(1) For all watercourses, proposals for appropriation during periods of flood flows and high water levels shall be given first consideration unless this is not practical, reasonable, or feasible (Minnesota Statutes, section 103G.261).

(2) For natural and altered watercourses, except for drainage ditches established under Minnesota Statutes, chapter 103E, consumptive appropriation may be limited consistent with Minnesota Statutes, section 103G.285, subdivision 2, provided that adequate data are available to set such limits for watercourses. Where protected flow is designated by the commissioner, no appropriation shall be allowed when the flow is below that protected flow.

(3) Permits to appropriate water for any purpose from streams designated trout streams by rule, pursuant to Minnesota Statutes, section 97C.021, shall be limited to temporary appropriations when not in conflict with the special designation, such as during periods of high flows or high water levels (Minnesota Statutes, section 103G.285, subdivision 5).

(4) For natural and altered basins the commissioner shall:

(a) Establish a protection elevation below which no appropriation shall be allowed (Minnesota Statutes, section 103G.285, subdivision 3, paragraph (b)).

(b) Limit the collective maximum annual withdrawals to not exceed a total volume of water amounting to one-half acre-foot per acre of surface water basin based on Minnesota Department of Natural Resources Bulletin No. 25, "An Inventory of Minnesota Lakes." The actual collective annual allocation may be considerably less than the maximum. This limitation is as provided by Minnesota Statutes, section 103G.285, subdivision 3, paragraph (a).

(c) For natural and altered basins less than 500 acres, an application shall not be approved if the commissioner determines that the proposed appropriation would lower the water level in the basin to an extent which would deprive the public and riparian property owners of reasonable use of and access to the water.

(5) The establishment of protection elevation and limitation on maximum withdrawals contained in units (a) and (b), shall not apply to artificial and altered basins constructed primarily for the

Copyright ©2008-2010 by the Revisor of Statutes, State of Minnesota. All Rights Reserved.

purpose of storing high waters and flood flows as water conservation or contingency flow alternatives when such alternatives are approved by the commissioner.

(6) Protected flows and protection elevations shall be established for the purposes as defined in part 6115.0630 and shall be based on available information considered in subpart 2, items B and C. For new applications the proposed establishment of protected flows or protection elevations shall be part of the permit process outlined in subpart 3 including opportunity for public hearing. Existing permittees who will be affected by the proposed establishment of protected flows or protection elevations shall be notified of such proposals and shall be provided opportunity for public hearing before modification of their permits based on the procedures outlined in part 6115.0750, subpart 5, item B. Upon the submission of data set forth in part 6115.0670, subpart 2, item A or B for the specified watercourse segment or basin by a state agency agreeing to pay the costs of any necessary public hearings, the commissioner shall establish requested protected flows and elevations.

C. Approval of appropriation from ground water shall be further subject to the following:

(1) The amounts and timing of water appropriated shall be limited to the safe yield of the aquifer to the maximum extent feasible and practical.

(2) If the commissioner determines, based on substantial evidence, that a direct relationship of ground and surface waters exists such that there would be adverse impact on the surface waters through reduction of flows or levels below protected flows or protection elevations the amount and timing of the proposed appropriation from ground water shall be limited.

(3) Appropriation of ground water shall not be approved or shall be issued on a conditional basis in those instances where sufficient hydrologic data are not available to allow the commissioner to adequately determine the effects of the proposed appropriation. If a conditional appropriation is allowed, the commissioner shall make further approval, modification, or denial when sufficient hydrologic data are available.

(4) The commissioner shall limit the use of dug pits for appropriating water when such pits are so located that they may reasonably be expected to affect protected flows of watercourses or protection elevations of basins.

Subp. 4. **Waiver.** The commissioner shall waive any of the provisions of subpart 3 if it is determined that conditions are such that implementation of a provision would be unnecessary or inapplicable or if an applicant provides sufficient evidence to show just cause why such provision would not be reasonable, practical, or in the public interest. In the event the commissioner does not grant an applicant's request for waiver the applicant may demand a hearing.

Subp. 5. **Specific types of appropriation and use.** Additional requirements and decisions governing agricultural irrigation, public water supplies, dewatering, water level maintenance, and mining are also contained in parts 6115.0680 to 6115.0720.

6115.0680 ADDITIONAL REQUIREMENTS AND CONDITIONS FOR AGRICULTURAL IRRIGATION.

Subpart 1. **Additional application information.** For ground water appropriation, the applicant must submit to the commissioner the following data in addition to the requirements of part 6115.0660:

A. If the application is for use of groundwater from an aquifer system for which adequate groundwater availability data are available and therefore is designated by the commissioner as a Class A application, (Minnesota Statutes, section 103G.295, subdivision 3):

(1) copies of test hole log(s) to identify the aquifer the proposed well will penetrate;

(2) copies of the water well record(s) and production test data;

(3) additional aquifer test data as may be required by the commissioner if the test holes, water well records, and production test data are insufficient to allow the commissioner to properly assess the capability of the aquifer system in the area of withdrawal, or are inadequate to allow assessment of the effects of the proposed appropriation on other nearby wells.

B. If the application is for use of groundwater from an aquifer system for which inadequate groundwater availability data are available and therefore is designated by the commissioner as a Class B application, (Minnesota Statutes, section 103G.295, subdivision 3) the applicant shall supply the following additional information as required by Minnesota Statutes, section 103G.295, subdivision 4, including:

(1) copies of test hole log(s) to identify the aquifer the proposed well will penetrate;

(2) copies of water well record(s) and production test data;

(3) the anticipated groundwater quality in terms of the measures of quality commonly specified for the proposed water use, when existing data indicate the water supply is not suitable for irrigation;

(4) the location of each domestic well, for which information is readily available, located within the area of influence or within 1-1/2 mile radius of the proposed irrigation well, whichever is less;

(5) readily available information from water well records, reports, studies, and field measurements regarding the domestic wells within the area of influence or a 1-1/2 mile radius of the proposed irrigation well whichever is less, such as:

(a) owner's name, address, and phone number;

(b) depth of well in feet;

(c) diameter of well and casing type (concrete curb, steel, wooden, clay tile, etc.);

(d) nonpumping water level (in feet) below land surface;

(e) age of well (when constructed);

(f) type of pump (shallow-jet, deep well jet, submersible reciprocating, etc.) and rate of discharge; and

(g) length of drop pipe in well;

(6) results of a pumping test of the aquifer system as required in Minnesota Statutes, section 103G.295, subdivision 4, paragraph (a), clause (5).

Copyright ©2008-2010 by the Revisor of Statutes, State of Minnesota. All Rights Reserved.

(7) The commissioner shall in any specific application, waive any of the requirements of subitems (1) to (6), when the necessary data are already available, as required in Minnesota Statutes, section 103G.295, subdivision 4.

Subp. 2. **Commissioner's actions.** The commissioner shall analyze and evaluate applications based on facts supplied by the applicant pursuant to parts 6115.0660 and subpart 1 of this part. Decisions shall be subject to the applicable procedures outlined in part 6115.0670 and based on recommendations of the soil and water conservation district, soil surveys, and other available data on soil characteristics relating to soil suitability for agricultural irrigation and adequacy of existing or proposed soil and water conservation measures in order to protect water quality and prevent erosion and sedimentation.

The commissioner shall determine the amount of water allowed to be used under the above

paragraph based on:

A. Acreage of lands involved.

B. Climatic characteristics of the area involved.

C. Dominant soil types of the acreage to be irrigated and major crops to be irrigated.

D. Best available technology, methodology, and crop-water use requirement information including, but not limited to, Irrigation Guide for Minnesota, Soil Conservation Service, U.S. Department of Agriculture, Saint Paul, Minnesota, 1976.

E. When adequate data on soil moisture and local climatic conditions are available for the area, the commissioner may in cooperation with irrigators and agricultural experts establish an irrigation scheduling system to provide for improved conservation of water.

F. For irrigation from surface water, where stream flow or lake level records are unavailable or when available records indicate that flows or levels during the irrigation season would be inadequate if all potential riparian landowners would use the water for irrigation, the amount of appropriation shall be limited to no more than one-half acre-foot per acre of riparian land owned or controlled by the applicant except for appropriation for wild rice paddies as is provided in item G. Riparian lands for the purpose of these rules shall be those 40-acre tracts or government lots, or portions thereof, that directly abut a basin or watercourse. This provision shall apply until a protected flow or protection elevation has been established in accordance with part 6115.0670, subpart 3, item B.

G. The amount of appropriation for wild rice paddies shall be based on consideration of climatic characteristics of the area and the best available technology relating to amounts of water needed to raise wild rice.

6115.0690 ADDITIONAL REQUIREMENTS AND CONDITIONS FOR PUBLIC WATER SUPPLIES.

Subpart 1. **Additional application information.** The applicant shall be required to submit to the commissioner all or portions of the following data in addition to the requirements of part 6115.0660:

A. the number of domestic users;

Copyright ©2008-2010 by the Revisor of Statutes, State of Minnesota. All Rights Reserved.

B. reasonable projection of population growth;

C. the number and type of industrial and commercial users of the public water supply system;

D. the amount of water to be supplied to domestic, industrial, and commercial users respectively;

E. other users by type of use and amount to be used from the public water supply system such as golf courses, recreational lake level maintenance, water transferred to other supply systems;

F. information regarding the quantity of the appropriated water to be used in distribution and waste water treatment facilities, not including volume of actual waste water; and

G. details on emergency plans for water shortage periods outlining public information programs, priorities for limitations of discretionary water use, and alternate sources of public water supplies.

Subp. 2. **Commissioner's actions.** The commissioner shall allow the appropriation of water for public water supply systems based on evaluation and analysis of the data submitted by the applicant under provisions of parts 6115.0660 and subpart 1 of this part and the procedures outlined in part 6115.0670 and subject to subpart 3.

Subp. 3. **Other requirements.** Appropriation permits issued to public water supply authorities shall be subject to requirements of Minnesota Statutes, section 103G.291, relating to critical water deficiency periods and restriction of nonessential uses.

Statutory Authority: *MS s 103G.315; 105.415*

6115.0700 ADDITIONAL REQUIREMENTS AND CONDITIONS FOR WATER LEVEL MAINTENANCE FOR BASINS.

Subpart 1. **Additional application information.** For water appropriation applications for the purpose of establishing and maintaining water levels for basins the applicant shall submit the following data in addition to the requirements of part 6115.0660:

A. information on the basin and proposed source of supply or source of discharge, including facts indicating how the water will be appropriated and discharged and the proximity of the basin to the proposed source of supply or source of discharge; and

B. information on the design of any discharge facility into or out of the basin.

Subp. 2. **Commissioner's actions.** The commissioner shall evaluate and make decisions on applications based on facts supplied by the applicant and subject to the applicable procedures outlined in part 6115.0670 and the following determinations:

A. effects on public welfare of the proposed appropriation;

B. the proposed appropriation is reasonable, practical, technically feasible, and effectively accomplishes its purpose;

C. the proposed appropriation will have minimal or no detrimental effect on the basin, the proposed source of supply, or the receiving water and property of riparian owners;

D. the quality of the water of the basin or the receiving water source will not be detrimentally impaired by the appropriation; and

Copyright ©2008-2010 by the Revisor of Statutes, State of Minnesota. All Rights Reserved.

E. the proposed appropriation is consistent with part 6115.0221, item A, subitem (2), public waters permits rules.

6115.0710 ADDITIONAL REQUIREMENTS AND CONDITIONS FOR DEWATERING.

Dewatering, which involves appropriation of water from ground or surface water sources for purpose of removing excess water, shall be subject to water appropriation permit requirements, unless otherwise exempted by these parts. The commissioner shall evaluate and make decisions on such application based on applicable provisions of parts 6115.0660 and 6115.0670 and the following additional requirements:

A. The applicant must show there is a reasonable necessity for such dewatering and the proposal is practical.

B. The applicant must show that the excess water can be discharged without adversely affecting the public interest in the receiving waters, and that the carrying capacity of the outlet to which waters are discharged is adequate.

C. The proposed dewatering is not prohibited by any existing law.

6115.0720 ADDITIONAL REQUIREMENTS AND CONDITIONS FOR MINING AND PROCESSING OF METALLIC MINERALS AND PEAT.

Subpart 1. **Additional application information.** All applicants for permits for mining and processing of metallic minerals and peat must provide the following information in addition to the requirements of Minnesota Statutes, section 103G.297 and part 6115.0660:

A. all plans and specifications regarding withdrawal, use, storage, and disposal of waters of the state;

B. details of the rates, volumes, and source of water to be appropriated and consumed in the processing, including all losses such as uncontrolled seepage, evaporation, plant losses, and discharge volumes;

C. criteria used in estimating the proposed appropriation, distribution, and discharge based on climatic averages and extremes;

D. details of the sources, rates, and volumes of water released from the mining operations involved;

E. details of the hydrologic and hydraulic impacts and effects of the operation on the watershed(s) including changes in basins, watercourses, and groundwater systems.

Subp. 2. **Commissioner's actions.** The commissioner shall analyze, evaluate, and make decisions on appropriations for mining and processing of metallic minerals based on facts submitted by the applicant

Copyright ©2008-2010 by the Revisor of Statutes, State of Minnesota. All Rights Reserved.

pursuant to subpart 1 and part 6115.0660, subject to the conditions outlined in part 6115.0670 and the following considerations:

A. The commissioner shall direct the applicant to utilize available surplus water from preexisting mining operations or facilities, whether owned or controlled by the applicant or others, whenever feasible and practical unless justification is provided on why such practice should not be allowed. If the commissioner finds that an existing permittee has available unused water, for which there is inadequate justification, the commissioner, after notice and opportunity for hearing, shall amend the existing permit to promote better utilization of the water.

B. The commissioner shall base the allocation of water on consideration of the legal requirements for water quality, the impact of the appropriation on those requirements, and the following order of priorities of water supply sources located within reasonable distance to the mining or processing site:

(1) runoff from the mining areas;

(2) water from active mine pits and tailing basins when such water is not utilized for other purposes or operations;

(3) water from existing mining operation reservoirs where such water is not utilized for other purposes or operations;

(4) water from other mining and processing operations;

(5) water from inactive mine pits;

(6) water from streams appropriated during periods of high flows;

(7) water from groundwater sources;

(8) water collected and stored behind off-stream impoundments;

(9) water collected and stored behind impoundments on streams; and

(10) water from natural basins greater than 500 acres in size.

C. If the disposal of excess water is necessary and if any mining operation in the area has caused or will cause a substantial reduction in watercourse flow, the commissioner shall where feasible and practical require the permittee to discharge excess water in a manner that would restore the flow. Such action shall consider the existing and anticipated use of excess water by higher priority users and must be in compliance with appropriate rules of the Minnesota Pollution Control Agency.

6115.0730 WELL INTERFERENCE PROBLEMS INVOLVING APPROPRIATION.

Subpart 1. **For new applications.** If the commissioner determines that an adequate supply of water is available and that the proposed project is reasonable and practical as determined based on parts 6115.0670 and 6115.0680 to 6115.0720, but that there is a probable interference with public water supply well(s) and private domestic well(s) which may result in reducing the water levels beyond the reach of those wells, the following procedures shall apply:

Copyright ©2008-2010 by the Revisor of Statutes, State of Minnesota. All Rights Reserved.

A. The applicant shall be responsible for obtaining and providing to the commissioner, available information including depth, diameter, nonpumping and pumping levels, quality, and well construction details for all domestic and public water supply wells located within the area of influence of the proposed appropriation well.

B. The commissioner may require aquifer tests or other field tests to be conducted.

C. The commissioner shall determine the probable interference with the domestic and public water supply wells based on theoretic computations using available information regarding the aquifer characteristics obtained from aquifer tests and/or from hydrologic studies, and the probable effects of lowering the water levels in the domestic and public water supply wells due to the proposed appropriation in the area. For public supply wells only the probable interference with that portion which is used for domestic water supply is considered.

D. The commissioner shall provide the prospective appropriator with an evaluation of the nature and degree of effect of the appropriation on the water levels of the domestic well(s) and public water supply well(s).

E. The commissioner shall not issue the permit until the applicant agrees to exercise any of the following options within 30 days after written notification by the commissioner:

(1) accept a modification or restriction of the permit application to provide for an adequate domestic water supply; or

(2) submit a written agreement signed by the applicant and all parties identified under item C as having probable interference. Such agreement shall outline the measures that will be taken to ensure maintenance of water supplies to such identified parties to the extent that would have existed absent the proposed appropriation. In cases where no agreement can be reached, the commissioner shall implement the settlement procedure identified in item D.

Subp. 2. **For existing permits.** If complaints are made to the commissioner by private domestic well owner(s) or public water supply authority regarding the effects of a water appropriation on the domestic water supplies, the following procedures shall be followed:

A. The commissioner shall provide complaint forms to the parties making the complaint, thereafter referred to as "complainant."

B. Upon receipt of the completed complaint forms the commissioner shall notify the permittee, the applicable watershed district, and the soil and water conservation district and any other governmental agency or person who may be affected or has expressed interest in the complaint.

C. The commissioner shall investigate and assess the complaint by:

(1) Analyzing and evaluating the submitted complaint forms, hydrologic facts and characteristics of the water supply systems involved.

(2) Requesting additional facts from the complainant(s) and the permittee when necessary. In order to assure that available data on domestic well(s) are provided, the complainant shall cooperate with the permittee in providing such facts as may be available and allowing the commissioner access to obtain necessary available facts. If the complainant does not cooperate in providing available facts or allowing the commissioner access to the domestic well(s), the commissioner shall dismiss the complaint.

(3) Conducting, if necessary, a field investigation.

Copyright ©2008-2010 by the Revisor of Statutes, State of Minnesota. All Rights Reserved.

(4) Additional hydrologic tests and evaluation shall be required if hydrologic information is unavailable or inadequate to make a determination of necessary facts in the matter. For irrigation appropriations, the timing and conduct of such tests shall be in accordance with the provision of Minnesota Statutes, section 103G.271, subdivision 3, relating to modifying or restricting appropriation for irrigation.

(5) In evaluating the probable influence of the water appropriation on the domestic well(s) and public water supply well(s) the commissioner shall consider whether the domestic well(s) provides a dependable water supply while meeting the appropriate health requirements for the existing use of the affected well. For public water supply wells only the probable interference with that portion which is used for domestic water supply is considered.

D. Where adverse effects on the domestic well(s) are substantiated, the commissioner shall notify the permittee of the facts and findings of that complaint evaluation. In the event that the commissioner determines that the domestic water supply is endangered the commissioner shall, pursuant to part 6115.0750, subpart 7, unless a temporary solution is worked out, restrict or cancel the appropriation until such time as a decision has been made by either negotiation, settlement, or hearing.

E. The permittee shall within 30 days after written notification by the commissioner take appropriate action by exercising any of the following options:

(1) Requesting the commissioner to modify or restrict the permit in order to provide for an adequate domestic water supply.

(2) Negotiating a reasonable agreement with the affected well owner(s). If no agreement is reached, the settlement procedure outlined in subpart 4 shall apply; or

(3) Requesting a public hearing.

Subp. 3. **New domestic wells installed after appropriation permits have been issued.** In the event that new domestic wells, exempt from permit requirements, are installed in area of adequate ground water supplies where permits have been issued for appropriation the following shall apply:

A. It shall be the responsibility of the prospective new domestic well owner to ensure that the new domestic well will be constructed at adequate depth so that it will provide an adequate domestic water supply which will not be limited by the permitted appropriation.

B. Holders of valid permits for appropriation of water in areas where adequate water supplies are available shall not be responsible for well interference problems, involving new domestic wells exempt from permit, when such exempt domestic wells are installed subsequent to authorized appropriation.

Subp. 4. **Settlement.** If the applicant or permittee and the complainant(s) have been unable to negotiate a reasonable agreement pursuant to subparts 1, item E and 2, item E, the following procedure shall be implemented:

A. The applicant or permittee shall submit to the complainant a notarized written offer including a statement that the complainant must respond in writing to the commissioner within ten days from the receipt of the offer either accepting the offer or explaining why it is rejected. The offer must be submitted to the complainant with a copy to the commissioner within 40 days after the receipt of the written notification provided in subparts 1, item E and 2, item E, based on the following:

(1) If an existing domestic well provides an adequate domestic water supply which meets state health standards, and such well no longer serves as an adequate supply because of the proposed or permitted appropriation in the vicinity the applicant or permittee shall be responsible for all costs necessary

Copyright ©2008-2010 by the Revisor of Statutes, State of Minnesota. All Rights Reserved.

to provide an adequate supply with the same quality and quantity as prior to the applicant's or permittee's interference.

(2) If an existing well provides an adequate domestic water supply but does not meet state health standards and such well would no longer serve as an adequate supply because of the proposed or permitted appropriation in the vicinity, the applicant or permittee shall be responsible for that portion of costs of providing an adequate water supply, but shall not be responsible for those costs necessary to bring the domestic well(s) to state health standards.

B. The complainant shall, within ten days from the receipt of the notarized written offer, respond to the commissioner in writing either accepting the offer or making argument on why the offer is not reasonable. If no response is received from the complainant, within the time limit, the commissioner shall dismiss the complaint.

C. If the offer is not accepted, the commissioner shall make a decision based on the written offer and arguments and available facts, within ten days as follows:

(1) that the applicant or permittee has submitted a reasonable offer, the commissioner shall issue or continue the permit involved;

(2) that the applicant or permittee has not submitted a reasonable offer, the commissioner, after notice and opportunity for hearing, shall deny, modify, or terminate the permit involved;

(3) that there is a need for a public hearing in which case it is ordered.

Statutory Authority: *MS s 103G.315; 105.415*

6115.0740 WATER USE CONFLICTS.

Subpart 1. **Conflict defined.** For the purpose of these rules a conflict occurs where the available supply of waters of the state in a given area is limited to the extent that there are competing demands among existing and proposed users which exceed the reasonably available waters. Existing and proposed appropriations could in this situation endanger the supply of waters of the state so that the public health, safety, and welfare would be impaired.

Subp. 2. **Procedure.** Whenever the total withdrawals and uses of ground or surface waters would exceed the available supply based on established resource protection limits, including protection elevations and protected flows for surface water and safe yields for groundwater, resulting in a conflict among proposed users and existing legal users the following shall apply:

A. In no case shall a permittee be considered to have established a right of use or appropriation by obtaining a permit.

B. The commissioner shall analyze and evaluate the following:

(1) the reasonableness for use of water by the proposed and existing users;

(2) the water use practices by the proposed and existing users to determine if the proposed and existing users are or would be using water in the most efficient manner in order to reduce the amount of water required;

(3) the possible alternative sources of water supply available to determine if there are feasible and practical means to provide water to satisfy the reasonable needs of proposed and existing users.

Copyright ©2008-2010 by the Revisor of Statutes, State of Minnesota. All Rights Reserved.

C. If conflicts can be resolved by modifying the appropriation of the proposed and existing users, the commissioner shall do so.

D. If conflicts cannot be resolved through modification of proposed and existing permits the commissioner shall base the decision regarding issuance of new applications and retention, modification, or termination of existing permits on the basis of existing priorities of use established by the legislature as follows:

(1) If the unresolved conflict involves users who are or would be in the same priority class, the commissioner shall require the proposed users and existing permitted users to develop and submit a plan which will provide for proportionate distribution of the limited water available among all users in the same priority class. The commissioner shall withhold consideration of new applications and shall, if the existing permitted appropriations endanger the supply of waters of the state, suspend or limit existing permits until a plan is approved by the commissioner.

The plan must include proposals for allocating the water which address the following: possible reduction in the amounts of appropriation so that each user would receive a proportionate amount of water for use; and possible restrictions in the timing of withdrawals so that each user would be allowed to withdraw a proportionate share of water for use over certain periods of time.

If the commissioner approves the proposed plan, new permits will be issued and existing permits will be amended in accordance with that plan.

If the commissioner determines that the proposed plan is not practical or reasonable, the commissioner shall develop a new plan or modify the proposed plan to provide proportionate share of water among the users involved. The commissioner shall issue new permits and amend existing permits based on that plan.

(2) If the unresolved conflict involves users who are or would be in a different priority class the available water supply shall be allocated to existing and proposed users based on the relative priority of use. Highest priority users shall be satisfied first. Any remaining available water supply shall be allocated to the next succeeding priority users, until no further water is available. Users in the same priority class shall be offered the same options as provided in subitem (1).

Subp. 3. **Notice and hearing.** All actions by the commissioner shall be made after notice and opportunity for public hearing.

Statutory Authority: *MS s 103G.315; 105.415*

Posted: *June 11, 2008*

6115.0750 PROVISIONS AND CONDITIONS OF WATER APPROPRIATION PERMITS.

Subpart 1. **In general.** Water appropriation permits shall include the following provisions and conditions, unless otherwise required by law.

Subp. 2. **Term of permits.** Permits shall be issued for temporary or for long-term appropriation.

Temporary permits involve a one-time, limited life, not more than 12 months, nonrecurring appropriation of waters of the state, such as for highway construction, exploratory drilling for minerals, hydrostatic testing of pipelines and other short-term projects. Requested time extensions shall be permitted, but in no case shall the total length of time the permit remains in force exceed two years.

Long-term permits will remain in effect subject to applicable permit provisions and conditions of the permit, the law, and these parts, provided that in cases where the permittee is not the landowner of record, the term of the permit shall be the same as that of the property rights or license held.

Subp. 3. **Monitoring.** Monitoring:

A. All permittees shall measure and keep monthly and yearly records of the quantity of water used or appropriated at the point of taking from each source under permit.

B. Each installation for appropriating or using water shall be equipped with a device or employ a method to measure the quantity of water appropriated to within ten percent of actual withdrawal.

The commissioner shall determine the method to be used for measuring water appropriated based on: the quantity of water appropriated or used; the source and location of the appropriation; the method of appropriating or using water; other facts supplied by the permittee.

The commissioner shall require flow meters to be used whenever the rate of appropriation is greater than 1,500 gallons per minute, unless the permittee can show justification why flow meters cannot practically be used or are not necessary considering the factors contained in the two preceding paragraphs. Such justification must be supported by facts which indicate the technical difficulties which would be encountered if flow meters were required.

C. For surface water appropriations, where applicable, the permittee shall measure flows or levels in the watercourse or basin at a specific gauge designated by the commissioner and located within the area of appropriation. The commissioner shall require permittees to pay necessary costs of establishing and maintaining such gages as provided in parts 6115.0010 to 6115.0100, rules for permit fees.

Copyright ©2008-2010 by the Revisor of Statutes, State of Minnesota. All Rights Reserved.

For groundwater appropriation, the commissioner, based on availability of hydrologic data on the aquifer involved, frequency and rate of pumping, and probability of conflict or well interference, shall require the permittee to measure and keep records of the water levels in each production well at reasonable times prescribed in the permit. Observation wells may be required as a condition of the permit to better evaluate hydrologic conditions and effects in areas where hydrologic data are unavailable, where probable conflict or well interference problems may occur and where such wells are required by law.

Subp. 4. **Reporting.** Annual calendar year monthly records of the amount of water appropriated or used and the water level measurements shall be recorded for each installation. Such readings and the total amount of water appropriated and used shall be reported annually to the commissioner, on or before February 15 of the following year upon forms to be supplied by the commissioner unless otherwise specified in the permit.

Such records shall be submitted with an annual water appropriation processing fee as required by Minnesota Statutes, sections 103G.271, subdivision 6, and 103G.281, subdivision 3, for each permit whether or not any water was appropriated during the year.

Additional information shall be required such as acreage irrigated, identification of water disposal sites, and amount of water discharged, when necessary for the statewide water information system (Minnesota Statutes, section 103G.275, subdivision 2).

Failure to report and pay the fee shall be sufficient cause for terminating a permit 30 days following written notice by the commissioner of the violation of the permit.

No fee is required from any state agency as defined in Minnesota Statutes, section 16B.01, subdivision 2, or any federal agency.

Subp. 5. **Amendments to permits.** Amendments to permits:

A. Major modification of any water appropriation permit shall not be made before obtaining the written permission from the commissioner. Major modification includes changes such as substantial increase or decrease in the rate and quantity of water withdrawn, any change in source of appropriation or substantial change in the amount of land irrigated, when applicable.

Request for amendment can be made by letter or on forms supplied by the commissioner. New applications shall be required when there are changes in the source of supply, the purpose of appropriation,

Copyright ©2008-2010 by the Revisor of Statutes, State of Minnesota. All Rights Reserved.

or when the proposed increases in rates and amounts of water would probably create conflict or well interference.

Requests for amendments shall be reviewed as if they were for a new application, subject to provisions of parts 6115.0600 to 6115.0800.

B. Pursuant to authority in Minnesota Statutes, section 103G.315, subdivision 11, the commissioner may modify or amend any existing permits based on the following procedures and the criteria in parts 6115.0670 to 6115.0720, where applicable.

The commissioner shall notify the permittee of the intent to amend the permit. The notice will include details on modifications to be implemented by the permittee and the timing to complete the modifications.

The permittee shall respond within 30 days from receipt of the notice. Such response period shall be thereafter extended by the commissioner for good cause shown.

If no response is received in 30 days and no extension of response time is authorized by the commissioner, the proposed amendments shall be made.

The commissioner based on the permittee's response and the criteria established in these rules shall either modify the proposed amendment or adopt the original proposed amendment.

C. All amendments and modifications are made after notice and opportunity for hearing.

Subp. 6. **Transfers or assignments of permits.** If the property involving a water appropriation permit is sold, transferred, or assigned to another person, the permit may be transferred to the transferee without the necessity of reapplication, subject to the following.

The transferee shall, within 90 days after date of property sale, transfer, or assignment, or within a longer period of time allowed by the commissioner for good cause shown, submit written notification to the commissioner stating the intention to continue the appropriation as stated in the permit. If the transferee intends to make major modifications to the existing permit, a new application shall be required subject to the provisions of subpart 5.

No permit is assigned except with the written consent of the commissioner.

Subp. 7. **Limitations on permits.** All permits issued by the commissioner since 1949 are subject to the provisions of Minnesota Statutes, section 103G.315, subdivision 11, relating to cancellation and

Copyright ©2008-2010 by the Revisor of Statutes, State of Minnesota. All Rights Reserved.

conditions of permits and Minnesota Statutes, section 103G.315, subdivisions 2 to 6, 8, and 9, relating to terms and reservations with respect to the amount and manner of such use or appropriation or method of construction or operation of controls as appears reasonably necessary for the safety and welfare of the people of the state.

The commissioner, subject to the terms and conditions of such existing permits, may modify, restrict, or cancel an existing appropriation or use until such time as a decision has been reached by either negotiation, settlement, or after a public hearing. If a permit does not contain a provision which restricts appropriation or use for the protection of safety or welfare of the people of the state the commissioner cannot modify or restrict an existing appropriation until opportunity is provided for a public hearing and where ordered a public hearing has been completed.

Subp. 8. **Terminations.** Permits shall be terminated under the following:

A. Request by the permittee.

B. When any of its provisions are violated.

C. When the permittee sells, transfers, or assigns the property described in the permit and the transferee does not wish to continue appropriating.

D. Upon finding that the permittee has violated the provisions of any applicable laws and rules.

E. Where the permittee has not for five consecutive years, from the date of issuance of the permit, appropriated the water. Such time shall be extended by the commissioner for good cause shown.

F. When the lease or contract for deed is forfeited or canceled.

G. Permits for agricultural irrigation shall be subject to termination by the commissioner upon justifiable recommendation of the supervisors of the soil and water conservation district, wherein the land irrigated is located, regarding the inadequacy of the soil and water conservation measures.

H. When the commissioner deems it necessary for the conservation of the water resources of the state or in the interest of public health, safety, and welfare.

I. When the commissioner deems it necessary pursuant to parts 6115.0730 and 6115.0740.

J. Any action pursuant to items B and D to I shall be subject to appropriate notice and opportunity for hearing, except as provided in subpart 7.

K. In the case of permits for mining issued in conjunction with Minnesota Statutes, section 103G.297, procedures for termination shall be subject to provisions of Minnesota Statutes, section 103G.297, subdivision 8.

6115.0760 LOCAL PERMITS.

The commissioner, pursuant to Minnesota Statutes, section 103G.271, subdivision 4, shall delegate to municipal, county, or regional level of government the authority to process and approve permit applications for the appropriation and use of waters of the state in amounts of more than 10,000 gallons per day and more than 1,000,000 gallons per year, but less than 3,600,000 million gallons per year. Such delegation shall be made at the municipal, county, or regional level which means a governmental entity, or several governmental entities in combination, having authority or jurisdiction over areas of geographical extent beyond the limits of a single county, or a watershed district. The delegation by the commissioner shall be subject to the following requirements:

A. The authorized unit of government has established an administrative process which includes provisions for establishing a water appropriation management planning process consistent with part 6115.0810.

B. The review and approval of applications are consistent with the applicable provisions of these parts.

C. A formalized agreement is made and signed by the commissioner and the appropriate municipal, county, or regional level authority involved.

D. Copies of all applications and records of local actions on applications are provided to the commissioner upon receipt and action.

E. Records of water appropriation amounts and the processing fee shall be submitted by the permittee to the commissioner as required by part 6115.0750, subparts 3 and 4, and Minnesota Statutes, sections 103G.271, subdivision 6, and 103G.281, subdivision 3.

6115.0770 WATER CONSERVATION.

In order to maintain water conservation practices in the water appropriation and use regulatory program it is necessary that existing and proposed appropriators and users of waters of the state employ the best available means and practices based on economic considerations for assuring wise use and development of the waters of the state in the most practical and feasible manner possible to promote the efficient use of waters.

Based on data submitted by applicants and permittees and current information on best available water conservation technology and practice the commissioner, in cooperation with the owners of water supply systems, may analyze the water use practices and procedures and may require a more efficient use of water to be employed by the permittee or applicant, subject to notice and opportunity for hearing.

6115.0780 ABANDONMENT OF WELLS.

The permittee shall notify the commissioner prior to abandoning, removing, covering, plugging, or filling the well or wells by means of which a water appropriation was made. The commissioner shall require abandonment procedures and methods consistent with the Minnesota Department of Health rules, parts 4725.2300 to 4725.3200.

6115.0790 FIELD INVESTIGATIONS.

In order to fully evaluate water appropriations, the commissioner shall conduct field investigations to determine the nature and scope of the appropriation and the impact it has or will have on water and related land resources. Such field inspection shall be made in a timely fashion and shall be coordinated with one or more of the following divisions of the department: Enforcement, Fish and Wildlife, Forestry, Minerals, Lands, and Parks and Recreation. A fee shall be charged for field inspections subject to rules for permit fees, part 6115.0080.

6115.0810 WATER APPROPRIATION AND USE MANAGEMENT PLANS.

Subpart 1. **In general.** In order to address the provisions of Minnesota Statutes, sections 103B.155, 103G.261, 103G.265, and 103G.271, subdivision 2, the commissioner, in cooperation with other state and federal agencies, regional commissions and authorities, local governments and citizens, establishes the following process for the preparation and implementation of the elements of any state, regional, and local plan relating to water appropriation and use.

