). Full reliance shall not be placed on instrumentation alone to find problems or to forecast performance since it is impossible to install sufficient instrumentation to monitor every possible problem area. An extremely important part of the monitoring program is visual observation to determine evidence of distress and unsatisfactory performance (reference A.90). Project personnel shall receive training in basic engineering considerations pertaining to major structures, with procedures for surveillance, monitoring, and reporting of potential problems, and with procedures for emergency operations.

12.5 Reporting Distress.

12.5.1 General. Evidence of distress in dams, and other water control structures shall be immediately reported to the district Dam Safety Officer. If an engineering evaluation of the evidence of distress indicates the need for immediate remedial action, the Dam Safety Officer shall immediately report such conditions through command channels to the USACE Dam Safety Officer. The USACE Dam Safety Officer shall notify the Director of Civil Works and the USACE Commander, if necessary.

12.5.2 Procedures. When evidence of distress is reported to the district Dam Safety Officer, the DSO shall confirm the situation and determine if an engineering evaluation of the condition is needed or remedial measures are required. Initial notification shall be made by telephone (or e-mail for minor distress) to the MSC Dam Safety Officer and Dam Safety Program Manager. The MSC DSO shall notify USACE DSO. If the USACE Dam Safety Officer cannot be contacted, the reporting office shall follow the notification sequence shown in HQUSACE Dam Safety Notification Plan. A narrative summary, with appropriate photographs, endorsed by the MSC Dam Safety Officer shall follow the initial notification. After actions report shall be prepared and submitted to the MSC and HQUSACE. A post distress inspection shall be performed to evaluate damages or changes caused by any event listed in Chapter 13 of this regulation. If the distress is significant enough to require operational restrictions, the implementation of restrictions shall be reported as well.

12.5.3 HQUSACE Dam Safety Notification Plan. The Corps Dam Safety Program Manager shall maintain and periodically publish an official HQUSACE Dam Safety Notification Plan. This plan shall be distributed electronically to all DSO's and DSPM's.

It shall be updated each January, or as needed, to ensure that names and telephone numbers are current and accurate. If none of the individuals on the notification plan can be reached, the HQUSACE Operations Center should be notified at (202) 761-1001.

12.6 Operations and Maintenance Program.

12.6.1 Operations activities for Dam Safety includes instrumentation readings, daily monitoring of the structures, routine equipment testing, and other work items included in the Operations and Maintenance Manual as routine operations items.

12.6.2 Maintenance activities are divided into two categories. Normal repair and rehabilitation work that does not qualify for funding under either the Dam Safety Assurance Program or the Major Rehabilitation Program shall be funded under the regular O&M Program. Work recommended in the Periodic Inspection Report shall be prioritized and funded through this program unless qualifying under another program.

12.6.2.1 Recurring Maintenance for Dam Safety includes maintenance of instrumentation, cleaning and flushing toe drains and relief wells, and other work items included in the Operations and Maintenance Manual as recurring maintenance items.

12.6.2.2 Major Maintenance for Dam Safety includes non-routine major repairs that exceed $2,000,000. Some examples of major maintenance include concrete and riprap repairs and/or replacements.

12.6.3 The establishment, maintenance, and control of vegetation pose Engineering, as well as routine maintenance considerations. In accordance with ETL 1110-2-571 (reference A.67), this guidance establishes minimum requirements for maintenance/control of vegetation at USACE-owned dams, abutments, spillways, inlet/outlet channels, and other appurtenances. Details concerns vegetation maintenance is included in Appendix Y.

This Page Left Blank

CHAPTER 13

Reporting Evidence of Distress in Civil Works Structures

13.1 Purpose. This chapter prescribes the responsibilities and procedures for the immediate notification to higher authority of evidence of major distress or potential failure of civil works projects. These procedures apply to projects under construction or currently in operation.

13.2 General. Evidence of distress in dams, levees, and other water control structures shall be immediately reported to the district Dam Safety Officer. If an evaluation of the evidence of distress indicates the need for immediate remedial action, the Dam Safety Officer shall, as soon as practical, report such conditions through command channels to the USACE Dam Safety Officer. Actions that could impact life safety shall take precedence over notifications to command. The USACE Dam Safety Officer shall notify the Director of Civil Works, the Deputy Commander for Civil Works and Contingency Operations, and the USACE Commander, if necessary.

13.3 Discussion. The intent of these requirements is to keep the USACE chain of command situational aware of dam safety-related issues by ensuring the immediate reporting, inspection, and follow-up evaluation of conditions that demonstrate evidence of distress or conditions that could result in a potential hazard at civil works projects. In all cases the overriding concern must be to get the information in the hands of the technical staff as quickly as possible so that appropriate evaluation and response decisions can be made. This is even more critical in cases involving severe distress (sinkholes, significant seepage, large slides, gate failures, etc…) because the response time may be critical in limiting damage and saving lives. In these types of situations it would be better to have a “chain of command violation” rather than lose valuable time in the reporting process. It would also be better to raise the alarm of concern on something that ultimately turned out to be only a moderate issue as opposed to under-reacting on a problem that turned out to be severe. It is not the intent for reporting requirements to ever interfere with the local responsibility to react appropriately in the event of severe distress. The primary focus must always remain on taking all necessary emergency measures with the appropriate notification following thereafter as quickly as possible.

13.4 Procedures.

13.4.1 When evidence of distress is reported to the district Dam Safety Officer, the DSO shall confirm the situation and determine if an engineering evaluation of the condition is needed or remedial measures are required. Initial notification shall be made by telephone to the MSC Dam Safety Officer and Dam Safety Program Manager, with follow-up documentation and digital photos via email or express mail. The MSC DSO shall notify USACE DSO. If the USACE Dam Safety Officer cannot be contacted, the reporting office shall follow the notification sequence shown in HQUSACE Notification Plan. A narrative summary with an assessment of risks, and with appropriate

photographs, endorsed by the MSC DSO shall follow the initial notification to the HQUSACE DSO and be recorded in the Dam Safety Program Management Tools (DSPMT). The DSPMT software contains a built-in mechanism to enter details of the observed distress. The use of DSPMT is encouraged because it has the capability to generate a report that can be promptly and simply attached to an e-mail.

13.4.2 After action reports shall be prepared and submitted to the MSC and HQUSACE. A post-distress field inspection, and if necessary, a periodic assessment of risk shall be performed to assess damages or physical changes caused by any event listed in the following subparagraph. If the distress is significant enough to require operational restrictions, the implementation of restrictions shall immediately be coordinated with the Special Assistant for Dam Safety. See Chapter 7 for guidance on interim risk reduction measures.

13.4.3 HQUSACE Dam Safety Notification Plan. The USACE Dam Safety Program Manager shall maintain and periodically publish an official HQUSACE Dam Safety Notification Plan. This plan shall be distributed electronically to all DSOs and DSPMs. It shall be updated each January, or as needed, to ensure that names and telephone numbers are current and accurate. If none of the individuals on the notification plan can be reached, the HQUSACE Operations Center should be notified at (202) 761-1001.

13.5 Signs of Distress. Typical examples of distress are:

13.5.1 Sloughs, settlement, or slides in embankments such as earth or rock fill dams, and bridge abutments or slopes of spillway, channels, and lock and dam abutments.

13.5.2 Evidence of piping, muddy water boils in the areas of a structure such as embankments, abutments, dam monoliths, outlet works structures, lock walls, or cofferdams.

13.5.3 Abnormal increase or decrease of flow from foundation drains, structural joints, or face drains of concrete dams.

13.5.4 Any increase in seepage quantities through or under embankments or in abutments.

13.5.5 Any significant change in pore-water pressure in either embankments or their foundations or abutments.

13.5.6 Any significant change in uplift pressures under concrete structures.

13.5.7 Unusual vertical or horizontal movement, bulges, or cracking of embankments, abutments, or structures.

13.5.8 Significant cracking of mass concrete structures, either during construction or after completion.

13.5.9 Sinkholes or local subsidence in the foundation of or adjacent to embankments or other pertinent structures critical to the safe operation of the project.

13.5.10 Excessive deflection, displacement, or vibration of concrete structures (e.g. tilting or sliding of intake towers, bridge piers, lock walls, or floodwalls).

13.5.11 Erratic movement, binding, excessive deflection, or vibration of outlet and spillway gates and large flow control valves.

13.5.12 Significant damage to any structure (e.g. barge damage to bridge piers/lock walls or ice flow damage to intake towers and access bridge piers, spillway erosion damage (lined and unlined), stilling basin damage, cavitation damage to outlet works and spillways).

13.5.13 Significant damage to, or changes in, structures, foundations, reservoir levels, groundwater conditions, and adjacent terrain as a result of seismic events. Special inspections for damages should be made immediately following the events as described in ER 1110-2-1802 (reference A.55).

13.5.14 Any other indications of distress or potential failure that could inhibit the operation of a project or endanger life and property.

13.5.15 Excessive vibration, binding, unusual noises, movements, or deflections of gate hoist operating equipment.

13.5.16 Actual hydraulic equipment operating pressure in excess of 125% of the normal operating pressure. Electric motor operating equipment overheating or stalling.

13.5.17 Erratic movement or unusual sounds such as bumping, jumping, or popping miter gates.

13.5.18 Wire rope lifting cables or lifting chains having broken strands or deformed, worn, or severely corroded links.

13.5.19 Frequent power interruptions.

13.5.20 Excessive movement of penstock flexible couplings.

13.5.21 Penstocks or turbine spiral cases that show signs of distress such as deformation or cracking.

13.5.22 Failure of major mechanical or electrical equipment at locks and dams or local flood protection projects.

13.6 Inspections. Special inspections to evaluate damages or changes should be made immediately following any of the events outlined above. Results of these inspections and associated recommendations should be forwarded to the district Dam Safety Officer. The report should include what is believed to have lead to the situation, a description of the incident, damage occurred, distress seen, etc. Actions taken to remedy and future changes to surveillance and monitoring plans. The Risk Management Center will maintain a record of these reports to help in identifying trends and/or reoccurring problems. The DSO shall ensure that this information is promptly communicated through command channels (MSC and HQUSACE) so that appropriate decisions regarding the project's DSAC rating and national priority can be made. HQUSACE will ensure proper coordination and involvement of the Risk Management Center.

CHAPTER 14

Instrumentation for Safety Evaluations of Civil Works Structures

14.1 Policy. All Civil Works water control projects shall have an adequate level of instrumentation to enable design engineers to monitor and evaluate the safe performance of the structures during the construction period and under all operating conditions. The term "project" includes all dams, appurtenant structures, facilities, saddle dams, and any other feature whose failure or malfunction would cause loss of life, severe property damage, or inability to perform the authorized purpose.

14.1.1 The District Dam Safety Officer is responsible to ensure projects are adequately monitored and shall advise the District Commander, MSC, and Headquarters (HQ) if performance does not comply with safety thresholds or suggests distress of the structure. Concerns regarding the adequacy of instrumentation, funding, frequencies, procedures, and staffing shall be elevated to the Dam Safety Officer for resolution with District Senior leadership.

14.1.2 Appropriate instrumentation and monitoring frequency shall be based on that Dam's potential failure modes analysis. Seepage for example is a pervasive risk driver within the USACE inventory of dams. Districts must ensure that critical seepage areas are instrumented and equipment is in good working order. Monitoring programs shall be tailored to each individual dam.

14.2 Risk Informed Instrumentation Monitoring. Instrumentation data is an extremely valuable asset that supplies insight into the actual behavior of the structure relative to design intent for all operating conditions. Instrumentation data establishes performance that is uniquely characteristic to the structure and provides a basis for predicting future behavior.

14.2.1 The number of instruments, locations, types, and frequency of readings shall be commensurate with the risk classification and dominant failure modes identified for each project. Redundancy and use of automated data collection should be considered for high risk features or for locations that have limited on site staff or are difficult to access for monitoring and emergency response. Repair, replacement, and installation of new devices shall be evaluated throughout the life of the project subject to potential failure modes analysis (PFMA), flood performance, and other risk considerations. Increased data monitoring and analysis shall be performed in conjunction with unusual loading events, such as high reservoir levels or following earthquakes. Specific devices and frequency of readings shall be documented in project specific surveillance plans and be included as an appendix to the Emergency Action Plan.

14.2.2 The planning, design, and layout of an instrumentation program are integral parts of the project design and operation. A life cycle approach is needed; instruments that were critical for construction phase work may not be critical for the operations

phase. The number and locations of instruments shall be annually reviewed to assess if devices should be abandoned, added, or read at different time intervals. As structures age and new design criteria are developed, the historical data are relied upon to evaluate the safety of the structure with respect to current standards and criteria. Older structures may require additional instrumentation to gain a satisfactory level of confidence in assessing safe performance.

14.2.3 Instrumentation data can be of benefit only if the instruments consistently function reliably, the data values are compared to the documented design limits and historical behavior, and the data are received and evaluated in a timely manner.

14.2.4 Automation of dam safety instrumentation is a proven, reliable approach to obtaining instrumentation data and other related condition information, particularly when investigating and analyzing performance conditions that require frequent, and/or difficult access for obtaining measurements. Automated instrumentation must be periodically calibrated and verified manually. Further guidance for instrument automation is available through ER 1110-1-8158 (reference A.45). Automation should augment field visual inspection and not take the place of it. It is not recommended that automation be accomplished for all instrument requirements, but only to achieve those monitoring objectives that require automation.

14.2.5 Successful risk management requires a healthy routine monitoring program, including maintenance, repair, and staff who are trained in data collection and interpretation. Data assessment must consider the anticipated design performance of the project, and whether the actual performance meets design safety thresholds. Data anomalies in critical areas must be promptly evaluated by experienced technical staff and may include but not limited to verification readings, verification of calibration and collection methods, visual observation of area and instrument for damage or distress of structure, and comparison with redundant instrumentation if available.

14.2.6 In some cases, where data is complex and is relied upon for life safety risk reduction decisions, it may be appropriate to utilize independent expert consultants to review instrumentation data analyses and help validate conclusions.

14.3 Planning.

14.3.1 Instrumentation Systems. The design and construction of new projects as well as the rehabilitation, dam safety modifications, and normal maintenance of older projects present opportunities for planning instrumentation systems for the future engineering analyses of structural performance. Careful attention and detail shall be incorporated into the planning of instrumentation systems and programs to ensure that the concerns are adequately monitored. Once the parameters that are critical to satisfactory performance are determined by the design, appropriate instrument devices are selected to provide the engineering measurements to the magnitude and precision, and response time necessary to evaluate the parameters. Generally, the types of measurements are as follows;

14.3.1.1 Horizontal and vertical movement,

14.3.1.2 Alignment and plumb,

14.3.1.3 Stresses and strains in soil and rock-fill,

14.3.1.4 Pore pressure,

14.3.1.5 Uplift pressure,

14.3.1.6 Phreatic surfaces,

14.3.1.7 Seismic effects,

14.3.1.8 Seepage clarity and quantity.

14.3.2 References. ER 1110-2-103 (reference A.46) gives guidance on instrumentation for seismic effects, including instrumentation, automation, and determination of performance parameters. EM 1110-1-1005 (reference A.8) gives guidance on monitoring horizontal and vertical movements. EM 1110-2-2300 (reference A.25) provides information on design and construction of earth and rock-fill embankments. EM 1110-2-4300 (reference A.30) provides information on instrumentation requirements for concrete structures. EM 1110-2-1908 (reference A.15) provides detailed information on all aspects of instrumentation, including staffing qualifications, data management, analysis and long-term reassessments. EM 1110-2-1901 (reference A.12) provides information on analysis of seepage.

14.3.3 Instrumentation System Requirements. Baseline readings for all instrument data must be generated. Statistical and graphical methods are simple ways to establish this baseline. In all circumstances, background information that may affect the validity of the data or the analysis of the performance shall be documented, archived, and readily available for data reviewers. Other considerations include the potential for damage during construction and operations; the effects of a severe environment on the instruments; the personnel requirements for maintenance and data collection; and the evaluation of the instrument data. Automated systems have additional requirements as follows:

14.3.3.1 Each instrument should maintain the ability to be read manually or as appropriate have adjacent redundant manual system to verify automated data.

14.3.3.2 Each instrument shall have the capability to be read at the site in addition to upload to the network via satellite / radio / or other.

14.3.3.3 A backup communication link to the district shall be provided for the data transmission to allow redundancy for data acquisition.

14.3.3.4 Automated data acquisition system should include (1) desktop microcomputer and (2) laptop/portable microcomputer and / or (3) hand held rugged reader. Desktop microcomputer serves as the local monitor station to collect, process, display and produce a hard copy of the data at the project office or other designated point. This local monitoring station must also be capable of performing a quality control check of instrument readings, responding to a preset threshold level, interfacing with existing project hardware and software applications and should have the ability to be queried from the district or other remote location. The laptop/portable microcomputer is for infield trouble shooting and maintenance. This laptop/portable microcomputer will also serve as a backup capable of collecting data manually from the infield data loggers. Hand held reader may be used as a more rugged and portable alternative for many of the laptop/portable microcomputer purposes.

14.3.3.5 The automated system does not relieve or replace the normal visual inspection schedule of the project features to include the instrumentation. Rather, automation should supplement those critical activities.

14.3.3.6 In addition to these primary automation requirements, consideration shall also be given to backup power supply, lightning protection, maintenance, vandalism, system diagnosis, and software versatility.

14.4 Installation and Maintenance.

14.4.1 New Projects. Instrumentation for a project shall be included in the design phase, during construction, and throughout the life of the project as conditions warrant. After a project has been operational for several years, appropriate maintenance, repair, and replacement of instrumentation must be accomplished during the normal operation to ensure continuous data acquisition and analyses of critical performance parameters. Specialized expertise may be required to install and maintain instrumentation. Installation should be closely coordinated with construction activities to minimize instrument damage.

14.4.2 Existing Projects. Existing projects shall be evaluated to ensure that the original instrumentation is functioning as intended and is still appropriate. Threshold limits determined for original design condition or major modifications shall be examined and reviewed against current criteria. The instrumentation plan may require modification to delete some instruments and/or add other instruments in areas on the project where additional monitoring is required by performance concerns or advances in design practices. Changes to the instrumentation should be budgeted through normal operations and maintenance funding procedures.

14.5 Data Collection, Interpretation and Evaluation.

14.5.1 Collection Frequency. The frequency with which instrumentation data is obtained must be tailored to the instrument purpose, period of construction, investigation or other interest, and project operating conditions. In all cases, sufficient

calibration and background data shall be obtained to ensure that a reliable database is available to facilitate subsequent comparisons. The subsequent reading frequency of instruments during construction and operating conditions shall be based on an anticipated rate of loading or changes in reservoir levels to be determined by a dam safety engineer familiar with the design and performance parameters of the project.

14.5.2 Data Interpretation. The timely reduction and interpretation of instrumentation data is essential for a responsive safety evaluation of the project. For all USACE projects, this reduction and interpretation shall occur as soon as conditions warrant from the time that the data was obtained. The evaluation of the data shall follow immediately. As a minimum, all data shall be plotted as instrument response with respect to time, as well as to reservoir level or other range of loading. All instrumentation data shall be reviewed monthly and evaluated not less than annually. More frequent readings may be required when operating under Dam Safety Action Classification (DSAC) –based Interim Risk Reduction Measures (IRRM) or other critical Dam Safety events such as surcharge pool or near record pool. The district shall document instruments critical for monitoring during IRRM in an addendum to the project specific surveillance plan. High risk conditions will require more frequent and intensive scrutiny of instrumentation data in accordance with established plans.

14.5.3 Performance Prediction. During the initial project design, or reevaluation in the case of existing structures, the physical properties of the construction materials, design data, loading conditions, and the appropriate factors of safety shall be utilized to determine the desired threshold limits for each performance parameter. Quantitative values shall be established for these limits that can be accurately translated into measurements that are easily and readily obtained in the field, which will enable the designers and operators to evaluate the behavior and performance of the structure. A detailed discussion of the design assumptions shall be presented in the design documentation report (DDR) for new or modified features. The threshold limits along with the predicted performance levels shall be addressed in the project instrumentation DDR and in detailed instructions to project personnel and any other personnel involved with the instrumentation. The method of deriving the thresholds shall be documented to aid response to future exceeded thresholds. Exceeded thresholds shall trigger increased scrutiny and analysis of structural integrity and shall not be relied upon for sole basis of evacuation requests.

14.5.4 Monitoring Plans. Monitoring plans should remain adaptive to real time events and accelerate as appropriate to conditions. Data collection, reduction, and evaluation methods should be assessed routinely to try to shorten the process as appropriate to monitoring frequencies. If resources limit data collection / reduction / evaluation, priority shall be given to gather and assess data associated with high risk project features, based on a PFMA or detailed risk assessment. More detailed guidance for data acquisition, interpretation and presentation can be found in EM 1110-2-1908 (reference A.15) and EM 1100-2-4300 (reference A.30).

14.6 Reporting.

14.6.1 Upon completion of new projects or significant modifications to projects, the instrumentation data along with the written evaluation shall be consolidated and submitted to the MSC Dam Safety Officer in accordance with ER 1110-1-1901 (reference A.44). Written evaluation should also be incorporated in the subsequent periodic inspection reports.

14.6.2 The District Dam Safety Officer shall provide a written summary and evaluation of the district's instrumentation program annually to the MSC Dam Safety Officer. This annual program review shall include a specific write up on the performance of high risk (DSAC I and II) dams. The project information obtained annually shall be included in the periodic inspection report of the project. Instrumentation program records shall also be reported to and retained by the operations project staff.

14.7 Funding. The appropriate funding (General Investigation, Construction General, Operation and Maintenance, General appropriations, etc.) shall be utilized to accomplish the level of instrumentation outlined in this regulation. Funding for maintenance of instrumentation, data collection, data analysis, and reporting shall be included in the minimum routine program of the annual Operations and Maintenance budget submission. New or replacement instruments shall be programmed in the annual budget submissions as non-routine work items, and prioritized based on criticality. The DSAC rating and risk based failure modes shall be considered in budget prioritization, and coordinated with Operations and Programs staff.

CHAPTER 15

Dam Safety Training

15.1 Overview. The Corps of Engineers has an extensive program for training personnel in all matters related to its mission in water resources development. Much of the training is directly or indirectly related to dam safety. A comprehensive training program is conducted for dam operation and maintenance personnel. This program is designed to acquaint project personnel with basic engineering considerations pertaining to the major structures, with procedures for surveillance, monitoring and reporting of potential problems, and with emergency operations. In addition, the technical staff at the district office requires training to build expertise and ability to respond to emergencies. The Corps of Engineers has a training course on “Dam Safety in the Corps of Engineers” and has supported the development of the Training Aids for Dam Safety (TADS) Program. In 1991, the Federal Energy Regulatory Commission initiated a training course on “Emergency Action Plan”. ASDSO maintains a list of currently scheduled dam safety training courses on the web site at http://www.damsafety.org.

15.2 Corps of Engineers Training Course on Dam Safety. The Corps of Engineers Proponent Sponsored Engineer Corps Training (PROSPECT) program offers a course titled “Dam Safety in the Corps of Engineers”. Through lectures, case histories, and structured student discussions, the course covers all aspects of a dam safety program. The course outlines technical considerations (hydrologic, seismic, geotechnical, electrical/mechanical and structural) as well as the operational requirements (operation, maintenance, surveillance, preparedness, training, and notification). The scope and implementation details of the Dam Safety Assurance Program are covered in detail. Presentations, video modules, case histories, and a walk-through inspection are used to effectively present a multidiscipline approach to the successful monitoring and evaluation of Corps of Engineers dams.

15.3 National Dam Safety Conferences. National dam safety conferences, such as the Association of State Dam Safety Officials annual conference, the United States Society on Dams annual conference, the Corps of Engineers Infrastructure Conference, and conferences sponsored by other agencies, have speakers who are involved in state-of-the-art dam safety evaluations and remediation. These conferences are a great opportunity to share the technology and experiences of dam safety with people from other agencies, and within the Corps of Engineers. Participation in these conferences can be valuable training in dam safety activities.

15.4 Exchange Training – District to District. Participation in other district’s dam safety training, periodic inspections, and emergency exercises can be good training in dam safety and can spread the good things learned in one district to other districts. Other districts should be invited to attend periodic inspections, dam safety training, and emergency exercises, and whenever feasible, dam safety personnel should participate in those activities in other districts. There is a lot of information and experience available

that could be beneficially shared within districts and both districts could gain from the activities.

15.5 Training Program for Operations and Maintenance Personnel.

15.5.1 Dam Safety. Recognizing the important role that onsite operations and maintenance personnel have in dam safety, MSC commanders were directed in 1978 to develop a training program that addresses the following items:

15.5.1.1 Discussion of basic typical design considerations for various types of construction, including hydraulic considerations and foundation factors

15.5.1.2 Procedures for monitoring potential problem areas

15.5.1.3 Dam safety features in design and construction.

15.5.1.4 Normal operation, surveillance, monitoring, and reporting procedures

15.5.1.5 Emergency operations, surveillance, monitoring, and reporting procedures

15.5.1.6 Project specific features and history of problems and potential problems.

15.5.2 Training Frequency. All new field employees and field contractor personnel shall have a minimum of 6 hours training shortly after starting duty and at least 6 hours refresher training every five years.

15.5.3 Records. The Operations Project Manager shall document all formal training. These records shall be kept on file at the employee's project office and shall be available to the periodic inspection team and readily accessible for emergency response.

15.5.4 Exercises. Upon completion of the initial safety training at a new project, EAP exercises are developed based on the most probable emergency situations that might occur on each major dam feature.

15.6 Sample Dam Safety Training Course Outline for Project Personnel.

15.6.1 Purpose of Training Program. Basic objectives, history of dam failures, and films or slides depicting dam safety problems or failures.

15.6.2 Dam Safety Features in Design and Construction. Design philosophy for dams, design assumptions, construction history, salient features and regulating philosophy for the project, and past monitoring, experiences and performance for projects.