Subp. 2. **Criteria and procedures.** Since the availability, distribution, and utilization of waters of the state and the character and use of related land resources vary considerably throughout the state, a comprehensive water appropriation management planning process must be based on these considerations and according to the following principles and procedures:

A. Water appropriation management plans should be prepared for specific definable areas of the state on consideration of:

(1) The hydrologic and physical characteristics of the water and related land resources for which a management plan is necessary. The area must be of sufficient size and areal extent so that the interrelationship of geohydrologic and climatic factors can be adequately defined and managed.

Copyright ©2008-2010 by the Revisor of Statutes, State of Minnesota. All Rights Reserved.

(2) The determination by the commissioner of the need for establishment of a water appropriation management plan for the waters of the state within a specific definable area based on:

(a) areas where development of the waters of the state is, or is likely to, increase considerably within the next five to ten years;

(b) areas where severe water availability problems exist or are soon likely to exist;

(c) areas where there are adequate facts and available geohydrologic data relating to the availability, distribution, and use of the waters of the state and where there is local interest in establishing water appropriation management plans.

B. Upon establishment of the need for a water appropriation management plan pursuant to item A, the commissioner shall establish a management planning process including procedures, a public participation process, and development of a planning team consisting of representatives of the department, permittees, any other interested, concerned, and involved government or citizen group listed in subpart 1 to review and cooperate in preparation of the plan.

Subp. 3. **General requirements and contents of plans.** Every water appropriation plan should, at a minimum, include:

A. An evaluation of the amount and dependability of information on the hydrologic systems of the area and the adequacy of the information to provide necessary facts on the amounts of water which can be reasonably withdrawn from the waters of the state in the area without creating major environmental problems or diminishing the long-term seasonal supply of water for various purposes. This will provide essential background information for establishing protected flows and protection elevations, part 6115.0670, subpart 3, item B, subitem (6).

B. An evaluation of data on stream quality and flows, lake water quality and levels, groundwater quality and levels, and climatic factors. This will provide essential data useful to the applicant and the commissioner in permit application considerations, parts 6115.0660 to 6115.0720.

C. An evaluation of present and anticipated future use of waters and lands and the amounts and distribution of use within the area. This will facilitate the determinations necessary under part 6115.0670, subpart 2, item A, subitem (2).

D. An evaluation of the problems and concerns relating to use of the waters within the area.

E. Water conservation alternatives and methods and procedures for dealing with water shortages or excesses during periods of deficient or excess water. See parts 6115.0660, subpart 3, item F; 6115.0690, subpart 1, item G; and subpart 2 of this part.

F. Considerations of the relationship of the water appropriation and use management plan to other water resources programs of the state, such as floodplain management, shoreland management, water surface use management, water quality management, soil and water conservation management, and agricultural land management.

LAKE IMPROVEMENT DISTRICTS

6115.0900 PURPOSE.

In order to provide for the orderly establishment of lake improvement districts in a manner that will preserve and protect the lakes of Minnesota and increase and enhance the use and enjoyment of these lakes, the commissioner of the Department of Natural Resources does hereby provide guidelines, criteria, and standards for establishment of lake improvement districts by counties, cities, and towns, as authorized by Minnesota Statutes, sections 103B.511 to 103B.581, 103G.605, 103G.621, and 459.20, in furtherance of the policies declared in Minnesota Statutes.

These rules establish minimum guidelines, criteria, and requirements relating to:

A. procedures by which proposed lake improvement districts shall be reviewed prior to establishment;

B. standards and criteria which all proposed lake improvement districts shall meet before establishment, modification, or termination.

Statutory Authority: *MS s 103B.511; 378.41*

Posted: *June 11, 2008*

6115.0910 SCOPE.

These parts shall apply to all existing and proposed lake improvement districts. These parts shall not apply to lake conservation districts established by special legislation of the Minnesota state legislature.

Statutory Authority: *MS s 378.41*

Posted: *June 11, 2008*

6115.0920 DEFINITIONS.

Subpart 1. **Shall.** For the purpose of these parts, certain terms or words used herein shall be interpreted as follows: the word "shall" is mandatory, not permissive.

Subp. 2. **Agency.** "Agency" means the Minnesota Pollution Control Agency.

Subp. 3. **Commissioner.** "Commissioner" means the commissioner of the Department of Natural Resources or authorized representative.

Subp. 4. **Direct drainage basin.** "Direct drainage basin" means that portion of a lake's total watershed which is not drained to an upstream water basin, as defined herein. The determination of size and physical limits of a lake's direct drainage basin shall be made by the commissioner.

Subp. 5. **District boundaries.** "District boundaries" means, for the purpose of these parts, the territorial boundaries of a lake improvement district. All lands and waters within the direct drainage basin, as defined herein, shall be included within the district boundaries, except those exclusions for which written approval is obtained from the commissioner. The boundaries shall include a sufficient amount of the lake's watershed and related land to develop and implement feasible solutions to the problems the district intends

Copyright ©2008-2010 by the Revisor of Statutes, State of Minnesota. All Rights Reserved.

to address. The boundaries shall also include all lands and waters which can reasonably be considered adversely affected by the proposed programs, plans, or actions of the lake improvement district.

Subp. 6. **Lake.** "Lake" means, for the purpose of these parts, any public water basin identified and classified in the shoreland management ordinances of the local county or municipal unit of government.

Subp. 7. **Lake improvement district.** "Lake improvement district" means a district formed around a lake in accordance with Minnesota Statutes, sections 103B.501 to 103B.581. A lake improvement district is a local unit of government established by resolution of appropriate county boards and/or city governing bodies, or by the commissioner, for the implementation of defined lake management projects and for the assessment of the costs thereof.

Subp. 8. **Natural hydrologic boundaries.** "Natural hydrologic boundaries" means the boundaries of a lake's direct drainage basin, as defined herein.

Subp. 9. **Resident.** "Resident" means a person 18 years of age or older who meets the residency requirements of Minnesota Statutes, section 200.031.

Subp. 10. **Resident owner.** "Resident owner" means a Minnesota resident who is the owner of land or the contract purchaser of land within the boundaries of a lake improvement district.

Subp. 11. **Water basin.** "Water basin" means an enclosed basin normally partly or completely filled with water. The water basin may have inlet and outlet streams, it may have only an inlet or outlet, or it may be completely enclosed.

Subp. 12. **Watershed.** "Watershed" means the entire surface drainage area that contributes water to a lake.

6115.0940 GOALS FOR LAKE IMPROVEMENT DISTRICTS.

Proposals for the establishment of lake improvement districts shall be evaluated according to the degree to which they promote the following goals:

A. lake protection and rehabilitation;

B. protection and enhancement of environmental values by preventing degradation of fish and wildlife habitat, surface and ground water quality, natural beauty and unique scientific values, recreational values, and the quality of life generally;

Copyright ©2008-2010 by the Revisor of Statutes, State of Minnesota. All Rights Reserved.

C. preservation of the public rights in the public waters of the state and to provide the public use of the lake consistent with the preservation of environmental values;

D. ensuring local involvement in the project and a commitment to future lake management;

E. conformity with federal, state, regional, and local laws, rules, and water and related land management policies; and

F. fair and objective resolution of conflicts between competing lake related interests in and around the district.

Statutory Authority: *MS s 378.41*

Posted: *June 11, 2008*

6115.0950 ELIGIBILITY FOR LAKE IMPROVEMENT DISTRICTS.

The types of lake improvements in items A to H are eligible for the creation of a lake improvement district:

A. studying the sources of and solutions to lake problems;

B. preserving and improving water quality by means of water and related land management, excluding land use zoning authority; and in-lake water treatment;

C. sedimentation and siltation control;

D. shoreline erosion control;

E. aquatic nuisance control;

F. preserving and improving fish and wildlife habitat;

G. preserving and improving recreational potential of the lake; and

H. any other purposes approved by the county board pursuant to Minnesota Statutes, sections 103B.551, subdivision 3; 103G.605; and 103G.621.

Statutory Authority: *MS s 103B.511; 378.41*

6115.0960 CRITERIA AND STANDARDS FOR ESTABLISHMENT OF LAKE IMPROVEMENT DISTRICTS.

Subpart 1. **In general.** Proposals for the establishment of lake improvement districts shall be evaluated based on the extent to which they demonstrate the following.

Subp. 2. **Local need for district.** The proposal shall demonstrate the need for the district and why another unit of government with similar powers, or a voluntary lake association, cannot or will not satisfactorily accomplish the district's proposed purposes.

Subp. 3. **Appropriateness of proposed boundaries.** The proposed boundaries shall be consistent with district boundaries as defined in part 6115.0920. The proposed boundaries shall include all lands and waters within the lake's direct drainage basin, unless justification is provided for including a lesser area and approved in writing by the commissioner. The proposed boundaries shall include a sufficient amount of

Copyright ©2008-2010 by the Revisor of Statutes, State of Minnesota. All Rights Reserved.

the lake's watershed and related land to develop and implement feasible solutions to the identified problems. The proposed boundaries shall include those lands and waters which can reasonably be considered adversely affected by the proposed actions of the district. The proposed boundaries shall be delineated so as to provide appropriate public representation and the equitable distribution of benefits and levying of costs.

Subp. 4. **Appropriateness of proposed purposes.** The proposed purposes shall be consistent with existing state, federal, regional, and local laws, policies, objectives, and plans pertaining to water and related land management, fish and wildlife habitat, surface and ground water quality, natural beauty and unique scientific values, economic and recreation values, and the quality of life. The proposed purposes shall be consistent with the public rights in the public waters of the state. When a district is proposed for the purpose of conducting a feasibility study of the sources of and solutions to lake problems, the proposal shall demonstrate an understanding that subsequent lake restoration measures may require modification of the district's boundaries and statement of purposes, pursuant to part 6115.0980, subpart 1, and Minnesota Statutes, section 103B.575.

Subp. 5. **Technical feasibility of proposed plans and programs.** The proposal shall demonstrate the technical feasibility of the proposed plans and programs, or provide for the determination of technical feasibility.

Subp. 6. **Adequacy of proposed means of financing.** The proposal shall demonstrate capability of raising sufficient funds to meet district purposes, to ensure continuity of district operations, and to meet the requirements of these parts.

Subp. 7. **Adequacy of procedures for planning, decision-making, and public involvement.** The proposal shall assure consideration of the interests of concerned citizens both within and outside the boundaries of the proposed district. The proposal shall include the identification of varying and often conflicting interests regarding water and related land management in and around the proposed district, and procedures to assure the consideration of such diverse interests so that decisions are made in the best overall interests of fairness and public health, safety, and welfare.

Subp. 8. **Public access.** The proposed plan shall provide for public access when adequate public access consistent with size of the lake, the extent of public interest in using the lake, and the combined uses of the lake is unavailable. Service charges may not be imposed on the use of a public access if other units of government cost share the acquisition, development, or maintenance of the public access.

Subp. 9. **Adequacy of long-range monitoring of environmental effects of district programs.** The proposed plan shall demonstrate an understanding of potential environmental effects of the proposed district plans and programs, and provide for a long-range monitoring of such effects.

Subp. 10. **Coordination with other special purpose districts.** The proposal shall demonstrate how the proposed district programs will be coordinated with existing special purpose districts formed for water and related land management. Examples of such units of government are watershed districts, sanitary districts, drainage and conservancy districts, lake conservation districts, and soil and water conservation districts. Lake improvement districts shall not be established where a special purpose unit of government for water and related land management exists which can implement the purposes of the proposed lake improvement district, unless written approval is acquired from such unit of government or

Copyright ©2008-2010 by the Revisor of Statutes, State of Minnesota. All Rights Reserved.

from the commissioner. The proposal should demonstrate efforts in good faith to resolve at the local level any conflicts between an existing special purpose district and the proposed lake improvement district.

Statutory Authority: *MS s 103B.511; 378.41*

Posted: *June 11, 2008*

6115.0970 CREATION OF LAKE IMPROVEMENT DISTRICT.

Subpart 1. **Petition or county board document.** A county board document proposing the creation of, or a petition to create, a lake improvement district shall contain the following elements:

A. A written statement of lake problems and objectives.

B. The proposed type or types of water and related land resource management programs to be undertaken by the proposed district. This shall include a detailed statement of intended studies, management programs, remedial actions, and construction projects.

C. A statement of the means by which the programs will be financed.

D. A map showing the boundaries of the proposed lake improvement district. The map shall show the number and location of permanent homes and seasonal dwellings in the district. The scale of the map, and basic geographical information, such as range, township, and section numbers, shall be clearly indicated on the map.

E. The number of directors proposed for the district.

F. Copies of local ordinances which regulate use of the lake or any public access.

G. Any information indicating the degree of local interest and commitment to future management.

H. The identification of any lands and waters which may be adversely affected by the implementation of district purposes, and a preliminary assessment of these adverse effects.

I. A statement outlining the adequacy and ownership of public accesses, including public lands and beaches.

J. An estimate of the total equalized valuation of the property within the district.

K. Any other information demonstrating accordance with the criteria and standards for establishment as contained in part 6115.0960.

Subp. 2. **Submission of petition or resolution.** Initial submittal of petition or resolution to county board, the commissioner, and the agency for:

A. Creation by petition. No later than five days after the official filing of a petition for the establishment of a lake improvement district with the county board, the citizens or organization sponsoring the petition shall provide a certified copy of the petition to the commissioner and the agency. This is necessary in order to facilitate preliminary review of the proposed district boundaries prior to the notification of the public hearing.

B. Creation by resolution. At least 40 days prior to the public hearing, the county board shall provide a certified copy of the document containing the information required by this part to the commissioner and the agency. This is necessary to facilitate preliminary review of the proposed district boundaries prior to notification of the public hearing.

Copyright ©2008-2010 by the Revisor of Statutes, State of Minnesota. All Rights Reserved.

Subp. 3. **Notification of public hearing.** At least 21 days prior to the public hearing, the county board shall give notice of the public hearing to the commissioner and the agency, and make a reasonable attempt to notify every resident and every resident owner within the proposed district of the pending resolution or petition and the public hearing. A reasonable attempt to notify shall consist of mailing notice to the last known address of each landowner within the proposed district, publication of notice in two successive issues of a newspaper widely circulated in the proposed district, and posting notice in public buildings and several leading commercial establishments in or near the proposed district, as appropriate and reasonable. All local and regional units of government, special purpose districts, and development commissions within and adjacent to the boundaries of the proposed district shall be given notice of the public hearing. All corporations and utilities owning real estate or corporate property within the proposed district shall be given notice of the public hearing.

As part of the notification procedure, a statement shall accompany the notice setting forth the following:

A. a description of the proposed purposes, programs, funding, and boundaries of the proposed district, and the name proposed for the district;

B. the time and place of the public hearing; and

C. the following paragraph shall be included:

"The establishment of the proposed lake improvement district requires review by the commissioner of natural resources and the approval of the (as appropriate) county board(s) (and/or city governing body). Concerned citizens may submit evidence at a public hearing to be held prior to the passage of any resolution establishing the proposed lake improvement district. Concerned citizens may also submit evidence and opinions to the commissioner of natural resources. A copy of the petition (or document, as appropriate) for the establishment of the lake improvement district is available for public review at the (as appropriate) county courthouse (or other appropriate public building; give address and telephone number where interested citizens can review the document)."

If the establishment of the lake improvement district is proposed by the county board pursuant to subpart 2, item B and Minnesota Statutes, section 103B.515, the following paragraph shall be included in the notice of the public hearing:

"Citizens may call for a referendum on the question of whether or not to establish a lake improvement district by filing a petition requesting such a referendum. The petition shall be signed by 25 percent of the land owners within the territory of the proposed district, who are Minnesota residents.

Copyright ©2008-2010 by the Revisor of Statutes, State of Minnesota. All Rights Reserved.

Upon receipt of such a petition prior to the effective date of creation of the district, the county board shall hold the creation in abeyance pending the referendum vote of all qualified voters residing within the boundaries of the proposed district."

Subp. 4. **Public review of petition or resolution.** The county board shall make the petition or document containing the information required by this part available for review by concerned citizens, at the county courthouse or other appropriate public building.

Subp. 5. **Review by commissioner and agency.** Upon receipt of a copy of the petition or document, the commissioner shall:

A. Review the petition or document and any evidence presented by the agency or concerned citizens pertaining to the establishment of the proposed district. This review shall include an evaluation of the statement of district purposes and its relation to existing laws, rules, and regulations, units of government, water and related land management programs and policies. The proposed district boundaries shall be examined to assess their consistency with these parts. When one or more of the stated purposes of the proposed district relate to pollution control, this review shall be conducted with the assistance of the agency.

B. Prepare an advisory report stating findings as to whether the proposed lake improvement district should be established. The commissioner shall set forth in the report any matters pertaining to the district which should be further investigated and evaluated. On determining that the establishment of the proposed district is not in the public interest, the commissioner shall so report the specific reasons and inadequacies. The commissioner may request additional time for review of the proposed district in such cases where additional time can be shown to be necessary for proper evaluation. The commissioner's report may contain reports by the agency.

Subp. 6. **Request for continuance or postponement of hearing.** The county board may grant requests by citizens, the commissioner, or the agency for postponement or continuance of the public hearing to a time more than 30 days after receipt of the petition and verification of the signatures thereon. Such requests may be granted if the county board determines that the additional time requested is appropriate and reasonable in order for the requesting organization or citizens to adequately prepare for the public hearing, and consistent with the goals of promptness and fairness in the proceedings.

Subp. 7. **Advisory report.** The commissioner's advisory report shall be publicly read into the record at the public hearing.

Subp. 8. **Modification of findings.** The commissioner may modify findings based on evidence presented during and subsequent to the public hearing.

Subp. 9. **Formal meeting to approve or disapprove district.** No sooner than ten days but within 30 days following the holding of the public hearing, the county board shall formally convene to approve or disapprove the establishment of the proposed lake improvement district. At least ten working days' notice shall be given to the commissioner of the time and place where the board will formally convene for this purpose. If the commissioner or the commissioner's representative does not appear, any modifications of the commissioner's advisory report shall be publicly read into the record.

6115.0980 ADMINISTRATION OF LAKE IMPROVEMENT DISTRICTS.

Subpart 1. **Modification.** No program, remedial action, project, or change of district boundaries which is not specified in the resolution creating a lake improvement district may be undertaken, except by modifying the appropriate items listed in part 6115.0970, subpart 1, items A to E.

For an established district, any of the items listed in part 6115.0970, subpart 1, items A to E may be modified by petition to or resolution by the county board, in the same manner that a district is created.

Subp. 2. **Legal responsibilities and liabilities of lake improvement districts.** Nothing in these parts shall be construed to relieve a lake improvement district of the legal duties, obligations, or liabilities incident to the programs, plans, or actions of the district.

The lake improvement district shall assume all legal risks and liabilities, including those for damages or any injury to persons or property, arising from the construction, operation, maintenance, alteration, or abandonment of its programs, plans, or actions.

In the event of termination of the district, or failure of the district to meet its obligations, these responsibilities and liabilities shall fall upon the unit or units of government which established the lake improvement district.

Subp. 3. **Limited state liabilities.** The establishment of a lake improvement district shall not impose any liability upon the state of Minnesota, its officers, employees, agents, or consultants, for any damage or injury to any persons or property resulting from the activities of the lake improvement district.

Subp. 4. **Rights of lake improvement districts.** Nothing in these parts shall be construed to deprive any lake improvement district of such recourse to the courts as it may be entitled to under the laws of this state.

Subp. 5. **Inspections.** The commissioner shall be given prompt access to and inspection of all records, structures, facilities, and operations at all reasonable times as may be necessary to monitor compliance with the terms of existing permit and to ensure protection of the public health, safety, and welfare. The commissioner's inspections shall not relieve the lake improvement district from the full responsibility of providing adequate inspection and supervision for all programs and projects undertaken by the district.

Subp. 6. **Compliance with other laws and water management policies.** Lake improvement districts shall conform to federal, state, regional, and local laws, rules, and fish and wildlife, water, and related land management policies. Lake improvement districts shall obtain all necessary permits, as required by law, prior to implementing district purposes and programs.

Subp. 7. **Compliance by preexisting lake improvement districts.** Within one year following promulgation of these parts, lake improvement districts in existence prior to the promulgation of these rules shall submit to their county board and to the commissioner a certified copy of a document containing the

Copyright ©2008-2010 by the Revisor of Statutes, State of Minnesota. All Rights Reserved.

information required by part 6115.0970. This document shall also contain a report on the past and current activities and financial condition of the district.

The commissioner shall review the document and prepare an advisory report stating findings as to whether the district is consistent with these parts. The report may contain such recommendations as the commissioner determines is necessary to bring the district into compliance with these parts.

Within 60 days following the official filing of the commissioner's report with the county board, the board shall formally convene to consider the report. The county board shall give ten working days' notice to the commissioner of the time and place where it will convene to consider the commissioner's report. If the commissioner or the commissioner's representative does not appear, the report shall be publicly read into the record.

STATE WATER BANK PROGRAM

6115.1200 STATUTORY AUTHORITY AND PURPOSE.

These parts are promulgated under the authority of Minnesota Statutes, sections 103F.601, subdivisions 1 and 2, and 103G.315, subdivision 15. Their purpose is to implement and make specific the state water bank program and the indemnification process established by Minnesota Statutes, sections 103G.211 and 103G.221, for the purpose of compensating farmers for not converting certain kinds of wetlands to cropland.

Statutory Authority: *MS s 103F.601; 103G.315; 105.392; 105.415*

Posted: *June 11, 2008*

6115.1210 DEFINITIONS.

Subpart 1. **Adjacent land.** "Adjacent land" means any lands abutting a basin that is eligible for inclusion in the state water bank program.

Subp. 2. **Commissioner.** "Commissioner" means the commissioner of the Department of Natural Resources or designated agents.

Subp. 3. **Drain.** "Drain" means to conduct drainage activities that will remove or reduce the surface water from the basin. Acts constituting draining include, but are not limited to pumping, lowering the outlet, enlarging the outlet, tiling, or reducing the amount of water entering the basin. (Drainage does not include temporary water level reduction for conservation purposes.)

Subp. 4. **Fair market value.** "Fair market value" is an estimate of a property's value based upon standard and accepted land appraisal methods. The appraisal for eligible wetlands will estimate the potential value of the area as agricultural cropland less the cost of drainage.

Copyright ©2008-2010 by the Revisor of Statutes, State of Minnesota. All Rights Reserved.

Subp. 5. **Less than 50 acres in area.** "Less than 50 acres in area" means the area of a plane bounded by the ordinary high water mark which is a mark delineating the highest water level which has been maintained for a sufficient period of time to leave evidence upon the landscape. The ordinary high water mark is commonly that point where the vegetation changes from predominantly aquatic to predominantly terrestrial.

Subp. 6. **Professional soil classifier.** "Professional soil classifier" is a person who qualifies as a professional soil classifier on the basis of criteria specified by the Minnesota Association of Professional Soil Classifiers. The requirements are a bachelor of science degree in soil science or adequate credits (15 semester or 23 quarter hours) in soil science, and four years of field experience in mapping soils.

Subp. 7. **Public waters.** "Public waters" for the purposes of these rules means waters of the state so designated in a county by the process described in Minnesota Statutes, section 103G.201, and those waters that have been determined to be public waters or navigable waters by the district court or if appealed, by the state or federal Supreme Court.

Statutory Authority: *MS s 103F.601; 103G.315; 105.392; 105.415*

History: *17 SR 1279*

Posted: *June 11, 2008*

6115.1220 PROCEDURES.

Subpart 1. **Permit applications.** Application for a permit to drain basins that are potentially eligible for compensation from the department because of being declared public waters shall be made on such forms as the commissioner may provide and shall include all data specified by the form and any required application fees.

The applicant shall include the following information to enable the commissioner to determine the

feasibility, practicality, and lawfulness of the proposed drainage:

A. a statement by the owner that there are no burdens on the property or agreements which drainage would violate;

B. a demonstration by the owner that the right to use the outlet can be obtained;

C. a description of the proposed drainage project;

D. a demonstration of the project costs, showing how the costs were estimated, together with an explanation of why the investment would be profitable; and

E. a statement by a professional soil classifier that the basin would be high quality cropland. The determination shall be based on the following criteria. The kinds of soils that will that will qualify as high quality cropland are based on the following method arranged from best to poorest.

Rating Value	Soil Properties

Copyright ©2008-2010 by the Revisor of Statutes, State of Minnesota. All Rights Reserved.

1. Loamy or clayey mineral soils (loamy or clayey average particle size in the control section.)
2. Deep organic soils (Typic subgroups,) and shallow organic soils with a loamy or clayey substratum (Terric subgroups with loamy or clayey particle size.)
3. Shallow organic soils with a sandy or gravelly substratus (Terric subgroups with sandy or sandy skeletal particle size.)
4. Sandy or gravelly mineral soils (Aquents, aquepts, and Aquolls with sandy or sandy skeletal average particle size in the control section.)
5. Other soils (mostly soils with limnic materials dominating the control section.)

Growing degree days (GDD) will be used as a climatic parameter to use for accessing soil quality.

The groups from best to poorest are:

Rating Value	Climate Parameter
1.	More than 4400 GDD
2.	3400 - 4400 GDD
4.	Less than 3400 GDD

The following counties fall within the individual climate parameters:

More than 4400 GDD

Anoka	Lac Qui Parle	Rice
Big Stone	Le Sueur	Rock
Blue Earth	Lincoln	Scott
Brown	Lyon	Sibley
Carver	McLeod	Steele
Chippewa	Martin	Stevens
Cottonwood	Meeker	Swift
Dakota	Mower	Traverse
Dodge	Murray	Wabasha
Faribault	Nicollet	Waseca

Copyright ©2008-2010 by the Revisor of Statutes, State of Minnesota. All Rights Reserved.

Fillmore	Nobles	Washington
Freeborn	Olmsted	Watonwan
Goodhue	Pipestone	Wilkin
Hennepin	Ramsey	Winona
Houston	Redwood	Wright
Jackson	Renville	Yellow Medicine
Kandiyohi		

3400 - 4400 GDD

Aitkin	Hubbard	Otter Tail
Becker	Isanti	Pennington
Beltrami	Itasca	Pine
Benton	Kanabec	Polk
Carlton	Kittson	Pope
Cass	Koochiching	Red Lake
Chisago	Lake of the Woods	Roseau
Clay	Mahnomen	Sherburne
Clearwater	Marshall	Stearns
Crow Wing	Mille Lacs	Todd
Douglas	Morrison	Wadena
Grant	Norman	

Less than 3400 GDD

Cook	Lake	St. Louis

To arrive at a value, an index is determined by multiplying the soil property rating by the GDD rating. A value of four or less shall be considered high quality cropland.

The determination of soil properties shall be done by a professional soil classifier with at least one observation of soil properties to depths of 50 inches for each ten acres of the wetland. Points of

Copyright ©2008-2010 by the Revisor of Statutes, State of Minnesota. All Rights Reserved.

observations should be located systematically in the wetland, recorded on a map, and a log of soil made for each observation. The information shall be included with the permit application.

Subp. 2. **Eligible water basins.** If the public water basin is eligible for compensation the commissioner shall mail to the applicant, within 60 days of receipt of an application for a permit to drain, the various choices of indemnification, to include:

A. An offer:

(1) to place the basin in the state water bank program, together with a sample water bank agreement;

(2) to acquire the basin and such interest as is necessary to make entry upon the acquired area available to the public;

(3) to acquire an easement in the nature of a conservation restriction as described by Minnesota Statutes, sections 84.64 and 84.65, together with a sample of such an easement; or

(4) to acquire a lease on the basin, together with a sample lease agreement.

B. A statement:

(1) If such be the case, that the wetland appears to be eligible for the federal water bank program and who the landowner should contact. The state program, however, does not incur any obligations on the federal program and if the landowner chooses to select this option the landowner will be subject to the federal program's priorities and procedures.

(2) That the landowner may suggest any other appropriate indemnification method, along with the proposed terms and conditions that the landowner would like to have included.

(3) That the landowner and commissioner may agree to include adjacent property in the terms of the agreements.

(4) That the landowner may choose any one of the indemnification offers or any other method of indemnification that the commissioner will agree to.

C. An explanation of the balance of these procedures in order to establish the dollar amount of each offer as soon as the landowner specifies what adjacent land, if any, the landowner would like to have included.

Subp. 3. **Ineligible areas.** If the area is ineligible for compensation the commissioner will so inform the applicant and advise the applicant that a Minnesota Statutes, section 103G.311 hearing on the issue of eligibility may be demanded.

Subp. 4. **Right to drain basin.** If within 60 days of receipt of an application for a permit to drain, the commissioner does not mail the landowner a choice of indemnification, the landowner is entitled to drain the basin.

Subp. 5. **Adjacent land.** Upon receipt of an offer of indemnification, the landowner shall inform the commissioner of the amount, if any, and location of adjacent land that the landowner would like to have included in the agreement, and what alternative, if any, methods of indemnification the landowner would like the commissioner to consider.

Copyright ©2008-2010 by the Revisor of Statutes, State of Minnesota. All Rights Reserved.

Subp. 6. **Certification.** Within 60 days of receiving the above information the commissioner shall complete an appraisal of the property and submit it to the Department of Administration for certification. If it is not so submitted within the 60-day period, the landowner may drain the basin.

Subp. 7. **Negotiations.** When an appraisal has been certified, the commissioner shall inform the landowner of the dollar amount of each offer, and begin negotiations. The outcome of the negotiations can be either:

A. the landowner accepts one of the offers made or agreed to by the commissioner;

B. the landowner places the basin in a federal water bank program;

C. the landowner signs a consent to condemnation pursuant to Minnesota Statutes, section 84.027, subdivision 9, specifying which of the methods of indemnification offered or agreed to by the commissioner that the landowner has selected; or

D. the landowner does none of the above, in which case the basin cannot be drained unless and until a new application for a permit to drain is submitted and the commissioner does not make an offer of indemnification.

Subp. 8. **Sale of basin to commissioner.** If the landowner chooses to sell the basin and access area to the commissioner the landowner shall obtain from the county board of commissioners the approval to sell the property as required by Minnesota Statutes, section 97A.145. The commissioner must be supplied with a copy of the board's resolution and if the county board refuses approval, the applicant must select from among those options not requiring county board approval. This procedure does not apply in those counties where blanket approval to sell the property to the state has been granted to those landowners who are eligible for compensation under Minnesota Statutes, section 105.391, subdivision 3.

Subp. 9. **Recording and indexing documents.** Water bank, lease, and easements obtained on an area shall be recorded and indexed in the office of the county recorder in the county where the basin lies.

6115.1230 EFFECTIVE DATE.

These parts apply to applications for permits to drain received after the water basin involved has been designated a public water pursuant to Minnesota Statutes, section 103G.201, or has been identified as public waters or navigable waters by a district court or if appealed, by the state or federal Supreme Court.

6115.1240 PAYMENT RATES.

Subpart 1. **Water bank program.** Annual payment rates for the state water bank program will be determined by multiplying the fair market value of the water basin and any adjacent lands by five percent.

Subp. 2. **Water basin and adjacent lands.** Annual lease payments for the water basin and any adjacent lands will be based on a fair market rental rate.

Copyright ©2008-2010 by the Revisor of Statutes, State of Minnesota. All Rights Reserved.

Subp. 3. **Easements.** Conservation restrictions in the form of easements will be established by an appraisal and their lengths will be subject to negotiation.

Subp. 4. **Other method of indemnification.** The rate for any other method of indemnification that is agreed to will be negotiated with the landowner and judged on its merits based upon the proposed restrictions and their relationship to the other payment rates.

Posted: *June 11, 2008*

6115.1250 TERMS FOR WATER BANK AND LEASE AGREEMENTS.

Subpart 1. **Agreement period and beginning date.** Agreement period and beginning date:

A. Eligible basins are placed in the state water bank program for a period of ten calendar years and under a lease agreement for, not to exceed, 20 calendar years.

B. The lease agreement is continuous and shall transfer with the property if ownership changes during the time of the lease agreement.

C. A water bank or lease agreement finalized during the current calendar year shall be effective January 1 of that year. Exception: in cases where compliance with the terms of agreement cannot be rendered during the current calendar year, the beginning date of the agreement shall be January 1 of the following year.

D. Water bank or lease payments for the first year of an agreement will be made as soon as possible after an agreement has been finalized. Payments for the duration of a water bank or lease agreement will be made on or about August 1 of each continuous year thereafter.

Subp. 2. **Terms.** Terms:

A. Waterbasins. In return for receipt of an annual payment the landowner must agree not to adopt any practice which would tend to defeat the purposes of the agreement. At a minimum, the designated basin may not be:

(1) Drained, burned, filled, clipped, or otherwise used in such a manner that would effect its wetland character. Exception: noxious weeds may be controlled by the landowner by spot clipping and spot spraying. If cutting is used the area should not be clipped closer than six inches so as to protect nesting wildlife.

(2) Harvested for agricultural purposes.

(3) Grazed.

(4) Used as a source of irrigation water.

(5) Used as a receptacle for draining other wetlands.

Exception: the commissioner may approve designated acreage to receive limited drainage waters if such use is in keeping with sound wetlands management and prescribed in a mutually agreed upon conservation plan.

Copyright ©2008-2010 by the Revisor of Statutes, State of Minnesota. All Rights Reserved.

B. Adjacent lands. On finding it desirable the commissioner may mutually agree with the landowner upon the amount and location of adjacent lands to include in the agreement. Up to one acre of adjacent land may be obtained for each acre of water basin. The commissioner may negotiate and outline a conservation plan for the water basin and adjacent lands. Upon signing the agreement, the landowner shall agree to effectuate the wetland conservation and development plan. Terms that may be included are:

(1) development of food and/or cover plots;

(2) specified planting and harvesting dates;

(3) areas desirable for permanent cover;

(4) habitat improvement methods such as: clearing, tilling, reestablishment of former wetlands or the creation of new wetlands, fencing to protect the area;

(5) advice on conservation and development practices; and

(6) any other mutually agreed upon practice that would effectuate wetland conservation and development.

Subp. 3. **Signatures.** The agreement shall be on forms provided by the commissioner and shall be signed by the owner of the designated acreage, and the commissioner.

Statutory Authority: *MS s 103F.601; 103G.315; 105.392; 105.415*

History: *17 SR 1279*

Posted: *June 11, 2008*

6115.1260 MODIFICATIONS OF WATER BANK AND LEASE AGREEMENTS.

Subpart 1. **In general.** The commissioner and the landowner may mutually agree to any modification of agreement terms that may be desirable to carry out the purposes of the program or facilitate its administration. Exception: no changes in payment rates for acreage under agreement is authorized during the term of the water bank or lease agreement.

Subp. 2. **Change in ownership of lands underlying public waters.** All landowners shall notify the commissioner of the sale of property that is covered by the water bank or lease agreement. Upon transfer of an individual's right and interest in lands subject to a water bank agreement during the agreement period, the former landowner forfeits all rights to further payments under the agreement and refunds to the state all payments received thereunder during that year of the transfer. Forfeiture of payments is not required for those participating in a lease agreement nor if the transferee of any such land agrees with the commissioner to assume all obligations of the former owner.

The new landowner may choose not to participate in the water bank program; however, any water declared public shall not be drained. If an alternative form of indemnification is desired, or if the new owner wishes to have payment rates adjusted on the existing water bank agreement, a permit application will have to be submitted to the commissioner to initiate the procedures in these parts. The requirement for

Copyright ©2008-2010 by the Revisor of Statutes, State of Minnesota. All Rights Reserved.

soils information and borings shall be waived on those basins that have been determined eligible for the water bank program by previous permit applications.