15.6.3 Normal Operation, Surveillance, Monitoring and Reporting Procedures. The value and use of instrumentation, effect of pool rises on monitoring requirements, reservoir regulation manuals, day-to-day surveillance, documentation of plans, records, reports, etc, generalizations on what is and what is not critical to safety of the structure, public relations with local communities, and coordination and notification to downstream water users and recreationists on controlled releases and flushing operations.

15.6.4 Emergency Operation, Surveillance, Monitoring and Reporting Procedures. Observations of evidence of distress, methods of treating obvious safety problems, knowledge of potential flood area downstream, alerting Corps of Engineer offices to emergency conditions, and alerting police and local civil defense groups to emergency conditions.

15.7 Dam Safety Training Courses.

15.7.1 Existing Available Courses.

15.7.1.1 *Bureau of Reclamation Safety Evaluation of Existing Dams (SEED)*. The Bureau of Reclamation has a dam safety training course for their personnel. In some cases it is more cost effective for Corps personnel in the western portion of the country to attend these courses than the PROSPECT courses. This training is another option that should be considered when selecting training for Corps personnel in dam safety.

15.7.1.2 *Training Aids for Dam Safety*.

15.7.1.2.1 Background. In 1986, the Corps of Engineers, along with 13 other Federal Agencies, all members of the Interagency Committee on Dam Safety, joined forces to develop a professionally prepared TADS Program. The TADS materials are arranged in three components that cover dam safety inspections, dam safety awareness and program development, and evaluations and remedial actions (references A.72 and A.78).

15.7.1.2.2 Structure. The entire package consists of 21 self-paced individual instruction modules that focus on performance of job tasks. Each module features a workbook text. The material is presented in a straightforward, easy-to-manage manner. Each workbook contains a glossary of terms and a list of references from which to obtain additional information. Some modules are supplemented with videotapes that illustrate certain concepts. Because the modules are self-contained, individuals may tailor a learning program to meet specific work requirements or personal needs.

15.7.1.2.3 Utilization of the Program. The TADS Program offers a standardized approach to dam safety training. The Corps of Engineers, as one of the primary sponsors of the TADS Program, distributes the TADS materials to each Corps of Engineers field office through the Engineering and Construction, Directorate of Civil Works, HQUSACE. All MSC's and districts shall maintain a complete set of modules including the videotape supplements.

15.8 Risk Assessment Training. The Risk Management Center will provide training on those activities and procedures that support risk assessments.

15.9 Consequence Training. Training on state-of-the-art USACE approaches for estimating consequences with initial emphasis on life loss and direct economic loss. As the tools evolve, training in additional consequences such as indirect economic losses, environmental and other non-monetary consequence will be offered. This training in support of dam safety risk assessments is provided by several means. For district staff committed to providing consequence assessment services to the Modeling, Mapping, and Consequence Center (MMC), annual courses are provided by the USACE Hydrologic Engineering Center (HEC). The focus is on bringing these staff up-to-speed so that they can fulfill the requirements of their agreement with the MMC. At present, there is an agreement between the MMC and the trainee's district that requires the district to allocate 50% of the trainees' time to support the MMC for a period of 2 years. Also, consequence assessment training can be provided by HEC on a reimbursable basis. A PROSPECT course presenting HEC-FIA (Flood Impact Analysis - the most common tool used for estimating consequences in support of dam safety risk assessments) will be available starting in FY 2012. Over the coming years, consequence estimates for risk assessments material will be worked into other regular PROSPECT courses to enable access by a broader audience.

CHAPTER 16

Emergency Action Plans

16.1 General. An Emergency Action Plan (EAP) is a formal document that identifies potential emergency conditions (either dam failure or large spillway releases) at a dam and specifies preplanned actions to be followed in order to minimize property damage and loss of life. The EAP specifies actions the dam owner[4] should take to moderate or alleviate the problems at the dam. It contains procedures and information to assist the dam owner in issuing early warning and notification messages to responsible downstream emergency management authorities in the event of an emergency. It also may contain inundation maps intended to highlight the critical areas for action for these emergency management authorities.

16.1.1 Historical references that provide the background for emergency action plans with the Corps of Engineers are as follows:

16.1.1.1 U.S. Army Corps of Engineers, Hydrologic Engineering Center, 1980 (Jun), “Flood Emergency Plans Guidelines for Corps Dams,” Research Document No. 13. Davis, CA (reference A.95).

16.1.1.2 U.S. Army Corps of Engineers, Hydrologic Engineering Center, 1982 (Jan), “Emergency Planning for Dams, Bibliography and Abstracts of Selected Publications,” Davis, CA (reference A.96).

16.1.1.3 U.S. Army Corps of Engineers, Hydrologic Engineering Center, 1983 (Aug), “Example Emergency Plan for Blue Marsh Dam and Lake,” Research Document No. 19, Davis, CA (reference A.97).

16.1.1.4 U.S. Army Corps of Engineers, Hydrologic Engineering Center, 1983b (Aug), “Example Plan for Evacuation of Reading, Pennsylvania, in the Event of Emergencies at Blue Marsh Dam and Lake,” Research Document No. 20, Davis, CA (reference A.98).

16.1.2 While the dam owner retains overall responsibility for the development of the EAP, this (and all subsequent revisions) must be done in close coordination with those having emergency management responsibilities at the state and local levels. Emergency management agencies will use the information in a dam owner's EAP to

[4] As used in this chapter, the term “dam owners” and their responsibilities are intended to have the same meaning as used in FEMA’s dam safety guidelines for emergency action planning, issued in 1998 by the Interagency Committee on Dam Safety to supplement the 1979 Federal Guidelines on Dam Safety. See Federal Guidelines for Dam Safety: Emergency Action Planning for Dam Owners” (1998) (April 2004 reprint) at page 3, footnote 1 (“The term dam owner, as used in these guidelines, refers to the individual dam owner or the operating organization.”).

facilitate the implementation of their responsibilities. State and local emergency management authorities will generally have some type of plan in place, either a Local Emergency Operations Plan or a Warning and Evacuation Plan.

16.1.3 The effectiveness of an EAP is greatly enhanced by utilizing a consistent format which ensures that all aspects of emergency planning are covered in each plan. Having both a uniform EAP and advance coordination with local and state emergency management officials/organizations are critical in facilitating a timely response to a developing or actual emergency situation. Ownership and development of the floodplain downstream from dams varies, therefore the potential for loss of life as a result of failure or operation of a dam will also vary. For this reason every EAP must be tailored to site-specific risks/conditions and failure modes yet should remain simplistic enough to encourage its use. This should include the full range of failure scenarios (including upstream landslide failures, if appropriate) as well as different detection times for the incident.

16.1.4 Recognizing the importance of overall federal uniformity in the management and design of dams, an ad hoc interagency committee on dam safety (ICODS) was established and issued a report containing the first guidelines for federal agency dam owners. The Federal Guidelines for Dam Safety (reference A.71) generally encourage strict safety standards in the practices and procedures employed by federal agencies or required of dam owners regulated by the federal agencies. To supplement these published guidelines, ICODS also prepared and approved specific federal guidelines related to emergency action planning. The final document was published in 2004 and is entitled “Federal Guidelines for Dam Safety: Emergency Action Planning for Dam Owners” (reference A.74). This document is intended to serve as the over-arching guidance which governs the content, structure, and implementation of EAPs for the U.S. Army Corps of Engineers.

16.2 Requirements. There are a few exceptions/elaborations to the Federal Guidelines related to EAPs that should be noted. These include:

16.2.1 EAPs are required for all Corps of Engineers Dams, including appurtenant structures having separate consequences from the main dam**.** This is more comprehensive than the Federal Guidelines, which specify EAPs only for high and significant hazard potential dams. EAP format/content for dams with high and significant hazard potential should follow the specifics outlined in this document and the Federal Guidelines. For Dams that are very similar and possibly on the same waterway such as navigation projects, you may want to have one EAP for the system with different call sheet for each project. For dams classified as low hazard, whether flood risk management or navigation, dam owners should scale back the complexity of the EAP to better fit the unique situation at the project. However, as a minimum the EAP should still include information on notification, emergency detection, responsibilities, and preparedness.

16.2.2 Inundation maps are required for any dam whose failure could result in loss of life or significant property damage as a direct result of the incremental flooding caused by failure of the dam. When required, inundation maps must be prepared for the following three scenarios: 1) Sunny day with dam failure, 2) Flood with dam failure, and 3) Flood without dam failure. Coordination with the Risk Management Center is required to obtain the most current and appropriate definitions of these scenarios for a particular project or study. Inundation maps are generally not required when the dam failure does not cause any incremental flooding, when dam failure discharges would not exceed downstream channel capacities or flood stages, or when consequences are limited to loss of service (e.g. navigation or hydropower disruption due to loss of pool).

16.3 Emergency Exercises.

16.3.1 Emergency Incidents. Emergency incidents at dams are not common events. Therefore, training and regular exercises are necessary to maintain proper operational readiness. In addition, annual meetings between a dam owner and emergency responders can facilitate a better understanding of roles and responsibilities and will enhance emergency readiness. The state of readiness should also be determined through periodic and regular simulations of emergency events. These emergency exercises should be initiated by the dam owner and should involve all of the key players who would normally be involved in an actual event. Consideration should be given to combining exercises for projects in the same watershed or multiple projects in the same geographical area. Periodic exercises will result in an improved EAP as lessons learned during the exercise can be incorporated into the updated document.

16.3.2 Participants in Exercises. Because nearly any dam safety incident has detection and reaction components, conduct of these exercises should be jointly led by a district's dam safety/technical elements (DSO, DSPM, and technical elements) and the Emergency Management Office. Exercises should ensure that both the technical aspects (i.e. internal district performance relating to detection and decision-making) as well as emergency management aspects of dealing with appropriate state/local officials are fully covered and evaluated. Focusing on only one aspect at the expense of the other can be dangerous as it could lead to a false sense of security regarding performance.

16.3.3 Exercise Frequency. The frequency of emergency exercises should correspond directly to the Dam Safety Action Classification (DSAC) rating and hazard potential of the project. The definition of the various hazard potential levels is given in Appendix Z. That is, the lower the DSAC rating the more frequently exercises should be conducted. As a minimum the EAP exercise schedule listed in table 16.1, Emergency Exercise Frequency, shall be followed for all projects having significant life/property loss implications. Note that actual emergency events may be substituted for the appropriate exercise provided they are properly documented and the lessons learned from that event are incorporated into the updated EAP.

16.3.4 Exercise Levels. The definitions of the exercise levels are included in Glossary. It is recommended that all exercises be based on a failure mode of concern for the particular dam. If an exercise has not been done in the last 5 years, it is recommended to start with a table top exercise and work up to the level appropriate for the DSAC. Low hazard potential projects, regardless of DSAC rating, require only an annual orientation seminar or drill. At their discretion and judgment, districts may choose to periodically conduct something more elaborate (i.e., tabletop, functional, or full-scale) if they deem the situation warrants.

Table 16.1 Emergency Exercise Frequency

Exercises* / Classifications	Drill	Tabletop	Functional Exercise	Full Scale Exercise
DSAC I and High Hazard Potential		Year 1, 3, 5, etc….	Year 2, 4, 6, etc….	At DSO discretion
DSAC II or III and High Hazard Potential	Year 1, 3, 5, etc…	Year 2, 4, 6, etc	At DSO discretion	At DSO discretion
DSAC IV or V Significant Hazard Potential	Year 1 – 4 and 6 - 9. etc….	Year 5, 10, etc…	At DSO discretion	At DSO discretion
Low Hazard Potential	At DSO discretion			

*Orientation Seminars shall be held for all new dams and whenever new information is developed.

16.3.5 Homeland Security Exercise and Evaluation Program (HSEEP). This is a national exercise program being developed by the Department of Homeland Security.

16.3.5.1 The Homeland Security Exercise and Evaluation Program (HSEEP) is a capabilities and performance-based exercise program which provides a standardized policy, methodology, and terminology for exercise design, development, conduct, evaluation, and improvement planning. HSEEP Policy and Guidance is presented in detail in HSEEP Volumes I-III. Adherence to the HSEEP policy and guidance ensures that exercise programs conform to established best practices and helps provide unity and consistency of effort for exercises at all levels of government.

16.3.5.2 HSEEP constitutes a national standard for all exercises. Through exercises, the National Exercise Program supports organizations to achieve objective assessments of their capabilities so that strengths and areas for improvement are identified, corrected, and shared as appropriate prior to a real incident.

16.3.5.3 Use of the policy and guidance presented in HSEEP is recommended to ensure that exercise programs conform to established best practices and aids

interaction with emergency service partners. Additional information about HSEEP is available from DHS at https://hseep.dhs.gov/pages/1001_About.aspx.

16.4 Modeling, Mapping, and Consequence Center. Inundation maps and data are one of the most useful tools to the emergency responders when dealing with an emergency event. They delineate the areas that would be flooded due to a dam failure or flooding resulting from large operational releases. Recognizing the need to have a more consistent, user friendly (i.e. easier to read/interpret), and accurate product the Mapping, Modeling, and Consequence Center has been established as a virtual asset under the Risk Management Center. The mission of this virtual center (comprised of H&H, GIS, and economist professionals from across the Corps) is to employ the latest technological tools to ensure consistency in how inundation maps and associated consequences are developed. While the actual production work may still be completed locally, coordination with this center is mandatory prior to work beginning so that the most current and appropriate guidance can be provided for a specific study or project.

16.5 Security Provisions. In recent years, man-made disasters (i.e. acts of terrorism) have been a cause of increasing concern. A comprehensive EAP should not only include security provisions surrounding a dam during an emergency event but must also consider actual failure modes (and associated consequences) initiated by such an event. These are particularly critical as they can potentially occur with no warning thereby resulting in very little response time

16.6 Communications. Good communication is a key element for successful execution of any EAP. This includes not only internal communications between Corps team members, but also between others who could potentially play a role in an emergency event. The dam owner should always strive to raise the level of public awareness (e.g. utilization of the media and internet) as it relates to dam operations and emergency response procedures. A detailed communications plan is recommended to be included as part of the official notification flowchart/chapter or as a stand-alone appendix to the EAP in order to reinforce its importance. Items recommended for inclusion are:

16.6.1 Notification Lists. Listing of persons to be notified about each emergency condition for which plans are made and procedures for notification. This should include a description of primary and secondary means of communication to be used, listing of telephone numbers and addresses, and other information needed for reliable and prompt contact for:

16.6.1.1 Notifications Internal to the Corps. This would include all communications within the district (e.g. notification to DSO, DSPM, EM, and/or appropriate technical element) as well as formal notification through command channels in accordance with this regulation.

16.6.1.2 Notifications from the Corps to Principal Local Officials.

16.6.1.3 Notifications from the Corps to Other Federal Officials.

16.6.1.4 Distribution of Warnings. Distribution of warnings from the Corps to officials responsible for dissemination to the general public (e.g. National Weather Service for use in public warning system).

16.6.1.5 Dissemination of warnings by the Corps directly to the general public in the immediate vicinity of the dam and reservoir.

16.6.1.6 As a minimum, full descriptions and separate actions required under each of three emergency classifications (failure imminent or has occurred, failure situation is developing, and non-failure emergency condition).

16.6.2 Example Press Releases. Example press releases for each emergency condition for which a plan is prepared and instructions for adaptation before their use to the specifics of an emergency situation including but not limited to:

16.6.2.1 Exact nature of emergency and degree of danger

16.6.2.2 Remedial action under way

16.6.2.3 Expected course of events and timing

16.6.2.4 Appropriate action for public to take

16.6.2.5 Description of the procedure and means for dissemination of warnings directly to the general public in the immediate vicinity of the dam and reservoir

16.7 Dam Owner's Responsibilities. Each EAP shall include information to help guide the dam owner in making immediate operational decisions in the event of various types of emergencies. Information shall be included to identify the need for equipment, material, labor, and other necessities for carrying out emergency repairs. Items to be considered include:

16.7.1 Identification of the appropriate response to the type and severity of existing or potential emergencies.

16.7.2 Emergency gate operation.

16.7.3 Reservoir dewatering plan.

16.7.4 Description of equipment and materials to be stockpiled for use in carrying out emergency operations and repairs.

16.7.5 Assignments of responsibilities for carrying out emergency operations and repairs.

16.7.6 Description of needs for equipment, material, and labor not available at the site which are needed to carry out each type of emergency operation or repair.

16.7.7 Listing of nearby contractors and other sources of needed equipment, material, and labor and description of procedures for securing their assistance on an emergency basis.

16.8 Responsibility for Evacuation (Non-Federal).

16.8.1 Non-Federal officials are to be encouraged to develop evacuation sub-plans as a complement to the EAP prepared by the Corps. Evacuation sub-plans should be considered for the following conditions:

16.8.1.1 Flood without dam failure

16.8.1.2 Flood with dam failure

16.8.1.3 Dam failure under sunny day or normal pool conditions.

16.8.2 Coordination with the Risk Management Center is required to obtain the most current and appropriate definitions of these scenarios for a particular project or study.

16.8.3 The objectives of the evacuation sub-plan are to provide for the timely and safe evacuation of threatened areas and the minimization of property damage. Items that might be covered in the sub-plan would include:

16.8.3.1 Description of traffic control arrangements to expedite evacuation and passage of emergency vehicles and prevent accidental travel into dangerous areas.

16.8.3.2 Provisions for any necessary assistance to evacuees such as transportation and aid to invalids.

16.8.3.3 Arrangements for sheltering, feeding, and other care of evacuees.

16.8.3.4 Description of actions to be taken to reduce damages and other losses.

16.8.3.5 Arrangements for security of evacuated areas.

16.8.3.6 Listing of vital services and facilities outside the area of inundation which will or may be disrupted by the level of inundation associated with each emergency condition for which plans are made.

16.8.3.7 Listing of major secondary problems resulting from the level of inundation associated with each emergency condition for which plans are made.

16.8.3.8 All areas which should be evacuated because of inundation, secondary problems, loss of services, isolation, or other reasons which are associated with each emergency condition for which plans are made.

16.8.3.9 Major evacuation routes.

16.8.3.10 Areas requiring priority in evacuation.

16.8.3.11 Potential obstacles to timely evacuation.

CHAPTER 17

Reservoir Filling Plans

17.1 Applicability. This regulation applies to all new and existing flood damage reduction dams and to all new navigation dams.

17.2 Introduction. Reservoir filling is defined as a deliberate impoundment to meet project purposes and is a continuing process as successively higher pools are attained. This may take place over only a few months but in many instances may be a process that takes several years. The initial reservoir filling is the first test of the dam to perform its design function. For this reason it is imperative that a comprehensive reservoir filling plan be developed well in advance of any actual impoundment event. It must also be recognized that existing reservoirs which have not yet experienced a design pool are actually undergoing a type of initial filling each time they achieve a new pool of record. Likewise, significant repairs or modifications to a dam might also necessitate the need to view the project as though it is once again undergoing an initial filling.

17.3 Reservoir Filling Plan.

17.3.1 A detailed reservoir filling plan shall be established on a dam-by-dam basis for all reservoirs which are new, significantly modified, or those which have yet to be filled to their design elevation. In general, the objective is to provide a planned program which allows adequate time for monitoring and evaluating the performance of the dam and its foundation as the reservoir is being filled (or as it achieves periodic record pool levels). This plan will utilize all pertinent hydrologic, hydraulic, structural, and geotechnical criteria that was developed during the design and construction of the project. If the plan is being developed for an existing dam, it must consider operational experiences. It must also consider all significant potential failure modes for monitoring and evaluation. Just because a dam is old in terms of years does not mean that it is old in terms of experience. Many factors must be considered when new or record impoundments are expected. These considerations might include:

17.3.1.1 Purposes of the new, modified or existing reservoir.

17.3.1.2 Risks associated with the filling - including potential failure modes.

17.3.1.3 Hazard potential both upstream and downstream.

17.3.1.4 Type of dam.

17.3.1.5 Dam Safety Action Class (DSAC) rating of the dam.

17.3.1.6 The geology and seismicity in the vicinity of the dam/reservoir.

17.3.1.7 Landslide potential along the banks.

17.3.1.8 Inflow characteristics (controlled or uncontrolled).

17.3.1.9 Hydrology of the river/basin as it relates to the time necessary to fill the reservoir.

17.3.1.10 Releases that must be made to meet project requirements.

17.3.1.11 Potential for flood releases.

17.3.1.12 Flood Emergency Plan and associated requirements.

17.3.1.13 Amount/type of instrumentation installed.

17.3.1.14 Provisions for monitoring/evaluating the instrumentation. Note: threshold readings should be established for instruments that change readings as a function of pool fluctuation.

17.3.1.15 Communicating the event.

17.3.2 Reservoir filling plans shall consider all of the items listed above and shall be organized to include (as a minimum):

17.3.2.1 Introduction and scope.

17.3.2.2 Project background and pertinent data (including history of pools experienced).

17.3.2.3 Preparations needed ahead of reservoir first filling.

17.3.2.4. Definition of reservoir filling which is specific to the reservoir (elevations, durations, etc…).

17.3.2.5 The preferred filling rate (for new projects), reasoning behind the recommended rate, and means to be used to control the rate of reservoir rise (if possible).

17.3.2.6 An inspection/surveillance plan designed to detect the most likely occurring problems. This shall be tied to the identified significant potential failure modes associated with the dam. A visual inspection checklist shall be developed to facilitate the effectiveness of the surveillance efforts and the reporting of results. Specific distress indicators for various failure modes shall be identified in the checklist.

17.3.2.7 A plan for reading the instruments and evaluating the data throughout the entire filling process. This shall also include the expected readings (i.e. what is normal for pools already experienced and what is expected for pools higher than yet experienced) and shall be tied to specific responses in the event of readings outside the

prescribed range. Reference EM 1110-2-2300 (Appendix E) (reference A.25) for detailed guidance relating to the establishment of performance/monitoring parameters and threshold limits.

17.3.2.8 Instructions for observers (inspectors and/or instrumentation evaluators) on conditions that require immediate attention of personnel authorized to make emergency decisions. Plan shall clearly define reporting requirements and specific actions to be taken for all observed problems. An appropriate level of response should be clearly identified and matched with the severity of the observation.

17.3.2.9 Discussions regarding public safety contingency plans. The Emergency Action Plan for the project should be complete, current and shall have been tested in accordance with the provisions of Chapter 16.

17.3.3 Initial reservoir filling plans for new reservoirs should be very comprehensive and exhibit an overall conservative approach due to the large number of unknowns. For existing reservoirs, the level of inspection, monitoring, etc… prescribed in the reservoir filling plan should be directly proportional to the perceived/identified risks as categorized by the project's Dam Safety Action Class (DSAC) rating. Because of their higher level of assigned risk, projects designated as DSAC I, II and III should strongly consider establishing elevations (or pool frequencies) somewhat lower than the pool of record where actions in the reservoir filling plan would be initiated. In any event, a thorough review and testing of the reservoir filling plan should routinely be included as part of any project's Interim Risk Reduction Measures Plan (IRRMP).

17.3.4 A completed and approved reservoir filling plan shall be furnished to design, inspection, monitoring and operations personnel prior to any applicable event. It is recommended that an on-site meeting be held prior to the initiation of any filling event. This would include both initial filling as well as forecasted record pools. This meeting would bring all of the interested parties together and would assure the plan, including all roles and responsibilities, is clearly understood. In addition, periodic emergency exercises (as outlined in Chapter 16) should introduce scenarios whereby record pools are forecast so that implementation of the reservoir filling plan can be tested and improved.

17.4 Plan Approval. Reservoir filling plans shall be prepared by the District, approved by the District Dam Safety Officer and furnished to the MSC Dam Safety Officer for informational purposes.

17.5 Performance Report. A performance report shall be prepared upon completion of a first filling (or new pool of record) event. This report will be transmitted through the appropriate district technical elements to the district Dam Safety Officer within 2 weeks of the event.

This Page Left Blank

CHAPTER 18

Risk Assessment Methodology

18.1 General.

18.1.1 The Risk Management Center (RMC) is responsible for the development, dissemination, and interpretation of methodology guidance for use in conducting dam safety risk assessments. As the state of the practice for risk assessment continuously evolves and improves, the RMC should be contacted for the most current risk assessment methodology guidance. Methodology guidance is developed and provided at two basic levels. A best practices manual has been developed jointly with the United States Bureau of Reclamation (USBR) as the top level for the purpose of summarizing the overall philosophy, methods, and approach to risk assessment for dam safety. In support of the best practices manual, a suite of toolboxes has been developed to provide specific methods and tools for performing analyses of loading, failure modes, and consequences needed to inform inputs to a risk assessment.

18.1.2. A goal is that models and software tools used for dam safety risk assessment will be certified following procedures outlined in EC 1105-2-410 as good practice. Occasionally, a dam safety study will involve significant environmental concerns and the study will necessarily need a certified environmental model. If an existing certified model does not exist, it may be necessary to fund certification of the model with dam safety modification study funds.

18.2 Philosophy and Approach.

18.2.1 The methodology contained in the best practices manual and supporting toolboxes provide a suite of scalable assessment approaches that provide information to promote critical thinking and guide a risk assessor’s judgment. These methods can be tailored and used with varying degrees of effort (time and cost) to provide the appropriate level of accuracy and rigor required to make credible risk informed decisions. It is important to understand that every decision does not require a high level of rigor, detail, and accuracy in the risk estimate in order to be credible.

18.2.2 Risk assessment cadres and others implementing the methodology are accountable for understanding what is happening inside the methodology, making and documenting credible and transparent decisions on key input parameters, explaining why the results either do or do not make sense, and adjusting the risk estimate accordingly. The cadre will always decide the final answer, not the methodology. This may require some judgment and expert elicitation to translate the results obtained from the toolboxes to the risk estimate. Analysts must use understanding of the failure mode, key factors, uncertainty, and sensitivity to obtain a risk estimate that they are willing and able to defend with a set of logical arguments.