When two or more farms are combined that share mutual public waters the landowner who is adding property shall have the option of adding the new property to the original agreement, continuing the former owners' agreement, or decide not to participate in the program and not be able to drain the basin.

When a transfer of ownership occurs on or before August 1 of the current calendar year and the new owner agrees to continue the former owner's obligation, payments due will be made to the new owner.

Subp. 3. **Registration of modification.** All modifications will be completed on amendment forms provided by the commissioner. Modifications will be noted on the original agreement and the original amendment forms will be retained by the commissioner.

Statutory Authority: *MS s 103F.601; 103G.315; 105.392; 105.415*

History: *17 SR 1279*

6115.1270 AGREEMENT TERMINATIONS.

Subpart 1. **Forfeit of rights to further payments.** Upon termination of an agreement the landowner shall forfeit all rights to further payments.

Subp. 2. **Termination by mutual consent.** The commissioner may terminate any agreement with mutual consent of the landowner if the commissioner determines that termination would be in the public interest. If such be the case, no refund of payments made under the agreement is required.

Subp. 3. **Refund of payments.** The landowner must refund to the state all payments, partial or in full, received under the agreement upon any violation of the agreement terms during the time that the landowner has control of the property.

A. Subject to the commissioner's determination that the violation is material and of the nature that warrants termination of the agreement the landowner shall:

(1) refund to the state all payments received;

(2) forfeit all rights to further payments;

(3) not be entitled to drain the affected basin; and

(4) not have the basin considered for a permit to drain or be allowed compensation under Minnesota Statutes, sections 103G.211 and 103G.221, until a transfer of ownership has taken place.

B. Subject to determining that the violation does not warrant termination of the agreement, the commissioner may require partial refunds or make payment adjustments as the commissioner deems appropriate.

Subp. 4. **Termination action.** The commissioner shall notify each party to the agreement of the termination:

Copyright ©2008-2010 by the Revisor of Statutes, State of Minnesota. All Rights Reserved.

A. the reason for termination;

B. the amount of payment refund due;

C. that the landowner is no longer required to comply with the agreement terms and that the public waters cannot be drained; and

D. that the landowner may challenge the termination by demanding a hearing under Minnesota Statutes, section 103G.311.

Statutory Authority: *MS s 103F.601; 103G.315; 105.392; 105.415*

History: *17 SR 1279*

Posted: *June 11, 2008*

6115.1280 EXTENSION OF WATER BANK OR LEASE AGREEMENT.

At the end of an agreement period the commissioner shall offer the landowner the landowner's choice of the five indemnification offers without requiring a new application for a permit to drain. The landowner has 60 days to notify the commissioner, in writing, if the landowner will be:

A. continuing the former agreement terms, subject to any rate redetermination; or

B. dissolving the former agreement; and

C. changing to another form of indemnification; or

D. deciding not to participate in the program with the knowledge that the basin cannot be drained.

If the landowner chooses to select another indemnification method, the choice must be specified in the landowner's notice to the commissioner.

If the notification of the landowner's intent to continue in the program is not given, the landowner will be required to submit an application for a permit to drain the basin to establish future eligibility to the water bank program.

Upon receipt of the landowner's choice, the commissioner shall conduct an appraisal to establish the fair market value of the property. Once completed, the agreement may be finalized.

AGRICULTURAL DIKE CONSTRUCTION ALONG THE

Copyright ©2008-2010 by the Revisor of Statutes, State of Minnesota. All Rights Reserved.

RED RIVER OF THE NORTH AND BOIS DE SIOUX RIVERS

6115.1300 PURPOSE.

The purpose of these parts is to provide for the orderly and consistent review of permit applications to construct, relocate, rebuild, or alter agricultural dikes along the Red River of the North and Bois de Sioux Rivers in order to assure that the granting of such permits would be in the best interests of the people of Minnesota and North Dakota. These parts are mutually applicable in both states. The authority to establish these joint criteria is granted to the commissioner of Natural Resources in Minnesota Statutes, sections 103G.105, 103G.245, and 471.59 and to the North Dakota State Water Commission by Sections 61-02-24 and 61-16-15 of the North Dakota Century Code. The two states recognize that establishment of these parts governing the issuance, review, and denial of permits to construct, relocate, rebuild, or alter agricultural dikes along the boundary rivers is but the first step in the exercise of joint control over those activities which could contribute to an increased flood potential of these rivers. The two states further recognize the need to exercise this joint control in that water management decisions which appear logical in a local or statewide context may have negative interstate and international impacts.

These parts are being established at this time because there is a current need to provide a basis for the review of existing, unauthorized agricultural dikes and permit applications for the construction of additional agricultural dikes along the boundary waters. Local land owners view such dikes as interim solutions to local flood problems.

Statutory Authority: *MS s 103G.105; 103G.315; 105.415; 105.49; 471.59*

Posted: *June 11, 2008*

6115.1310 SCOPE.

These parts governing the review, issuance, and denial of permits to construct, relocate, rebuild, or alter agricultural dikes along the boundary rivers pertain to all such dikes located within the floodplains of the Red River of the North and the Bois de Sioux Rivers. Floodplain areas of the Red River of the North are defined by Appendix O, Volume 8, of the Souris-Red-Rainy Basins Comprehensive Study as Red River of the North Main Stem Regional Floodplain Area, and the floodplain of the Bois de Sioux River is defined by the U.S. Geological Survey one percent chance of recurrence area flood quadrangles. These rules apply to dikes constructed on tributaries within the floodplains of these boundary rivers. These parts shall be superseded by local authority adoption of commissioner approved floodplain ordinances which include agricultural diking provisions as conditional uses.

6115.1320 DEFINITIONS.

Subpart 1. **Scope.** For the purposes of these parts certain terms or words used herein shall be interpreted as follows.

Subp. 2. **Boundary rivers.** "Boundary rivers" means the Red River of the North and the Bois de Sioux River as they form a natural boundary between the states of Minnesota and North Dakota.

Copyright ©2008-2010 by the Revisor of Statutes, State of Minnesota. All Rights Reserved.

Subp. 3. **Dike.** "Dike" means an embankment constructed of earth and/or other suitable materials to protect agricultural lands.

Subp. 4. **Farmstead.** "Farmstead" means a farm dwelling and/or associated farm buildings.

Subp. 5. **Flood frequency.** "Flood frequency" means the average frequency, statistically determined, for which it is expected that a specific flood stage or discharge may be equalled or exceeded. This frequency is usually expressed as having a probability of occurring, on the average, once within a specified number of years.

Subp. 6. **Flood waters.** "Flood waters" means those waters which temporarily inundate normally dry areas adjoining a watercourse. This inundation results from an overflow of the watercourse caused by excessive amounts of rainfall and/or snowmelt which exceed its capacity.

Subp. 7. **Public waters.** "Public waters" means all natural and altered natural watercourses with a total drainage area greater than two square miles, except that trout streams officially designated by the commissioner shall be public regardless of the size of their drainage area.

Subp. 8. **Watercourse.** "Watercourse" means a channel in which a flow of water occurs either continuously or intermittently in a definite direction. The term applies to either natural or artificially constructed channels.

6115.1340 DESIGN CRITERIA.

Subpart 1. **Dike setbacks and elevation.** Dikes are to be constructed at a location and elevation so as not to cause an increase in elevation of the 100-year frequency flood of more than one-half foot at any point along the river. Calculation of the effects of the dikes shall be based on an assumed equal degree of encroachment along the opposite side of the river. If mutual agreement has been reached between persons on both sides of the river, dikes on one side may utilize up to the entire increase in flood elevation allowable. In all instances the applicants maintain the liability for damages resulting from any and all activities.

Subp. 2. **Dike dimensions.** Dike top width shall not be less than six feet. Side slopes shall not be steeper than 3:1, except where slope stability analysis and slope erosion control can justify steeper slopes. No organic soil or material shall be allowed in the foundation of the fill of dikes.

Subp. 3. **Vegetative cover and riprap.** A protective cover of grasses shall be established on all exposed surfaces of the dike. Riprap shall be used where required for control of erosion.

Copyright ©2008-2010 by the Revisor of Statutes, State of Minnesota. All Rights Reserved.

Subp. 4. **Interior drainage.** Dikes shall have provisions for interior drainage. The design shall include plans to handle the discharge from the drainage area based on drainage design requirements for the local area.

Posted: *June 11, 2008*

6115.1350 HYDROLOGIC DATA FOR DESIGN.

The North Dakota State Water Commission and the Minnesota Department of Natural Resources shall provide the discharges and corresponding elevations of the various frequency floods (and other available flood data), in relation to known historic floods, for use in dike design.

Statutory Authority: *MS s 103G.105; 103G.315; 105.415; 105.49; 471.59*

6115.1360 DIKES ACROSS NATURAL WATERWAYS AND LEGAL DRAINS.

Dikes shall not be constructed across public waters or watercourses without permit from the commissioner of natural resources, under Minnesota Statutes, section 103G.245. Dikes constructed across legal drains or public ditch systems shall require the approval of the appropriate local authority (watershed district, county, city, etc.).

Statutory Authority: *MS s 103G.105; 103G.315; 105.415; 105.49; 471.59*

Posted: *June 11, 2008*

6115.1370 FARMSTEAD DIKING.

Within an existing dike system, ring dikes around individual farmsteads shall not require dike permits if they are not provided with tiebacks to existing roadways or dikes. Ring dikes provided with tiebacks shall be considered part of the overall dike system and will be required to secure diking permits. Outside the dike system there shall be no limitations on tiebacks of dikes around farmsteads. However, appropriate authorization must be obtained from the local land use authority consistent with adopted codes or ordinances.

Statutory Authority: *MS s 103G.105; 103G.315; 105.415; 105.49; 471.59*

6115.1380 PERMIT APPLICATION.

Subpart 1. **Forms; plans and specifications.** All applications submitted by the owner to construct, to relocate, rebuild, or alter dikes shall be made on forms provided by the commissioner and shall be accompanied by two complete sets of plans and specifications. Such plans and specifications shall include the following:

A. a general location map with a minimum scale of 1" = 800' showing the following: location of the dike with respect to the watercourse; location of field inlets to provide for internal drainage; and location of legal drains and natural channels tributary to the main river channel;

Copyright ©2008-2010 by the Revisor of Statutes, State of Minnesota. All Rights Reserved.

B. detailed cross-sections of the dike showing elevation, in relation to mean sea level, and side slopes; and

C. other data as deemed appropriate by the commissioner to properly evaluate the application for permit.

Subp. 2. **Cross-sections.** After review of the information required above and other available data, the state agency to which the application is made shall determine the location and number of required cross-sections of the river channel and overland areas. These locations shall be provided to the applicant who shall then provide the required cross-section data. The applicant shall undertake and agree to pay the expenses incurred in securing these cross-sections.

Subp. 3. **Joint permit applications.** Joint permit applications involving two or more landowners or a permit application on behalf of two or more landowners will be accepted by the state agencies. These permit applications, taken together, must meet the above rules.

Subp. 4. **Joint administration.** A copy of each application for a permit shall be forwarded by the state agency receiving the initial application to the other state for comment and recommendation before final approval is granted. If no response is received within 30 days, the commissioner shall process the permit without such comments or recommendations.

Subp. 5. **Permit revocation.** The applicant shall provide for certification by a licensed land surveyor, engineer, or other qualified person or agency that the finished dike elevations are not higher than those approved by the commissioner. The permit will be revoked for failure to provide this certification. The permit may be revoked for failure to construct the dike in accordance with the plans and specifications submitted. Structural alteration of the dike without permission of the appropriate state agency will also result in having the permit revoked.

Subp. 6. **Reconstruction; maintenance.** Reconstruction of any authorized dike may be performed after notification to the commissioner of the repair needed. Permittee shall again certify the repair concurrent with this section. The maintenance of dikes must include periodic removal of woody vegetation (for example, trees and shrubs) which may become established on the embankment.

Subp. 7. **General administration.** All applicants for permit to construct dikes shall be subject to the provisions of parts 6115.0240 to 6115.0260.

6115.1390 EXCEPTION TO CRITERIA.

Under special circumstances, exceptions to the dike rules may be authorized on an individual basis but they must have the concurrent approval of the North Dakota state engineer, local water management board in North Dakota, Minnesota Department of Natural Resources, and local watershed district in Minnesota. Factors that will be considered include but shall not be limited to dike setback line, location of farmsteads, property lines, existing roads, stream velocity, environmental effects, and acquisition of flowage rights. Request for exceptions must be accompanied by a plan satisfactory to all agencies.

6115.1400 APPLICATION OF RULES TO EXISTING DIKES.

These parts shall apply to all unauthorized dikes constructed in the past for the protection of those agricultural lands located within the floodplains of the Red River of the North and the Bois de Sioux, as defined in part 6115.1310. Exceptions are farmstead dikes if they meet the provisions of part 6115.1370.

The commissioner shall have the authority to order removal, modification, or reconstruction of dikes not conforming to these parts.

Statutory Authority: *MS s 103G.105; 103G.315; 105.415; 105.49; 471.59*

CONSOLIDATED CONSERVATION AREAS DRAINAGE PROJECTS

6115.1500 PURPOSE.

The purpose of parts 6115.1500 to 6115.1550 is to establish criteria and procedures for determining drainage benefits to state-owned lands in consolidated conservation (con-con) areas administered under Minnesota Statutes, chapter 84A. Con-con areas are found in parts of Aitkin, Beltrami, Koochiching, Lake of the Woods, Mahnomen, Marshall, and Roseau Counties.

Statutory Authority: *MS s 84A.55*

History: *32 SR 1697*

6115.1510 DEFINITIONS.

Subpart 1. **Scope.** The terms used in parts 6115.1500 to 6115.1550 have the meanings given in this part.

Subp. 2. **Commissioner.** "Commissioner" means the commissioner of natural resources or the commissioner's designated representative.

Subp. 3. **Department.** "Department" means the Department of Natural Resources.

Subp. 4. **Drainage.** "Drainage" means any method for removing or diverting waters from wetlands. The methods include, but are not limited to, excavating an open ditch, installing subsurface drainage tile, filling, diking, or pumping.

Subp. 5. **Drainage authority.** "Drainage authority" has the meaning given under Minnesota Statutes, section 103E.005, subdivision 9.

Subp. 6. **Drainage project.** "Drainage project" means a new drainage system, an improvement of a drainage system, an improvement of an outlet, a lateral, a repair, or a redetermination of benefits involving state-owned lands in consolidated conservation areas administered under Minnesota Statutes, chapter 84A, where:

A. the drainage authority will make assessments to state-owned lands; or

B. the commissioner will be asked or must consider whether to participate in the project through assessments or a lump sum, by joining the petition, by consent, or by approval.

Copyright ©2008-2010 by the Revisor of Statutes, State of Minnesota. All Rights Reserved.

Subp. 7. **Drainage system.** "Drainage system" has the meaning given under Minnesota Statutes, section 103E.005, subdivision 12.

Subp. 8. **Improvement.** "Improvement" means the tiling, enlarging, extending, straightening, or deepening of an established and constructed drainage system, including construction of ditches to reline or replace tile and construction of tile to replace a ditch.

Subp. 9. **Lateral.** "Lateral" has the meaning given under Minnesota Statutes, section 103E.005, subdivision 15.

Subp. 10. **Public waters.** "Public waters" has the meaning given in Minnesota Statutes, section 103G.005, subdivision 15.

Subp. 11. **Public waters wetlands.** "Public waters wetlands" has the meaning given in Minnesota Statutes, section 103G.005, subdivision 15a.

Subp. 12. **Repair.** "Repair" means to restore all or a part of a drainage system as nearly as practicable to the same condition as originally constructed and subsequently improved, including resloping of ditches and leveling waste banks if necessary to prevent further deterioration, realignment to original construction if necessary to restore the effectiveness of the drainage system, and routine operations that may be required to remove obstructions and maintain the efficiency of the drainage system. "Repair" also includes:

A. incidental straightening of a tile system resulting from the tile-laying technology used to replace tiles; and

B. replacement of tiles with the next larger size that is readily available, if the original size is not readily available.

6115.1520 DRAINAGE PROJECTS.

Subpart 1. **Notification and documentation.** For the commissioner to consider participating in a drainage project that would have assessments within a consolidated conservation area, the drainage authority must follow the procedures described in this subpart. The drainage authority must notify the commissioner, in writing and as soon as practicable, with specifics about the proposed project. The specifics must describe the purpose of the project and what kind of project it is. The drainage authority must show the extent of the project on a map. The drainage authority must provide the commissioner with copies of all written documents, including any petition and engineer's report that have been filed or used in connection with the drainage project proceedings, as they are available.

Subp. 2. **Investigation.** After receiving notification and all documentation required under subpart 1, the commissioner must complete an investigation to determine whether the proposed drainage project benefits state-owned lands for the purposes for which they were established. In the investigation, the commissioner must:

A. determine, which, if any, state-owned lands are positively impacted by the proposed drainage project according to subpart 3; and

Copyright ©2008-2010 by the Revisor of Statutes, State of Minnesota. All Rights Reserved.

B. determine which, if any, state-owned lands are negatively impacted by the proposed drainage project according to subpart 4.

Subp. 3. **Positive impacts.** Positive impacts to state-owned lands occur when a proposed drainage project allows the department or department's lessee to continue to use or enhances its ability to use drainage to achieve management purposes as provided in Minnesota Statutes, section 84A.55. The following criteria are evidence that the department uses drainage to achieve a management purpose:

A. the department utilizes a drainage system to outlet water into a public ditch from agricultural cropland it manages;

B. the department leases the land for commercial purposes such as agriculture, agro-forestry, aquaculture, wild rice paddies, peat mining, or mineral extraction, and the lessee utilizes a drainage system to outlet water into a public ditch from the leased lands;

C. the department petitions for a drainage project;

D. the department outlets water from state-owned lands into a public ditch from an impoundment that is designed and used exclusively for wildlife management purposes;

E. timber production is improved by the project; or

F. wildlife habitat is improved by the project.

Subp. 4. **Negative impacts.** Negative impacts to state-owned lands occur when a drainage project adversely affects the management of the land for its intended purposes. The following criteria are evidence that a drainage project negatively impacts state-owned lands. The drainage project:

A. degrades public waters, public waters wetlands, or wetlands on state-owned lands;

B. causes direct physical disturbance to rare species or significant natural communities through project activities such as, but not limited to, ditching and depositing soils;

C. causes an alteration of the hydrology that disturbs rare species, natural communities, or peatland features;

D. causes an alteration of the hydrology that degrades designated peatland scientific and natural areas;

E. restricts management options for state-owned lands; or

F. results in the reduction or elimination of access to state-owned lands.

6115.1530 DETERMINING BENEFIT AND PARTICIPATION.

Subpart 1. **Commissioner's determination.** Following the investigation under part 6115.1520, for all drainage projects except those classified as repairs, the commissioner must determine whether the drainage project benefits state-owned lands and whether to participate in the project. In making the determination, the commissioner shall evaluate state-owned lands, on a parcel-by-parcel basis, with each parcel consisting of no more than 40 acres. A drainage project benefits a parcel of state-owned land only when the investigation shows that the positive impacts outweigh the negative impacts to that

Copyright ©2008-2010 by the Revisor of Statutes, State of Minnesota. All Rights Reserved.

parcel of state-owned land. Where the commissioner determines that the project results in a net benefit to state-owned lands, the commissioner shall participate in the project. Having determined to participate, the commissioner shall authorize the imposition of assessments for the project on the lands in any amounts the commissioner determines or may make lump sum contributions to the county or other public funds established for the payment of the cost of the project. The commissioner may also set conditions to modify the project before approving or joining a petition. Before cooperating in a project by joining in the petition or consenting to or approving it, the commissioner may identify conditions that must be satisfied or modifications that must be made in the proposed project if such conditions or modifications are necessary to ensure that the project will benefit state-owned lands in con-con areas.

Subp. 1a. **Commissioner's determination for repairs.** Following the investigation under part 6115.1520, for drainage projects considered repairs, the commissioner must determine whether the repair project benefits state-owned lands and whether to participate in the project. In making the determination, the commissioner, following consultation with drainage authorities, shall develop a table that identifies the benefits for each 40-acre parcel. A repair project benefits a parcel of state-owned land only when the investigation shows that the positive impacts outweigh the negative impacts to that parcel of state-owned land. Where the commissioner determines the project results in a net benefit to state-owned lands, the commissioner shall participate in the project. Having determined to participate, the commissioner shall authorize the imposition of assessments for the projects on the lands in any amounts the commissioner determines or may make lump sum contributions to the county or other public funds established for the payment of the cost of the project. The commissioner may also set conditions to modify the project before approving or joining the petition. Before cooperating in a project by joining in the petition or consenting to or approving it, the commissioner may identify conditions that must be satisfied or modifications that must be made in the proposed project if such conditions or modifications are necessary to ensure that the project will benefit state-owned lands in con-con areas.

Subp. 2. **Routine repair exception.** If a drainage authority's notification and documentation made under part 6115.1520, subpart 1, shows that the total cost of a proposed drainage repair under Minnesota Statutes, section 103E.705, is less than $20,000 and the commissioner has previously determined the benefits to the state-owned lands within that drainage system, the commissioner may, without investigation, authorize the imposition of assessments for the proposed repair proportionate to the overall benefits to the state-owned lands as previously determined by the commissioner. If the commissioner authorizes assessments under this subpart, the commissioner need not issue the findings and report required under part 6115.1540. Where the commissioner does not authorize an assessment for a repair under this subpart, the commissioner shall issue the findings and report as set forth in part 6115.1540.

Statutory Authority: *MS s 84A.55*

History: *32 SR 1697*

Posted: *June 11, 2008*

6115.1540 FINDINGS AND REPORT.

Upon completion of the table described in part 6115.1530, subpart 1a, for repairs and following the investigation under part 6115.1520, the commissioner must provide the drainage authority with findings within 60 days after the commissioner has received all notifications and documentation required under part 6115.1520, subpart 1. For repairs over $20,000, and upon completion of the table described in part 6115.1530, subpart 1a, the commissioner must provide the drainage authority with findings within 60 days.

Copyright ©2008-2010 by the Revisor of Statutes, State of Minnesota. All Rights Reserved.

The findings must convey the results of the investigation, state whether the commissioner will participate in the project, and state the reasons for the commissioner's decisions. The findings must identify which state-owned lands are benefited and which are not and set forth any conditions the commissioner attaches to the project and the amount of the contribution if the commissioner will participate.

Statutory Authority: *MS s 84A.55*

History: *32 SR 1697*

Posted: *June 11, 2008*

6115.1550 APPEAL.

The findings and report of the commissioner under part 6115.1540 may be reviewed by a declaratory judgment action in the district court of the county wherein the proposed project, or any part thereof, would be undertaken. Judicial review under this part must be initiated within 60 days after receipt of the findings by the drainage authority.

Statutory Authority: *MS s 84A.55*

History: *32 SR 1697*

Minnesota Water Statutes and Rules

What are Statutes?

Statutes are laws that apply to all citizens and cover a variety of topics. Laws refer to all laws passed by the Legislature, which are subsequently bound in the Session Laws of that year. Statutes are a codification of those laws, which are compiled and published every year as Minnesota Statutes. By codifying laws into Minnesota Statutes, the laws are placed into context of statutes that have been on the books in previous years.

What are Rules?

Administrative rules are not actually enacted by the Legislature. Rather, the Legislature merely gives the state agency or unit the authority to establish its own rules. These administrative rules have the force and effect of law.

An agency may adopt a rule only after the legislature has enacted a law granting this authority to the agency. An agency rule that is adopted under the rulemaking provisions of **Minnesota Statutes, chapter 14**, has the force and effect of law. ***Rulemaking in Minnesota: A Guide*** explains each step of the rulemaking process in Minnesota.

CHAPTER 10
GENERAL

10. INTRODUCTION

10.1 Acknowledgment

The technical guidance in this document has primarily been taken from Design of Small Dams, 3rd Edition, U.S. Bureau of Reclamation, Earth Dams and Reservoirs TR-60, NRCS, Earth and Rockfill Dams – General Design and Construction Considerations, EM 1110-2-2300, U.S. Army Corps of Engineers, Technical Manual: Conduits through Embankment Dams, FEMA.

10.2 Applicability

This document, Guidance for the Design of Dams in Mississippi ("Guidance"), should be used as a guide in the design and preparation of plans, specifications and engineering reports for dams, insofar as this guidance is applicable to normal situations for an individual project. Plans, specifications, contract documents and engineering reports required by regulation shall conform to the applicable items in this Guidance.

This document is not a regulation or a standard and has therefore not been adopted by the Commission on Environmental Quality. However, owners, consulting engineers, and other parties involved in the construction of any dam in the State should be aware of, and must comply with, the Commission's "Dam Safety Regulations LW-4", and all other applicable laws and regulations. This guidance does not supersede any existing laws, ordinances, regulations, or standards. If such conflicts arise, the designer should contact the Division of Dam Safety and the other appropriate agencies for instruction on how to proceed.

It should be recognized that simply complying with the items herein does not ensure that a design is correct, or even adequate, but only minimally acceptable to the Department. High quality projects will routinely exceed the minimum standards stipulated herein, and such quality will likely be reflected in the performance, value and satisfaction obtained from such a design.

There are some differing requirements depending on the hazard classification (Low, Significant or High), **the dam height** (Small dams are those less than 25 feet in height, Medium dams are greater than 25 feet and less than 50 feet in height and Large dams are greater than 50 feet in height), and **the storage volume** (Small lakes are less than 150 acre-feet maximum storage, Medium lakes are greater than 150 acre-feet maximum storage and less than 1,000 acre-feet maximum storage and Large lakes are greater than 1,000 acre-feet maximum storage).

Currently, the Dam Safety Regulations LW-4 do not require Low Hazard dams be designed by a registered professional engineer (state law or local ordinances may have different requirements, see previous paragraph). However, owners should consider having the spillway of their Low Hazard dam designed to High Hazard standards. This will help the owner avoid the risk of having to upgrade their dam if the hazard classification changes due to downstream development. Further, the Office of Land and Water, Division of Dam Safety neither warrants

nor assumes any responsibility for any design of any project governed by this Guidance. It is the owner's and/or design engineer's responsibility to ensure that such project designs and specifications are correct and adequate. Should anything contained herein appear to conflict with good design practice, such instance should be brought to the Division of Dam Safety's attention immediately for resolution.

Plans, specifications and engineering reports that vary from this guidance may be submitted and approved (as specified by applicable regulations) when properly justified by the consulting engineer and/or supported by reference to Design of Small Dams 3rd Edition, NRCS technical releases, U.S. Army Corps of Engineers engineering manuals, or other appropriate publications. Although the words "shall" and "must" are used extensively, they are to be interpreted in the context of this section (10.2 Applicability) of the Guidance.

It is recognized that this Guidance does not completely address every conceivable situation concerning the design, inspection, testing, or contracting of dam construction. Therefore, when any issue arises which is not explicitly covered by the Guidance, the Division of Dam Safety may require additional documentation or justification of the reasonableness or adequacy of the plans, specifications and engineering reports. The Division of Dam Safety may withhold completion of review or approval until such documentation, justification, or document changes are submitted and determined acceptable.

Any revisions, changes, addenda, etc. to reviewed and/or approved plans or specifications shall also be made in accordance with this section. Such revisions shall be submitted to the Division of Dam Safety for review and approval. Record drawings (As-built) clearly showing such alterations shall be submitted to the Division of Dam Safety at the completion of the work.

11. PLANS

11.1 General

___ All plans shall bear a suitable title block showing the name of the project, the name of the owner and a clear indication whether the owner is a state agency, municipality, district, association, institution, or private individual. The plans shall be signed, sealed, and dated by the Mississippi Registered Professional Engineer responsible for their development in a manner consistent with the requirements of the State Board of Registration for Professional Engineers and Land Surveyors, as they apply generally to the practice of engineering. Nothing herein is to be construed as allowing any such work to be performed other than by or under the direct supervision of a Registered Mississippi Professional Engineer.

___ The plans shall be of professional quality, clear and legible (suitable for microfilming). They shall be drawn to a scale that will permit all necessary information to be plainly shown. They shall show the scale in feet, a graphical scale, the north point, and date. Datum used shall be indicated. Locations and data of test borings and wells, when made, should be shown on the plans or reference made to their location in the geotechnical report. Generally, the plans should be full size, but not larger than 30 inches x 42 inches.

Submittal of draft plans for review may be legal size (8.5 x 14) or the AutoCAD project file may be sent in for review. Final submittal of plans shall consist of two (2) complete sets.

___ The plans for dams shall include a site plan which shows the surrounding property, all property lines, and ownership information as recorded in the tax assessor's record. The plans shall include the location, orientation and outline of the lake and dam relative to its surroundings. The drainage direction and receiving stream shall be shown.

___ Detail plans shall consist of: plan views, elevations, sections and supplementary views which, together with the specifications and general layouts, provide the working information for the contract and construction of the dam and its appurtenances. Plans shall also include: dimensions and relative elevations of the spillways / outlet structures, the location and outline form of monitoring equipment / wells, location, size and type of piping for outlets or drains, water levels, location and description of benchmarks used and ground elevations.

11.2 Plans of Dams

11.2.1 General Plan

A complete plan of existing and/or proposed dams shall be submitted for projects involving new dams and/or additions to existing dams. This plan shall show the following:

11.2.1.1 Geographical Features

___ a. Topography and elevations - Existing or proposed streets and all ditches, streams, rivers and water surfaces shall be clearly shown. Contour lines at suitable intervals should be included. Location and description of benchmark used.

___ b. Boundaries - The boundary lines of the subdivision or the dam owner's property and the surrounding landowners shall be shown.

11.2.2 Detail Plans

___ Detail plans shall be submitted. Profiles should have a horizontal scale of not more than 100 feet to the inch and a vertical scale of not more than 10 feet to the inch. Plan views should be drawn to a corresponding horizontal scale and preferably be shown on the same sheet. Plans and profiles shall show:

___ a. Location of primary and emergency spillway.

___ b. Profile and plan drawings of spillways with elevations.

___ c. Embankment zones, cutoff trench, soil borings, borrow areas.

___ d. Special detail drawings, drawn to a scale that clearly shows the nature and details of the design of all joints, connections, thrust blocks, re-bar placement, instrumentation, drains, filters, etc.

12. SPECIFICATIONS

___ Complete technical specifications for the construction of the dam and all appurtenances, shall accompany the plans.

___ The specifications shall be signed, sealed, and dated by the Mississippi Registered Professional Engineer responsible for their development in a manner consistent with the requirements of the State Board of Registration for Professional Engineers and Land Surveyors, as they apply generally to the practice of engineering. Nothing herein is to be construed as allowing any such work to be performed other than by or under the direct supervision of a Mississippi Registered Professional Engineer.

___ The specifications accompanying construction drawings shall include, but not be limited to, all construction information not shown on the drawings which is necessary to inform the builder in detail of the design requirements for the quality of materials, workmanship and fabrication of the project. They shall also include: the type, size, strength, operating characteristics, and rating of equipment; earthwork and compaction; the complete requirements for all mechanical and electrical equipment, including piping, and joining of pipe, machinery, valves, corrosion protection; electrical apparatus, wiring, instrumentation, and meters; operating tools, construction materials; special filter materials, such as filter fabric, stone, sand, or gravel; miscellaneous appurtenances; chemicals when used; instructions for testing materials and equipment as necessary to meet design standards; and performance tests for the completed works and component units. It is suggested that these performance tests be conducted at design load conditions wherever practical.

13. OPERATION DURING CONSTRUCTION

___ Plans and specifications shall contain provisions for routing stream flow and runoff during the entire period of dam construction.

14. RECORD DRAWINGS

___ The owner shall ensure that written notification of completion of the dam is provided to this office within 30 days of completion of the dam. The completion notice shall be accompanied by a set of “as-built” plans (marked as record drawings or as-built) with the engineer’s certification that the project was completed in substantial compliance with the approved plans and specifications and any approved revisions.

15. STORM WATER PERMITTING REQUIREMENTS

Has the applicant fulfilled the storm water permitting requirements as outlined below?

( ) Yes ( ) No ( ) NA

a. Construction activities where less than one (1) acre of land is disturbed. **(No Permit Required)** ( ) Yes ( ) No ( ) NA

b. Construction activities where *more than one (1) acre but less than (5) acres* of land is disturbed. **A "Small Construction General Permit" is required.** The dam safety engineer checks to see if the applicant has obtained a copy of: (a) Small Construction Storm Water General Permit (which includes the notice of intent (NOI)); and, (b) Construction Guidance Manual (for the storm water pollution prevention plan (SWPPP)).

( )Yes ( )No ( ) NA

All of these items are also available to the applicant for download on the MDEQ website www.deq.state.ms.us. Click "permits" under "Key Topics", then click "Storm water", then scroll down and look for Small Construction for the two forms listed above.
NOTE: None of the above listed items for small construction general permits need be submitted to MDEQ unless specifically requested.

c. Construction activities where *(5) acres or more* of land is disturbed. **A "Large Construction General Permit" is required.** The dam safety engineer checks to see if the applicant has obtained a copy of: (a) Large Construction Storm Water General Permit; (b) Large Construction Storm Water NOI; and, (c) Construction Guidance Manual (for the storm water pollution prevention plan (SWPPP)).

( )Yes ( )No ( ) NA

All of these items are also available to the applicant for download on the MDEQ website www.deq.state.ms.us.
NOTE: All the above listed items are required to be submitted to the Environmental Permitting Division (EPD) at MDEQ. Coverage will be granted under the large construction general permit once these submittals are determined acceptable by MDEQ Environmental Permitting Division.

16. OTHER

a. Has the appropriate U. S. Army Corps of Engineers District Office been notified to see if a 404 Permit is required?

( ) Yes ( )No ( )NA

NOTE: If "yes" then a copy of the Corps' correspondence, application, or authorization letter shall be submitted.

b. Has the applicant obtained a groundwater withdrawal permit from the Office of Land and Water for wells used to augment lake water levels?

( ) Yes ( ) No ( ) NA

CHAPTER 20
HYDROLOGIC AND HYDRAULIC ANALYSIS

20. INTRODUCTION

The technical guidance for this chapter has primarily been taken from Applied Hydrology by Chow, Maidment and Mays, Hydrologic Analysis and Design by Richard McCuen, Handbook of Hydraulics 7th Edition by Brater, King, Lindell and Wei, Open Channel Hydraulics by Terry Sturm, assorted technical papers by Arthur Miller, Ph.D., P.E. on hydrologic analysis and assorted technical papers by Danny Fread, Ph.D. on dam failure analysis.

21. HYDROLOGY REPORT

A hydrology report shall be submitted for the construction of all new high and significant hazard dams as well as evaluation of existing high and significant hazard dams to meet dam safety program requirements during a formal inspection (if a report hasn't already been prepared). The report shall contain the following:

___ The report shall be signed, sealed, and dated by the Mississippi Registered Professional Engineer responsible for its development in a manner consistent with the requirements of the State Board of Registration for Professional Engineers and Land Surveyors, as they apply generally to the practice of engineering. The hydrologic analysis and report may also be done by a registered professional hydrologist, however all design and recommendations that affect public safety must be performed by or under the direct supervision of a Mississippi Registered Professional Engineer.