18.2.3 The risk assessment results will be challenged and debated. The risk analyst must be prepared to explain and defend the logic behind the risk estimate. This process leads to better decisions in an environment of imperfect information. A group of experts will rarely agree on all of the details of a risk assessment but they will usually obtain agreement on the key decisions and the path forward. This agreement is achieved by working for consistency between the risk estimate, recommended actions, and understanding of the situation (i.e. does it make sense).

18.2.4 All risk estimates must give due consideration for intervention. An intervention is an action taken during the sequence of any failure mechanism either when failure has been initiated or later to prevent or delay completion of failure progression. This includes routine, non-routine, and heroic actions. Risk estimates are to be made and presented for both with and without intervention scenarios. It is important to understand the potential benefits of intervention while at the same time not masking the potential seriousness of a dam safety issue by using intervention to reduce the estimated risk. The risk estimates for with and without intervention scenarios will be plotted on the tolerable risk guidelines.

18.2.5 All risk estimates must give due consideration for uncertainty and sensitivity. Key areas of uncertainty and sensitivity are to be identified and their potential effect on the risk estimate and resulting decisions presented. It is important to understand that lack of information does not increase risk, but rather it increases uncertainty.

18.2.6 The event of interest in a dam safety risk assessment is failure which is defined as a set of events leading to sudden, rapid, and uncontrolled release of the reservoir impoundment. The probability of exceeding a limit state (i.e. factor of safety less than one) is not the same as probability of failure. Limit state exceedance is only one of several potential branches of a fully developed failure mode event tree. Similarly, the probability of a serious incident is not the same as probability of failure. An incident only addresses a portion of a fully developed failure mode event tree.

18.3 Best Practices. The Best Practices manual shall be maintained and updated on an as needed basis by the RMC. The current version of the Best Practices Manual may be obtained from the RMC. The risk assessment cadres shall use the Best Practices manual to guide their efforts in determining the loads, the conditional probability of failure associated with each failure mode, and the consequences associated with each failure mode.

18.4 Combining and Portraying Risks. After all potential failure modes have been identified, described, and evaluated relative to the risk they pose, the results need to be combined and portrayed so that the technical reviewers and decision makers can understand and act upon them. This requires some attention to detail, which if not undertaken properly, can result in an improper portrayal of the risk. During risk assessments, whether completed by a team or by an individual, estimates of risk are generated for individual failure modes. These estimates might include probability or risk values for different loading conditions, loading ranges, failure modes, spatial segments,

or other situations. Not only do the individual estimates result from an aggregation of their own constituents, but they themselves are often combined in some way to express their collective effect. In practice, the most common problems encountered during risk assessments are related to systems, correlations, common-cause loading, and combining risks. Although the methods to evaluate these issues can become complex, some simplifications can be applied to situations commonly seen when evaluating risks for dams. The Best Practices Manual guidance provided the details on how to properly combine and portray risks.

18.5 Risk Assessment Documentation.

18.5.1 The basis for the recommended actions should be documented in an objective, transparent manner, portraying the data, analysis, findings and any associated uncertainties in data or analysis on a factual basis. The findings and recommendations are presented in the formal risk assessment report in support of the IES or the DSM study. The objective of the risk assessment report is to present logical and rational documentation of analysis and results that accurately portray the risk assessment and recommended course of action in a manner and style that is to be read and understood by senior decision makers. The three basic risk components, (i.e. load probability, response probability, and consequences) should portray the dam's existing condition and ability to withstand future loading, the risk estimates, and provide the basis for the recommended actions. Since uncertainty is inherent in data, analysis, and conclusions/interpretations, the documentation should also address whether confidence is high enough for the recommendations to stand on the basis of existing evidence. The risk assessment report should present information regarding two main issues. First, data, analysis, and conclusions should support that risk falls within one or the other of the action-justification categories. Second, the risk assessment report must substantiate the confidence in the risk category, and whether additional exploration, investigation, or analysis has a reasonable likelihood of changing the perceived risk such that if falls in a different category. It is the factual information and associated interpretation presented in the risk assessment report that determines whether the risk numbers generated and the actions recommended make sense or 'feel right' in light of an understanding of the condition of the facility and its recent history of structural behavior.

18.5.2 A risk assessment report built upon sensitivity studies should investigate what would happen if more information was gathered, and whether the information is important. Plausible upper and lower bound values for variables in question can be chosen and processed through whatever assessment is being considered. When this test causes the perceived risk to move significantly, there may be justification to obtain additional information. A move is significant if it changes the risk tolerability category. Additional reasoning to show why the upper or lower bound values are plausible is necessary to support a recommendation for acquiring additional information and why the additional information being requested is likely to reduce the uncertainty.

18.6 Qualitative and Semi-Quantitative Risk Assessments. Qualitative or semi-quantitative risk assessments can be desirable in some cases such where it is desired to apply risk assessment principles to the decision making without the time, cost, and data/assessment requirements associated with a full blown quantitative risk assessment; for screening assessments of a portfolio where it is desired to get a quick evaluation of the risks so that risk reduction studies and actions can be prioritized; and for sensitive cases that involve the public to a high degree whereby those involved are more likely to understand qualitative assessments than full blown numerical analyses.

18.7 Facilitating Risk Assessments.

18.7.1 Facilitators are assigned to teams to assist them through a potential failure mode analysis (PFMA) and the risk assessment process. The facilitator contributes to the process by bringing experience with risk assessments, consistency in approach, knowledge of latest technology in risk assessments, and serves as a resource to the risk assessment team for technical input and questions. The facilitator must be experienced and generally familiar with most aspects of dam behavior. In addition, skills are needed to guide a team through the process. Facilitation is a critical part of the process to develop credible risk estimates during an assessment of risk. In general, the facilitator meets with the team prior to a risk assessment to ensure engineering analyses are completed to support the team assessment and ensure the team composition is appropriate to develop credible risk estimates, facilitates the team risk assessment, helping the team develop potential failure modes, event trees, strategies for estimating risks, and developing ranges of likelihood and consequence estimates; and reviews the final report.

18.7.2 The facilitators are primarily tasked to ensure appropriate methodologies are followed to develop risk estimates; the methods used during the assessment are consistent with current practice; alternative viewpoints are elicited, discussed, and recorded; the team contains the appropriate staff to arrive at a credible risk estimate; the final risk assessment report contains failure modes that are adequately described; the recommendations reflect the information developed during the risk assessment; and risk assessment report adheres to the principles described in this engineering regulation.

CHAPTER 19

Program Administration and Funding Process

19.1 Purpose. The Dam Safety Officer (DSO) and the Dam Safety Program Manager (DSPM) at the district and regional levels are responsible for the local and regional dam safety programs. To accomplish these duties the DSO and DSPM work closely with the Operations, Engineering, and Program elements in developing and administrating the dam safety program.

19.2 Program Documentation. Dam Safety is documented for each dam in the DSPMT. The DSPM manages input into DSPMT by the project operating personnel and various other personnel within the district. From the DSPMT, the status of each project is reviewed using the dam safety scorecard.

19.2.1 The DSPM should maintain a file copy of all appointment orders, the minutes of the dam safety committee meetings, and a copy of all Emergency Action Plans.

19.2.2 On a three year cycle (or as otherwise required by Army), the Dam Safety Officers should review the questions on the Management Control Checklist and complete DA Form 11-2-R (Management Control Evaluation Certification Statement). The Management Control Checklist for Dam Safety activities is in Appendix AA for this regulation.

19.3 Funding Process. The majority of the dam safety work in the district is funded through the Operations appropriation at the individual projects. This work includes the routine annual activities for inspections and instrumentation and any special interim risk reduction measures for the dam. When additional studies are required, funding for an Issue Evaluation Study should be requested from the Construction appropriation.

19.3.1 The annual budget cycle for a project is divided into three phases that run concurrently.

19.3.1.1 Prepare. This phase runs from January FY-2 until February FY-1. The district DSPM works with the Operations and Program elements to insure that the annual fiscal year dam safety requirements are included in the budget submission. The MSC DSPM and the Corps DSPM review the information from the districts and work with the business line managers to help prioritize the work. During this phase, the district DSPM should be reviewing the cycles for Periodic Assessments and Periodic Inspections to insure that approximately 10% of the district's required assessments and inspections are included in each year.

19.3.1.2 Defend. This phase runs from February FY-1 to the start of the fiscal year. The DSPM's at all levels work with Program elements to provide background information on the dam safety program as requested.

19.3.1.3 Execute. This phase runs from the start of the fiscal year on 1 October to the end of the fiscal year on 30 September. The district DSPM works with the Operations, Engineering, and Programs elements to insure that the program is fully executed. Work item changes between projects are coordinated with the district to make allowances for changed conditions since the start of the budget cycle 21 months earlier. Adjustments are subject to the annual reprogramming limits established by policy or enacted in legislation.

19.4 Funding Appropriations. Dam safety is funded from the following appropriations on a routine basis.

19.4.1 Routine Work is funded from the Operation and Maintenance appropriation (or MR&T Operations). This includes training, instrumentation readings and analysis, all levels of inspections, and other work items. Interim Risk Reduction Measures are also funded from the Operation and Maintenance appropriation. Minor dam safety repairs or modifications can be funded for the maintenance portion of this appropriation.

19.4.2 Evaluation Studies and Dam Safety Modification Studies are funded from the Construction appropriation. Districts submit requests for studies through the MSC and the RMC to HQUSACE for prioritization based on the project's DSAC level.

CHAPTER 20

Asset Management and Condition Assessments

20.1 Purpose. This chapter describes the direction of the Corps Asset Management (AM) Program and how it relates to the Corps Dam Safety Program. It includes information on the Asset Management Program vision and approach for the coordination of Dam Safety and Asset Management. The chapter is subject to modification as the Corps Asset Management program continues to mature.

20.2 General. USACE Asset Management vision is to incorporate a holistic and integrated approach that embraces a risk informed life-cycle watershed portfolio management perspective. This enhanced AM outlook will enable risk-informed, life-cycle investment decisions to include an assessment of sustainment, restoration, modernization, and disposition projects, as well as portfolio trade-offs. AM is the unifying catalyst to ensure integration of business lines, major programs, and initiatives to improve communication and collaboration. AM will leverage resources, eliminate duplication, evaluate economic and other consequential trade-offs, adapt to new and anticipated requirements, and benefit from synergy. This life-cycle watershed portfolio management approach is asset based and recognizes the multi-business line purpose, risk, and consequence in meeting the various mission requirements.

20.3 Policy. It is the policy of USACE Asset Management to corporately determine condition of the assets and components. Pursuant to this approach are the development (if required) and/or use of existing nationally consistent condition assessment and inspection processes and procedures to meet overall portfolio investment requirements.

20.3.1 Asset Management broadly uses the “feature codes” found in the Finance and Accounting regulations as the “primary constructed asset categories” that support the water resource mission portfolio. These codes are the two digit account numbers found in Appendix A, Chapter 14 of ER 37-1-30, “Financial Administration: Accounting and Reporting” (reference A.36) and as shown in Table 20.1 below.

20.3.2 Reference Memorandum for MSC Commanders dated 16 October 2009, subject “Interim Guidance – Operational Condition Assessments for Inland Navigation” co-signed by the Chiefs of Engineering and Construction and Operations and Regulatory (reference A.78). It is recognized that these baseline operational condition assessments require a similar skill set and experience utilized in the Dam Safety Periodic Inspections as discussed in Chapter 11, “Periodic Inspection, Periodic Assessment and Continuing Evaluation.” MSC’s should plan to transition the baseline operational condition assessments to coincide with the 5-year Periodic Inspection schedule. If the MSC determines that a more aggressive condition assessment schedule is required, they may supplement the 5-year schedule as necessary.

Table 20.1 – Applicable Feature Codes

Feature Code	Title
01	Land
02	N/A
03	Reservoirs
04	Dams
05	Locks
06	Fish and Wildlife
07	Power Plants
08	Roads, Railroads, and Bridges
09	Channels and Canals
10	Breakwaters and Seawalls
11	Levees and Floodwalls
12	Navigation Ports and Harbors
13	Pumping Plants
14	Recreation
15	Floodway Control and Diversion Structures
16	Bank Stabilization
17	Beach Replenishment
18	Cultural Resource Preservation
19	Buildings, Grounds, and Utilities
20	Permanent Operating Equipment

20.3.3. It is also the policy of Asset Management to eventually integrate and use the Facilities and Equipment Maintenance (FEM) day-to-day work maintenance records and other applicable data where applicable to inform and adjust the condition for critical components that may lead to mission interruption.

CHAPTER 21

Dam Safety Policy for Planning and Design

21.1 Purpose and Status. This chapter provides guidance on incorporating USACE dam safety policy into the planning and design of new dams and modification of existing dams through the Civil Works and Dam Safety Portfolio Risk Management processes. It applies to all structures that meet the definition of a dam in the National Dam Safety Program. It encompasses the dam safety requirements from WRDA '86 for new projects (reference A.99).