___ A description of the drainage basin which includes the name of the stream impounded and/or discharged to, the county the basin is located in, a physical description of the basin's characteristics as they affect runoff, soil type(s) using SCS names, SCS hydrologic group(s) and curve number(s), the amount of urban development present as well as a 5 year projection of urban development, size of the drainage area in square miles or acres and average slope of the basin.

___ A topographical map showing scale, name of USGS quadrangle map from which it was produced, outline of drainage area and sub-basins (if any), longest flow path from basin boundary to point of concentration (used for calculating time of concentration), the dam, the area that will be submerged at normal pool, outline of area submerged at maximum pool if dam is a flood control structure with low normal pool, downstream area and any development, section, range and township where lake is located and name and outline of stream impounded and/or discharged to.

___ A description of the design storm(s) used with the amount of inches of rainfall in a 24 hour period shown (refer to Dam Safety Regulation LW-4, Section IV, A, B, and D). For analysis of the principal spillway capacity of High Hazard dams, the 100-year, 24 hour storm event must be modeled using the SCS Type II or Type III dimensionless design

storm distribution. Analysis of the Probable Maximum Precipitation (PMP) design storm must use the dimensionless design storm distribution as shown in the regulations (SCS Emergency Spillway Hydrograph) or SCS Type II or Type III dimensionless design storm distribution. If the drainage area is larger than 10 square miles then the areal adjustments may be used. (See Page 6 & 7)

___ The method and calculations used to calculate time of concentration must be shown.

___ The program used to do the hydrologic analysis shall be named and all inputs and assumptions listed as well as the outputs. The equation method used to determine the peak discharge shall be stated (Note – the Rational Method shall not be accepted). A summary shall be included which states the peak inflow for each design storm, the time to peak, the volume of inflow to the reservoir, the volume of available storage, the capacity of the principal spillway when the auxiliary spillway activates as well as the maximum capacity of the principal spillway, the capacity of the auxiliary spillway and the maximum elevation of the pool for each design storm evaluated.

___ The runoff flow (in cfs) into the proposed impoundment versus time shall be plotted and the volume under the curve stated.

___ The storage volume and surface area of the impoundment versus elevation shall be plotted with the elevation of the dam toe (where zero storage occurs), the normal pool elevation, the auxiliary spillway crest elevation and the crest of the dam shown on the chart.

___ If augmentation for dry years or initial filling is considered in the design then the primary source shall be from surface water source(s). Groundwater augmentation to fill and/or maintain water levels shall be reviewed on a case by case basis and only allowed for special circumstances.

22. HYDRAULIC REPORT

The hydraulic analysis is usually done using the same program that is used for the hydrologic analysis. Required information may be provided in the same report as the hydrologic analysis and is acceptable where provided on the same output printout as the hydrologic analysis. The report shall contain the following:

___ A description of the principal and auxiliary spillways.

___ A plan and profile sketch of the principal and auxiliary spillways showing dimensions and elevations of the invert, outlet, control section, slope of spillway, crest of the dam and toe of the dam. The sketch shall show the location of the spillways in relation to the dam and the outlet channel.

___ The hydraulic equations (weir, orifice, culvert or gate) used for determining discharge shall be shown along with all coefficients used. If the spillway is a culvert(s) then the governing flow condition assumed shall be stated.

___ The stage-storage-discharge or stage-discharge relationship shall be plotted. If principal spillway is a riser and conduit configuration, then the elevation where full conduit flow develops shall be shown.

___ The velocity for open channel spillways (chute spillways and vegetated earthen spillways) shall be computed and shown as well as where flow transitions from sub-critical to critical to super-critical. Control section shall be placed where flow passes through critical depth.

___ Exit velocity or tractive forces for vegetated earthen spillways shall be computed. Type of vegetation shall be described. Earthen spillways should be cut through natural ground around the abutment of the dam. Earthen spillways that must go through fill or easily erodible soils shall be armored. Exit velocity for a vegetated earthen spillway shall not exceed the permissible velocities shown on the attached table from the USDA-SCS Engineering Field Manual.

___ Froude number shall be calculated for exit velocity at end of spillway(s) (flow entering hydraulic jump) for large dams (see Section 10.2). The depth after the jump shall be calculated and the stilling basin sized based on calculated depth (USBR recommends that length be approximately 6 times the calculated depth). A description of the stilling basin and a sketch showing dimensions and elevations shall be provided. For small and medium dams standard stilling basin guidelines (NRCS, COE, DEQ planning manual for storm water, etc.) are acceptable.

23. BREACH ANALYSIS

A breach analysis and inundation mapping shall be done for all high and significant hazard dams.

___ The method of breach analysis shall be based on lake size (see Section 10.2) unless special circumstances dictate otherwise. For small lakes breach analysis shall be by overtopping. For medium lakes breach analysis shall be by overtopping and sunny day failure (piping) at normal pool. For large lakes the breach analysis shall be sunny day failure at crest of auxiliary spillway.

___ The report shall be signed, sealed, and dated by the Mississippi Registered Professional Engineer responsible for its development in a manner consistent with the requirements of the State Board of Registration for Professional Engineers and Land Surveyors, as they apply generally to the practice of engineering. Nothing herein is to be construed as allowing any such work to be performed other than by or under the direct supervision of a Mississippi Registered Professional Engineer.

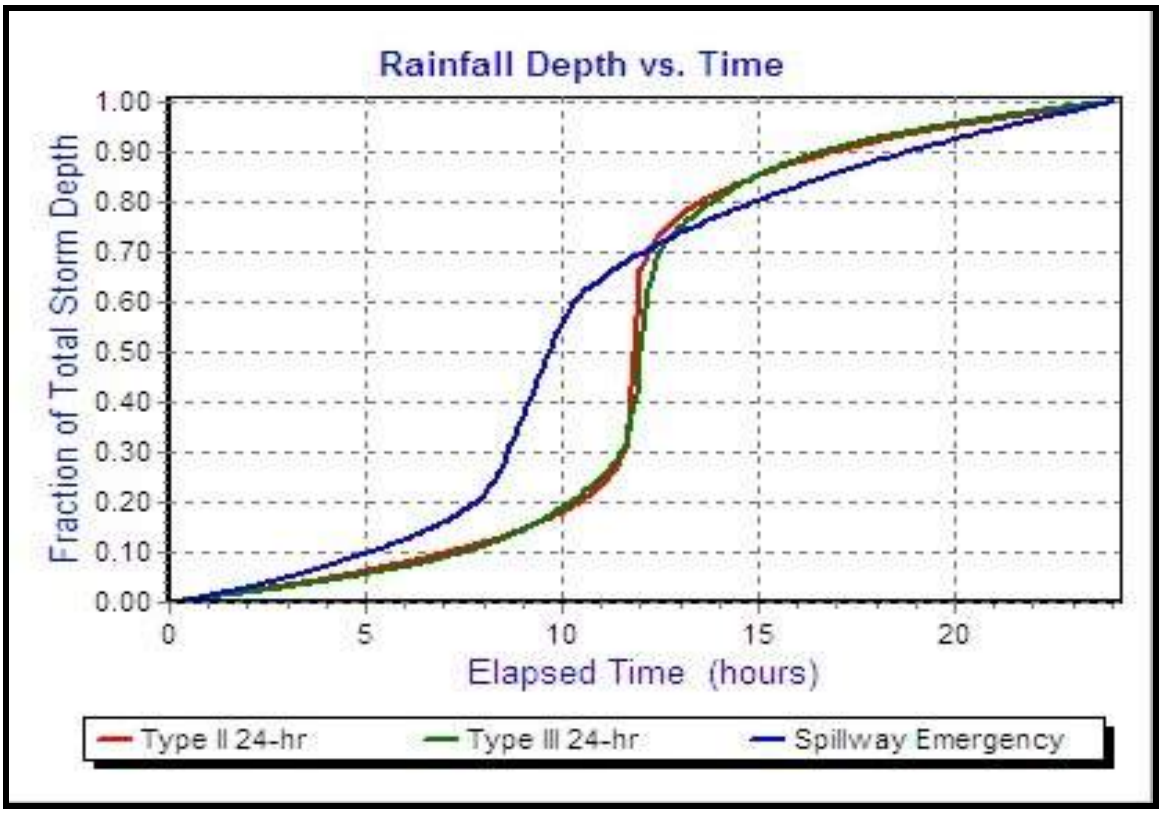
___ A description of the reservoir and downstream area which includes the name of the stream impounded and/or discharged to, the volume of the reservoir, the dam and the material (soil type) that it is constructed of, whether or not there is a core in the dam, the height of the dam and elevations for the toe, normal pool and crest, the county (and municipality if reservoir will impact a municipality) the reservoir is located in and a physical description of the downstream area including the amount and type of development present and key elevations shall be provided.

___ The method and calculations used to determine the breach formation factors (time of breach, size of breach) must be shown.

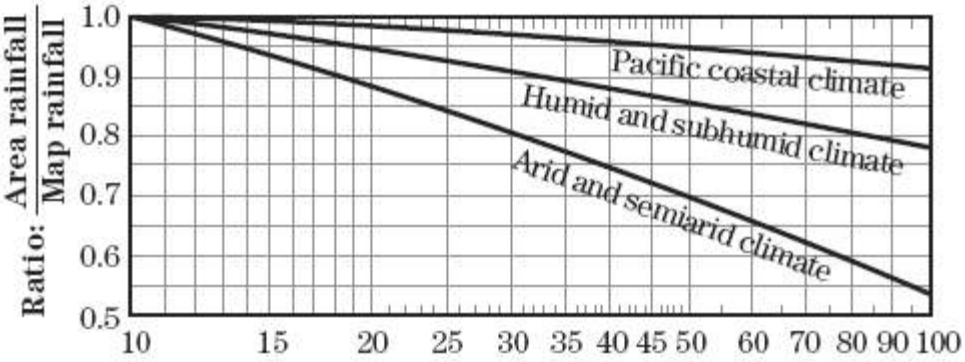
___ The program used to do the breach analysis shall be named and all inputs and assumptions listed as well as the outputs. A map shall be included showing and identifying the downstream cross sections (identify by labeling with the same number as in the program). An electronic copy of the project file shall be submitted along with the written report.

___ Comprehensive surveys of the downstream area for the purposes of establishing cross sections, unless the breach analysis is for the purpose of requesting a lower hazard classification, are at the discretion of the engineer preparing the analysis as to whether they are necessary. Elevations for cross sections may generally be obtained from U.S.G.S. quadrangle maps. More accurate data, such as GIS mapping from LIDAR data with 1 or 2 foot contours, or survey data, if easily obtainable, is recommended.

24. INUNDATION MAPPING



An inundation map shall be provided along with the breach analysis *unless* the breach analysis is for the purpose of proving that the dam is not a high or significant hazard.



___ Map shall be in color and shall be at a scale where lake and impacted structures downstream may be clearly seen. If inundation area is too large to be shown on one map then an index map shall be included which shows the full extent of the inundation area and the outline of the detailed maps with an identifier for each map sheet. Outline of inundation area shall be marked in permanent ink in a color that is easily distinguishable. If inundation area is marked with hatching, then hatching will be done in such a manner as to not obscure impacted structures, roads and identifying labels.

___ Identifying features shall be clearly labeled (main roads, subdivisions, commercial complexes, etc.) so as to aid emergency responders in quickly locating impacted areas and conducting evacuations.

___ Suggested evacuation routes should be included and be marked with a direction arrow so as to assist emergency responders in directing evacuees to safety.

___ Travel times shall be marked on the map with increments no less than 20 minutes. Dams where everything downstream that will be impacted, will be impacted within the first hour, do not require travel times to be marked on the map.

Areal precipation adjustments for drainage areas 10 to 100 square miles

DAM SAFETY REGULATION (LW-4)

I. Definitions - The words and phrases used in this regulation shall have the meanings set forth in this section:

A. Adverse Effects –Negative impacts that may occur at the site of the dam, upstream, downstream, or at locations remote from the site of the dam. The primary concerns are loss of human life, economic loss (including property damage), lifeline disruptions (such as damage to roads, bridges, or utilities), and adverse environmental impact.

B. Abutment—That part of the undisturbed valley side or a constructed concrete wall against which the dam is constructed. Right and left abutments are identified from the perspective of an observer standing on the dam looking downstream.

C. Alter or Repair— Any change in the surface or cross-section of existing dams and/or appurtenant works or any modification to appurtenant structures, other than minor grading and fill associated with routine slope and turf maintenance activities. Examples of alterations or repairs include such work as adding significant amounts of material to, or removing material from, the cross-section of a dam; changing the dimensions or elevations of an emergency or overflow spillway; replacing pipe or in any other way altering a principal spillway; making any repairs of erosion or undermining associated with seepage through the dam; building a roadway on or across any part of a dam; burying pipelines; or in any way altering the approved operational features of a dam.

D. Appurtenant Works – This term includes, but is not limited to; spillways, either in the dam or separate therefrom; the reservoir and its rim or shoreline; low level outlet works; and water conduits such as tunnels, pipelines, or penstocks, either through the dam or its abutments.

E. Breach—Partial removal of a dam by creating a channel through the dam to the original stream bed elevation, so that no water is impounded by the breached structure.

F. Commission**---** The Mississippi Commission on Environmental Quality, or its designee.

G. Dam—Any artificial barrier, including appurtenant works, constructed to impound or divert water, waste-water, liquid borne materials, or solids that may flow if saturated. All structures necessary to maintain the water level in an impoundment or to divert a stream from its course will be considered one dam.

H. Days—Calendar days including Saturdays, Sundays, and Holidays; unless specifically indicated otherwise in the body of this regulation.

I. Department or MDEQ--- The Mississippi Department of Environmental Quality.

J. Emergency Action Plan--- A formal written document identifying the area that would be inundated in the event of a dam failure and setting forth the plans and procedures for notifying the individuals, agencies, and public officials that would mobilize resources to respond to the emergency.

K. Emergency –This term includes, but is not limited to, uncontrolled breach of a dam; or any conditions leading to, or causing, a breach, overtopping, or any other condition in the dam and/or its appurtenant works that may lead to failure of the dam or otherwise pose a threat to life or property.

L. Enlarge –Any change in, or addition to, an existing dam or reservoir, which raises, or may raise the water storage elevation or storage volume of the water, waste-water, or liquid-borne material impounded by the dam.

M. High Hazard–A class of dam in which failure may cause loss of life, serious damage to residential, industrial, or commercial buildings; or damage to, or disruption of, important public utilities or transportation facilities such as major highways or railroads. Dams which meet the statutory thresholds for regulation that are proposed for construction in established or proposed residential, commercial, or industrial areas will be assigned this classification, unless the applicant provides convincing evidence to the contrary.

N. Impoundment or Reservoir — A man-made dammed, leveed, or diked area or basin designed to store water or other liquids above surface levels that would occur under natural conditions.

O. Low Hazard—A class of dam in which failure would at the most result in damage to agricultural land, farm buildings (excluding residences), or minor roads.

P. Permit Board or Board --- The Mississippi Environmental Quality Permit Board.

Q. Person—The state or other agency or institution thereof, any municipality, political subdivision, public or private corporation, individual, partnership, association or other entity, and including any officer or governing or managing body of any municipality, political subdivision, or public or private corporation, or the United States or any officer or employee thereof.

R. Probable Maximum Precipitation (PMP) **—**The rainfall event used for hydraulic design of dams and appurtenant spillways in Mississippi. The Probable Maximum Precipitation (PMP) varies by location within the state and the event used in design shall be as defined for the proposed construction location by Hydrometeorological Reports published by the Office of Hydrology, National Weather Service.

S. Professional Engineer**—**An engineer with experience in the design of dams who is registered with the State of Mississippi Board of Registration for Professional Engineers and Land Surveyors.

T. Professional Geologist---A geologist with experience in determining and analyzing geologic conditions

affecting the siting of dams who is registered with the Mississippi State Board of Registered Professional Geologists.

U. Removal—Complete elimination of the dam embankment or structure to restore the approximate original topographic contours of the area.

V. Significant Hazard—A class of dam in which failure poses no threat to life, but may cause significant damage to main roads, minor railroads, or cause interruption of use or service of public utilities.

W. Water Storage Elevation—The maximum surface elevation of water that can be maintained by a dam or reservoir.

X. Written Authorization**---** Official written correspondence or permit document from the Board, or its designee, authorizing construction, enlargement, repair, or alteration of a dam; including any specified conditions or limitations under which the work is to be performed by the person to whom the approval is granted.

II. Authorization

A. Applicability

1. Except as otherwise provided in this section, any person or entity proposing to construct, enlarge, repair, or alter a dam or reservoir in the state of Mississippi must obtain written authorization from the Permit Board, or its designee, prior to commencement of any site work related to the project. For high hazard and significant hazard dams, the written authorization will be in the form of a permit document. Application for such permits shall be made on a form prescribed by the Board and will be processed by the Board in accordance with Mississippi Code Annotated, Section 49-17-29.

2. The Board may require submittal of any information deemed necessary to evaluate a proposal to construct, enlarge, repair, or alter a dam or reservoir. Once the Board has authorized the project, the applicant shall not modify the approved design, plans, specifications, or construction methods, or act according to such modified documents, without the prior written authorization of the Permit Board.

3. Any person intending to acquire the right to store or use water from a reservoir formed by a dam, regardless of whether or not written construction authorization is required under this regulation, shall submit an application for a surface water use permit to MDEQ in accordance with Mississippi Code Annotated, Sections 51-3-5 and 51-3-7, and the regulations of the Commission promulgated thereunder.

B. Exceptions

1. Prior written authorization is not required for emergency repairs to a dam which is in imminent danger of failing. However, the dam owner shall report such emergency repairs to MDEQ by close of business on the next business day following the incident and file a written report with MDEQ within five (5) days of the incident.

2. Written construction authorization shall not be required for:

a.) a peripheral dam or levee eight (8) feet or less in height, measured from the point of lowest elevation of its toe, regardless of the impounded storage volume; or

b.) a dam that impounds twenty-five (25) acre-feet or less at maximum storage volume; or

c.) a dam that does not impound a watercourse with a continuous flow of water, as determined by the Commission;

Any person or entity proposing to construct, enlarge, repair, or alter any dam or reservoir in reliance upon the provisions of paragraphs II.B.2.(a.-c.) to exempt the project from the requirement to obtain

written authorization must submit a notification of the planned project to MDEQ prior to the onset of construction. If, upon review of such notification, the Commission determines that the proposed dam poses a potential threat to downstream lives and property; the person or entity proposing the project may be required to comply with design and safety requirements contained in Section IV of this regulation. The Commission may enforce compliance with such design and safety standards in the interest of public safety, notwithstanding the fact that written authorization may not be required for the project. The pre-construction notification shall be submitted on a form prescribed by the Permit Board.

3. Prior written authorization is not required for recurring routine maintenance activities including but not limited to mowing, grading or filling ruts in roadways that cross the dam, filling ruts or repairing other surface damage caused by vehicles or animals on the slopes, filling eroded areas in the surface of an embankment to establish or maintain the turf, or other similar activities.

C. Limitations

1. The Board's receipt, comment, or approval of any design, construction, or modification does not relieve the dam's owner, consulting engineer, consulting Geologist, contractor, equipment supplier, attorney, or any other party of any liabilities or responsibilities. Board and/or MDEQ approval of, or comment on, any document does not establish or convey any liability or responsibility to the Board and/or MDEQ, nor does such approval or comment represent any assurances that the project will comply with any authorization requirements or otherwise perform as intended by the owner, consulting engineer, consulting Geologist, contractor, equipment supplier, attorney or other parties. The dam owner and/or any person responsible for constructing, enlarging, repairing, or altering a dam or reservoir shall comply with all conditions of the Board's authorization to construct and ensure that all construction, operation, and maintenance activities achieve such compliance. It is the responsibility of the dam owner/applicant to obtain all other approvals, permits, clearances, easements, and/or agreements for the construction and/or operation of the dam which may be required by federal, state, or local law or regulation.

2. Written authorizations by the Board expire one (1) year from the date of issuance if work has not commenced on the project. If the work cannot be commenced within the one-year period, the dam owner or any other person responsible for the project must request a time extension from the Board, in writing, at least thirty (30) days prior to the expiration of the one-year authorization period. The written request shall provide an explanation of project delays and an estimated construction commencement date. The Board will normally grant a time extension, on proper application therefor, unless the Board determines that circumstances surrounding the project have so changed that the construction and operation of the dam as originally proposed would violate state or federal laws or regulations. If the applicant allows the authorization to expire, a new application must be submitted and approved prior to the onset of construction.

3. The hazard classification assigned to a dam by the Board is subject to change based on future developments that may increase the potential threat to life and property in the event of a dam failure. The dam owner and/or any person responsible for the construction and/or operation of a dam or reservoir assume all risks associated with designing and constructing the dam to meet less than the most stringent design criteria for high-hazard dams, including the risk of having to make modifications to the dam to meet future heightened regulatory requirements associated with a change in classification.

III. Application Content and Procedure

A. Any person or entity proposing to construct, enlarge, repair, or alter a dam or reservoir shall submit either an application or a pre-construction notification (if the provisions of paragraph II. B. apply) to the Board, on forms prescribed by the Board, at least thirty (30) days prior to the anticipated commencement of construction. The submittal must have a United States Geologic Survey (USGS) topographic map, or portion thereof, attached to it showing the location of the proposed dam and reservoir including a clearly marked access route to the site and marked locations and general descriptions of all buildings, drainage

structures or culverts, roads, railroads, bridges, and utility lines within two-miles downstream of the site of the proposed dam.

B. If the provisions of paragraph II. B. do not apply, and the potential threat to life or potential property damage that would result from failure of the proposed dam rises to the level of significance characteristic of a high hazard or significant hazard classification, the application package also must include two complete sets of design documents prepared in accordance with the following requirements:

1. Engineering drawings, specifications, and engineering reports shall be prepared, signed, and sealed by a professional engineer.

2. Drawings shall be prepared to a scale that provides sufficient detail for review of all project components.

3. Specifications shall include detailed descriptions of all work to be performed and materials to be used in the construction.

4. Engineering reports shall include, but not be limited to, hydrologic calculations, hydraulic calculations, geotechnical investigation, stability analysis, dewatering plan, and provisions for internal drainage. Portions of the investigation at the site of the dam and within the catchment area including, but not limited to, characterization of geologic formations, assessment of groundwater conditions, and/or other geologic conditions, factors, and processes which may impact the design of the dam may be performed by a professional geologist. If a professional geologist produces documents in support of the design of a project, the work products must be signed and sealed by the professional geologist.

5. If a professional geologist produces documents in support of the design of a project, the work products must be signed and sealed by the professional geologist.

C. The Board may require the applicant to supply any additional information necessary to evaluate an application, including the following:

1. Whether the proposed dam will provide adequate safety for lives and property; and/or

2. Whether the proposed dam will adversely affect riparian or other beneficial water uses, or plans for the proper utilization of the water resources of the state, and/or

3. Any other information the Board deems appropriate.

IV. Design and Safety Requirements

A. Any modification, alteration, enlargement, or major repair of an existing dam, whether requested by the owner or directed by the Commission, will be subject to the current design standards for the appropriate hazard classification as set forth in this regulation.
.

B. The owner of any existing dam, regardless of its condition, that poses an unacceptable threat to downstream lives or property may be required by the Commission either to bring the dam into compliance with current standards or take the dam out of service by draining the impoundment and removing the dam.

C. High Hazard dams must be capable of safely passing the runoff from a 100-year rainfall event through the principal spillway without activating the emergency spillway. The 100-year rainfall event is established by the National Weather Service and varies for different areas of the state. The proper design rainfall event for the county where the proposed dam is located can be obtained from MDEQ or from the nearest Natural Resources Conservation Service (NRCS) office. The runoff from one hundred percent (100%) of the Probable Maximum Precipitation (PMP), as defined in paragraph 1.R. of this regulation, must be passed

through the principal and emergency spillway and/or stored in the reservoir without overtopping the dam. The appropriate PMP for each county as obtained from the National Weather Service Bulletins and the rainfall distribution curve to be used in design routings are provided at Appendix A to this regulation. The Commission may require the owner or operator of a high hazard dam that does not meet this requirement to take remedial action to bring the dam into compliance with all current dam safety requirements or to breach the dam.

D. Within thirty (30) days after completion of a high hazard dam, the owner shall submit one (1) complete set of as-built plans and specifications to the Board. The submittal also shall include a letter signed by the professional engineer responsible for the project, certifying that the dam was constructed in accordance with the Board approved plans and specifications.

E. Significant hazard dams shall be designed to control the contributory watershed runoff from at least fifty percent (50%) of the PMP without overtopping the dam. The owner and any other persons responsible for the construction and operation of the dam shall assume all risks for future costs to upgrade a dam in the event the hazard classification changes. Applicants for authorization to construct significant hazard dams must comply with the document submittal requirements set forth for high hazard dams in paragraph III.B. Within thirty (30) days after completion of a significant hazard dam, the owner shall submit one (1) complete set of as-built plans and specifications to the Board accompanied by a letter signed by the professional engineer responsible for the project, certifying that the dam was constructed in accordance with the Board approved plans and specifications.

F. Low hazard dams shall be designed to control the contributory watershed runoff from at least thirty-five percent (35%) of the PMP without overtopping the dam. The owner and any other persons responsible for the construction and operation of the dam shall assume all risks for future costs to upgrade a dam in the event the hazard classification changes. Drawings to be submitted with the application for a low hazard dam shall include, but not be limited to, a plan view of the dam (including all appurtenant works) and sections through the dam at the centerline of the principal spillway and at the centerline of the emergency spillway if it is located in the dam. The applicant shall provide written notification of completion of the dam to the Board, within thirty (30) days after the dam has been constructed, and either certify that the dam was constructed as shown in the drawings previously submitted or submit new as-built drawings.

G. Because the size and type of pipe used for the principal spillway is one of the most critical elements in the design of high hazard and significant hazard dams, the professional engineer responsible for the project shall provide the Board with detailed hydraulic, hydrologic, and structural computations supporting selection of the size and type of pipe to be used. Detailed drawings and specifications relating to the installation of the pipe shall include, but not be limited to, construction measures that adequately address critical loading, bedding, backfill, compaction, and seepage precautions related to installation of the pipe.

H. The Freeboard Hydrograph shall be used to determine the top of dam elevation and the size and crest elevation of the emergency spillway for high hazard dams.

I. The soils in an earthen emergency spillway shall be capable of withstanding the water velocities generated when the emergency spillway is activated without experiencing excessive erosion.

J. Side slopes of all dams shall be a minimum of three horizontal to one vertical (3:1).

K. The owner or operator of a high hazard dam shall develop an Emergency Action Plan (EAP) for the dam. The Board may direct the owner or operator of a significant hazard dam to develop an Emergency Action Plan (EAP). The EAP shall be submitted to the Board for approval. Once approved, a copy of the EAP will be maintained on file by the Board. The owner or operator of the dam shall review the EAP on an annual basis to assure that the information contained therein is current. Revisions to the EAP, as necessary, shall be furnished to the Board and all other persons involved in the implementation of the EAP. The owner or operator also shall be responsible for conducting or coordinating periodic training and exercises to assure that personnel involved in the implementation of the EAP are properly prepared to carry out their responsibilities in the event of an emergency.

V. General Conditions of Authorization

A. No materials shall be placed in a watercourse that will impede or block the natural flow of water without prior written authorization from the Permit Board and other appropriate federal, state, and local authorities. Additionally, any activity involving the discharge of dredged or fill material or any other construction in any state waters that are also subject to federal regulation under Section 404 of the 1972 Clean Water Act and/or Section 10 of the Rivers and Harbors Appropriation Act of 1899 shall be conducted in accordance with appropriate provisions of those federal statutes.

B. A permit or written authorization issued by the Permit Board does not convey any property rights in either real or personal property, or any exclusive privileges, nor does it authorize any injury to private property or any invasion of personal rights, nor any infringement of federal, State, or local laws or regulations. No impoundment may be constructed that will adversely affect riparian or other beneficial water uses or plans for the proper utilization of state waters, or that will cause flooding of upstream property unless the owner of the proposed dam has legally aquired the right to do so. The Commission may prescribe minimum flow releases from any dam or reservoir, as necessary, to protect downstream uses or otherwise prudently manage available surface water.

C. Any dam that impounds a watercourse with a continuous flow shall be designed so that the established minimum flow for the stream (as established by the Commission) is maintained.
D. The owner and/or any person responsible for the construction, enlargement, repair, or alteration of a dam on a watercourse lying, in whole or in part, within a levee district duly constituted under the laws of the State of Mississippi, shall first obtain permission for the work from the board of the levee district and shall provide proof of such permission with the application to the Board.

E. Owners of earthen dams covered under this regulation shall establish and maintain a healthy turf on the exposed faces of the dam to prevent erosion, and shall mow frequently enough to prevent the encroachment of woody vegetation into the slopes of the dam embankment.

F. Owners of High Hazard or Significant Hazard dams will be required to prohibit livestock grazing on the dam in order to prevent damage to the turf and to prevent erosion associated with establishment of animal trails

G. In addition to the general conditions contained herein, the Board may place special conditions on any authorization to construct or modify a dam.

H. The Commission may order the removal of a dam after it has been constructed or modified when it is determined that the dam does not meet criteria and/or standards established by the Board or the Commission and/or otherwise fails to adequately protect lives and property.

I. A Surface Water Use Permit may also be required for any person to impound and store water behind a dam.

J. The owners or operators of high hazard or significant hazard dams shall maintain records and documents related to the original construction, recurring inspections, maintenance, repairs, and alterations of the dam for the life of the project. Such records shall be made available for inspection, or copies of such records furnished, upon request by the Department.

VI. Inspection and Reporting

A. The owner and the operator of a dam shall be responsible for the proper operation and maintenance as well as the structural integrity of the dam. In order to fulfill this responsibility, the owner and/or the operator should perform a visual inspection of the dam at least every sixty (60) days and after every major rainfall event over the watershed. Any symptoms of dam failure observed during such visual inspections shall be immediately reported

to MDEQ.

B. The owner or operator of a high hazard or significant hazard dam shall have a detailed inspection of the dam performed by a registered professional engineer with experience in the design and construction of dams not later than March 1, 2006, and thereafter at such recurring intervals as may be directed by the Department. A checklist form prescribed and furnished by MDEQ shall be used to record observations during the inspection. The report on findings of scheduled detailed inspections (including the completed MDEQ prescribed checklist and an evaluation of the operation, maintenance, and the structural integrity of the dam), bearing the signature and seal of the professional engineer performing the inspection, shall be submitted to the Board within sixty (60) days after completion of the inspection.

C. MDEQ employees are authorized to make inspections at any time to evaluate the operation, maintenance, and structural integrity of dams and reservoirs. The owner or operator shall be required to perform, at the owner's or operator's expense, such work as may be necessary to correct deficiencies in maintenance and operation or accomplish necessary repairs identified by such inspections. If deficiencies are not corrected or repairs are not made as specified in the inspection report, the Commission may order owners or operators to take remedial action or remove the dam in order to safeguard lives and property.

D. If, upon inspection, the Board or the Commission determines that:

1. A dam was constructed without obtaining required prior written authorization from the Permit Board;

2. A dam was not constructed in accordance with the plans and specifications upon which the Board based its written authorization;

3. The dam may not provide adequate safety for lives and property;

4. The dam may adversely affect riparian or other beneficial water uses, or plans for the proper utilization of the water resources of the state; or

5. The owner and/or operator of the dam has allowed the dam to deteriorate and remain in an unsafe condition after having been ordered to make the necessary repairs or modifications, the Board or the Commission may:

a.) cause the dam to be removed or breached;

b.) require the owner and/or operator to take remedial action;

c.) revoke or modify any authorization pertaining thereto; or

d.) take other action the Commission deems appropriate, within its jurisdiction.

VII. Confidential Information

Procedures for declaring submitted information confidential and for agency handling of such information are found in Miss. Code Ann. Section 49-17-39, Section 51-3-44, and the Commission's Regulations Regarding the Review and Reproduction of Public Records (MCEQ-2).

VIII. Enforcement

A. Any person who allows a dam to deteriorate to an unsafe condition may be ordered to make necessary repairs to restore it to a safe condition. If appropriate repairs are not made, the Commission may take action to correct unsafe conditions, or to require removal of the dam, and the Board may revoke or modify any written authorization pertaining thereto.

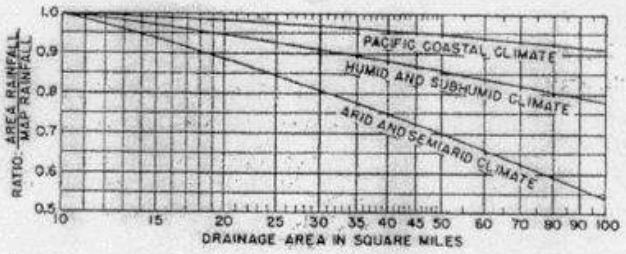
B. Enforcement of this regulation shall be governed by Miss. Code Ann. Sections 49-17-31, 49-17-

33, 49-17-35, 49-17-37, 49-17-41, and Sections 51-3-49, 51-3-51, and 51-3-55.

IX. Correspondence and Adequacy of Notice

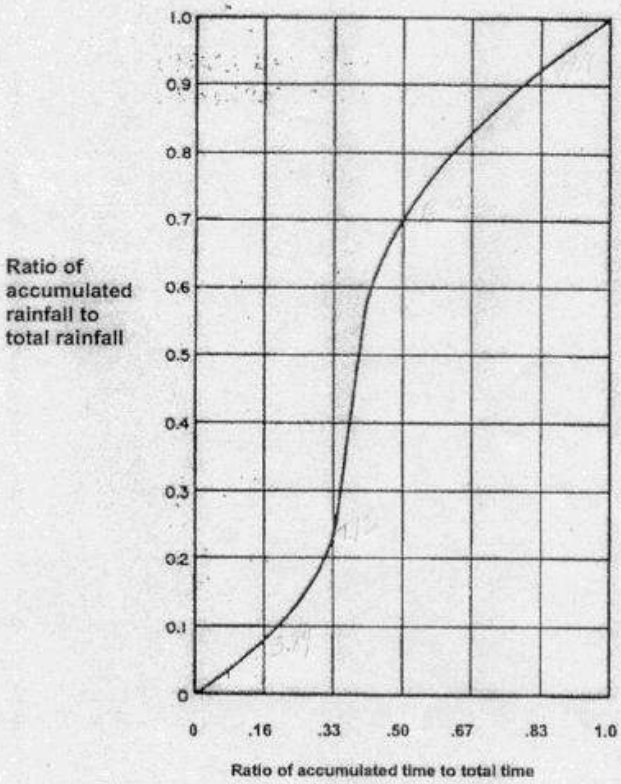
A. General -- All regulated dam owners shall inform MDEQ of any address changes, changes in ownership, or changes in the designated agent of the owner within fifteen (15) days of any such changes, and must readily accept all mail sent to them from the Commission, MDEQ, or the Permit Board.

B. Registered or certified mail -- Registered or Certified Mail sent with proper postage and to the last address provided to MDEQ by the dam owner of record shall be considered adequate notification of notice served if MDEQ is notified that the mail was delivered and accepted or if the mail is returned as rejected or unclaimed by the addressee.



C. Refusal to accept mail -- Refusal to accept mail from the Commission, the Permit Board, the Department, or its designee, shall be considered a violation of this regulation.

X. Hearings and Appeals



Any person aggrieved by any initial action of the Permit Board to issue, deny, transfer, modify or revoke a permit or written authorization may request an evidentiary hearing before the Permit Board regarding the decision. Procedures for hearings and further appeals of Permit Board decisions are set forth in Mississippi Code Annotated Section 49-17-29.

INTRODUCTION

The Dam and Reservoir Safety Council and the Dam and Reservoir Safety Program within the Missouri Department of Natural Resources were established by House Committee Substitute for House Bill 603 as passed by the first regular session of the 80th General Assembly. The bill was signed by the governor and subsequently became law on September 28, 1979. This law is Sections 236.400 through 236.500 in the Revised Statutes of Missouri as printed in the 1986 Supplement. The Dam and Reservoir Safety Program was assigned to the Geological Survey and Resource Assessment Division within the Department of Natural Resources for administration.

The Governor began appointment of the first Council during April of 1980. Employment of the Chief Engineer and initiation of recruitment for the additional authorized staff commenced in July 1980. A working Council with a quorum of four members had been appointed by September 1980.

From September 1980 to August 1981 the Council, with help from the Chief Engineer and his staff, promulgated the first set of rules. These rules provide the information that is necessary in order to implement the law. These rules became effective on August 13, 1981 and are contained in the Code of State Regulations under Title 10, Division 22, Chapters 1 through 3.

In June 1984, the seventh member of the Council was appointed by the Governor, and the first full seven member council meeting was held in July 1984. From January 1984 to December 1984, the Council, with help from the Chief Engineer and his staff, made extensive revisions to the August 13, 1981 edition of the rules. These revisions became effective on January 1, 1985 and are contained in the Code of State Regulations under Title 10, Division 22, Chapters 1 through 4. The Council has taken action on four other occasions to make minor modifications to the rules. These revisions became effective on January 1, 1987; January 1, 1989; January 1, 1991; and June 9, 1994.

The Dam and Reservoir Safety Council is a non-paid policy-making body appointed by the Governor with the consent of the Senate. Communication with the Council is normally handled through the paid staff, which is directed by the Chief Engineer. Questions, comments, requests, and other inquiries should be addressed to the Chief Engineer for action or referral to the Council. The Chief Engineer may be contacted at the following address or telephone number.

CODE OF STATE REGULATIONS – RULES
TITLE 10 – DEPARTMENT OF NATURAL RESOURCES
DIVISION 22 – DAM AND RESERVOIR SAFETY COUNCIL

CHAPTER 1 – ORGANIZATION, DEFINITIONS AND IMMUNITY

10 CSR 22-1.010 General Organization

PURPOSE: The purpose of this rule is to comply with section 536.023, RSMo (1978) which requires each agency to adopt as a rule a description of its operation and the methods whereby the public may obtain information or make submissions or requests.

(1) Section 236.410, RSMo (1986) establishes a Dam and Reservoir Safety Council of the state of Missouri. The council consists of seven (7) members appointed by the governor with the advice and consent of the Senate. The council holds a minimum of four (4) regular meetings each year and such special meetings and hearings as the council chairman may deem necessary.

(2) The Missouri dam and reservoir safety law and rules, regulations, guidelines and standards provide for the construction, management and operation of dams and reservoirs in a manner which will provide adequate protection of public safety, life or property. To achieve this purpose the council has statutory powers as listed in sections 236.405 and 236.415, RSMo (1986) for policy making, adopting rules, regulations, standards and guidelines and issuing of permits.

(3) The Department of Natural Resources is authorized under section 236.405, RSMo (1986) to administer and enforce all rules, regulations, standards and guidelines adopted by the council and assist the council in achieving its statutory duties. The department has designated the dam and reservoir safety program as the agency within the department responsible for administering the dam and reservoir safety law. The director of the Department of Natural Resources appoints a chief engineer who is the dam and reservoir safety program director and a staff as provided in section 236.405, RSMo (1986). The chief engineer and staff provide day-to-day operation of the dam and reservoir safety program.

(4) Among its operations, the dam and reservoir safety program performs administrative and technical functions including: review permit applications and recommend approval or denial of such applications; inspect dams and reservoirs; enforce the law and all rules, regulations, standards and guidelines adopted pursuant to Chapter 236, RSMo (1986); employ necessary staff, develop facts as may be required by the council; recommend rules, regulations, standards and guidelines required by Chapter 236, RSMo (1986); mitigate or eliminate unsafe dam or reservoir conditions; and other functions as described in section 236.420 to 236.500, RSMo (1986).

(5) Requests for permit applications, requirements or other permit information, copies of these rules and the dam and reservoir safety law, dam inspections, technical information and assistance, requests for public hearings and any other submissions are to be made to the Department of Natural Resources, Dam and Reservoir Safety Program, PO Box 250, Rolla, MO 65402-0250.

Auth: chapter 236.RSMo (1986). Original rule filed April 14, 1981, effective August 13, 1981.

10 CSR 22-1.020 Definitions

PURPOSE: The following terms when used in rules, regulations, standards and guidelines adopted by the Dam and Reservoir Safety Council pursuant to the "dam safety law" shall have the meaning respectively ascribed to them by this section.

Editors note: The secretary of state has determined that the publication of this rule in its entirety would be unduly cumbersome or expansive. The entire text of the rule has been filed with the secretary of state. The entire text of the rule may be found at the headquarters of the agency and is available to any interested person at a cost not more than the actual cost of reproduction.

(1) **"Agency engineer"** means an experienced engineer, not necessarily registered as a professional engineer in Missouri, who works for an engineering division of a state or federal agency regularly engaged in dam and reservoir design and construction for soil and water conservation or irrigation or relating to wildlife conservation.

(2) **"Agricultural dam"** means any dam, the primary use of which is to impound water for use in irrigation, livestock watering, or commercial fish rearing and sale.

(3) **"Alterations", "repairs",** or either means such alterations or repairs as affect the safety of a dam or reservoir, or public safety, life or property.

(4) "**Appurtenant works**" means the structures or materials incident to or annexed to dams that are built or maintained in connection with such dams and which are used primarily in connection with their proper operation, maintenance or functioning. This includes, without limitation, such structures as spillways, either in the dam or separate therefrom; the reservoir rim; low level outlet works; and water conduits such as tunnels, pipelines or penstocks, either through a dam or its abutments.

(5) **"Area capacity curves"** means graphic curves, which show the relationship between reservoir surface area and the storage capacity of the reservoir at given elevations.

(6) **"Chief engineer"** means the head of the dam and reservoir safety program of the Department of Natural Resources or his representative.

(7) **"Commercial Fish Rearing"** reservoir means a reservoir which was designed specifically for fish rearing purposes and the primary use is to provide water for commercial fish rearing and sale to other parties in a "for profit" venture. This does not include activities such as sport fishing.

(8) **"Construction permit"** means a written authorization issued by the council giving the owner the right to construct, alter, enlarge, reduce, repair or remove a dam or reservoir or appurtenances thereto, with such conditions as are necessary to adequately protect the public safety, life, property, the dam or reservoir.

(9) **"Conventional dam"** means any dam other than an industrial water retention dam.

(10) **"Council delegate"** or **"authorized representative"** means an individual, usually the chief engineer, authorized by the council to act in its behalf.

(11) **"Crest"** or **"dam crest"** means the top surface of the dam.

(12) **"Crest elevation"** or **"dam crest elevation"** means the lowest elevation of the crest exclusive of the spillway(s).

(13) **"Dam"** means any artificial or man-made barrier which does or may impound water, and which impoundment has or may have a surface area of fifteen (15) or more acres of water at the water storage elevation or which is thirty-five feet (35') or more in height measured either from the natural bed of the stream or watercourse or lowest point on the toe of the dam (whichever is lower) up to the crest elevation, together with appurtenant works. Sections 236.400 and 236.500 shall not apply to any dam which is not or will not be in excess of thirty-five feet (35') in height or to any dam or reservoir licensed and operated under the Federal Power Act.

(14) **"Dam and Reservoir Safety Council"** referred to as the "council" means seven (7) members appointed by the governor for purposes of implementing the dam safety law.

(15) **"Dangerous Dam or Reservoir"** is a dam or reservoir which is in an advanced state of deterioration such that if deterioration continues, the threat of dam failure and flooding would be imminent and substantial.

(16) **"Department"** means the Department of Natural Resources.

(17) **"Downstream environment zone"** means the area downstream from a dam that would be affected

by inundation in the event the dam failed when filled to the emergency spillway crest elevation, or to the dam crest elevation, in the absence of an emergency spillway.

(18) **"Earthquake Intensity"** means Modified Mercalli intensity which is used to describe the degree of shaking a dam will experience.

(19) **"Enforcement Order"** means a written directive issued by the council or the chief engineer to the owner of a dam for correction of defects in the dam or reservoir which have been determined to make the structure a threat to public safety, life or property. The order will contain specific actions with which the owner must comply to remove the threat the dam or reservoir poses to public safety, life or property.

(20) **"Enlargement"** means any change in or addition to an existing dam or reservoir, which raises the height of the dam, increases the watershed for the reservoir or raises the water storage elevation of the water impounded by the dam or reservoir.

(21) **"Environmental class"** means classification of the downstream environment zone based on the contents of that zone (see 10 CSR 22.2.040(1)). Class I represents the most severe threat to public safety, life or property and Class III represents the least threat.

(22) **"Factor of safety"** means the resultant of the summation of the forces resisting failure divided by the summation of the driving forces tending to cause failure.

(23) **"Freeboard"** means the difference in elevation between the dam crest elevation and the water storage elevation in the reservoir.

(24) **"Height"** or **"height of dam"** means the difference in the elevation of either the natural bed of the stream or watercourse or the lowest point on the toe of the dam (whichever is lower) and the dam crest elevation.

(25) **"Industrial building"** means a permanent, enclosed structure used by groups of workers usually involved in some type of manufacturing, processing or industrial related process.

(26) **"Industrial water retention dam"** means a dam used to retain the solids transported as waterborne industrial byproducts and the associated water. This includes, but is not limited to, tailings dams, slime impoundments and settling ponds.

(27) **"Inundation"** means water, two feet (2') or more deep, over the general level of the submerged ground affected outside the stream channel.

(28) **"Inspection"** means scheduled and unscheduled examinations of a dam and reservoir with the primary objective of making safety observations and recording them in a written description.

(29) **"Irrigation Reservoir"** means a reservoir whose primary use is to provide water for the irrigation of agricultural lands for the production of grains, hay, pasture, fruits, vegetables and animal feeds which are for sale or to be used by the owner.

(30) **"Law"** means the dam and reservoir safety law, as contained in chapter 236, RSMo, and all rules, regulations, standards and guidelines adopted thereto.

(31) **"Liquefaction"** is a condition where a soil will undergo continued deformation at a constant low residual stress or with low residual resistance, due to the build-up and maintenance of high pore water pressures, which reduce the effective confining pressure to a very low value.

(32) **"Livestock Water Reservoir"** means a reservoir whose primary use is to provide water for livestock that are raised for breeding or marketing purposes.

(33) **"Maintenance"** means the proper keeping of all aspects of a dam or reservoir and appurtenances thereto, that pertain to safety, in a state of repair and working order as necessary to comply with the law and any permit issued thereunder and to protect public safety, life or property.

(34) **"Modification"** or **"modifications"** means changes or revisions to the design, construction, maintenance, operation or repair or the alteration, enlargement, reduction, removal or natural physical change that may occur to a dam or reservoir that were not included in the approved plans for the construction permit, or such changes or revisions to a dam or reservoir where a registration or safety permit is in effect or required hereunder, if such changes or revisions would endanger public safety, life or property as a result of creating a potential

failure in the dam or reservoir, except that modification or modifications do not mean or include approved anticipated enlargements, outlined by design plans and specifications submitted and approved with the original application for a construction, safety or registration permit for industrial water retention dams and reservoirs.

(35) **"Observable defects"** are those defects which would be detectable by an experienced professional engineer making an on-site visual inspection of the dam in accordance with current engineering, geologic and construction practices.

(36) **"Owner"** or **"dam owner"** means a person who owns, controls, operates, maintains, manages or proposes to construct a dam or reservoir including: the state and its departments, institutions, agencies, and political subdivisions, but not the United States government; a municipal or quasi-municipal corporation; a district; a public utility; a natural person, firm, partnership, association, corporation, political subdivision or legal entity; the duly authorized agents of leasees, or trustees of any of the foregoing; or receivers or trustees appointed by any court for any of the foregoing.

(37) **"Permanent dwelling"** means a dwelling occupied at least ninety (90) days a year.

(38) **"Permit"** means construction, safety or registration permit.

(39) **"Permit application"** or **"applicant"** means an owner who applies for a construction, safety or registration permit.

(40) **"Probable maximum acceleration"** means the horizontal acceleration developed at a dam as a result of an earthquake with a probability of occurrence similar to the probable maximum precipitation. The probable maximum acceleration is readily available from a Corps of Engineers Report entitled "Earthquake Potential of the St. Louis District – Ground Motion Supplement" which is on file with the chief engineer of the Dam and Reservoir Safety Program. *(See Editors Note.)*

(41) **"Probable maximum precipitation"** or **"PMP"** means the precipitation that may be expected from the most severe combination of critical meteorological conditions that are reasonably possible in an area. The probable maximum precipitation (PMP) is readily available from the National Weather Service in Hydrometeorological Report 51, *"Probable Maximum Precipitation Estimates, United States East of the 105h Meridian." (See Editors Note.)*

(42) **"Public building"** means a permanent, enclosed structure used by the general public but not necessarily owned by the public.

(43) **"Registration Permit"** means a permit issued for a period not to exceed five (5) years by the council to the owner of a dam or reservoir in existence or in the progress of construction on August 13, 1981 or which becomes subject to the law for such dams and reservoirs by a change in factors or circumstances subsequent to that date. Such permits shall only be issued for dams which are in properly maintained condition or which have made and complied with recommendations for corrections of observed defects of the dam or reservoir and have been examined and approved in accordance with the law.

(44) **"Reservoir"** means any basin, including the water, which contains or will contain the maximum amount of water impounded by a dam.

(45) **"Safety Permit"** means a permit issued to the owner of a dam for a period of five (5) years, or less if safety considerations so require, by the council indicating that the dam meets the requirements of the law, and containing such conditions as to operations, maintenance and repair as are necessary to adequately protect public safety, life and the dam or reservoir.

(46) **"Seepage"** means the migration of water though a dam or foundation.

(47) **"Significant Modification"** means changes, alterations, or modifications to an existing dam or reservoir or changes to the construction documents for a new dam. These include but are not limited to: changes in the location of the dam or reservoir, changes in the storage capacity or drainage area, changes in the capacity of the spillway system, modification of the embankment slopes, changes in the height of the dam or structure or the use of different construction methods or procedures than those submitted with the permit application.

(48) **"Spillway"** means any passageway, channel, or structure, open or closed, or both, designed expressly or primarily to discharge excess water from a reservoir after the water storage elevation has been reached.

(49) **"Spillway design flood"** or **"SDF"** means the specified flood discharge that may be expected from the most severe combination of critical meteorological and hydrologic conditions that are reasonably possible in an area and for which the dam and reservoir are designed. The "SDF" is derived from the rainfall values given in Table 5.

(50) **"Stability"** means the properties of a dam or reservoir that cause it, when disturbed from a condition of equilibrium, to develop forces or moments that restore the original condition.

(51) **"Starter dam"** means a pervious or impervious dam constructed as the first phase in the building of an industrial water retention dam and reservoir.

(52) **"Storage"** means the volumetric capacity of the reservoir below the water storage elevation or other selected reference on the dam.

(53) **"Stream"** means any river, creek or channel, having well-defined banks, in which water flows for substantial periods of the year to drain a given area.

(54) **"Tailings"** means the material generated by a mining/milling operation, which is deposited in slurry form in an impoundment for storage and/or disposal or both.

(55) **"Tailings dam"** means an existing dam or reservoir used for the impoundment or retention of tailings or a proposed, existing or newly constructed dam and reservoir for which the anticipated or contemplated use is the impoundment or retention of tailings.

(56) **"Toe"** or **"toe of slope"** means the line of the fill (dam embankment) slope where it intersects the natural ground.

(57) **"Water"** means water, other liquids or tailings.

(58) **"Watercourse"** means a valley, swale, depression, or other low place in the topography occupied by flowing water during conditions of runoff.

(59) **"Water storage elevation"** means that elevation of water surface at the principal spillway, which could be obtained by the dam or reservoir were there no outflow and were the reservoir full of water.

(60) **"Watershed"** means the area that contributes or may contribute surface water to a reservoir.

Auth: sections 236.405 and 236.415, RSMo (1986). Original rule filed April 14, 1981, effective August 13, 1981. Amended: Filed June 14, 1984, effective January 1, 1985. Amended: Filed September 7, 1993, effective May 9, 1994.

10 CSR 22-1.030 Immunity of Officers

PURPOSE: The purpose of this rule is to restate the immunity from damages provided in section 236.475, RSMo (1986)

(1) In the absence of willful and wanton misconduct, no action shall be brought against the council, the chief engineer or his agents, or department employees or private individuals employed as consultants by the department for the recovery of damages caused by the partial or total failure of any dam or reservoir or through the use of operation of any dam or reservoir upon the ground that such person is liable by virtue of any of the following: the approval of a dam or reservoir or permits therefore; the issuance or enforcement or orders relating to maintenance, operation or repair of a dam or reservoir; control or regulation of a dam or reservoir; measures taken to protect against failure during an emergency; or denial of a permit.

Auth: sections 236.475, RSMo (1986). Original rule filed April 14, 1981, effective August 13, 1981.

TITLE 10 – DEPARTMENT OF NATURAL RESOURCES
DIVISION 22 – DAM AND RESERVOIR SAFETY COUNCIL

CHAPTER 2 – PERMITS

10 CSR 22-2.010 Who Needs a Permit

PURPOSE: The purpose of this rule is to identify those persons who need to obtain a permit for their dam and reservoir and to identify those persons who do not need to obtain a permit for their dam and reservoir.

(1) The owner of a proposed new dam thirty-five feet (35') or more in height is required to obtain a construction permit and a safety permit for his dam and reservoir. The owner of an existing dam thirty-five feet (35') or more in height is required to obtain a registration permit within the time set forth in 10 CSR 22-2.020(2).

(2) By definition, the United States government is not considered an owner. Therefore, no federal dam and reservoir is regulated by section 236.400 to 236.500, RSMo (1986), and no permits are required.

(3) Agricultural dams are exempted from all permit requirements as long as the agricultural dam and reservoir continue to be used primarily for agricultural purposes, (see 10 CSR 22-1.020(2)). The owners of agricultural dams and reservoirs over thirty-five feet (35') in height must notify the council of their reliance on this exemption and their basis for application of this exemption to their dams. If an agricultural dam and reservoir is constructed after the effective date of the law, but subsequently becomes subject to the provisions of the law, the owner shall, prior to obtaining a registration permit, provide evidence that the dam meets the construction permit criteria in effect at the time the dam was constructed.

(4) Dams and reservoirs licensed and operated under the Federal Power Act are exempted from all permit requirements.

(5) Dams and reservoirs that were designed by and the construction monitored by an agency engineer (see 10 CSR 22-1.020(1)) do not need a construction permit but a set of plans shall be filed with the chief engineer prior to the initiation of the construction activity. These dams and reservoirs are required to have a registration or safety permit subsequent to construction.

(6) Industrial water retention dams (see 10 CSR 22-1.020(26)) and reservoirs regulated by another state agency or federal agency are exempted from all permit requirements. For the exemption to apply the industrial water retention dam and reservoir must be subject to safety inspections by the other state agency or federal agency and standards used must be at least as stringent as those required by the law. In addition the owner must notify the council that another agency is regulating his dam and reservoir and explain the basis for the exemption to apply.

Auth: sections 236.400, 236.405, 236.415, 236.435, 236.440, and 236.465, RSMo (1986). Original rule filed April 14, 1981, effective August 13, 1981. Amended: Filed June 14, 1984, effective January 1, 1985. Amended: Filed September 7, 1993, effective May 9, 1994.

10 CSR 22-2.020 Types of Permits

PURPOSE: The purpose of this rule is to describe the three (3) types of permits and their uses that the Dam and Reservoir Safety Council will issue.

(1) There are three (3) types of permits – registration permits, construction permits and safety permits and each one is intended to regulate a separate and distinct type of activity. A dam and reservoir will have only one (1) type of permit in effect at any given time although they may have more than one type of permit during their existence.

(2) Registration permits (see 10 CSR 22-1.020(43)) apply to and are required for the continued operation of a dam and reservoir that was in existence on the effective date of this paragraph, August 13, 1981. A registration permit also applies to and is required for structures which become subject to the provisions of the dam and reservoir safety law that were in existence prior to the date that they became sub-

ject to the law. Registration permits may be issued for a time period up to five (5) years. The owner of a dam and reservoir on the effective date of the law shall obtain his first registration permit in accordance with the height of his dam. For dam heights of thirty-five feet (35') to less than fifty feet (50'), fifty feet to seventy feet (50'-70'), and over seventy feet (70'+), the maximum time to obtain the first registration permit is respectively within nine (9) years, four (4) years, and two (2) years from the effective date of this section, August 13, 1981.

(3) Construction permits (see 10 CSR 22-1.020(8)) apply to the construction of a new dam and reservoir, or the alteration, enlargement, reduction, repair, or removal of a new or existing dam, reservoir or appurtenances. New dams are dams for which construction commences after the effective date of this section, August 13, 1981. For dams that were under construction on August 13, 1981, construction must be completed by August 13, 1987 or the owner will be required to obtain a construction permit. If completed prior to August 13, 1987, the owner will be required to obtain a registration permit as outlined in 10 CSR 22-2.020(2). A construction permit may be issued for any reasonable length time period required to complete construction and it may contain appropriate restrictions placed on the owner for construction and operation of the dam and reservoir during that period. At the conclusion of construction, a safety or registration permit shall be obtained by the owner.

(4) Safety permits (see 10 CSR 22-1.020(45)) apply to the operation of a dam and reservoir constructed pursuant to a construction permit. The safety permit is not a guarantee of the dam and reservoir's safety and does not alter the owner's liability; it is simply an operating permit. If a dam and reservoir were not subject to the provisions of the law when they were constructed but subsequently become subject to the provisions of the law, the owner shall obtain a registration permit, not a safety permit. Safety permits may be issued for a time period up to five (5) years, and they may contain appropriate conditions for the operation and safety of the dam and reservoir.

Auth: sections 236.400, 236.405, 236.415, 236.435, 236.440 and 236.465, RSMo (1986). Original rules filed April 14, 1981, effective August 13, 1981. Amended: Filed June 14, 1984, effective January 1, 1985. Amended: Filed May 15, 1987, effective September 15, 1987.

10 CSR 22-2.030 Types of Dams and Reservoirs

PURPOSE: The purpose of this rule is to describe the two (2) fundamentally different types of dams and reservoirs that will be required to obtain permits from the Dam and Reservoir Safety Council.

(1) There are two (2) types of dams and reservoirs, conventional dams and reservoirs and industrial water retention dams and reservoirs. The two (2) types of dams and reservoirs are distinguished on the basis of their reservoir contents and the length of the time period during which active dam building occurs.

(2) Conventional dams and reservoirs (see 10 CSR 22-1.020(9)) are dams and reservoirs used for purposes other than tailings, slime, settling or other similar industrial water retention purposes. A conventional dam is constructed in one relatively continuous operation over a short time span (compared to the design life of the reservoir). Filling and use of the reservoir occurs after construction is completed.

(3) Industrial water retention dams and reservoirs (see 10 CSR 22-1.020(26)) are dams and reservoirs used for the purpose of storing solids and the water associated with the particular industrial process such as tailings, slime and other similar industrial materials. An industrial water retention dam may be constructed in phases and steps or continuously, over a long period of time (compared to the design life of the reservoir). Filling and use of the reservoir may occur during most phases of construction. An industrial water retention dam and reservoir in existence or under construction on the effective date of 10 CSR 22-2.020(2), August 13, 1981, shall obtain a registration permit which may include approval to make enlargements. The owner of any such dam and reservoir shall apply for and obtain new construction and/or registration permits for any modifications to that dam and reservoir other than enlargements covered by an existing permit. A construction permit is required and shall be obtained by the owner, for the initial construction phase of any new industrial water retention dam and reservoir built after the effective date of 10 CSR 22-2.020(3), August 13, 1981. Upon completion of the initial construction phase, the owner shall apply for a safety permit for the operation and enlargement of the new dam and reservoir.

Auth: sections 236.405, 236.415, 236.435, 236.440, and 236.465, RSMo (1986). Original rule filed April 14, 1981, effective August 13, 1981. Amended: Filed June 14, 1984, effective January 1, 1985.

10 CSR 22-2.040 Classes of Downstream Environment

PURPOSE: The purpose of this rule is to describe the three (3) environmental classes for the downstream environmental zone that will be used by the Dam and Reservoir Safety Council when considering permits.

(1) The downstream environment zone is the area downstream from a dam that would be affected by inundation in the event the dam failed. Inundation is defined as water, two feet (2') or more deep over the general level of the submerged ground affected outside the stream channel. Based on the content of the downstream environment zone, three (3) environmental classes are defined. They are: class I, which contains ten (10) or more permanent dwellings or any public building; class II, which contains one (1) to none (9) permanent dwellings, or one (1) or more campgrounds with permanent water, sewer and electrical services or one (1) or more industrial buildings; and class III, which is everything else.

(2) Spillway design standards are based on the environmental class of the downstream environment zone of a dam and reservoir. The standards become more stringent for lower environmental class numbers. If conditions change in the downstream environment zone and it becomes necessary to change the environmental class of the dam and reservoir, the owner must then meet the standards and criteria for the new environmental class of the dam and reservoir. A dam and reservoir may be in only one (1) environmental class at any given time.

(3) Inundation, the downstream environment zone and the associated environmental class are analyzed assuming the dam fails with the reservoir at the emergency spillway crest elevation or the dam crest elevation in the absence of an emergency spillway. If the spillway standards for class I are used, the failure analysis does not have to be performed. If a failure analysis is made, the contents of the downstream environment zone used to determine the environmental class are only the features that would be inundated by the flooding resulting from the dam failure.

Auth: sections 236.405, 236.415, 236.435, 236.440 and 236.465, RSMo (1986). Original rules filed April 14, 1981, effective August 13, 1981. Amended: Filed June 14, 1984, effective January 1, 1985.

10 CSR 22-2.050 Issuing First Permit

PURPOSE: The purpose of this rule is to describe the procedure for issuing the first permit to a dam and reservoir owner for a particular dam and reservoir.

(1) A permit will be issued or a letter will be sent to the owner with comment within forty-five (45) days after the receipt of a properly prepared application or after the completion of any hearings or record period conducted by the council in connection with such application, whichever is later. The council, upon hearing the recommendations of the chief engineer, shall approve or deny the permit application.

(2) A permit will be issued if a complete and proper application has been submitted and the dam and reservoir comply with the law.

(A) A registration permit may be denied if it is determined that the owner has not complied with the experienced professional engineer's or agency engineer's inspection recommendations.

(B) A construction permit may be denied if there is insufficient information to determine that the proposed construction, alteration, enlargement, reduction or removal of a dam or reservoir would not endanger public safety, life or property.

(C) A safety permit may be denied if it is determined that there are violations of the construction permit or the law.

(D) If revisions have been made which vary substantially from the provisions of the construction permit, the owner must show that the revisions do not endanger public safety, life or property before a safety permit will be issued.

(3) Conditions contained in a construction permit shall include that the construction work must be under the responsible charge of an experienced professional engineer and that records be kept and made available as required by the chief engineer including, without limitation, for the foundation excavation and inspection and placement of backfill in the core trench. It is not necessary for the engineer in responsible charge to be on site continuously. During construction, the council or its del-

egate, or the chief engineer, may make periodic site inspections for the purpose of inspecting for and securing conformity of construction with the approved plans and specifications, and the owner shall, upon reasonable notice, permit such person entry upon its property to make such inspections. The owner may be required to perform, at their own expense, reasonable work or tests as are necessary to provide sufficient information to enable the council to determine that there is such conformity. Usually, such testing will be limited to verification of embankment compaction, concrete strengths and other similar requirements. It is expected that such tests will be required where the owner's inspection records are lacking.

(4) Any significant modifications from construction permit or approved plans makes the permit void and requires the owner to obtain a new permit. Significant modifications to the plans and specifications must be prepared by an experienced professional engineer. The council or its delegate will follow the same evaluation procedures for the modifications as used with issuance of the original construction permit. Special attention will be given to these modification requests to provide a quick decision.

(5) The owner of a dam and reservoir that is removed under a construction permit must notify the council or its delegate when this work is completed and in conformity with the provisions of the construction permit. The council or its delegate will then issue a final approval to relieve the owner of the requirement to have a permit upon a showing that the requirements of the law for removal have been satisfied.

(6) Approval by the council for a construction permit becomes invalid within one (1) year unless work on the construction has begun within that period, except that the owner may be excused from beginning work for such period of time that the work is prevented by flood, shortage of materials or regulation of government which cannot be met for reasons over which the owner has no control or other causes beyond the owner's control. The same applies to construction of approved modifications contained in the conditions of a registration or safety permit for industrial water retention dams unless the conditions specify a different time schedule.

Auth: sections 236.400, 236.405, 236.415, 236.435, 236.440 and 236.465, RSMo (1986). Original rule filed April 14, 1981, effective August 13, 1981. Amended: Filed June 14, 1984, effective January 1, 1985.

10 CSR 22-2.060 Issuing Permit Renewals

PURPOSE: The purpose of this rule is to describe the procedure for renewing a permit.

(1) The owner of a permitted dam and reservoir must apply for the renewal of the permit not less than sixty (60) days prior to expiration of that permit. Before any permit may be renewed, the chief engineer must determine that the dam and reservoir are essentially as described in the latest permit and approved plans; they satisfy the law; and that no inspection conducted in connection with the permit renewal reveals any defect which would threaten public safety, life or property. The council or its delegate will issue another permit within forty-five (45) days of the receipt of a complete and proper application unless it is determined that the dam and reservoir are not as described in the latest permit and approved plans; not properly maintained; do not satisfy the law; or that the defects are not corrected.

(2) The council may require the owner to furnish a certification by an experienced professional engineer or an agency engineer that the dam and reservoir are as described in the latest permit and approved plans; are properly maintained, satisfy the law; and have all the defects corrected.

Auth: sections 236.405, 236.415, 236.440 and 236.465, RSMO (1986). Original rule filed April 14, 1981, effective August 13, 1981. Amended: Filed June 14, 1984, effective January 1, 1985.

10 CSR 22-2.080 Revoking Permit

PURPOSE: The purpose of this rule is to describe the reasons for revoking a permit.

(1) Approval of the council or its delegate, the chief engineer, shall be obtained for modifications that substantially alter or adversely affect the safety or stability of the dam or reservoir. Such modifications, without the approval of the council or its delegate, the chief engineer, are cause for suspension or revocation of any permit. It the chief engineer finds that the condition of the dam and reservoir has deteriorated substantially from those conditions present when the permit was issued, or that has defects which adversely affect the safety or sta-

bility of the dam and reservoir or threatens public safety, life or property, he shall suspend or revoke the permit. It a permit is suspended or revoked, the dam owner will be in violation of the law and may be subject to prosecution for a misdemeanor.

(2) If the chief engineer determines that a dam or reservoir constitutes a threat to public safety, life or property, he may order its removal or take any other actions necessary to reduce or eliminate such threat. Failure of a dam owner to alter or remove his dam and reservoir, as directed, when it is found to be a threat to public safety, life or property will result in revocation of the permit and, if necessary, removal of the dam or any other action necessary to reduce or eliminate the threat to public safety, life or property by the state at the owner's expense.

Auth: sections 236.405, 236.415, 236.445, 236.495 and 236.500, RSMo (1986). Original rule filed April 14, 1981, effective August 13, 1981. Amended: Filed June 14, 1984, effective January 1, 1985.

10 CSR 22-2.090 Transferring Permit

PURPOSE: The purpose of this rule is to describe the procedure for transferring a permit with ownership changes.

(1) Permits issued pursuant to 10 CSR 22-2.050 and 10 CSR 22-2.060 are transferable only as provided in section 236.460 RSMo (1986). If ownership or other transfer of interest in the dam and reservoir changes, the former owner must notify the chief engineer of the sale or transfer and the permit will be transferred to the new owner after determination that such transfer will not endanger the public safety, life, property, the dam or reservoir. The permit holder of record will be held responsible for maintaining compliance with these rules and standards. If the former owner does not have the permit transferred, the new owner may submit the appropriate application and documents necessary to obtain a new permit. The new owner must, in this case, also show proof of ownership. The old owner's responsibilities of ownership under the law will not be extinguished until the permit is transferred to an eligible owner. Nothing in these regulations shall be construed to eliminate the liability of the previous owner for injuries caused by a dam failure, nor a new operator who has not obtained a permit nor had an existing permit transferred to his name.

Auth: sections 236.405, 236.415, and 236.460, RSMo (1986). Original rule filed April 14, 1981, effective August 13, 1981. Amended: Filed June 14, 1984, effective January 1, 1985.

10 CSR 22-2.100 Appeal of Action on Permits

PURPOSE: The purpose of this rule is to describe the procedure for appealing the results of any action taken with regard to a permit.

(1) Permits revoked or denied are subject to council appeal. All parties shall be afforded an opportunity for hearing before the council for review of denial or revocations decisions, if request is made within thirty (30) days after notice is served personally or by certified or registered mail upon such parties or their agents. Except for emergency action, further legal action shall not be taken until after such hearing and council decision.

(2) The record of hearing shall include all written testimony, data, records, etc. as well as all oral proceedings recorded stenographically or by such other means that will preserve the testimony. Rules of discovery, evidence and privilege as applied in civil cases in the circuit courts shall be followed.

(3) A final decision will be in writing, and the party or their agents will be notified personally or by registered or certified mail of the final decision. A copy of any opinion in support of this decision will be furnished upon request. Such decisions are subject to judicial review pursuant to provisions of section 236.480, RSMo (1986).

Auth: sections 236.405, 236.415, 236.425, 236.440, 236.445, 236.470 and 236.480, RSMo (1986). Original rule filed April 14, 1981, effective August 13, 1981. Amended: Filed June 14, 1984, effective January 1, 1985.

TITLE 10 – DEPARTMENT OF NATURAL RESOURCES
DIVISION 22 – DAM AND RESERVOIR SAFETY COUNCIL

CHAPTER 3 – PERMIT REQUIREMENTS

10 CSR 22-3.010 General Information

PURPOSE: The purpose of this rule is to provide general information about permit requirements.

(1) Requirements for existing or proposed dams and reservoirs must allow for variations in conditions and materials from site to site. Therefore, this rule and rules 10 CSR 22-3.020 to 10 CSR 22-3.050 describe the minimum general requirements which are consistent with current engineering, geologic, construction, operation and maintenance practices, necessary to obtain permits from the Dam and Reservoir Safety Council.