21.2 General. The civil works planning and design process for a new dam or for modification of an existing facility is continuous, although the level of technical detail varies with the progression through the different phases of project development and implementation. The phases of the process for a new dam or modification of an existing dam for non-dam safety reasons are reconnaissance, feasibility, pre-construction engineering and design (PED), construction, operation and maintenance[5], and finally decommissioning and removal. Detailed guidance on each phase is given in ER 1110-2-1150 (reference A.51). For modification of an existing dam due to dam safety issues the phases are issue evaluation study (Chapter 8), dam safety modification study (Chapter 9), PED (ER 1110-2-1150)(reference A.51), implementation of the risk reduction measures, and post implementation risk assessment (See Figure 3.1).

21.3 Project Delivery Team. A Project Delivery Team (PDT) is established for all projects in accordance with ER 5-1-11 (reference A-35). The PDT consists of a project manager and the technical personnel from engineering, planning, operations, public affairs office, and others necessary to develop the project. When more than one individual from the engineering organization is on the PDT, the technical chief shall designate a "lead engineer." While not necessarily appropriate for later phases of a project when the administrative requirements significantly increase, the lead engineer should be strongly considered for assignment as the project manager during the Issue Evaluation Study phase. The lead engineer may change as the project moves through the different phases of development, however continuity is very important and changes should only be made after careful consideration. At each phase of a project it is also vitally important that team members (in particular the PM and lead engineer) possess a solid combination of both technical and communication skills. External communication with the public and stakeholders is a certainty on dam safety projects and guidance on how to properly communicate risk is covered in Chapter 10. Equally important is the internal communications aspect as it frequently involves team members from within the district, the MSC, HQUSACE, and the Risk Management Center to name just a few. Selection of team members and their specific roles should not overlook this fact. The PDT may also include personnel from the local sponsor's staff and from other Federal agencies. Partnering with the local sponsor is a key element during the design of a

[5] Operation and maintenance is used in this regulation to include both "Operation and Maintenance (O&M)" and "Operation, Maintenance, Repair, Replacement and Rehabilitation (OMRR&R)"

project and our partners are key members of the PDT. Partnering shall occur in all phases of project development (ER 1110-2-1150) (reference A-51).

21.4 Dam Safety Items for the Planning Phase.

21.4.1 Reconnaissance. During the reconnaissance phase, the Project Delivery Team (PDT) develops a Management Plan. At this phase the documentation requirements shall be identified, scheduled, and resourced in coordination between the PDT and the Dam Safety Officer or his representatives. Those documents generally include all Design Documentation Reports (DDR's), manuals, plans, and reports, including the Emergency Action Plan (EAP), Control of Water Plan (during construction), Initial Reservoir Filling Plan, Embankment Surveillance Plan, Project Security Plan, Instrumentation Plan, O&M (or OMRR&R) Plan, Turnover Plan, Water Control Plan (operational), Reservoir Control Report, and post-construction documentation of foundation, materials, and construction.

21.4.2 Feasibility. During the feasibility phase, the Project Delivery Team (PDT) develops a Management Plan. The feasibility study shall address the following items related to Dam Safety.

21.4.2.1 Project OMRR&R and dam safety requirements shall be identified and discussed with the sponsor and State. The local sponsor shall be informed that they shall be expected to comply with all State and Federal dam safety requirements. A turnover plan for non-Federally operated dams must be prepared to establish definite turnover criteria or date to the sponsor and to identify funding for the first and second periodic inspections. This information shall be documented in the Feasibility Report.

21.4.2.2 Project Cooperation Agreement. Guidance on policy and procedures for the turnover of completed dam projects to local sponsors is given in Policy Guidance Letter No. 39 (reference A.92). When the Project Cooperation Agreement is developed during the feasibility phase, the Dam Safety Officer or his representative shall ensure that all dam safety requirements are included in the agreement.

21.4.2.3 Consequence and Failure Mode Analysis and Preventative Measures. All reports to be submitted to Congress for authorization of water impoundment facilities shall include information on the consequences of failure and geologic or design factors which could contribute to the possible failure of such facilities (Water Resources Development Act of 1986 (Section 1202) (reference A.99) and ER 1105-2-100, *Planning Guidance Notebook, Appendix G* (reference A.42)). Consequences are defined as potential life loss, economic damages, and environmental damages. At the minimum estimate the consequences related to failure of the dam from a breach of the dam with the reservoir at the maximum pool – no spillway discharge, maximum pool with full spillway discharge, and overtopping of the dam. The geologic site conditions that could lead to failure are to identified, the associated failure mode described, and present the design steps taken to prevent the failure from occurring. Address the general potential

failure modes related to dams and present the how the design for this dam prevents these failure modes from occurring.

21.4.2.4 Downstream Lands. A real estate interest is required in downstream areas where a spillway discharge would create or significantly increase a potentially hazardous condition. Specific guidance on this issue is found in ER 1110-2-1451 (reference A.54).

21.4.2.5 Low-level Discharge Facilities. In 1975 a policy was established that all future lakes impounded by Civil Works projects would be provided with low-level discharge facilities capable of lowering the reservoir pool to a safe level within a reasonable time. This feature provides capability for safely responding to unanticipated needs such as repair or major rehabilitation for dam safety purposes. Specific guidance on this issue is found in Chapter 12 of this regulation.

21.5 Dam Safety Items for the PED Phase. During the PED phase the Dam Safety Officer, or his representative, shall ensure that the design criteria include the most current dam safety requirements and that the design is properly documented for the project records. Based on experience with the design, construction, and performance of existing dams, specific areas of dam safety concerns during the design phase include the following items.

21.5.1 Design Criteria. Current USACE criteria shall be used on all federally funded designs. When the design is being prepared for a sponsor on a cost-reimbursable basis, the district Dam Safety Officer may consider use of state criteria. Deviations from Corps criteria require written concurrence from the USACE Dam Safety Officer.

21.5.2 Public Safety Awareness. A policy of public safety awareness shall be adhered to in all phases of design and operation of dam and lake projects to ensure adequate protection for the general public.

21.5.3 Downstream Lands. See section 21.4.2.4 Downstream Lands.

21.5.4 Low-level Discharge Facilities. See section 21.4.2.5 Low-level Discharge Facilities.

21.5.5 Instrumentation and Monitoring. An adequate instrumentation and monitoring system is required by the “Federal Guidelines for Dam Safety” (reference A.71) as well as by good engineering practice.

21.5.5.1 Purpose. The purposes of the instrumentation are the following:

21.5.5.1.1 To provide data to validate design assumptions,

21.5.5.1.2 To provide information on the continuing behavior of the water control structure,

21.5.5.1.3 To observe the performance of critical features, and
21.5.5.1.4 To advance the state-of-the-art of dam engineering.

21.5.5.2 The rationale for the instrumentation shall be justified and thoroughly documented via the use of potential failure mode analysis. Use the potential failure mode analysis along with engineering analysis to identify the required type of instruments, general location, and expected range of performance.

21.5.5.3 The instrumentation plan shall be prepared and documented in the DDR. Although the monitoring system is expected to evolve commensurate with the observed performance of the dam, an initial system shall be designed and constructed to provide a background of data during initial reservoir filling, sufficient to identify problems and to verify design assumptions. Provide flexibility in the instrumentation plan to allow for changes from anticipated foundation conditions that are encountered during construction and/or operations. Specific guidance on design of instrumentation and monitoring systems is given in Chapter 14 of this regulation.

21.5.6 Operations during Construction. Safe operation of the dam during the construction of a new dam or modification of an existing dam needs to be considered during the development of the Water Control Plan (ER 1110-2-8156 (reference A.59)). A risk assessment should be used to inform the selection of the construction options and the results should influence the options selected.

21.5.7 Initial Reservoir Filling Plan. The Initial Reservoir Filling Plan (IFP) shall be prepared prior to construction, modified during construction to reflect the as built conditions, and documented in the DDR. As a minimum, the documentation on initial reservoir filling shall include:

21.5.7.1 The preferred filling rate and the available options to control the rate of reservoir rise.

21.5.7.2 The surveillance necessary to detect the most likely occurring failure modes.

21.5.7.3 A plan and schedule for reading the instruments and evaluating the data.

21.5.7.4 A plan and schedule for inspecting the dam and downstream areas.

21.5.7.5 Instructions for observers on observed conditions or instrumentation readings requiring immediate attention of personnel authorized to make emergency decisions.

21.5.7.6 An emergency plan listing responsibilities, name and/or positions, telephone numbers, and radio frequencies to be used (as appropriate).

21.5.8 Surveillance Plan. The Surveillance Plan shall be prepared during construction. The plan will address the routine and non-routine surveillance of the dam after the initial reservoir filling.

21.5.8.1 Define the level or intensity of the surveillance for given pool levels. For pool elevations above historical initial filling conditions exist and actions similar to the initial filling surveillance shall be addressed in this plan.

21.5.8.2 The surveillance necessary to detect most likely occurring failure modes.

21.5.8.3 A plan and schedule for reading the instruments and evaluating the data.

21.5.8.4 A plan and schedule for inspecting the dam and downstream areas.

21.5.8.5 Instructions for observers on observed conditions or instrumentation readings requiring immediate attention of personnel authorized to make emergency decisions.

21.5.9 O&M Manual. The O&M (or OMRR&R) Manual shall be prepared during construction. Specific guidance for preparation of the manual is given in ER 1110-2-401 (reference A.50) and ER 1130-2-500, (reference A.62).

21.5.10 Emergency Action Plan. The EAP shall be prepared during construction. Specific guidance for preparation of the EAP is given in ER 1130-2-530 (reference A.63), and in Chapter 16 of this regulation.

21.5.11. Water Control Plan. The Water Control Plan (Operational) shall be prepared during construction. Guidance on water control management is available in ER 1110-2-240 (reference A.49).

21.6 Consulting with State Dam Safety Officials. The district shall consult with state dam safety officials on the design, safety, and inspection of USACE dams when requested by state officials. This will be accomplished by making engineering design and construction criteria, studies, and reports available to the state officials, inviting state officials to attend design conferences and periodic inspections, and inviting state officials to participate in risk assessments.

CHAPTER 22

Dam Safety During Construction (Remediation and New Dams)

22.1 Purpose. Construction (design implementation) is a crucial phase in achieving an adequately safe dam. The objective for construction management is always to deliver a quality project in a timely manner at a reasonable cost. This is considered commensurate with the importance of the project to the Corps and all stakeholders. During construction, the entire project team (particularly the on-site construction staff) is required to assure the design is compatible with actual conditions encountered. Inspection and quality assurance are required to prevent deficiencies in materials and construction practices. This is particularly important when working on dam safety projects as these projects often have significant life and economic loss implications. General processes to manage construction are already covered in detail in existing Corps regulations. The intent of this chapter is simply to supplement those regulations and provide a perspective of their application from a dam safety perspective.

22.2 Design/Pre-Construction Phase. Involvement of construction personnel in the design phase of a project is vital to assure the development of a technical product of the highest quality. This is particularly true on a dam safety project because of the uniqueness of the technical requirements. Experiences offered from a construction perspective regarding things such as the structuring of bid items, phasing, proper construction techniques, buildability, biddability, etc… are invaluable in assuring the project meets technical requirements while at the same time limiting government contractual risk (reference A.39)

22.2.1 In order to provide the best opportunity for project success, a district should always strive to build a cohesive team built upon the principles in ER 5-1-11 (reference A.35). This entire team shall be involved in the project from planning, design, and through completion of construction. This includes not only the technical elements within a district (planners, designers, constructors, PMs, etc…) but also the involvement of vertical elements such as the regional/HQ staff and the Risk Management Center (RMC). While the day-to-day execution of a project remains the responsibility of a district, the RMC is able to bring an agency-wide perspective to the project to ensure uniformity and adoption of best practices from across USACE. Their early and continual involvement as part of the PDT is essential. Involving all elements from the inception of a project will ensure the failure modes are identified, the correct alternatives are evaluated, and that the best project solution is chosen.

22.2.2 It is vital that the construction staff be part of the PDT throughout the life of a project, beginning with the earliest planning phases. This will ensure that each potential alternative is evaluated from an implementation perspective and that all construction-related risks are fully identified and mitigated to an acceptable level. For the preferred alternative, a construction risk assessment may be required if the perceived risks during construction are significant. While restoring a dam to a fully functional condition so that it can safely meet its intended purpose is the ultimate goal,

the more fundamental premise is that any modification undertaken must first do no additional harm to a structure (thereby increasing risks of failure). The PDT should never lose sight of the unique risks that might be present during the construction period and should remain diligent in monitoring and mitigating those risks. One way this can be assured is through frequent instrumentation reading/analysis and on-site inspections throughout construction – particularly during high water periods. This can be accomplished using a combination of design, construction and/or operations personnel. Particular care and oversight should always be given to activities such as dewatering, spillway/gate/outlet works modifications, excavating/blasting, drilling, and grouting to name just a few. Analysis of the instrumentation data and inspection results as it relates to the expected behavior of the dam must be done by the Lead Engineer or his designated PDT representative throughout the construction period.

22.2.3 It is paramount to the success of the dam safety modification project that the PDT clearly defines and communicates the design intent, including the risk reduction objectives, as early as possible so it is conveyed through the specifications and enforced by the staff reviewing/inspecting the work. Clear communication of this information has the potential to avoid costly modifications and claims. Construction personnel must pay particular attention to the “Engineering Considerations for Field Personnel” prepared by the PDT during the PED phase in accordance with Appendix G of ER 1110-2-1150 (reference A.51). The document will outline the proposed risk reduction measures, the potential failure modes to be mitigated, the logic that has gone into previous decisions, as well as the expected risk reduction to be achieved. This effort would then carry forth, in a risk-informed framework, through the critical phases of construction. The document should be reviewed and revised, as necessary, as the project progresses through design and construction. It is USACE’s policy to include key design intent descriptions within the construction specifications.

22.2.4 The PDT/construction personnel should develop a construction schedule with appropriate logic and work breakdown structure (WBS) of the preferred risk management alternative to assess potential constraints based upon the site conditions, construction season and production rates to aid/facilitate the design and estimating phases.

22.2.5 To ensure dam safety risks are adequately addressed by the designs, Districts shall form a Biddability, Constructability, Operability, and Environmental (BCOE) team in accordance ER 415-1-11 (reference A.39) with emphasis on reviewing the designs from the standpoint of constructability. Conducting a BCOE review in the latter stages of design development is an effective method to achieve a quality, cost effective and operations and maintenance (O&M) efficient design. The guiding principle for the BCOE team shall be to act much like a contractor preparing a bid or proposal and look for flaws or defects in the technical specifications. The Lead Engineer/PDT may need to brief the BCOE team on the potential failure modes mitigated by construction and on potential failure modes that may be present during construction activities. In addition to the list of items contained in ER 415-1-11

(reference A.39), the following constructability issues should also be reviewed and discussed if applicable:

22.2.5.1 Borrow area locations, ownership, and access

22.2.5.2 Borrow areas with respect to flooding

22.2.5.3 Borrow materials characteristics in relation to processing requirements

22.2.5.4 In situ moisture conditions

22.2.5.5 Unwatering and dewatering requirements

22.2.5.6 Waste and stockpile issues

22.2.5.7 Zoning

22.2.5.8 Protection of work from flooding

22.2.5.9 Reservoir operations and associated construction constraints

22.2.5.10 Availability of equipment and materials, delivery times, and their sources

22.2.5.11 User deliveries and special needs

22.2.5.12 Climatic effects on construction schedules

22.2.5.13 Available right of way

22.2.5.14 Expected acquisition times

22.2.5.15 Road relocations

22.2.5.16 Material utilization

22.2.6 Construction personnel shall assist the Lead Engineer/ PDT with development of assumptions to be submitted to the cost estimating team in support of cost estimates that are prepared for the various levels of estimates that are prepared throughout the PED phase.

22.2.7 During the construction period the emergency action plan (EAP) shall be updated to reflect the specific risks that have been identified. This update should include identification of visual signs or instrument readings that could indicate a problem is developing. The EAP is to be used by operations and construction

personnel to trigger decisions points which may require implementation of emergency actions at the project.

22.2.8 During the PED phase the Lead Engineer/PDT shall identify those submittals that require review and comment by a specific engineering discipline. Once a submittal is received, comments shall be provided to the construction staff (either the construction manager or RE depending on district processes) in a timely manner. The appropriate construction staff member shall review/resolve all comments prior to sending them to the contractor to ensure the comments are consistent from both a technical and contractual standpoint.

22.3 Construction Phase. Similar to the importance of having construction personnel involved in the planning and design phases of a project, it is equally vital that the design team remain integrally involved and integrated throughout the entire construction period. This is consistent with ER 5-1-11 (reference A- 35) and ER 1110-1-12 (reference A.43).

22.3.1 Quality Assurance Plan (QAP). The construction staff shall prepare a project-specific Quality Assurance Plan (QAP) that is consistent with the scope and complexity of the work. It shall be in accordance with the specific requirements in ER 1180-1-6 (reference A.66). The plan shall ensure that the quality of the construction meets the specifications requirements and design intent. This plan should be prepared during the design phase of the project as it is important to help establish the complete project picture. It should be updated as required as the project scope is modified. The QAP should be included in the DDR/Plans and Specification package and be subjected to ATR and RMC/HQ review and approval.

22.3.2 On dam safety construction/modification projects it is imperative that construction management personnel are aware of design philosophies, intent and assumptions as to the site conditions and functions of project structures. They must also understand the designer's basis for special technical provisions in the specifications in terms of the intended risk reduction objectives of the design. To this end, the Lead Engineer/PDT shall facilitate a coordination meeting prior to the start of construction to ensure the entire project team fully understands the project scope, design intent, limitations, risks, roles and responsibilities of the staff, and other issues which could have an effect on the project. Documents which will form the basis of the discussions at the coordination meeting may include (but are not limited to) Engineering Considerations for Field Personnel; Design Documentation Report (DDR); Results of Risk Assessment study and summary of risk reduction objectives; project EAP; construction plans and specifications, NEPA compliance documents and permits; and Real Estate agreements. For projects that include special features such as load tests, pile driving monitoring, grout monitoring, etc the Lead Engineer shall conduct technical workshops for the field inspection personnel and appropriate construction management staff to assure there is a good understanding of the monitoring requirements and their design implications.

22.3.3 Large and complex dam safety modification projects will require the establishment of an on-site USACE field office that is functioning prior to the beginning of construction activities. Development of the Quality Assurance Plan (QAP) outlining the responsibilities and duties of on-site personnel should be reviewed and clearly understood by all USACE employees working in the Field Office. The logistics of Resident Management System (RMS) computer systems and the pertinent administrative personnel to aid with the RMS set-up should be staffed at the site to troubleshoot USACE/contractor system problems and to ensure that information can be processed properly at contract start-up. All field office quality assurance (QA) staff, including the technical personnel, should have access to RMS and ensure that detailed daily QA reports are generated. The RMS daily QA reports are the official contract documents of all construction processes. If the field office is not the office of record, the method of routing contract documents needs to be developed. The field office, however, should be the contractor's direct point of contact (POC) to USACE, and all documents should pass through the field office. The field office should also maintain a file copy of all contract documents.

22.3.4 Performance of Quality Assurance

22.3.4.1 Dams with safety deficiencies usually have a high potential for loss of life, a risk of significant property damage, potential significant costs to the Government, and negative political impacts. Therefore, dam safety projects are considered of such critical nature that, to the extent practicable, quality assurance shall be performed directly by USACE forces. This includes, but is not limited to, performing inspection of all contract-related construction operations, materials testing, equipment factory inspection, survey control, and foundation testing. Inspection or testing by private consultants should be utilized only in situations where it is impractical for USACE to perform the inspection or testing, or the work is of such a specialized nature that USACE is not capable of performing it. Use of third parties to provide quality assurance should be limited to noncritical items/features. All quality assurance processes shall be in accordance with ER 1180-1-6 (reference A.66).

22.3.5 A communication/ information protocol flow chart for the dissemination of information between the Resident Engineer and the contractor shall be developed ahead of any work beginning. This protocol should address external and internal communications so that real-time information is released in a timely manner. The communication/information protocol should increase the efficiency of the field office by eliminating the burden on the field office of having to deal with numerous requests from different offices for the same information.

22.3.6 Contractor designed construction features such as cofferdams and dewatering plans must be properly designed, approved, and monitored during the construction or modification of a dam. In many cases, they serve as the dam or structure for periods of time while modifications are being implemented. Where failure of these features could potentially cause loss of life and property damage these features will be designed and constructed using USACE criteria for permanent dam

features. The design of these features must be reviewed and approved by the project Lead Engineer.

22.3.7 When a project includes the installation or modification of major electrical or mechanical equipment, special inspections shall be performed at the place of manufacture, upon delivery to the site, during installation, and during acceptance testing.

22.3.8 The Lead Engineer/PDT shall be actively involved in the confirmation of design assumptions during construction. Frequent and mandatory inspections shall be scheduled during construction to confirm that site conditions conform to those assumed for design or to determine if design changes may be required to ensure risk reduction objectives will be met. Critical changes in field conditions must be carefully reviewed and forwarded to the Lead Engineer and the command chain, including the Dam Safety Officer. In accordance with ER 1110-2-112 (reference A.43), key design members of the PDT (with appropriate support of management) shall visit the site regularly to evaluate changed conditions and to evaluate any impact they might have on the design. When necessary, work may need to be stopped until the conditions are reviewed. It is imperative that any changed condition be properly documented and entered into RMS. Temporary duty assignments to the project construction site during critical phases of foundation and embankment construction are desirable and can serve as a unique opportunity to develop key technical skills.

22.3.9 Many dam safety modification projects are related to poorly excavated, cleaned and/or treated foundations during the original construction. For this reason, many dam safety modifications will involve a solution which exposes the bedrock foundations and abutments. Current state of the dam engineering practice involves careful excavation, cleaning and surface treatment prior to placement of any fill material. EM 1110-2-1911 (reference A.16) shall be referenced for additional details relating to the construction or modification of rock fill dams. As previously mentioned, risks to a dam during the construction phase must be carefully identified, monitored and mitigated. This is especially true on items such as dewatering, spillway/gate/outlet works modifications, excavation/blasting, drilling, and grouting to name just a few. A detailed plan shall be required for any work related to these items (or ones posing similar risks). For example, if blasting is required on a project, a detailed blasting plan shall be developed. This plan shall clearly show blast hole spacing, depths, orientation, delays, powder factors and monitoring for peak particle acceleration. It is critical that construction personnel monitor the drilling and loading of blasts to ensure that it follows the blasting plan. Not following the approved blasting plans may result in additional excavation, treatment and support creating contractual issues and quantity overruns. Where specialized blast procedures are required, consideration should be given to retaining a blasting consultant. All similar plans shall be reviewed by experienced personnel in order to assure the desired results are achieved without causing excessive damage requiring additional excavation, support and/or treatment. As with all construction activities, requirements of EM 385-1-1, Section 29 (reference A.7) shall be enforced as applicable.

22.3.10 All cleanup, treatment, and support (bolts, mesh, shotcrete, etc.) of dam or structure foundations and excavated slopes (temporary or permanent) shall be directed by trained and experienced USACE construction personnel, engineers, and geologists. It is critically important that these surfaces are photographed, geologically mapped and as-built geometry surveyed for subsequent dam safety evaluations.

22.3.11 All foundation surfaces that are to be covered by fill and/or concrete shall be formally inspected and approved by the Lead Engineer or their designated representatives. No foundation surface shall be covered until this formal review is completed. The specifications should include the following:

22.3.11.1 A specific period of contract time for geologic mapping by USACE personnel.

22.3.11.2 A specific amount of contractor's staff and/or equipment time to assist in the cleanup of the foundation to allow for either or both the geologic mapping and/or foundation inspection.

22.3.11.3 A specific notification period and specific period of contract time for foundation inspection by USACE personnel.

22.3.12 In order to effectively accomplish this critical task, the Lead Engineer/PDT and Resident Engineer should work together to establish the foundation inspection procedures. This should be accomplished prior to, or shortly following, award of the construction contract. The foundation and acceptance procedures should include the following:

22.3.12.1 Describe an adequate and inadequate foundation.

22.3.12.2 Measures to be considered where an inadequate foundation is identified.

22.3.12.3 Measures to ensure the integrity of an adequate foundation once it has been prepared and prior to placing the structure on the foundation.

22.3.12.4 Procedures to be used when inspection and approval are made onsite.

22.3.12.5 Procedure to be used when inspection is made by field personnel and approval made via telephone.

22.3.12.6 Identify appropriate field testing to be conducted prior to, or during, foundation inspections.

22.3.12.7 Preparation of a foundation inspection checklist which should be used by field personnel.

22.3.13 Formal approval shall be documented in a “Foundation Approval Memorandum” including photographs and geologic maps. Multiple memorandums may be utilized depending on the construction schedule/sequence. These shall be included in the final project geotechnical report (reference paragraph 22.4.4).

22.3.14 Engineering representatives from RMC and MSC office are an integral part of the PDT and thus should be continually advised of construction progress in order to permit participation by personnel from those offices in field inspections at critical construction stages in accordance with the requirements of ER 1110-2-112 (reference A.48). This includes their participation in the latter stages of construction (prior to final acceptance). This shall be accomplished through a regular project update prepared by the Project Manager and distributed to the entire vertical/horizontal team. This update shall highlight current construction progress, issues (both funding and technical), and a 30 to 90 day look-ahead.

22.3.15 Construction operations at an existing facility result in unique problems associated with existing O&M activities. The construction activities will directly overlap into the active O&M program in place at the site. Therefore, it is very important that problems encountered during construction be adequately documented and resolved with the PDT members prior to the operational phase. Special emphasis must be placed on coordination activities between the Resident Engineer and O&M manager in charge of the facility.