(2) These rules are not intended to define the only requirements for a dam and reservoir to comply with the law, or the only engineering, geologic and construction practices to be used in detailed site investigation or in the specific design and construction of individual dams. The detailed and specific information that outlines current and prudent engineering, geologic and construction practices is available in technical literature. Determinations by the Dam and Reservoir Safety Council, after hearing the recommendations of the chief engineer of the acceptability of a design and adequacy of plans, specifications and construction must, by necessity, be made on a case by case basis. Therefore, it is recommended that applicants unfamiliar with the way these rules are applied contact the council or the chief engineer prior to commencing extensive work or plan development.

(3) Adherence to the law does not guarantee the safety of any dam or reservoir or relieve the owner of any liability in the event of dam failure.

(4) A permit application form along with a copy of the laws, rules, standards, and guidelines relating to dam and reservoir safety can be obtained free from the Department of Natural Resources, Geological Survey and Resource Assessment Division, Dam Safety Program, PO Box 250, Rolla, MO 65402-0250. Persons seeking this and/or other information on dams in Missouri should address their inquiry to the chief engineer.

Auth: sections 236.400, 236.405, 236.415, 236.435, 236.440 and 236.465, RSMo (1986). Original rule filed April 14, 1981, effective August 13, 1981. Amended: Filed June 14, 1984, effective January 1, 1985.

10 CSR 22-3.020 General Requirements

PURPOSE: The purpose of this rule is to itemize the basic requirements and standards that apply to all permits.

(1) The permit application must contain information required by the council and the chief engineer including, but not limited to, the following information: type of permit being applied for; name of owners; mailing address of owners; telephone number(s) of owners; name of dam; name of reservoir; coordinate location of the dam centerline at the maximum section; purpose or use of dam and reservoir; name, address and telephone number of the experienced professional engineer or agency engineer who has provided or will provide required technical assistance; and the downstream environment zone environmental class for the dam and reservoir. The owners must complete applicable investigations required in 10 CSR 22-3.020 to 10 CSR 22-3.050 before filing a permit application. All permit applications must be filed with the chief engineer at the address listed in 10 CSR 22-3.010 (4).

(2) The owner must provide a determination of an environmental class for each dam and reservoir. The method, data, and assumptions used by the owner to determine environmental class shall conform to practices reputable and in current use in the engineering, geologic and construction profession or the chief engineer may reject the owner's classification. If an owner chooses not to have this done by an experienced professional engineer or an agency engineer, the chief engineer will assign the dam and reservoir to environmental class I or he may assign the dam and reservoir to the appro-

priate environmental class if he has justification to do so.

(3) The anticipated consequences of a dam failure with respect to public safety, life and property damage are important considerations in establishing acceptable methods for specific investigations and sites. Methods used in exploration, design, construction and maintenance must be in accordance with good engineering practices reputable and in current use in the engineering, geologic and construction professions.

(4) When the owner is applying for a construction permit, the required design factors of safety for slope stability for earth and rock conventional dams which are given in Table 1 shall be met. The required design factors of safety for concrete conventional dams are given in Table 2. The required design factors of safety for slope stability for industrial water retention dams are given in Table 3. Owners shall meet these requirements in the design of new dams prior to the issuance of the permit. Owners shall also meet these requirements when substantial changes are proposed to the height or slope of an existing conventional dam or structure prior to the issuance of the construction permit. (see following tables)

(5) For new dams constructed wholly or partially of cohesionless materials (such as sands and silts) or having a foundation of cohesionless materials, earthquake loading may result in the build-up of pore water pressures and a loss of strength. Engineers shall take this pore pressure increase and loss of strength into account when performing their stability analysis, but the degree to which liquefaction may affect the factor of safety for slope stability shall be left up to the engineer's best judgement. Bedrock accelerations and earthquake intensities are listed in Table 4.

(6) New dams constructed wholly of cohesive materials (such as clays) and having a foundation of cohesive materials or bedrock, can be expected to withstand significant earthquake shaking if it can be shown that other required design factors of safety for slope stability are met. Therefore, only new dams located in Bollinger, Butler, Cape Girardeau, Dunklin, Mississippi, New Madrid, Pemiscot, Ripley, Scott, Stoddard and Wayne counties must meet the requirements for slope stability during earthquake loading while dams located in other counties do not unless 10 CSR 22-3.020(5) applies to them. Bedrock accelerations and earthquake intensities are listed in Table 4.

(7) The required spillway design flood, which shall allow for flood storage in the reservoir, is to be derived by using the precipitation values given in Table 5 and shall apply to both new and existing dams.

Auth: sections 236.400, 236.405, 236.435, 236.440 and 236.465, RSMo (1986). Original rule filed April 14, 1981, effective August 13, 1981. Amended: Filed June 14, 1984, effective January 1, 1985.

10 CSR 22-3.030 Registration Permit Requirements

PURPOSE: The purpose of this rule is to itemize the requirements for a registration permit.

(1) In addition to the basic requirements for all permits listed in 10 CSR 22-3.020(1),(2),(3) and (7), the registration permit application for a conventional dam and reservoir must include certification by an experienced professional engineer or an agency engineer that the dam and reservoir have been inspected in accordance with the law and that the owner has complied with the engineer's recommendations to correct observed defects and an inspection report, as required by the law. The engineer must further show that the spillway can safely pass the spillway design flood derived from Table 5 and submit a report describing the correction of all observed defects and the description of an operation and maintenance program to be followed while the registration permit is in effect.

(A) The inspection of a dam and reservoir for a registration permit is intended to detect observable defects. The procedure to determine observable defects normally will be a surface examination by an experienced professional engineer or an agency engineer. The inspection must include all surface examinations necessary to determine if observable defects exist that affect the stability of the dam and reservoir or the adequacy of the spillway. Judgement of the structural stability and an evaluation of the spillway capacity must be made. Judgement shall be based upon the engineer's experience, training and knowledge of similar dams and in accordance with practices reputable and in current use in the engineering, geologic and construction professions.

1. Observed defects which may require correction, evaluated on the basis of current engineer-

TABLE 1

Required Design Factors of Safety for Slope Stability
Earth and Rock Conventional Dams

Loading Condition	Factor of Safety
End of construction, full reservoir*	1.4
Steady seepage, full reservoir*	1.5
Steady seepage, maximum reservoir*	1.3
Sudden drawdown, from full to empty reservoir (if applicable)	1.2
Earthquake***, steady seepage, full reservoir*	1.0

* Full reservoir means water level is at the water storage elevation
** Maximum reservoir means water level is at maximum water level attained during the spillway design flood or at the dam crest elevation, whichever is lower.
*** Earthquake loading will vary according to dam location in relation to seismic source zones and downstream environmental zones. See Table 4.

TABLE 2

Required Design Factors of Safety
Concrete Conventional Dams

Failure Mode	Loading Condition	Factor of Safety
Overturning	full reservoir*	1.5
	maximum reservoir**	1.3
Sliding	full reservoir*	1.5
	maximum reservoir**	1.3
Structural integrity	full reservoir*	1.5
	maximum reservoir**	1.3
Earthquake*** - any mode	full or maximum reservoir* & **	1.0

* Full reservoir means water level is at the water storage elevation.
** Maximum reservoir means water level is at maximum level attained during the spillway design flood.
*** Earthquake loading will vary according to dam location in relation to seismic source zones and downstream environmental zones. See Table 4.

TABLE 3

Required Design Factors of Safety for Slope Stability
Industrial Water Retention Dams

Loading Condition	Factor of Safety
Starter dam, end of construction, full reservoir*	1.4
Any other stage of construction, full reservoir*, steady seepage	1.3
Any other stage of construction, maximum reservoir**, steady seepage	1.0
Completed dam, full reservoir*, steady seepage	1.5
Completed dam, maximum reservoir**, steady seepage	1.3
Earthquake***, steady seepage, full reservoir*	1.0

* Full reservoir means water level is at the water storage elevation.
** Maximum reservoir means water level is at maximum water level attained during the spillway design flood or at the dam crest elevation, whichever is lower.
*** Earthquake loading will vary according to dam location in relation to seismic source zones and downstream environmental zones. See Table 4.

TABLE 4

Required Design Acceleration for Earthquake Design

Dam Type	Stage of Construction	Special Descriptions	Environmental Class I	II	III
Conventional or Industrial	Completed	New dams less than 50 feet in height	.75PMA*	.5PMA*	.25PMA*
		New dams greater than 50 feet in height**	.75PMA*	.5PMA*	.4PMA*
Industrial	Starter Dam	New Dams**	.5PMA*	.2PMA*	.1PMA*
	After starter dam is finished and before final dam is completed	New Dams**	.75PMA*	.5PMA*	.2PMA*

Zone:	A	B	C	D	E	F
PMA*:	0.31g	0.28g	0.26g	0.23g	0.20g	0.17g
Intensity***:	IX-X	IX	VIII-IX	VIII	VII-VIII	VII

* PMA is Probable Maximum Acceleration of bedrock which is determined by the zones as a fraction of the acceleration of gravity (g-32.2fps^2) for six zones in Missouri (See 10 CSR 22-1.010(40)).
** See 10 CSR 22-2.020(3) for clarification.

TABLE 5

Required Spillway Design Flood Precipitation Values

Dam Type	Stage of Construction	Special Descriptions	Environmental Class I	II	III
Conventional or Industrial	Completed	Any existing dam**	.75PMP*	.5PMP*	100 Yr****
		New dams less than 50 feet in height**	.75PMP*	.5PMP*	100 Yr****
		New dams greater than 50 feet in height**	.75PMP*	.5PMP*	100 Yr****
Industrial	Starter Dam	Any	.5PMP*	.2PMP*	.1PMP*
	After starter dam is finished and before final dam is completed	Any	.75PMP*	.5PMP*	.2PMP*

* PMP is Probable Maximum Precipitation.
** Existing dam means a dam which was completed by August 13, 1981 or which was started prior to August 13, 1981 and completed by August 13, 1987.
*** See 10 CSR 22-2.020(3) for clarification.
**** 100 Yr is the 100-year frequency rainfall event.

ing, geologic and construction practices, include but are not limited to: slides; slopes as steep as or steeper than those on similar types of dams and constructed of similar materials which have experienced slope stability problems; piping of fines; seepage that exits in an uncontrolled fashion on the downstream slope of or from the downstream foundation of the dam; unusual zones of softness and irregular settlement; erosion on the upstream or downstream slope of the dam; spillways that are calculated to be inadequate for the design flood; spillways that are eroded or otherwise in poor condition; and cracks in the embankment or structure.

2. Observed defects that are in an advanced state of deterioration must be immediately reported by the inspecting engineer to the owner and to the chief engineer.

(B) Proper maintenance and operation of a dam and reservoir are critical to the continuing safety of a dam and reservoir and to public safety, life and property. A maintenance program shall be required and shall include the following items: erosion control on the embankment; monitoring emergency spillway flow rates; vegetation control; spillway maintenance; emergency action plans; maintenance and monitoring of seepage observation devices, if any; and maintenance and monitoring of instruments used, if any, to observe the stability of the dam.

(C) Visits for the purpose of observation of maintenance and operation may be made by the council, the chief engineer or a member of the chief engineer's staff. Such visits will be at any reasonable time following reasonable notice, except that in the case of an emergency threatening public safety, life or property no such notice shall be required, and inspection may be at any time. Owners shall permit entry to its property for such persons to perform such inspections.

(D) The application need not state, nor is it necessary to show, that the dam is a safe dam. The intent of the registration permit is to show that the dam is performing adequately and that there are no observable indications that the dam is unsafe.

(2) In addition to the basic requirements for all permits listed in 10 CSR 22-3.020(1),(2),(3), and (7), the registration permit application for an industrial water retention dam and reservoir shall include certification by an experienced professional engineer or an agency engineer that the dam and reservoir have been inspected in accordance with the law and that the owner has complied with the engineer's recommendations to correct observed defects and an inspection report, as required by the law. The engineer must further show that the spillway can safely pass the spillway design flood derived from Table 5 and submit a report describing the correction of any observed defects, the operation and maintenance program to be made a part of the registration permit, and the phased, stepped, and/or continuous construction of the dam.

(A) The inspection of an industrial water retention dam and reservoir for a registration permit is intended to detect observable defects. The procedure to determine observable defects normally will be a surface examination by an experienced professional engineer or an agency engineer. The inspection must include all surface examinations necessary to determine if observable defects exist that affect the stability of the dam and reservoir or the adequacy of the spillway. Judgement of the structural ability and an evaluation of the spillway capacity must be made. Judgement shall be based upon the engineer's experience, training, and knowledge of similar dams and in accordance with practices reputable and in current use in the engineering, geologic and construction professions.

1. Observed defects which may require correction, evaluated on the basis of current engineering, geologic and construction practices, include but are not limited to: slides, slopes as steep as or steeper than those on similar types of dams and constructed of similar materials which have experienced slope stability problems; piping of fines; seepage that exits in an uncontrolled fashion on the downstream slope of or from the downstream foundation of the dam; unusual zones of softness and irregular settlement; erosion on the upstream or downstream slope of the dam; spillways that are calculated to be inadequate for the design flood; spillways that are eroded or otherwise in poor condition; and cracks in the embankment or structure.

2. Observed defects that are in an advanced state of deterioration must be immediately reported by the inspecting engineer to the owner and to the chief engineer.

(B) Proper maintenance and operation of a dam and reservoir are critical to the continuing safety of a dam and reservoir and the protection of public safety, life and property. A maintenance and operation program shall be required and shall include the following items: erosion control on the embankment; monitoring of storm runoff; vegetation control spillway maintenance; emergency action plans; maintenance and monitoring of seepage observation devices, if any; and maintenance and monitoring of instruments used, if any, to observe the stability of the dam.

(C) The council or chief engineer may require the owner to submit a report describing the phased, stepped and/or continuous construction of an industrial water retention dam and reservoir, containing information on the materials used, method of transport and placement of materials, the sequence and placement location of materials, spillway changes to be made, the anticipated final dimensions and configuration of the dam and the name, address and telephone number of the person(s) in responsible charge of this work.

(D) Visits for the purpose of inspecting during construction or enlargement or observation of maintenance and operation may be made by the council, the chief engineer or a member of the chief engineer's staff. Such visits will be at any reasonable time following reasonable notice, except that in the case of an emergency threatening public safety, life or property, no such notice shall be required, and inspection may be made at any time. Owners shall permit entry to its property for such persons to perform such inspection.

(E) It shall not be necessary for the owner to retain an experienced professional engineer or an agency engineer continuously during the entire permit period unless there is modification(s) in the construction method described in the permit application. However, personnel with adequate supervision and training in methods of safe construction, maintenance and operation of dams must be provided to insure that the construction, maintenance and operation of the dam and reservoir are carried out as described.

(F) The registration permit will be the only permit required for an industrial water retention dam and reservoir that was in existence prior to the effective date listed in 10 CSR 22-2.020(2) unless it is to be reduced and removed. If the dam or reservoir is to be reduced or removed, a construction permit will be required. Other changes will require the owner to obtain a new registration permit.

(G) The application need not state, nor is it necessary to show, that the dam is a safe dam. The intent of the registration permit is to show that the dam is performing adequately and that there are no readily observable indications that the dam is unsafe, and that phased, stepped and/or continuous construction of the dam will meet the requirements of the law.

Auth: sections 236.400, 236.405, 236.415, 236.420, 236.425, 236.440 and 236.465, RSMo (1986). Original rule filed April 14, 1981, effective August 13, 1981. Amended: Filed June 14, 1984, effective January 1, 1985.

10 CSR 22-3.040 Construction Permit Requirements

PURPOSE: The purpose of this rule is to itemize the requirements for a construction permit.

(1) In addition to the basic requirements for all permits listed in 10 CSR 22-3.020, the construction permit application for a conventional dam and reservoir shall be prepared by or under the direction of and certified by an experienced professional engineer and shall be in accordance with practices reputable and appropriate in the engineering, geologic and construction professions.

(A) The following requirements shall apply to, and the following information shall be provided by the owner:

1. Up-to-date topographic map(s) showing the location of the proposed or existing dam, the upstream watershed, the reservoir, and the downstream environment zone. The topographic map(s) of the project area must be at a scale appropriate to the size of the project area. An up-to-date US Geological Survey topographic map is considered a minimum;

2. Exploration records and results including the location of all exploration, especially in the area of the core trench, the method(s) used to explore the site, a record of what was found, the method(s) used to obtain samples and the number of samples taken;

3. Testing records and results including information on the care and treatment of samples, types of tests performed on samples or in situ, reference(s) to or the procedures used in testing, and the test results. Physical and mechanical properties of foundation and construction materials must include the information source for these values especially if they are not the results of testing;

4. The geotechnical design procedures or method(s) shall be identified and referenced or described so that they may be reviewed and their applicability verified. This shall include all assumptions made. The geotechnical procedure(s) or design results shall include the minimum computed factors of safety and they must meet or exceed the required design factors of safety (see 10 CSR 22-3.020(4)). The geotechnical design information shall be presented for the foundation, core trench, and dam embankment. Earthquake loading must be analyzed as outlined in 10 CSR 22-3.020(5) and (6);

5. The structural design procedure(s) or method(s) shall be identified and referenced or described so that they may be reviewed and their applicability verified. Design results for concrete dams and concrete structures appurtenant to embankment dams shall provide for and show an adequate factor of safety for normal and maximum loading conditions of compression, tension, shear, torsion, buckling, sliding, and overturning;

6. Hydrologic information used to evaluate the watershed, reservoir, spillway, and downstream environment zone including the watershed area, rainfall rate and duration, antecedent moisture conditions, time of concentration, area capacity curves, description of spillway elevation(s), type(s) dimensions, locations, cross-sections and profiles, dam crest elevation and the downstream valley cross-sections;

7. The hydrologic/hydraulic design procedure(s) or method(s) used shall be identified and referenced or described so that they may be reviewed and their applicability verified. This shall include all assumptions made. The hydrologic/hydraulic procedure(s) or design results shall include the reservoir inflow hydrograph, the reservoir outflow hydrograph, the spillway discharge capacity, the freeboard at the maximum water storage elevation and the environmental class of the dam. The dam shall be capable of safely containing or discharging the required design flood (see 10 CSR 22-3.020(7)).

8. Location and design of diversion channels or other structures to control stream flow during or after construction shall be provided if failure of these channels or other structures would affect hydrologic conditions of the dam. Stream diversion systems used during construction shall be designed to provide protection to the dam and the safety of the public.

9. Construction control and inspection procedures shall be used during the construction of a new dam and reservoir or modification of an existing dam and reservoir. Construction control and inspection procedures should include compaction testing and density testing;

10. Procedures shall be used for record keeping and monitoring throughout the construction or modification process to provide information about any construction progress and conditions that may cause difficulties during construction;

11. The location of and protective measures used in conjunction with all drain lines, sewer lines, utilities or other structures that pass through or under the dam;

12. Topographic surveys showing the location of baselines, centerlines, and other horizontal and vertical control points sufficiently accurate to locate the proposed construction and to define the volume of storage in the reservoir.

13. Two (2) sets of plans and specifications including:

A. Graphic scales shall be provided for all scaled drawings;

B. The title, which shall be identical on the plans and the specifications, shall include: the name of the dam; the name of the owner; whether the work shows an existing dam, a proposed dam or an enlargement, repair or alteration of the dam or reservoir; the county or counties the dam and reservoir are in; the location of the dam by quarter section, section, township, and range or by geodetic coordinates; and each sheet shall have in an appropriate title block the name of the dam as well as the sheet number in relation to the total, e.g. sheet 1 of 12; and

C. Certifications by the experienced professional engineer and the owner shall be placed near the lower right hand corner of the title sheet (first sheet) of the drawings. The certifications shall be similar to those presented in figures 1 and 2 (see figs. 1 and 2).

14. If a construction permit is requested to convert a dam to a retaining or retarding structure, the procedure to be followed in making the conversion shall be described by the owner; and

15. The procedures set up for regular inspection by the owner. The owner shall develop an emergency action plan, inspect his dam regularly and as necessary to protect public safety, life and property. A list of items to be inspected, a time schedule for these inspections and a form for reporting the results shall be established.

(B) The council or chief engineer may require the following action and information from the owner:

1. Procedures set up to provide regular maintenance and minor repairs to the dam and reservoir after construction and to continue or start record keeping and monitoring work so that the dam and reservoir are maintained in a safe condition and a complete history of its performance is available;

2. Location and types of instrumentation; drainage and/or seepage control facilities. Monitoring equipment and drainage control facilities are recommended for all dams and reservoirs; however, depending on conditions, they may be mandatory items if necessary to accomplish the purposes of the law;

3. The downstream environment zone warning procedure to be used if dam failure is a threat. A downstream environment zone warning system is recommended for all dams and reservoirs; however, depending on conditions, it may be necessary to accomplish the purposes of the law. This would consist of the current name(s) of the dam and reservoir owner's representative(s) responsible for giving notification of a threat and the current phone numbers of appropriate local police and other persons having emergency assistance authority;

4. Upstream slope protection from wave action; and

5. Additional actions or information as required to protect public safety, life and property and to accomplish the purposes of the law.

(C) Visits for the purpose of inspecting during or after construction or observation of operation and maintenance may be made by the council, the chief engineer or a member of the chief engineer's staff. Such visits will be at any reasonable time following reasonable notice, except that in the case of an emergency threatening public safety, life or property, no such notice shall be required and inspection may be made at any time. Owner shall permit entry to their property for such persons to perform such inspections.

(2) In addition to the basic requirements for all permits listed in 10 CSR 22-3.020, the construction permit application for an industrial water retention dam and reservoir shall be prepared by or under the direction of and certified by an experienced professional engineer and shall be in accordance with practices reputable and appropriate in the engineering, geologic and construction professions.

(A) The engineer who plans and designs an industrial water retention dam and reservoir or its modification shall assess the sequence, timing, method of placement and stability control program during construction from the beginning of the starter dam or modification through the life of the structure and after operation ceases or until the dam and reservoir no longer need a permit.

(B) Adequate records, as required by good practices in the geologic and engineering professions, shall be kept and made available to the council or chief engineer for the construction, maintenance, and operation procedures. Adequate instrumentation and monitoring of seepage water shall be provided where necessary. Any significant settling or movement in the foundation of the dam should be measured if possible. Trained personnel and adequate supervision shall be provided to insure the construction and operation of the dam and reservoir are carried out to specifications.

Certification by Experienced Professional Engineer

I hereby certify that these plans for the (insert the correct word or words choosing from: existing, construction of the, repair of the, enlargement of the, or alteration of the) _____ Dam were prepared by me (or under my direct supervision) for the owners thereof.
Name of Dam

_____
Firm Name

_____
Registered Engineer

FIGURE 2

Certification by Owner

I, _____, owner, whose Post Office Address is

_____, Zip _____, do hereby accept and approve these plans.

_____
Owner

(C) The following requirements shall apply to, and the following information shall be provided by the owner:

1. A description of the system used to deposit tailings on the dam;

2. Up-to-date topographic map(s) showing the location of the proposed dam, the upstream watershed, the reservoir and the downstream environment zone. The topographic map(s) of the project area must be at a scale appropriate to the size of the project area. An up-to-date U.S. Geological Survey topographic map is considered a minimum;

3. The location(s) of surface and underground mine workings if these workings would cause, would contribute to the cause, or would be affected in the event of failure;

4. Exploration records and results including the location of all exploration, especially in the area of the core trench, the method(s) used to explore the site, a record of what was found, the method(s) used to obtain samples and the number of samples taken;

5. Testing records and results including information on the care and treatment of samples, types of tests performed on samples or in situ, reference(s) to or the procedures used in testing, and the test results. Physical and mechanical properties of foundation and construction materials must include the information source for these values especially if they are not the results of testing;

6. The geotechnical design procedure(s) or method(s) shall be identified and referenced or described so that they may be reviewed and their applicability verified. This shall include all assumptions made. The geotechnical procedure(s) or design results shall include the minimum computed factors of safety and they must meet or exceed the required design factors of safety (see 10 CSR 22-3.020(4)). The geotechnical design information shall be presented for the foundation core trench and dam embankment. Earthquake loading must be analyzed as outlined in 10 CSR 22-3.020(5) and (6);

7. Type and physical properties of the liquid and solid materials to be used in construction of the dam and contained in the reservoir;

8. The changes created in the downstream environment zone as the dam and reservoir become incrementally larger;

9. The embankment changes and new factors of safety for stability as the dam and reservoir become incrementally larger;

10. If a starter dam is used, whether it will be pervious or impervious;

11. The expected crest elevation, dam configuration, spillway elevation, and the size and configuration of each successive stage of the dam shall be included;

12. Anticipated storage volume of solid or semi-solid materials and of liquids at the completion of the dam;

13. The structural design procedure(s) or method(s) shall be identified and referenced or described so that they may be reviewed and their applicability verified. Design results for concrete dams and concrete structures appurtenant to embankment dams shall provide for and show an adequate factor of safety for normal and maximum loading conditions of compression, tension, shear, torsion, buckling, sliding and overturning;

14. Hydrologic information used to evaluate the watershed, reservoir, spillway, and downstream environment zone including the watershed area, rainfall rate and duration, antecedent moisture conditions, time of concentration, area capacity curves, description of spillway elevation(s), type(s), dimensions, locations, cross-sections and profiles, dam crest elevation, and the downstream valley cross-sections;

15. Hydrologic/hydraulic design procedure(s) or method(s) used shall be identified and referenced or described so that they may be reviewed and their applicability verified. This shall include all assumptions made. The hydrologic/hydraulic procedure(s) or design results shall include the reservoir inflow hydrograph, the reservoir outflow hydrograph, the spillway discharge capacity, the freeboard at the maximum water storage elevation and the environmental class of the dam. The dam shall be capable of safely containing or discharging the required design flood (see 10 CSR 22-3.020(7)).

16. The hydrologic changes, the spillway alterations proposed and the freeboard changes as the dam becomes incrementally larger;

17. Location and design of diversion channels or other structures to control stream flow during or after construction shall be provided if failure of these channels or other structures would affect the stability or hydrologic conditions of the dam. Stream diversion systems used during construction shall be designed to provide protection to the dam and to protect public safety, life and property;

18. Location and design of any diversion channels or other structures to control runoff or reclaimed water;

19. Construction control and inspection procedures shall be determined by the engineer and used during the construction of a new dam and reservoir or modification of an existing dam and reservoir. Construction control and inspection procedures shall include compaction testing, density testing, and any other quality control measures used to insure compliance with the construction specifications;

20. Procedures shall be used for record keeping and monitoring throughout the construction, enlargement or modification process to provide information about construction progress and any conditions that may cause difficulties during construction.

21. The location of and protective measures used in conjunction with all drain lines, sewer lines, utilities or other structures that pass through or under the dam;

22. Topographic surveys showing the location of baselines, centerlines and other horizontal and vertical control points sufficiently accurate to locate the proposed construction and to define the volume of storage in the reservoir at each planned stage of construction.

23. Two (2) sets of plans and specifications including:

A. Graphic scales shall be provided for all scaled drawings;

B. The title, which shall be identical on the plans and the specifications shall include: the name of the owner; whether the work shows an existing dam, a proposed dam, or an enlargement, repair or alteration of the dam and reservoir; the county or counties the dam and reservoir are in; the location of the dam by quarter section, section, township and range or by geodetic coordinates; and each sheet shall have in an appropriate title block the name of the dam as well as the sheet number in relation to the total, e.g., sheet 1 of 12; and

C. Certification by the experienced professional engineer and the owner shall be placed near the lower right hand corner of the title sheet (first sheet) of the drawings. The certifications shall be similar to those presented in figures 1 and 2 (see figs. 1 and 2 preceding).

24. If a construction permit is requested to convert a dam to a retaining or retarding structure, the procedure to be followed in making the conversion shall be described by the owner; and

25. The procedure set up for regular inspection by the owner. The owner shall develop an emergency action plan, inspect his dam and reservoir regularly and as necessary to protect public safety, life and property. A list of items to be inspected, a time schedule for these inspections and a form for reporting the results shall be established by the council or chief engineer. Items that shall receive maintenance to and/or inspections on a daily basis during periods of active dam enlargement include: the spigots or cyclones; the decant lines; the position of the water pool in relation to the spillway, decant intake and crest of the tailings dam; drain lines checked for quantity of water and sediment; the embankment observed for visual defects such as slides or significant seepage changes; the spillway shall be checked to verify that it has not become blocked.

(D) The council or chief engineer may require the following action and information from the owner:

1. Procedures set up to provide regular maintenance and minor repairs to the dam and reservoir during construction and enlargement so that the dam and reservoir are maintained in a safe condition and a complete history of its performance is available;

2. Location and types of instrumentation, drainage, and/or seepage control facilities. Monitoring equipment and drainage and seepage control facilities are recommended for all dams and reservoirs; however, depending on conditions, they may be mandatory items if necessary to accomplish the purposes of the law;

3. The downstream environment zone warning procedure to be used if dam failure is a threat. A downstream environment zone warning system is recommended for all dams and reservoirs; however, depending on conditions, it may be necessary to accomplish the purposes of the law. This would consist of the current name(s) of the dam and reservoir owners representative(s) responsible for giving notification of a threat of failure and the current phone numbers of appropriate local police and other persons having emergency assistance authority;

4. Upstream slope protection from wave action; and

5. Additional actions or information as required to protect public safety, life and property and to accomplish the purposes of the law.

(E) Visits for the purpose of inspecting during or after construction or observation of operation and maintenance may be made by the council, the chief engineer, or a member of the chief engineer's staff. Such visits will be at any reasonable time following reasonable notice, except that in the case of an

emergency threatening public safety, life or property, no such notice shall be required and inspection may be made at any time. Owners shall permit entry to their property for such persons to perform such inspections.

(F) Drawings to show changes shall be submitted when such changes are made to the original plans including, without limitation, changes in incremental dam crest heights, spillway locations, and cross-sections.

Auth: sections 236.400, 236.405, 236.415, 236.420, 236.425, 236.435, 236.440 and 236.465, RSMo (1986). Original rule filed April 14, 1981, effective August 13, 1981. Amended: Filed June 14, 1984, effective January 1, 1985.

10 CSR 22-3.050 Safety Permit Requirements

PURPOSE: The purpose of this rule is to itemize the requirements for a safety permit.

(1) In addition the basic requirements for all permits listed in 10 CSR 22-3.020, the safety permit application for a conventional dam and reservoir shall include:

(A) Notification of the completion of construction and application for the first safety permit for the dam and reservoir shall be provided by the owner. The experienced professional engineer or agency engineer who was in responsible charge of the construction work shall certify that the construction was substantially in accordance with the approved plans and specifications. If revisions have been made which vary considerably from the provisions of the construction permit, it must be shown that the revisions do not endanger public safety, life or property. This subsection shall not be construed to excuse any person from the requirement to notify the council or chief engineer of modifications or revisions prior to commencing such actions and to obtain the required permits or authorization therefore;

(B) Notification of completion shall be within two (2) month's time after completion of construction; and

(C) As built drawings shall be submitted.

(2) In addition to the basic requirements for all permits listed in 10 CSR 22-3.020, the application for a safety permit for an industrial water retention dam and reservoir shall include:

(A) Notification of completion of the starter dam or the initial phase of construction shall be prepared by or under the supervision of an experienced professional engineer in accordance with the provisions of the construction permit;

(B) Notification of the completion of construction and application for the first safety permit for the dam and reservoir shall be provided by the owner or the experienced professional engineer who was in responsible charge of the construction work. The engineer shall certify that the construction was substantially in accordance with the approved plans and specifications. If revisions have been made which vary considerably from the provisions of the construction permit, it must be shown that the revisions do not endanger public safety, life or property. This subsection shall not be construed to excuse any person from the requirement to notify the council or chief engineer of modifications or revisions prior to commencing such actions and to obtain the required permits or authorization therefore;

(C) Notification of completion shall be within two (2) month's time after completion of construction; and

(D) As built drawings shall be submitted.

(3) Visits for the purpose of observation of operation and maintenance procedures may be made by the council, the chief engineer or member of their staff. Such visits will be at any reasonable time following reasonable notice, except that in the case of an emergency threatening public safety, life or property, no such notice shall be required, and inspection may be made at any time. Owners shall permit entry to their property for such persons to perform such inspections.

Auth: sections 236.400, 236.405, 236.415, 236.420, 236.425, 235.440, and 236.465, RSMo (1986). Original rule filed April 14, 1981, effective August 13, 1981. Amended: Filed June 14, 1984, effective January 1, 1985.

TITLE 10 – DEPARTMENT OF NATURAL RESOURCES
DIVISION 22 – DAM AND RESERVOIR SAFETY COUNCIL

CHAPTER 4 – ACTION TAKEN BY COUNCIL AND CHIEF ENGINEER

10 CSR 22-4.010 Emergency Action

PURPOSE: The purpose of this rule is to define the way emergency action is taken.

(1) In performing his duties, the chief engineer shall determine by inspection whether a dam or reservoir constitutes a threat to public safety, life or property. If it is determined that a dam is in an advanced state of deterioration and in such condition that continued deterioration could cause failure of the dam, the chief engineer may classify the dam as dangerous to public safety, life or property. If the chief engineer or council further determines that there is not sufficient time to issue an enforcement order to the owner to correct the hazard, or to take other legal action, the chief engineer or council may take any appropriate action necessary for emergency protection of public safety, life or property. The type of action depends upon the state of progression of the deterioration, the physical layout of the dam, reservoir and inundation zone below the dam, and the resources available to the chief engineer or council at the time of the emergency.

(2) The chief engineer or council, upon determining that a dam or reservoir is dangerous and constitutes a substantial threat of failure may request the attorney general or a prosecuting attorney to take any legal steps necessary for the protection of public safety, life or property. Such action may be brought in any county where the defendant or defendant's principal place of business is located or where the dam or reservoir is located. Nothing in this section shall preclude the chief engineer or council from taking immediate action under 10 CSR 22-4.010(1) above with respect to any dam or reservoir he has classified as dangerous to public safety, life or property.

Auth: sections 236.400, 236.405, 236.420, 236.425 and 236.455, RSMo. Original rule filed June 14, 1984, effective January 1, 1985.

10 CSR 22-4.020 Enforcement Orders and Enforcement Procedures

PURPOSE: The purpose of this rule is to identify the procedure to be taken for the issuance of enforcement orders.

(1) Enforcement orders shall be prepared by the chief engineer or council in cases where a dam or reservoir contains serious defects that pose a threat to public safety, life or property. Enforcement orders shall be sent to a dam owner by certified mail or served personally.

(2) If an owner does not initiate corrective actions to his dam and reservoir within thirty (30) days of the issuance of an enforcement order by the chief engineer or council, the council may request the attorney general or a prosecuting attorney to apply to the circuit court having jurisdiction to enforce compliance. Nothing in this section shall preclude the chief engineer from taking immediate action under 10 CSR 22-4.010(1) above with respect to any dam or reservoir he has classified as dangerous to public safety, life or property.

Auth: sections 236.400, 236.405, 236.410, 236.415, 236.445 and 236.450, RSMo. Original rule filed June 14, 1984, effective January 1, 1985.

REVISED STATUTES OF MISSOURI
CHAPTER 236
DAMS, MILLS, AND ELECTRIC POWER

Dam and Reservoir Safety

236.400. Definitions. As used in sections 236.400 to 236.500, standards, rules, and regulations promulgated hereunder, unless the context otherwise requires the following words and terms mean:

(1) **"Agricultural dam"**, any dam constructed to impound water for use in irrigation, livestock watering, or commercial fish rearing and sale;

(2) **"Alterations", "repairs",** or either of them, such alterations or repairs as affect the safety of a dam or reservoir, or public safety, life or property.

(3) **"Chief engineer"**, the head of the dam and reservoir safety program of the department of natural resources or his representative;

(4) **"Construction permit"**, a written authorization issued by the council giving the owner the right to construct, alter, enlarge, reduce, repair, or remove a dam or reservoir or appurtenances thereto, with such conditions as are necessary to adequately protect the public safety, life, property, the dam or reservoir;

(5) **"Dam"**, any artificial or manmade barrier which does or may impound water, and which impoundment has or may have a surface area of fifteen or more acres of water at the water storage elevation, or which is thirty-five feet or more in height from the natural bed of the stream or watercourse measured at the downstream toe of the barrier or dam, if it is not across a streambed or watercourse, together with appurtenant works. Sections 236.400 to 236.500 shall not apply to any dam which is not or will not be in excess of thirty-five feet in height or to any dam or reservoir licensed and operated under the Federal Power Act.

(6) **"Dam and reservoir safety council"**, as designed by sections 236.400 to 236.500 and referred to as the "council" shall consist of seven members appointed by the governor according to the provisions of sections 236.400 to 236.500;

(7) **"Director"**, the director of the department of natural resources of the state of Missouri;

(8) **"Enlargement"**, any change in or addition to an existing dam or reservoir which raises the height of a dam, increases the watershed for a reservoir, or raises the water storage elevation of the water impounded by a dam or reservoir;

(9) **"Experienced professional engineer"**, an engineer registered in the state of Missouri and experienced in hydraulics, hydrology and civil engineering as applied to dam design and construction;

(10) **"Maintenance"**, the proper keeping of all aspects of a dam or reservoir and appurtenances thereto, that pertain to safety, in a state of repair and working order as necessary to comply with sections 236.400 to 236.500, any permit hereunder, and protect public safety, life and property;

(11) **"Natural physical changes"**, those changes not directly or indirectly caused by man which affect the safety of the dam or reservoir.

(12) **"Operation"**, the physical changes, natural or manmade that occur or are made to a dam or reservoir, or operation of the mechanisms or appurtenances of the dam or reservoir which affect or may affect public safety, life or property;

(13) **"Owner"**, a person who owns, controls, operates, maintains, manages, or proposes to construct a dam or reservoir including:

(a) The state and its departments, institutions, agencies, and political subdivisions, but not the United States government;

(b) A municipal or quasi-municipal corporation;

(c) A district;

(d) A public utility;

(e) A natural person, firm, partnership, association, corporation, political subdivision, or legal entity;

(f) The duly authorized agents, lessees, or trustees of any of the foregoing;

(g) Receivers or trustees appointed by any court for any of the foregoing;

(14) **"Permit"**, a construction, safety, or registration permit;

(15) **"Permit applicant"**, an owner who applies for a construction, safety or registration permit.

(16) **"Reduction"**, any decrease in the height of a dam, watershed size, or watershed storage elevation of the water impounded by a dam or reservoir;

(17) **"Registration permit"**, a permit issued for a period not to exceed five years by the council to the owner of a dam and reservoir in existence on September 28, 1979, or which becomes subject to 236.500 for such dams and reservoirs which are in a properly maintained condition or which have made and complied with recommendations for corrections of observed defects of the dam or reservoir and have been* examined and approved in accordance with sections 236.400 to 236.500 and standards, rules and regulations and guidelines issued pursuant to sections 236.400 to 236.500.

(18) **"Reservoir"**, any impoundment which results from a dam as defined in sections 236.400 to 236.500;

(19) **"Safety permit"**, a permit issued to the owner for a period of five years, or less if safety considerations so require, by the council indicating that the dam meets the requirements of sections 236.400 to 236.500 and the guidelines, standards, rules and regulations issued pursuant to sections 236.400 to 236.500, and containing such conditions as to operations, maintenance and repair as are necessary to adequately protect public safety, life and the dam or reservoir.

(20) **"Water"**, water, other liquid or tailings.

(21) **"Water storage elevation"**, that elevation of water surface at the principal spillway which could be obtained by the dam or reservoir were there no outflow and were the reservoir full of water;

(22) **"Watershed"**, the area usually expressed in acres of square miles, that contributes or may contribute surface water to a reservoir.

(L. 1979 H.B. 603 § 1)

*Words "have been" not in original rolls.

236.405. Employment of engineer and assistants-records.- -1. There is hereby created a dam and reservoir safety program in the department of natural resources. The council shall promulgate rules, regulations, guidelines, and standards relating to the determination of whether a dam or reservoir constitutes a danger to public safety, life or property to be effective upon approval by the director.

2. The director of the department of natural resources shall employ an experienced professional engineer as chief engineer and assistants to administer the activities of the dam and reservoir safety program.

3. The chief engineer shall be selected under the state merit system on the basis of professional experience directly related to the design and construction of dams and reservoirs.

4. The findings, opinions, and orders of the council and the chief engineer shall be kept as permanent public records in the offices of the department of natural resources.

(L 1979 H.B. 603 § 2)

236.410. Council established-members, terms, qualifications, officers-meetings-quorum-compensation.- -1. There is hereby created a "Dam and Reservoir Safety Council" whose domicile for the purposes of sections 236.400 to 236.500 shall be the department of natural resources of the state of Missouri, for the regulation of dam and reservoir safety. The council shall consist of seven members, no more than four of whom shall be members of the same political party, appointed by the governor with the advice and consent of the senate.

2. The members of the council shall have a background of academic training or professional experience directly related to the design of dams and reservoirs. At least two members of the council shall

be professional engineers registered in the state of Missouri, one of whom shall represent the general public; at least one member shall be an engineering geologist; at least one member, in addition to the professional engineer, shall be a representative of the general public, and two members shall be from industry, one of whom shall be an earthmoving contractor; and one member shall be the owner of a dam or reservoir. The members shall serve for a term of two years; except, of the first appointments three shall be appointed for one year. The governor shall fill any vacancy on the council and may remove any appointed member for cause. The council shall annually elect a chairman and vice-chairman from among its members. The council shall meet regularly but not less than quarterly. Special meetings and hearings may be called upon delivery of written notice to each member of the council signed by the director, the chief engineer, the council chairman, or four of the council members. Four members of the council shall constitute a quorum to transact the business of the council. The council shall decide all questions by a majority vote of those present and constituting a quorum. The members of this council shall not receive any compensation other than for actual travel and subsistence when acting officially as members of the council.

(L. 1979 H.B. 603 § 3)

236.415. Council's powers and duties-public hearings required-adoption of rules and regulations, procedure-suspension and reinstatement, procedure.- -1. The council considering recommendations of the chief engineer shall, subsequent to a public meeting, adopt, subject to the approval of the director, the general technological guidelines and the standards, guidelines, rules and regulations applicable to permits, the design, construction, maintenance, operation, alteration, repair, enlargement, reduction, removal or natural physical changes that may occur to a dam or reservoir. Violations of guidelines, standards, rules and regulations are violations of sections 236.400 to 236.500 permitting the revocation, suspensions, or refusal to issue any permit required by sections 236.400 to 236.500. No standards, guidelines, rules or regulations shall be adopted, or any amendment or repeal thereof shall be effective, except after a public hearing to be held after thirty days prior notice by advertisement or press release, and publication as required in chapter 536, RSMo, of the date, time and place of the hearing and opportunity given to the public to be heard.

2. At the hearing, opportunity to be heard by the council with respect to the subject thereof shall be afforded any interested person upon written request to the council, addressed to the chief engineer, received not later than seven days prior to the hearing and may be afforded to other persons if convenient. In addition, any interested person, whether or not heard, may submit, within seven days subsequent to the hearings, a written statement of his views. The council may solicit the views, in writing, of persons who may be affected by, or interested in, proposed rules and regulations, standards or guidelines. Any person heard or represented at any hearing or making written request for notice shall be given written notice of the action of the council with respect to the subject thereof.

3. The council upon hearing the recommendations of the chief engineer and reviewing the application for a construction or registration permit shall approve or deny the permit application. The council may delegate authority to approve or deny permit applications to the chief engineer, whose actions shall be subject to appeal to the council as provided in subsection 2 of section 236.425.

4. No standard, rule or regulation or guideline, or amendment or repeal thereof, adopted by the council shall be in force and effect until it has been approved in writing by the director and the requirements of chapter 536, RSMo, are satisfied. The affirmative vote of at least four members of the council shall be required for adoption. Any rule or portion of a rule promulgated pursuant to sections 236.400 to 236.500 may be suspended by the joint committee on administrative rules if after hearing thereon the committee finds that such rule or portion of the rule is beyond or contrary to the statutory authority of the agency which promulgated the rule, or is inconsistent with the legislative intent of the authorizing statute. The general assembly may reinstate such rule by concurrent resolution signed by the governor.

(L 1979 H.B. 603 § 4)

236.420. Inspection of dams and reservoirs, when-report on conditions.- -The council, with the advice and assistance of the chief engineer, shall carry out a state program of inspection of dams and reservoirs in accordance with regulations adopted by the council. All dams and reservoirs in this state shall be inspected on a periodic basis to determine if they constitute a threat to public safety, life or property. The chief engineer shall submit reports to the

director and the council concerning the condition of each dam or reservoir inspected, and the recommendations as to any alterations or repairs needed.
(L 1979 H.B. 603 § 5)

236.425. Chief engineer's duties-search warrants-council to hear certain appeals.- -1. The chief engineer shall administer the provisions of sections 236.400 to 236.500 by:

(1) Recommending general technological guidelines that pertain to the design, construction, maintenance, operation, use alteration, repair, enlargement, reduction, or natural physical changes of, or that may occur to, a dam or reservoir including their removal; except that, detailed technical specifications shall not be promulgated to regulate the design, construction, operation, maintenance, use, alteration, repair or removal of a dam or reservoir. Such guideline shall not be effective until adopted by the council and approved by the director at a public meeting, after notice requirements set forth in subsection 1 of section 236.415 herein have been satisfied;

(2) Making* recommendations concerning the issuing, continuing in effect, revoking, modifying suspending, or denying, under such conditions as prescribed by sections 236.400 to 236.500 and such rules as may be adopted to protect public safety, life, property, dams and reservoirs, construction permits for the construction, alteration, enlargement reduction, repair or removal of dams or appurtenances thereto, and safety and registration permits to insure continuing protection of public safety, life, property, dams and reservoirs, for all dams subject to the provisions of sections 236.400 to 236.500.

(3) Making such investigations, including hearings, as are proper to protect public safety, life and property from an unsafe dam or reservoir, and to determine whether any permits should be issued, continued, revoked, modified, suspended, or denied or whether any violations of sections 236.400 to 236.500, standards, or rules or regulations have occurred or are occurring;

(4) Entering, at any reasonable time, any private or public premises as necessary to make an investigation or inspection of a dam or reservoir, or records kept, pertaining thereto, and such inspection shall follow reasonable notice to the owner given prior to such investigation or inspection except in the case of an emergency threatening public safety, life or property, in which case such inspection or investigation may be made without prior notice. A suitably restricted search warrant, upon a showing of probable cause in writing and upon oath, shall be issued by any judge or magistrate having jurisdiction, to the chief engineer or his representative for the purpose of enabling him to make the inspection.

2. The council shall meet with or hear the appeal of a permit application and his representative upon request of the permit applicant if the chief engineer has rejected the application for a construction, safety, or registration permit.
(L 1979 H.B. 603 § 6)
*Words "To Make" appear in original rolls.

236.430. Employees, council to provide for.- -The council shall retain, employ, provide for and compensate within appropriations available therefore, such consultants, assistants, and other employees on a full-or part-time basis as may be necessary to carry out the provisions of sections 236.400 to 236.500 and prescribe the times at which they shall be appointed and their powers and duties.
(L 1979 H.B. 603 § 7)

236.435. Permits required, when, procedure to obtain-chief engineer to make recommendation-exemptions-plans to be filed.- -1. Prior to the commencement of the construction, alteration, enlargement, reduction or removal of a dam or reservoir, the owner shall apply to the council and upon satisfying the requirements of sections 236.400 to 236.500 and the rules, regulations and standards promulgated pursuant hereto, obtain a construction permit.

2. The application for a construction permit shall bear the seal and signature of an experienced professional engineer registered in Missouri or employed by a qualified engineering division of a state or federal agency regularly engaged in dam construction for soil and water conservation, or irrigation or relating to wildlife conservation and shall be accompanied by the design report and plans and specifications of the proposed design, alteration, enlargement, reduction, repair or removal of the dam or reservoir.

3. Any person constructing or owning a dam or reservoir, or living or owning property in an area affected, or whose safety may be affected by such dam or reservoir may consult with the chief engineer concerning such dam or reservoir.

4. The council upon hearing the recommendations

of the chief engineer shall approve or deny an application for a construction permit within forty-five days after its receipt or the completion of any hearings in connection with such application, whichever is later. The permit shall be issued upon the receipt of the application if, in the judgement of the council, requirements of sections 236.400 to 236.500 and all standards, rules and regulations hereunder are satisfied and the design will be adequate to protect the public safety, life and property.

5. The council upon hearing the recommendation of the chief engineer may reject the application if it decides that there is insufficient information to determine the safety of the proposed construction, alteration, enlargement, reduction or removal of the dam or reservoir would endanger public safety, life or property, or otherwise not comply with sections 236.400 to 236.500 and any rules, standards, guidelines and regulations adopted hereunder.

6. A landowner that now owns or proposes to construct an agricultural dam or reservoir, which will be used primarily for agricultural purposes, will be exempt from all provisions of sections 236.400 to 236.500. If the council, with the advice of the chief engineer, determines that the dam or reservoir is no longer used primarily for agricultural services, it shall become subject to the provisions of sections 236.400 to 236.500.

7. Dams or their construction, alterations, enlargements, reductions or removals designed by, and their construction, alteration, enlargement, reduction or repair or removal monitored by, a qualified engineer regularly engaged in dam construction for soil and water conservation or irrigation or relating to wildlife conservation are for the purposes of such construction or other listed actions exempt from the provisions of this section except that the plans for the dam shall be filed with the chief engineer prior to construction, or other listed action. Amended plans shall be filed at the completion of construction or other listed action if there have been significant deviations from the previously filed plans.

(L 1979 H.B. 603 § 9)

236.440. Owner to notify council, when-council to issue safety permit-registration of existing dams, when-violations.- -1. The owner shall notify the council upon completion of construction, alteration, enlargement, or reduction of the dam and reservoir. This notification shall bear the seal and signature of an experienced professional engineer and shall be accompanied by an application for a safety permit. The owner of any dam or reservoir subject to the provisions of sections 236.400 to 236.500 shall obtain a safety permit following completion of construction.

2. Upon receipt of complete and proper application for a safety permit, including notification of completion by the owner and certification by an experienced professional engineer that the new construction, alteration, enlargement or reduction has been completed in accordance with the provisions of the construction permit and sections 236.400 to 236.500, the council shall upon receipt of the application issue a safety permit. The council upon advice of the chief engineer may deny the application if it determines that violations of the construction permit or sections 236.400 to 236.500 exist. If revisions have been made which vary substantially from the provisions of the construction permit, it must be shown that the revisions do not endanger public safety, life or property. The safety permit for dams constructed pursuant to a construction permit issued under sections 236.400 to 236.500, may contain conditions the council upon advice of the chief engineer determines are necessary for the protection of public safety, life or property and a schedule and timetable for the dam and reservoir to achieve compliance with the construction permit and provisions of sections 236.400 to 236.500, standards, rules and regulations promulgated hereunder, but such conditions shall not be more stringent or restrictive than those contained in the construction permit.

3. Owners of dams and reservoirs in existence on September 28, 1979, shall obtain registration permits for dams of fifty to seventy feet in height within four years, and for dams up to fifty feet in height within six years of September 28, 1979, or as otherwise required by the provisions of sections 236.400 to 236.500 and rules and regulations adopted hereunder. A registration permit shall be issued by the council upon the advice of the chief engineer for dams and reservoirs only after it is determined that the dam meets the standards of sections 236.400 to 236.500 and rules and regulations hereunder, and any recommendations made by the inspecting engineer pursuant thereto.

4. Upon complete and prior application for a registration permit, on forms provided by the department of natural resources, by the owner of a dam in existence upon September 28, 1979, including a cer-

tification by an experienced professional engineer or an engineering division of state or federal agency regularly engaged in dam construction for soil or water conservation, irrigation, or relating to wildlife conservation, that the dam has been inspected in accordance with sections 236.400 to 236.500, standards, rules and regulations and guidelines promulgated hereunder, and that the owner has complied with the inspecting engineer's or agency's recommendations necessary to correct observed defects of the dam or reservoir, the council shall, upon receipt of the application, issue a registration permit. The council upon hearing the recommendations of the chief engineer may deny the application if it determines that the owner has not complied with the inspecting engineer's or agency's recommendations.

5. For dams for which construction was completed prior to the effective date of the construction permit requirements hereunder, the registration permit may contain conditions the council upon hearing recommendations of the chief engineer determines to be necessary to bring the dam and reservoir into compliance with sections 236.400 to 236.500 and standards, rules and regulations promulgated hereunder.

6. If a dam or reservoir has been removed by the owner, the council shall issue a final approval upon notification by the owner and receipt of certification by an experienced professional engineer that the removal has been carried out in accordance with the provisions of the construction permit issued for such removal. Failure to obtain final approval shall be a violation of sections 236.400 to 236.500.

7. The council shall issue safety permits for dams or their construction, alterations, enlargements reductions or removals designed by, and their construction or other listed actions monitored by, a state or federal agency engaged in dam construction for soil and water conservation, irrigation or relating to wildlife conservation provided the owners obtain from such agency and file with the chief engineer a statement upon completion of the construction or other listed actions and at not greater than five year intervals, and with every application for renewal of a safety permit, that the dam conforms to the plans on file with the chief engineer and is in a safe, properly maintained condition.

8. The owner shall apply for renewal of a safety or registration permit not less than sixty days prior to expiration of the previously issued permit. The chief engineer shall determine if the dam and reservoir are essentially as described in the latest permit issued for that dam and reservoir, whether they satisfy the requirements of sections 236.400 to 236.500 and any rules, regulations, standards and guidelines adopted pursuant to sections 236.400 to 236.500 and whether any inspections conducted in connection with the permit renewal reveals any defect in the dam or reservoir which would threaten public safety, life or property. Unless the chief engineer determines that the dam and reservoir are not properly maintained, do not satisfy the requirements of the permit, act* of rules, regulations, standards and guidelines promulgated hereunder, or that defects revealed by the inspection are not corrected, the council upon hearing the recommendations of the chief engineer shall issue or renew the safety or registration permit upon forty-five days of the receipt of a complete and proper application. The council may require the owner to furnish a certification, as a part of an application to renew a permit hereunder, by an experienced professional engineer or a qualified engineering division of a state or federal agency regularly engaged in dam construction for water conservation, irrigation or relating to wildlife conservation that the dam is in a properly maintained condition and that any recommendation for correction of defects which violate sections 236.400 to 236.500, guidelines, rules, regulations and standards hereunder or which threaten public safety, life or property have been complied with and that the engineer detected no other such defects which have not been corrected.

9. If a barrier or water impoundment becomes a dam or reservoir through alteration or enlargement as defined herein, it shall be subject to the provisions of sections 236.400 to 236.500.

10. Failure to obtain and comply with a permit as required in this section is a violation of sections 236.400 to 236.500.

(L. 1979 H.B. 603 § 9)

* Word "act" apparently refers to "this act," now 236.400 to 236.500.

236.445. Permit may be suspended-alteration or removal may be required-violation.- -1. If it is found that a dam or reservoir presents a threat to public safety, life or property, or that the safety of the dam or reservoir is threatened, the permit for

the dam or reservoir shall be suspended and shall be reinstated only when the owner at his expense has completed the necessary alteration or has established such operational procedures as the council upon hearing the recommendations of the chief engineer deems necessary for the protection of the public safety, life, property, the dam or reservoir. If necessary for such protection, the council may require the owner at his expense to remove the dam or reservoir, or if the owner refuses or neglects to act, the state may alter or remove the dam or reservoir, and the chief engineer may recover the costs of such action as provided in section 236.450.

2. If the owner refuses to alter or remove a dam or reservoir as directed when found to be a threat as set forth in sections 236.400 to 236.500, he shall be in violation of sections 236.400 to 236.500 and the permit requirements hereunder and such action shall subject the owner to the enforcement provisions contained herein and revocation of the permit.

(L. 1979 H.B. 603 § 10)

236.450. Removal or repair of abandoned dam-recovery of expenses.- -An existing dam or reservoir which the chief engineer determines to be abandoned and considered to be a threat to public safety, life, or property may be altered, repaired, or removed upon such determination at the expense of the state of Missouri, and the chief engineer may request either the attorney general or a prosecuting attorney to bring an action in the name of the people of the sate of Missouri to recover such expenses from the owner through appropriate legal processes. Such action may be brought in any county where the defendant or defendant's principal place of business is located or where the dam or reservoir is located.

(L. 1979 H.B. 603 § 11)

236.455. Emergency action authorized.- -If it is determined at any time that the condition of a dam or reservoir is an imminent and substantial threat, and so dangerous to public safety, life or property as not to permit time for issuance of an enforcement order to correct the hazard, the chief engineer may take any appropriate action not prohibited by the constitution or laws of the state he deems necessary for emergency protection of public safety, life or property and may request the attorney general or a prosecuting attorney to take any legal steps necessary to accomplish such action and to recover the cost of such measures from the owner by appropriate legal action.

(L. 1979 H.B. 603 § 12)

236.460. Transfer of ownership, notice required.- -The owner shall notify the chief engineer upon the sale or other transfer or interest in a dam or reservoir, either existing or under construction, alteration or removal. The construction, safety or registration permit shall be transferred to the successive owner upon receipt of this notification and upon determination that such transfer will not endanger public safety, life, property, the dam or reservoir.

(L. 1979 H.B. 603 § 13)

236.465. Industrial water retention structures subject to provisions of sections 236.400 to 236.500-inspection-changes.- -Irrespective of any other provisions of sections 236.400 to 236.500, the following provisions shall apply to the construction, alteration or enlargement of tailing, slime and settling ponds and to other similar industrial water retention structures included within the definitions of dam or reservoir in section 236.400:

(1) Applications for construction, safety or registration permits shall be submitted as provided in section 236.435 and section 236.440 except that design plans and specifications which outline any anticipated enlargement of the industrial water retention structure shall be included;

(2) It shall not be necessary to reapply for a permit each time the structure is enlarged if the enlargement plans have been submitted in and approved with the original application, and the provision of subdivision (3) of this section have been satisfied.

(3) Upon notification of the chief engineer, bearing the seal and signature of an experienced professional engineer, that the initial phase of construction has been completed in accordance with the provisions of the construction permit and sections 236.400 to 236.500, or if a registration permit has been issued as provided in subdivision (1) of this section, and before any enlargement is begun, and if no violation of sections 236.400 to 236.500 can be shown, a safety permit or a registration permit with special provisions that authorize the planned enlargement to the initially constructed structure shall be issued, on application, if enlargement plans were included and approved in the original application;

(4) It is not necessary to retain continuously a professional engineer after the initial stage of construction;

(5) The dam shall be inspected by an experienced professional engineer registered in the state of Missouri as required to renew the safety permit or registration permit at five-year intervals unless safety or the public, life and property require a shorter period of time;

(6) The chief engineer shall make inspections of these structures as necessary to insure adequate protection for public safety, life and property;

(7) Where it is shown that a tailings, slime and settling pond, or other similar water retention structure is subject to inspection for safety, using standards at least as stringent as those required under sections 236.400 to 236.500, by a federal or state agency and the owner notifies the council that the structure is subject to such inspection, such structures shall be exempt from the provisions of sections 236.400 to 236.500.

(L. 1979 H.B. 603 § 14)

236.470. Conduct of hearings subpoenas-approval of final orders.- -1. At any public hearing all testimony taken before the council, or a hearing officer appointed by the council chairman, shall be under oath and recorded stenographically. The transcript so recorded shall be made available to any person upon payment of the usual charge therefore;

2. In any such hearing, any member of the council or the hearing officer shall issue in the name of the council notice of hearing and subpoenas. Subpoenas shall be issued and enforced as provided in section 536.077, RSMo. The rules of discovery that apply in any civil case apply to hearings held by the council.

3. All hearings to approve, amend or repeal guidelines, standards or rules and regulations shall be held before at least four members of the council.

4. All other hearings may be held before one council member designated by the council chairman or a hearing officer who shall be a member of the Missouri bar and appointed by the council chairman. The hearing officer or council member shall preside at the hearing and hear all evidence and rule on the admissibility of evidence. The hearing officer or council member shall make recommended findings of fact and may make recommended conclusions of law to the council.

5. All final orders or determinations or other final actions by the council shall be approved in writing by at least four members of the council. Any council member approving in writing any final order or* determination or other final action, who did not attend the hearing, shall do so only after reviewing all exhibits and reading the entire transcript.

(L. 1979 H.B. 603 § 15)

* Word "of" appears in original rolls.

236.475. Immunity of officers.- -In the absence of willful and wanton misconduct, no action shall be brought against the council, the chief engineer or his agents, or department employees or private individuals employed as consultants by the department for the recovery of damages caused by the partial or total failure of any dam or reservoir or through the use or operation of any dam or reservoir upon the ground that such person is liable for virtue of any of the following:

(1) The approval of a dam or reservoir or permits therefore;

(2) The issuance or enforcement of orders relating to maintenance, operation, or repair of a dam or reservoir;

(3) Control and regulation of a dam or reservoir;

(4) Measures taken to protect against failure during an emergency.

(L. 1979 H.B. 603 § 16)

236.480. Judicial review of actions-administrative review required-interpretation of administrative actions.- -1. All final decisions, orders, actions or determinations made pursuant to the provisions of sections 236.400 to 236.500 are subject to judicial review pursuant to the provisions of chapter 536, RSMo. No judicial review shall be available, however, until all administrative remedies are exhausted.

2. In any suit filed pursuant to section 236.400 to 236.500, RSMo, concerning the validity of the standards, rules, guidelines and regulations promulgated hereunder, the court shall review the record made pursuant to their adoption to determine the validity and reasonableness of such standards, rules, guidelines and regulations and may hear such additional evidence as it deems necessary.

(L. 1979 H.B. 603 § 17)

236.485. Water rights preserved.- -The provisions of sections 236.400 to 236.500 do not grant or diminish any right to that water entering, discharged from or impounded by a dam or contained in a reservoir.

(L. 1979 H.B. 603 § 18)

236.490. Enforcement of act.- -All duly constituted officers of the law of this state or any political subdivision thereof shall aid in the enforcement of the provision of sections 236.400 to 236.500.

(L. 1979 H.B. 603 § 19)

236.495. Legal actions for enforcement available, procedure.- -1. In carrying out the provisions of sections 236.400 to 236.500 and to the extent not inconsistent with chapter 491, RSMo, the chief engineer or council may subpoena witnesses and compel their attendance, and may also require the submission of books, papers, documents or other pertinent data in any hearing or enforcement proceedings hereunder or in any case wherein a violation of this chapter is alleged. Upon failure or refusal to comply with such order or upon failure to honor a subpoena, as herein provided, the council may request the attorney general or a prosecuting attorney to apply to the circuit court having jurisdiction to enforce compliance.

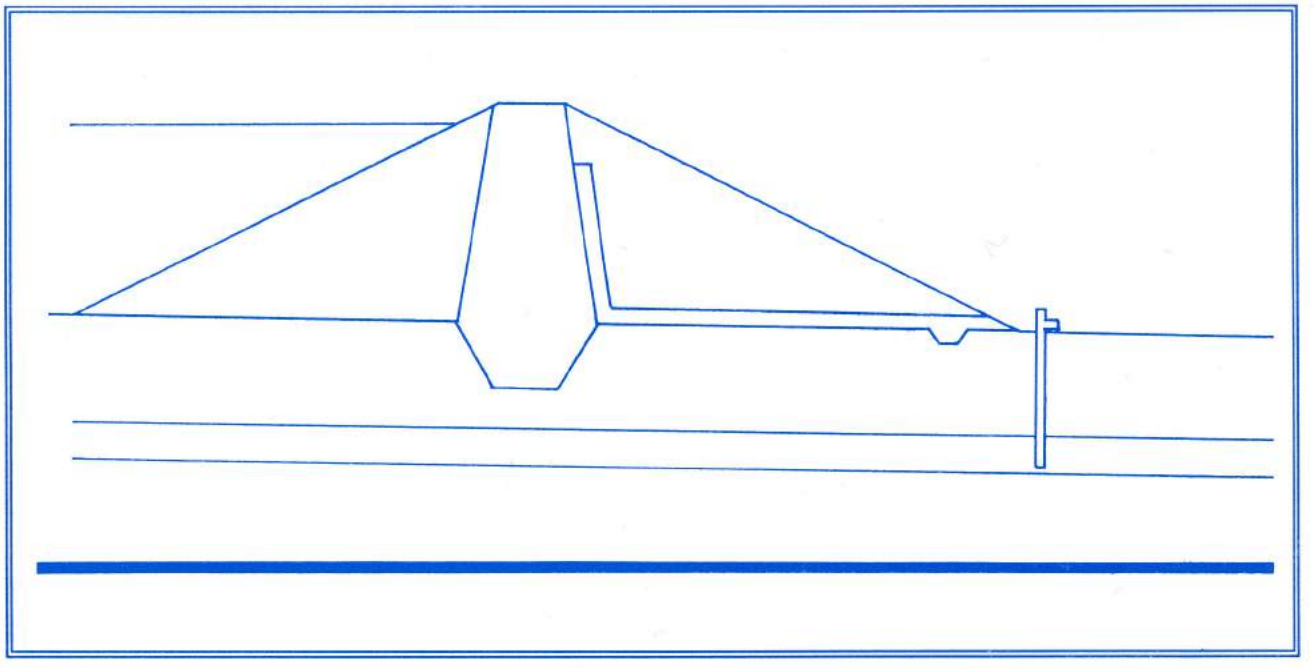
2. The council may request the attorney general or a prosecuting attorney, in the name of the state, to institute a suit for injunctive relief to stop or prevent violations of the provisions of sections 236.400 to 236.500,permits, standards, orders and rules and regulations promulgated hereunder, which shall be violations of sections 236.400 to 236.500, or to restrain any violation thereof, or after written notification of violation by the council, and a reasonable time to correct such violation, for the assessment of a penalty of up to one thousand dollars per day, for each day or part thereof the violation continues to occur after such notice. Such action may be brought in any county where the defendant's principal place of business is located, where the dam or reservoir is located, or the violation does or may occur.

(L. 1979 H.B. 603 § 20)

236.500. Penalties.- -1. Any person who willfully violates any of the provisions of section 236.400 to 236.500 is guilty of a misdemeanor and, upon conviction, shall be punished by a fine of not less than five hundred dollars nor more than ten thousand dollars, or by confinement in the county jail for a term of not less than thirty days nor more than one year, or by both such fine and confinement.

2. In the event of a continuing violation, each day that the violation continues shall constitute a separate and distinct offense.

3. Any person who willfully obstructs, hinders or prevents the council, the chief engineer or his agents or employees from performing the duties imposed by sections 236.400 to 236.500 and rules and regulations promulgated hereunder or who willfully resists the council, the chief engineer, or his agents in the performance of the duties imposed on them by sections 236.400 to 236.500 and rules and regulations promulgated hereunder is guilty of a misdemeanor and, upon conviction, shall be punished as provided in subsection 1 of this section.



4. Any owner who willfully engages in the construction, repair, alteration or removal of any dam or reservoir without a construction permit or in violation of a construction permit or willfully violates the requirements of or for a safety or registration permit is guilty of a misdemeanor and, upon conviction, shall be punished as provided in subsection 1 of this section.

(L. 1979 H.B. 603 § 21)

ENGINEERING ANALYSIS

OF

DAMS

BY
BRIAN J. SWENTY

MISSOURI DEPARTMENT OF NATURAL RESOURCES
DIVISION OF GEOLOGY AND LAND SURVEY
DAM AND RESERVOIR SAFETY PROGRAM

AUGUST 1989

FOREWORD

The first state legislation aimed at regulating dams was passed in 1889 and was called the Dams, Mills, and Electric Power Law. That law was concerned only with damages caused by construction and lake formation. It did not address the engineering aspects of design or safety of dams.

During the period 1977-81, the Corps of Engineers conducted a nationwide inventory and inspection of dams. The results indicated that Missouri ranked fourth in the United States in total number of dams and first in the total number of unsafe dams. Of 613 dams inspected, approximately 75% were considered unsafe. The final report submitted to Congress by the Corps cited Missouri as having inadequate legislation, regulatory procedures, technical staff, and funding.

In September 1979, the Governor signed House Bill 603 into law. The bill became sections 236.400 through 236.500 RSMo and is known as the dam safety law. It authorized the creation of a Dam and Reservoir Safety Council appointed by the Governor and a staff within the Department of Natural Resources to implement the law. Regulations were approved in August 1981 and Missouri began the process of upgrading unsafe dams.

Only dams 35 feet or greater in height are regulated by the Natural Resources' Division of Geology and Land Survey, dam and reservoir safety program. Exemptions to the dam safety law include:

- dams owned and operated by the federal government
- dams licensed by the Federal Energy Regulatory Commission
- dams impounding water used primarily for agricultural purposes

During the past eight years, numerous owners have had their dams inspected in accordance with the law. As these dams were evaluated and analyzed, it became clear that an engineering analysis manual was needed to provide engineers with a technical reference to perform their computations. An abundance of engineering text books, design manuals, and construction guidelines have been written which pertain to the design of dams, but there are few booklets dedicated to the subject of dam safety analysis.

Dam Safety is a complex issue. To determine whether a dam is safe requires a knowledge of hydrology, hydraulic engineering, geotechnical engineering, geology, seismology, surveying, and structural analysis. This manual is intended to provide engineers with a description of analytical techniques that can be used to evaluate the safety of dams.

Two of the goals of the dam safety law are to ensure that new dam construction meets minimum safety standards and defects at older unsafe dams are eliminated. It is my hope that this manual will provide the technical assistance necessary to accomplish these goals.

G. Tracy Mehan III

ENGINEERING ANALYSIS OF DAMS

By Brian J. Swenty, Ph.D., P.E.
Chief Engineer
Dam and Reservoir Safety Program

Department of Natural Resources
Division of Geology and Land Survey
P.O. Box 250, Rolla, MO 65401

ACKNOWLEDGEMENTS

This booklet was prepared under the direction of Dr. James H. Williams, Director of the Division of Geology and Land Survey, Missouri Department of Natural Resources, and the Missouri Dam and Reservoir Safety Council. The council is a non-paid policy making body appointed by the Governor with the consent of the Senate. Members of the council include Dr. John D. Rockaway, Jr., chairman; Charles I. Mansur, vice-chairman; Carol Eichling; Terry Perkins; Dean E. Freeman; Donald W. Laraway; and Stanfred L. Hilty.