22.4 Post Construction Phase.

22.4.1 Many important lessons, both positive and negative can be learned from dam safety projects. Near the end of construction (or as each phase of work is completed), the PDT (including all vertical and horizontal members) shall assemble and conduct a brainstorming session in order to capture lessons learned from both the design and construction phases of the project. The Lead Engineer and Resident Engineer shall ensure these lessons learned are officially entered into DrChecks, the Dam Safety CoP site on the Technical Excellence Network (TEN), or another accepted forum. These lessons should then be built into the official design/construction checklists (typically part of a Design Quality Management Plan) so that future projects can reap the benefits. The district shall organize and facilitate such brainstorming sessions. Typical subjects of discussion are:

22.4.1.1 Dam Safety Modification Studies (DSMS) problems/issues

22.4.1.2 Communications issues between design/construction/contracting and contractor as well as the public and other agencies/entities

22.4.1.3 Environmental issues

22.4.1.4 Procurement of the contract

22.4.1.5 Bid quantities

22.4.1.6 Key specification requirements

22.4.1.7 Problems encountered

22.4.1.8 Design issues

22.4.1.9 Contractor methods

22.4.1.10 Contract modifications

22.4.2 At the completion of the contract, all costs should be summarized and compared with the estimated costs. This will provide valuable information for future programmatic budgeting.

22.4.3 The Operation and Maintenance (O&M) Manual shall be revised/updated as a result of dam safety modifications. The O&M manual provides guidance and instructions to project personnel for proper operation and maintenance of the facility. It contains a narrative summary of the critical dam features including design features with safety limits, equipment operating and testing procedures, instrumentation requirements, potential failure modes, a history of problems, and how those problems could adversely affect the structure over the range of loading conditions. The O&M manual shall be prepared during the construction phase and shall be updated as features are added to the project, when equipment is replaced, or when changes in project operations are implemented.

22.4.4 ER 1110-1-1901 (reference A.44), Project Geotechnical and Concrete Materials Completion Report for Major USACE Projects, requires documentation of the as-constructed geologic, geotechnical and concrete materials aspects of all major, complex and unique engineered projects constructed by USACE, including all subsequent modifications. It is imperative that the report be all encompassing and records the geologic conditions encountered, solutions of problems, methods used, and experiences gained. It is imperative that data such as observations, notes, and photographs be collected and maintained during construction, describing procedures, conditions encountered, and the results of each major operation. This is particularly important for features representing departures from the anticipated conditions.

22.4.4.1 This report shall be identified, scheduled, and resourced in the Project Management Plan (PMP). The information and data in this document shall be presented and discussed with the sponsor/owner. The report provides significant information potentially needed by the sponsor, USACE technical staff, and other team members to become familiar with the project. The report shall facilitate accurate, timely inspections and performance assessments, and serve as the basis for developing and implementing appropriate and effective modifications, and emergency

and/or remedial actions to prevent flood damage, or required as a result of unanticipated conditions or unsatisfactory performance.

22.4.5 Post Implementation Risk Assessment. Review and update the DSM study risk assessment after implementation of the risk management remedial measures. The dam shall be evaluated to determine if the risk management objectives were achieved.

CHAPTER 23

Physical Security for Dams

23.1 Purpose and Status. The purpose of this chapter is to provide references and other information to guide dam safety personnel on physical security issues and facilitate in their coordination with security personnel and first responders.

23.2 Policy. All dams within USACE shall maintain an adequate security posture so as to allow the project to be operated in a safe and secure manner. The safety of employees, project visitors, and area residents is paramount. All project employees shall be familiar with all applicable security regulations, standard operating procedures, and regulatory guidance and be capable of discharging their duties on the project site relative to security matters. The operations chief is responsible for the implementation and oversight for project physical security. The engineering chief and the security chief provide technical support to the operations chief in execution of their responsibility. The District Engineer is ultimately responsible for the security of the project site and personnel within in the area of responsibility (AOR).

23.3 General. It shall be realized that the normal security posture will vary from project to project. The determination of the recommended steady-state security posture for USACE dams should be based on the completion of a security risk assessment. Enhanced security postures may be triggered by changes in the threat environment, new construction, changes of mission, change in condition of security systems, or changes in project operations. Normal and enhanced security postures should be described in the corresponding project specific physical security plan. Priority for completing security risk assessments and implementing enhanced security measures should be given to those USACE dams determined as most critical based on the Consequence-Based Top Screen methodology.

23.4 Physical Security Program. All USACE dams shall implement an appropriate physical security program designed to ensure effective and efficient uses of resources, meeting the needs of the command in protecting its assets against aggressors that are a threat to the project critical assets and hostile intelligence operations. The physical security program is required to include a project specific physical security plan, physical security inspections, and security systems designed and constructed in accordance with the appropriate chapters of AR 190-11 (reference A.1) and AR 190-13 (reference A.2).

23.5 Antiterrorism. All USACE dams shall have a viable, project specific Antiterrorism and Force Protection Plan in place and in accordance with Department of Defense (DoD) Directive Number 2000.12 “DoD Antiterrorism (AT) Program,” (18AUG03) (reference A.70), DoD Instruction Number 2000.16, “DoD Antiterrorism Standards,” (14JUN01) (reference A.69), and DoD O-2000.12-H, “Protection of DoD Personnel and Activities Against Acts of Terrorism and Political Turbulence,” (19FEB93) (reference A.68) that allows for the elevation and decrease of Force Protection Condition Measures as detailed in Chapter B, AR 525-13 (reference A.4).

23.6 Security Portfolio Prioritization. Consequence-based prioritization constitutes the first practical step towards implementation of a security risk management framework. The Consequence-Based Top Screen (CTS) methodology is used to identify the most critical facilities within a given portfolio from a critical infrastructure perspective. This methodology is based on characterizing impacts or effects associated with failure or disruption of a project, considering human impacts, economic impacts, and impacts on critical functions. The input data is developed by the USACE Modeling, Mapping, and Consequence (MMC) Production Center, which has overall responsibility for developing dam break failure modeling, flood inundation mapping, and consequence estimation studies for USACE dams.

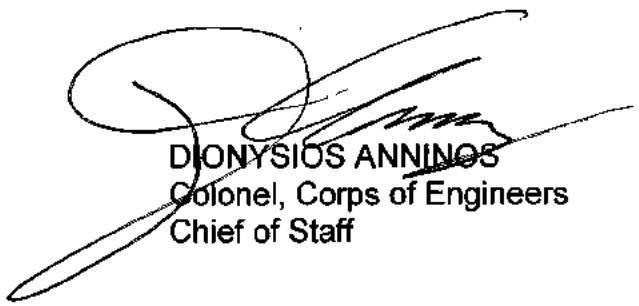
23.7 Security Risk Assessment. At a minimum, a security risk assessment should be conducted every five years in conjunction with the project's periodic inspection or periodic assessment.

23.7.1 The results of the security risk assessment should be documented with the periodic inspection or periodic assessment report. Consideration should be given to conducting a revalidation of the security risk assessment between periodic inspections/ assessments. Additionally, in cases where there has been "change" at the project (threat, construction, mission, criticality of a project asset, condition of security systems, project operation, etc.), the revalidation should be implemented immediately by the District to document any change(s) and impact it would have on the initial, or subsequent analysis.

23.7.2 The security risk assessment methodology should be complete (assess consequence, vulnerability, and threat for every defined scenario), documented (clearly document which information is used and how it is synthesized to generate a risk estimate), reproducible (produce comparable, and repeatable results), defensible (technically sound, free from significant errors or omissions, and address the uncertainties associated with consequence, vulnerability, and threat variables). The risk assessment methodology should identify specific attack methods and scenarios. The threat should be estimated as the likelihood that the adversary would attempt a given attack method against the target. The vulnerability assessment component of the methodology should develop estimates of the likelihood of an adversary's success for each attack scenario, accounting for any protective measures in place and considering law enforcement response capabilities. For a given attack scenario, the vulnerability should be defined as the probability of attacker's success, given that an attack is attempted. The Common Risk Model for Dams (CRM-D) risk assessment methodology and the tools and templates for implementing CRM-D, are available through the HQUSACE Office of Homeland Security. CRM-D meet the assessment criteria.

23.8 Security Training and Resources. The following training courses and resources are available to project personnel with security responsibilities:

23.8.1 The web-based training module "IS-870 Dams Sector: Crisis Management" is available on FEMA's Emergency Management Institute website. This is part of a



series of web-based training courses whose purpose is to provide general information pertaining to security awareness, protective measures, and crisis management of dams. This course explains how crisis management is an important component of an overall risk management program and provides guidelines to assist owners and operators in developing Emergency Action, Continuity of Operations, Pandemic Preparedness, and Exercise plans. The IS-870 module is available at the following link: http://training.fema.gov/EMIWeb/IS/IS870.asp.

23.8.2 The web-based training module "IS-871 Dams Sector: Security Awareness" is designated as 'For Official Use Only' and are thus only accessible through the Homeland Security Information Network – Critical Sectors (HSIN-CS) Dams Portal (https://cs.hsin.gov/C2/DS/default.aspx). This module provides information to enhance the ability to identify security concerns, coordinate proper response, and establish effective partnerships with local law enforcement and first responder communities. The training course describes common security vulnerabilities, potential indicators of threats, surveillance detection, and reporting of incidents and suspicious activities.

23.8.3 The web-based training module "IS-872 Dams Sector: Protective Measures" is designated as 'For Official Use Only' and are thus only accessible through the Homeland Security Information Network – Critical Sectors (HSIN-CS) Dams Portal. This module addresses protective measures related to physical, cyber, and human elements, and describes the importance of these measures as components of an overall risk management program. The training course describes the basic elements of the risk management model, and discusses the steps required to develop and implement an effective protective program.

23.8.4. Additional reference documents addressing security awareness, protective programs, and crisis management are available through the Homeland Security Information Network - Critical Sectors (HSIN-CS) Dams Portal. The District's Security Officer needs to understand the Homeland Security documents aforementioned and the applicable DoD requirements, and coordinate with the Division Security Officer and HQUSACE Office of Homeland Security as a security plan is developed for each dam.

APPENDIX B

Dam Safety in The Corps of Engineers

B.1 Background.

B.1.1 Corps Dam Safety. The safety of dams has been a major concern of the Corps of Engineers since it began building dams in the 1840s. As part of the flood control development of the Muskingum River in northeast Ohio in the 1930's, the Corps started a multiple level of review requirements for dam design. This is currently being performed by an Agency technical review at the district level. As dam designers and operators, USACE retains responsibility and accountability for the continued safe performance of our applicable dams and appurtenant structures, under the full range of anticipated loading conditions. For many years the Corps has made extensive use of experts to consult and advise on unusual and difficult designs. Advisory boards have been helpful in establishing design criteria and standards. Experience gained from the 1938 slide in the embankment of Fort Peck Dam led the Corps to adhere to the highest design standards and comprehensive inspection and testing for construction. The Corps was one of the first agencies to initiate a periodic inspection and evaluation program, and its program was used as input to the development of the "Federal Guidelines for Dam Safety" (reference A.71) due to its early, comprehensive and effective program.

B.1.2 Federal Dam Safety Action. As a result of several dam failures in the mid 1970's, none of which were Corps' owned or operated, a Presidential Memorandum was issued on 23 April 1977 that required each Federal agency having responsibility for dams to review their practices and activities related to dam safety. This memorandum also directed the Federal Coordinating Council for Science, Engineering and Technology to prepare guidelines for management practices and procedures to ensure dam safety. "Federal Guidelines for Dam Safety" (reference A.71) was published in June 1979, and with a memorandum dated 4 October 1979, President Carter asked each Federal agency having responsibility for dams to adopt and implement these guidelines and report their progress to the Federal Emergency Management Agency (FEMA) on a biennial basis. Executive Order 12148 gives FEMA the responsibility to coordinate dam safety in the nation. The purpose of these guidelines is to enhance national dam safety and to encourage high safety standards in the management procedures and technical activities of Federal agencies. The guidelines require the head of each Federal agency having responsibility for design, construction, operation and regulation of dams to establish a dam safety office (officer), which reports directly to the head of the agency. The Interagency Committee on Dam Safety (ICODS) was established in 1980 to promote and monitor Federal and State dam safety programs. The Corps of Engineers is the Department of Defense representative on ICODS.

B.1.3 Corps Dam Safety Officer. On 7 February 1980, the Chief of Engineers appointed the Chief of the Engineering Division, Directorate of Civil Works, as the HQUSACE Dam Safety Officer. This appointment also required that the Dam Safety Officer chair a standing committee composed of individuals having assigned

responsibilities for dam safety to include programming and policy functions. The purpose of this committee is to provide surveillance, evaluation, and guidance for the administrative, technical, and regulatory practices within the Corps of Engineers. The Dam Safety Officer is advisory to the Chief of Engineers, through the Director of Civil Works. The HQUSACE Dam Safety Officer is now Chief, Engineering and Construction.

B.2 Introduction. It is difficult to quantify the overall safety of a dam; however the way to achieve maximum dam safety is to apply the utmost care and competence to every aspect of design, construction, operation, and maintenance. The most important prerequisite for dam safety is the professional competence of persons associated with the dam over its life span. A dam with a record of safe performance may still experience failure from undetected deficiencies within the dam structure or in the foundation. Dam safety must take precedence over all other considerations (references A.86, A.88, A.89, and A.91).

B.3 History of Dam Safety.

B.3.1 Early Development of Dams. History indicates that dams have been vital to civilization for more than 5,000 years. The early United States settlers constructed dams in the 1600's for water supply and to power gristmills and sawmills. The oldest Corps of Engineers' dams are six locks and dams on the Green and Kentucky Rivers built between 1836 and 1844.