This booklet was printed with funding by a grant from the Association of State Dam Safety Officials (ASDSO) and the Federal Emergency Management Agency (FEMA). The support of these two organizations and their interest in dam safety is acknowledged and deeply appreciated.

Within the Missouri Department of Natural Resources, Division of Geology and Land Survey, there were several individuals who made significant contributions to the manual's development. James L. Alexander, Russell C. Adams, Robert A. Clay, and Ralph P. Hess of the Dam and Reservoir Safety Program staff reviewed the entire manuscript and made many helpful suggestions. Mr. Alexander and Mr. Clay also assisted in the preparation of many of the illustrations. Dr. Robert H. Hansman, Editor for the Division of Geology and Land Survey, edited the booklet and was especially helpful in developing and organizing the list of references. Dr. James H. Williams, State Geologist and Division Director, reviewed the chapter on geology. Robert E. Myers, State Land Surveyor, reviewed several chapters including the chapter on engineering surveys. Special thanks to Marge Paulsmeyer, Dam and Reservoir Safety Program Secretary, who assisted in typing the booklet and making necessary revisions.

The booklet was reviewed by several professional engineers in private practice, in government, and at the University of Missouri-Rolla. Among those reviewing all or parts of the booklet include Hugh A. Curry, Jerry Edwards, William F. Lueckenhoff, Albert B. Becker, Richard H. Frueh, Dr. Jerome A. Westphal, Dr. Richard W. Stephenson, J. Larry Hubbard, and Gene C. Bowen. Numerous comments were received and several changes and additions were made to the final draft.

Many state and federal agencies provided information on the subjects covered in this booklet. The use of references and other information is appreciated.

CHAPTER I

INTRODUCTION

The purpose of this booklet is to provide engineers with information regarding the analysis of dams in Missouri. This booklet does not represent and should not be considered a comprehensive step-by-step set of requirements for dam design and analysis. It should be used simply as a technical reference. No discussions were included regarding the preparation of plans and specifications for new dams. Other agencies, such as the Soil Conservation Service, the U. S. Army Corps of Engineers, and the Bureau of Reclamation, have publications which deal with this topic.

There are many acceptable methods that can be used to perform an engineering analysis of a dam and spillway. Suggested standards are listed in this booklet along with recommended methods and references. When a permit application is submitted to the Dam and Reservoir Safety Program, the engineering computations are reviewed by the Chief Engineer and his staff on a case-by-case basis. Engineers may use methods of analysis and design which differ from those presented in this manual. Latitude is provided to engineers who use other methods which produce a product that meets the minimum safety criteria in the regulations and the dam safety law.

A typical analysis includes all or part of the following aspects of engineering:

- Hydrological
- Hydraulic
- Geotechnical
- Structural Stability
- Seismic
- Geological

In this manual the word "dam" refers to any artificial or manmade barrier which is 35 feet or more in height measured either from the natural bed of the stream or watercourse or lowest point on the toe of the dam (whichever is lower) up to the crest elevation, together with appertenant works. Dams less than 35 feet in height are not regulated by the Dam and Reservoir Safety Program.

The objective of the Missouri Department of Natural Resources, Dam and Reservoir Safety Program is to insure that dams in Missouri are safely constructed, operated, and maintained. The Code of State Regulations contain minimum safety criteria for both new and existing dams. New dams are those constructed after August 13, 1981.

There are several differences between the criteria for new and existing dams. For example, engineers do not have to show that existing dams meet the stability criteria unless significant modifications are made to the height, slope, or water storage elevation. The seismic criteria apply only to new dams. For a complete description of the applicable criteria, see 10 CSR 22-3.020.

Geological considerations are very important in the analysis and design of new dams. A short discussion of geology and its relationship to dams is included in this booklet. More detailed information, such as geological maps, bore logs, and publications on Missouri geology, can be obtained from the Department of Natural Resources, Division of Geology and Land Survey.

New construction and the analysis of existing dams require field surveys of the embankment and spillways. A chapter on engineering surveying has been provided in this manual. Under Missouri law, engineering surveys can be performed by a registered professional engineer; however, boundary and property surveys must be performed by a registered land surveyor.

The appendices contain copies of permit applications and certification forms for engineers. For more information, contact:

CHAPTER II

PERMITS

The owner of a proposed new dam 35 feet or more in height is required to obtain a construction permit to build the dam and a safety permit to operate the dam and reservoir. Owners of existing dams 35 feet or more in height are required to obtain registration permits in accordance with the schedule in 10 CSR 22-2.020(2). Significant modifications to existing dams also require a construction permit. Significant modifications are defined in 10 CSR 22-1.020(50). Exemptions from these permit requirements have been provided in the dam safety law for the federal government and owners of agricultural dams which were constructed in accordance with 10 CSR 22-2.010(3).

A. Construction Permits

In order to show that a dam will meet the minimum safety criteria in the code of state regulations, an engineering report must be submitted with the permit application, plans, and specifications. In most cases, hydrologic, hydraulic, geotechnical, and structural computations must be performed. Sufficient detail must be included in the report for the analysis to be verified. The staff of the Dam and Reservoir Safety Program does not perform a comprehensive check of the engineer's computations. Instead, data is taken from the engineers report and an independent analysis is performed to insure that the minimum safety standards are met. If a discrepancy is found between the results of the staff analysis and the engineer's report, the engineer's computations are examined in more detail to resolve the problem.

When a construction permit is issued to build or modify a dam, the owner is required to notify the Chief Engineer when construction begins. An engineer from the Dam and Reservoir Safety Program normally inspects new dam sites during three key activities; the construction of the core trench, construction of internal drains, and installation of pipes through the embankment. It is important for the owner to maintain communication with his engineer, the contractor, and the Dam and Reservoir Safety Program staff throughout construction. Inspections during critical construction activities provide information needed to prepare as-built drawings and safety permit applications following construction.

Construction permits are normally issued for a period of one year to start construction and one additional year to complete construction.

B. Safety Permits

A safety permit is basically an operating permit for dams that were constructed after August 13, 1981. A copy of the permit application and the checklist used to review the applications are included in Appendix A. The owner's engineer must submit a certification that the dam was built substantially in accordance with the approved plans and specifications. Safety permit applications must include as-built drawings if significant modifications were made to the original design drawings during construction. Appropriate engineering computations should accompany the application if as-built drawings are submitted.

Safety permits are usually issued for a period of 5 years. During this time, the owner must maintain the dam in accordance with an approved maintenance and operation plan. The Missouri Department of Natural Resources (1986) published the booklet, Maintenance, Inspection, and Operation of Dams in Missouri which is a good reference for developing a maintenance and operation plan.

Sixty days prior to the expiration of the safety permit, the owner should contact the staff of the Dam and Reservoir Safety Program and request a permit renewal inspection. The permit renewal inspection includes visual observations of the dam, a review of maintenance records, and a site visit to the area downstream of the dam. Assuming no observable defects are found and the downstream hazard zone is unchanged, the permit is renewed for an additional five year period. If changes in the downstream hazard zone require spillway or dam crest modifications, a construction permit must be obtained to perform the work.

Safety permits for tailings dams constructed after August 13,1981 include provisions for phased, stepped, or continuous construction. They must be renewed at five year intervals or whenever major changes are made to the plans and specifications on file with the Dam and Reservoir Safety Program. Safety permits are required for tailings dams after closure of the mining and milling operation unless the dams meet the retaining/retarding structure exemption criteria listed in 10 CSR 22-2.010(7).

C. Registration Permits

There are approximately 640 dams in Missouri that are regulated by the Dam and Reservoir Safety Council. Over 95% of these dams were constructed prior to August 13, 1981. These older dams must be operated under the provisions of a registration permit. Like safety permits, registration permits are operating permits for dams that have been shown to meet the minimum safety criteria in the dam safety law.

Before a registration permit can be issued, the dam must be inspected and analyzed to show that it meets the

minimum safety standards in the Rules and Regulations of the Dam and Reservoir Safety Council. Dams must have sufficient spillway capacity to pass the design flood without overtopping and all observable defects must be corrected or monitored. Observable defects are described in 10 CSR 22-3.030(1)(A)1. Stability calculations are not required unless significant modifications are made to the height of the dam, the slopes, or the water storage elevation. Hydrologic and hydraulic calculations should be included in the inspection report or in a separate engineering report. If the dam must be modified to correct observable defects, a construction permit may be required depending on the extent of the modifications.

In addition to the spillway calculations, two certifications, a statement concerning the stability of the dam, and a maintenance and operation plan must be submitted prior to issuance of the first registration permit. A blank registration permit application, a review checklist, and a standard certification form are included in Appendix A. The booklet, Maintenance, Inspection, and Operation of Dams in Missouri is a good reference for developing a maintenance and operation plan.

Sixty days prior to the expiration of the registration permit, the owner should contact the staff of the Dam and Reservoir Safety Program and request a permit renewal inspection. Assuming no observable defects are found and the downstream hazard zone is unchanged, the permit is renewed for an additional five year period. If changes in the downstream hazard zone require spillway or dam crest modifications, a construction permit must be obtained to perform the work.

Registration permits for tailings dams in existance before August 13,1981 can include provisions for phased, stepped, or continuous construction. They must be renewed at five year intervals or whenever major changes are made to the plans and specifications on file with the Dam and Reservoir Safety Program. Registration permits are required for tailings dams after closure of the mining and milling operation unless the dams meet the retaining/retarding structure exemption criteria in 10 CSR 22-2.010(7).

CHAPTER III

HYDROLOGIC CONSIDERATIONS

The analysis of an existing dam and the design of a new dam includes the hydrological analysis of the watershed and a hydraulic analysis of the spillways. Generally the hydrologic computations conclude with the computation of the inflow hydrograph to the reservoir. Parameters used in the hydrologic analysis include the watershed area, unit hydrograph parameters, lag time, total rainfall, rainfall distribution (hyetograph), infiltration characteristics of the watershed, and initial abstraction. In the case of kinematic and dynamic wave modeling and breach analysis, channel routing will also be included in the definition of hydrological computations.

Hydraulic computations involve reservoir routing and rating open channel and closed conduit spillways. This differentiation, although not universal in the field of civil engineering, will nonetheless be used throughout this booklet.

The flood used for design to prevent the failure of the dam is termed the "spillway design flood" (SDF). As defined in 10 CSR 22-1.020 (52), the spillway design flood is the specified flood discharge that may be expected from the most severe combination of critical meteorologic and hydrologic conditions that are reasonably possible in an area and for which the dam and reservoir are designed. Determination of the spillway design flood is based on a rational consideration of the chances of the simultaneous occurrence of several elements or conditions which contribute to the flood. A major aspect of the spillway design flood computation is the determination of the runoff that would result from an occurrence of a percentage of the probable maximum precipitation. This hydrometeorological approach is necessary because contemporaneous site-specific meteorologic and streamflow data do not exist for most small watersheds in Missouri. If actual streamflow records of considerable length are available for the general region in which the dam is located, this data should be used in the determination of the SDF. This chapter, however, is primarily concerned with synthetic hydrology and techniques used to simulate the rainfall runoff process on a watershed.

A. Downstream Environment Zone

The downstream environment zone is defined as an area downstream from a dam that would be affected by inundation in the event the dam failed with the reservoir at the emergency spillway crest elevation or the dam crest elevation, in the absence of an emergency spillway. This is typically termed a "sunny-day" failure. Inundation is defined as a minimum of 2 feet of water over the first floor elevation of affected structures. Three environmental classes are defined in 10 CSR 22-2.040(1). Class I is high hazard, Class II is significant hazard, and Class III is low hazard. If a sufficient number of homes are located downstream of a dam, a breach analysis is required to justify a Class II or Class III downstream environmental zone designation. It may be advantageous to the engineer performing the computations to meet with the staff of the Dam and Reservoir Safety Program before a breach analysis is conducted. In many cases, a downstream enviornmental zone classification can be agreed upon without computations.

A dam breach analysis involves a specific analytical approach rather than the use of procedures described for spillway design. There are many models available for performing a breach analysis. The two most widely used models in Missouri are DAMBRK and HEC-1. Recently, private engineers have modified the input structure to the National Weather Service's DAMBRK program, originally developed by Fread (1984). These changes are an attempt to make the model more user friendly and add attractive graphics capabilities. The DAMBRK model considers rapidly varying, unsteady flow in channels and includes off channel storage. It provides an engineer with the most accurate method of simulating a dam failure and routing the flood wave downstream. Despite the capabilities of DAMBRK, the staff of the Dam and Reservoir Safety Program have found that the U.S. Army Corps of Engineers (1981) Hydrologic Engineering Center (HEC) Flood Hydrograph Model (HEC-1) produces reasonable results for dam break analyses.

In order to use HEC-1 to conduct a breach analysis and consider the effects of off-channel storage, the engineer must first rate the channel(s) downstream by performing a backwater analysis. The Corps of Engineers (1985) Water Surface Profile Model (HEC-2) is typically used to perform these computations. As a first estimate, the engineer can use cross sections derived from USGS topographic maps. However, these sections produce results only as reliable as the degree of accuracy of the map. This is normally 10 feet for maps with twenty foot contours and 5 feet for maps with ten foot contours. If additional accuracy is required, surveyed cross sections of the valley must be obtained.

When the channel has been rated for a range of flowrates, the engineer must select the dam failure criteria. The final breach geometry and the time to failure are the two most significant parameters to select. According to Fread (1984), the final breach width should be selected in the range of one to three times the height of the dam, the side slope of the breach should vary from 0-2 horizontal to 1

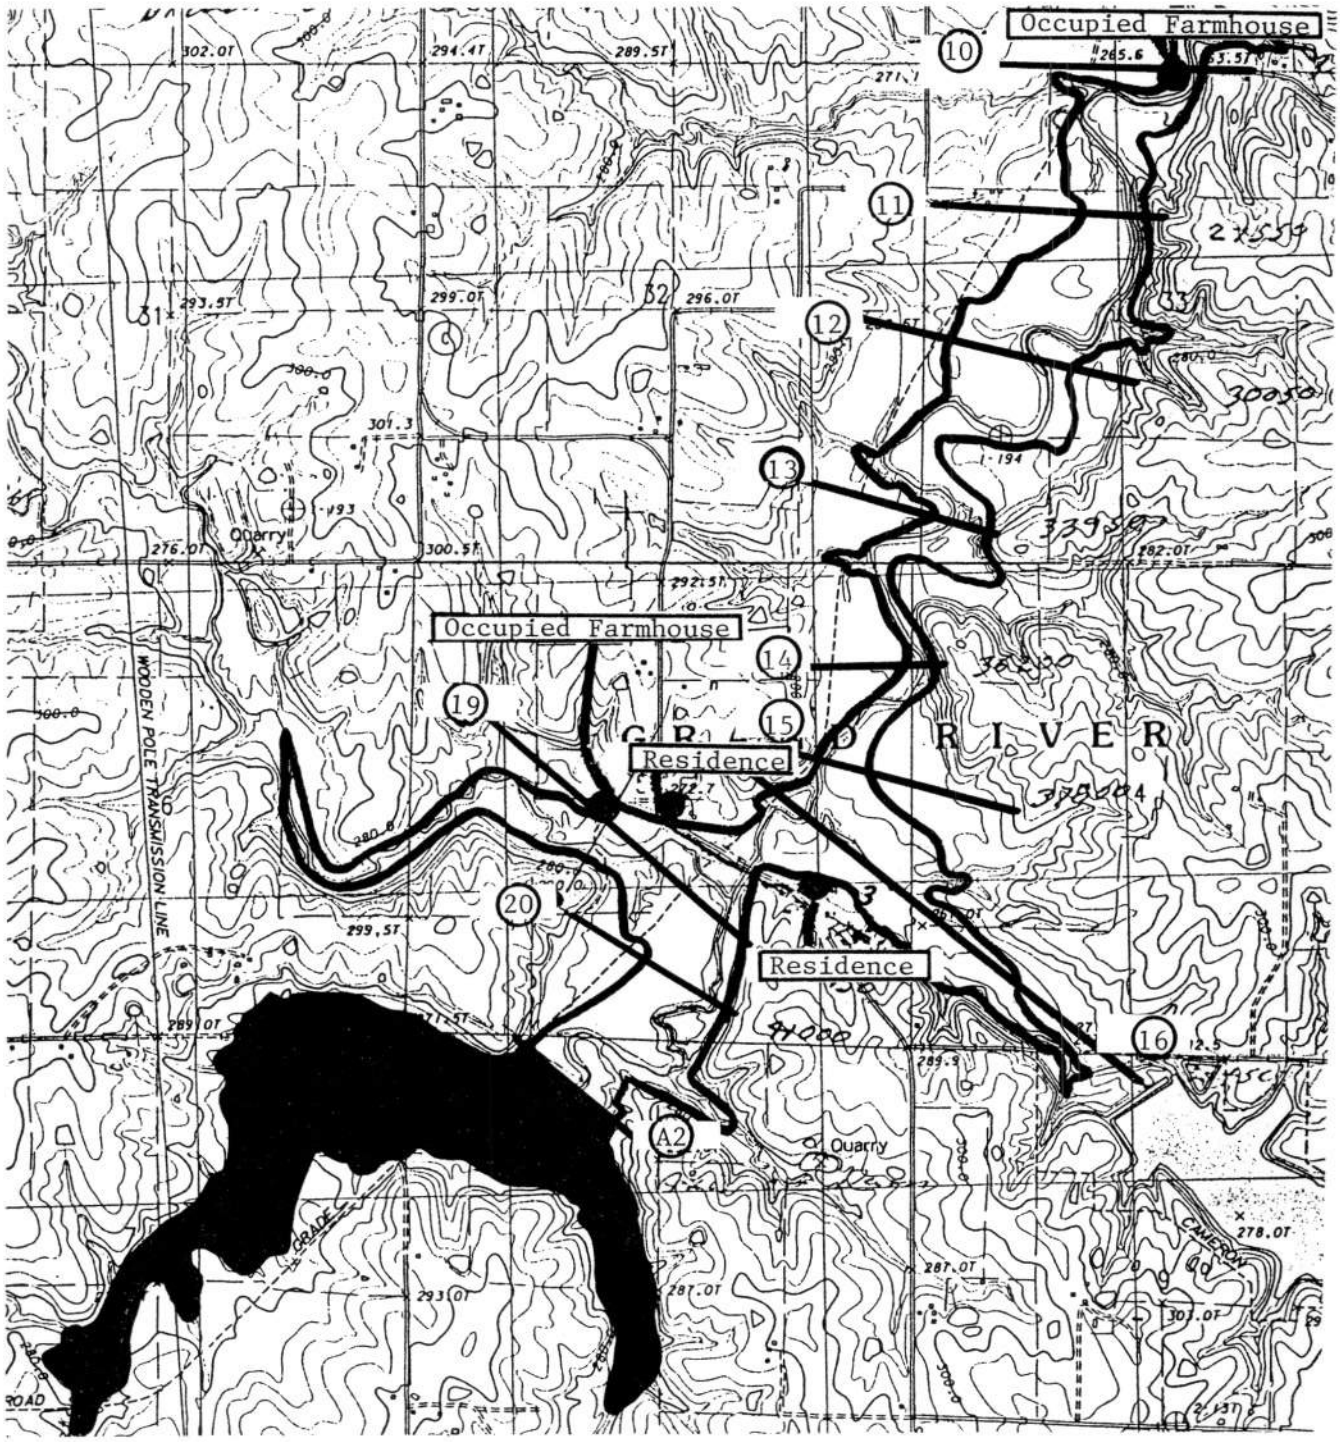

Figure 3.1 Topographic Map of Downstream Environmental Zone

vertical, and the time to breach should be in the range of 0.5 to 4 hours. For concrete gravity and arch dams, the time to breach is typically considered to be 10 minutes or nearly instantaneous. For earth dams, a breach width equal to the height of the dam and a sideslope of 1 horizontal to 1 vertical are normally used unless the dam contains observable geotechnical defects.

Upon completion of the breach analysis, a water surface profile should be drawn of the flood wave created by the failure of the dam. The profile should include the elevation of all homes that would be inundated by the flood wave. When topographic cross sections are used, the profile should also include the estimated elevations of all homes according to the degree of accuracy of the map.

Finally, a topographic map should be submitted as shown in Figure 3.1. It should include the location of the

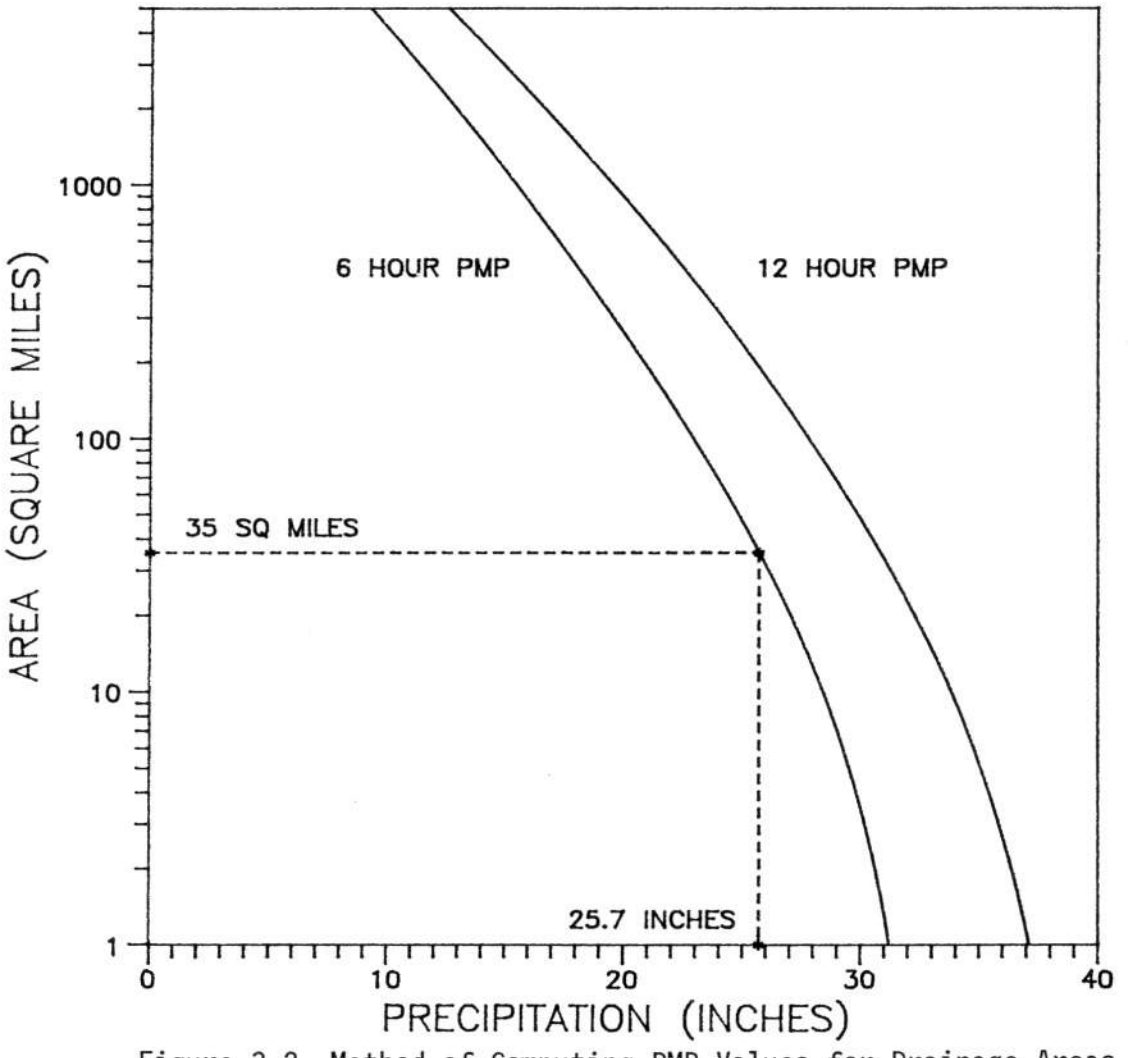

Figure 3.2 Method of Computing PMP Values for Drainage Areas

dam and reservoir, the location of stream cross sections used in the breach analysis, the boundary of the breach floodplain, and verified locations of permanent dwellings, campgrounds, industrial buildings, and public buildings within the breach floodplain. Because the cultural data shown on topographic maps may be several years old, field verification of the information on the map is essential.

B. Spillway Design Flood Precipitation Values

The precipitation values listed in Table 5, 10 CSR 22-3.020, must be used to determine the spillway design flood for both new and existing dams. After the downstream environmental class has been determined, the precipitation value to be used in the hydrologic computations can be selected. The probable maximum precipitation (PMP) can be obtained from Hydrometeorological Report 51, Probable Maximum Precipitation Estimates, United States East of the 105th Meridian, published by the U.S. Department of Commerce (1978). This publication contains PMP values for watersheds east of the 105th meridian that range in size from 10 to 20,000 square miles. Rainfall durations range from 6 to 72 hours. The National Weather Service states that "point" PMP values are likely to be greater than the 10 square mile values; however, in performing dam safety analyses, it is acceptable to use the 10 square mile PMP values rather than deriving a PMP value for a smaller area. This procedure is allowed to compensate for the unliklihood that a small watershed will receive the most intense rainfall in any storm. For drainage areas greater than 10 square miles, the engineer has the option of determining the PMP value for the area being considered by using the method shown in Figure 3.2. This method is explained in more detail in Hydrometeorological Report 51.

Several different duration rainfall events must be ana-

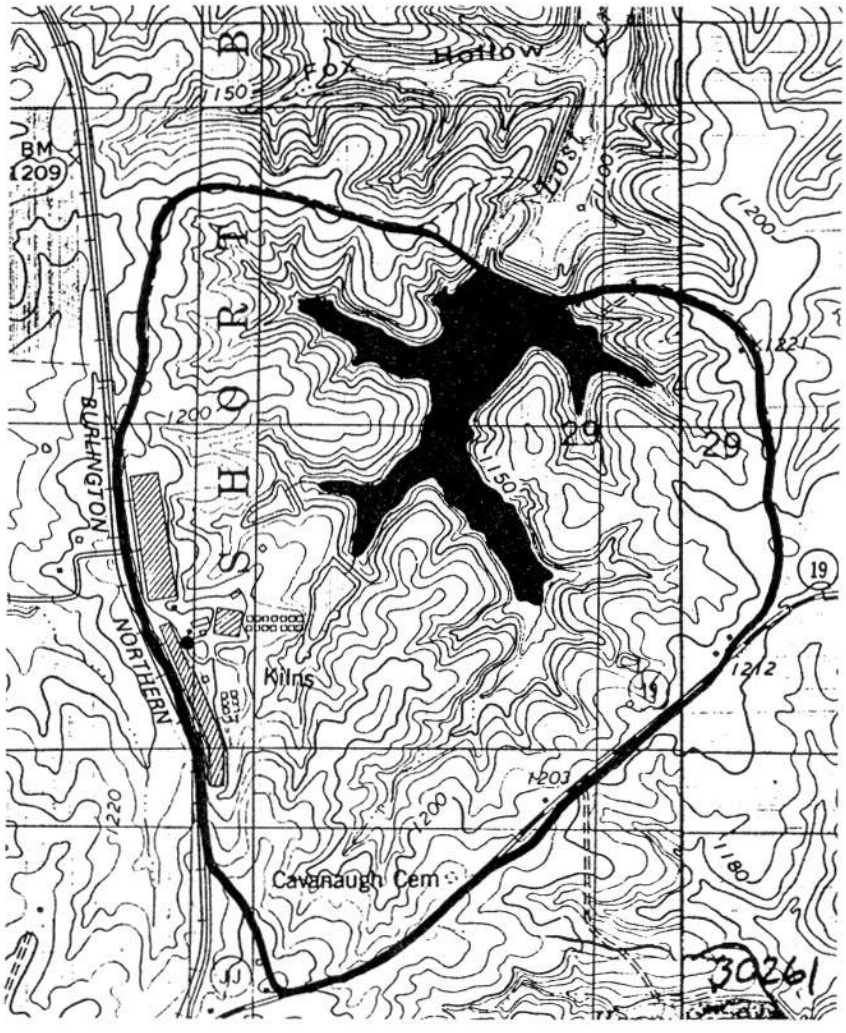

Figure 3.3 Topographic Map of Drainage Area

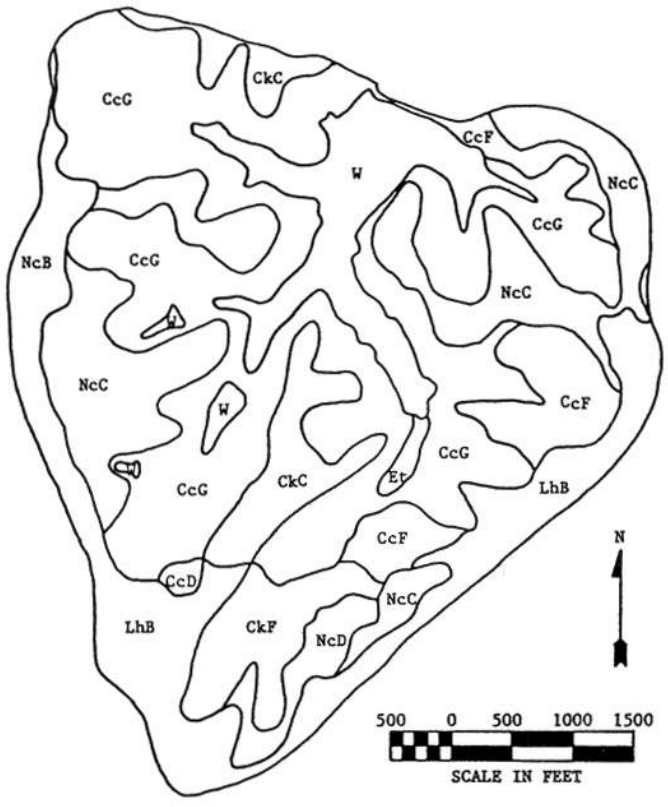
lyzed. The duration that produces the highest reservoir elevation in the overtopping analysis is termed the critical duration rainfall event. The search for this event is limited to the durations listed in Hydrometeorological Report 51 (6, 12, 24, 48 and 72 hour events). For watersheds less than 1 square mile in size the critical duration event is normally the 6 or 12 hour event.



If a grass lined emergency spillway is proposed for a new dam or the modification of an existing dam, it is advisable to design it so that it will only be used for rainfall events in excess of the 50 or 100-year events. Values for these frequency based rainfall events can be found in Technical Paper 40, Rainfall Frequency Atlas of the United States, published by the U.S. Department of Commerce (1961).

Appendix C contains total rainfall values, by county, for 6-hour, 12-hour, and 24-hour frequency based and PMP events in Missouri. The PMP values are for 10 square mile areas only. For other durations, areas, and return periods, engineers should consult Hydrometeorological Report 51 and Technical Paper 40.

C. Watershed Data

All available information concerning watershed characteristics should be assembled. As shown in Figure 3.3, a map of the drainage area should be prepared showing the drainage system, contours, drainage boundaries, and locations of any precipitation stations and streamflow gaging stations. Available data on soil types, cover, and land usage provide valuable guides to judgement and should also be assembled. If the Soil Conservation Service (SCS) has published a soil survey booklet for the county in which the drainage area is located, a soil map can be developed as shown in Figure 3.4. Engineers are advised to contact the county SCS office for a copy of the soil survey booklet.

Land use, such as woodland, pasture, farmland, and

SYMBOL	SOIL TYPE	SLOPE
CcD	Clarksville Cherty Silt Loam	9-14%
CcF	Clarksville Cherty Silt Loam	14-30%

NcC	Nixa-Clarksville Cherty Loam	5-9%
NcD	Nixa-Clarksville Cherty Loam	9-14%
W	Water	

Figure 3.4 Soil Map of Drainage Area

residential can be determined from several sources such as topographic maps, tax reassessment photographs, and Agricultural Stabilization and Conservation Service (ASCS) aerial photographs.

For large watersheds, it is advisable to divide the drainage area into subbasins on the basis of size, drainage pattern, existing and proposed facilities, vegetation, and soil and cover types. The subbasin hydrographs are channel routed downstream to the reservoir. Upstream dams and reservoirs may be included in the analysis. Any upstream dam that is found to overtop during the spillway design flood must either be considered to breach or omitted from the analysis. Breaching is assumed to commence when the reservoir exceeds the lowest elevation on the crest of the dam. The breach hydrograph is then routed downstream and added to the inflow hydrograph at the next reservoir. It is advisable to calibrate the spillway design flood results to historical flood events where adequate stream gage data are available. However, most small watersheds in Missouri are not gaged.

The USGS now has 7 1/2 minute topographic maps for the entire state of Missouri. These can be purchased from commercial businesses or ordered from Department of Natural Resources, Maps and Publications, P.O. Box 250, Rolla Missouri 65401; Phone (314) 364-1752. Watershed and subbasin areas should be determined by use of mechanical planimeters or electronic digitizers. Several area measurements should be taken to determine the value to use in the hydrological computations.

D. Initial Abstraction and Infiltration

Initial abstraction consists of the sum of interception, depression storage, and infiltration which occurs prior to runoff. After runoff begins, infiltration continues throughout the duration of the rainfall event.

Interception and depression storage are intended to represent the surface storage of water by trees, grass, and local depressions in the ground surface. These important hydrologic processes must be carefully considered in models which are used to describe the hydrology of a watershed.

Several empirical infiltration models have been developed but few include procedures for estimating interception and depression storage losses. Recognizing this problem, the SCS (1972) developed the curve number method which can be used to estimate runoff from small agricultural watersheds. In view of the general lack of available data pertaining to abstractions during storm events, the SCS curve number method is used by the staff of the Dam and Reservoir Safety Program to determine both initial abstraction and infiltration losses. If other infiltration models are used, the engineer should estimate the interception and depression storage losses based on a review of available soil and cover data.

In order to use the SCS curve number method to estimate the initial abstraction for a subbasin, an area weighted runoff curve number, CN, should be computed. The factors that determine the runoff curve number are the hydrologic soil group, land use, hydrologic condition and the antecedent moisture condition (AMC).

Hydrologic soil groups have been defined by the Soil Conservation Service (1986) for each of the soils in Missouri. They range from A (most permeable) to D (least permeable). The land use addresses the type of development in the subbasin. Typical values for CN for various land uses are shown in Tables 3.1, 3.2, and 3.3 (SCS, 1986). The hydrologic condition takes into account the effect of cover and is generally estimated from density and type of plant growth. The reservoir area can either be considered as an impervious area in the model or included in the weighted runoff curve number computations.

The antecedent moisture condition (AMC) is classified into three categories by the SCS (1972) depending on the available moisture capacity of the soil. Antecedent moisture condition II is used by the staff of the Dam and Reservoir Program to determine the weighted runoff curve number for a watershed. The values of CN in Tables 3.1, 3.2, and 3.3 are for AMC II conditions.

When the SCS curve number method is used in the HEC-1 model, the initial abstraction is computed for each subbasin by using the empirical relationship (SCS, 1972):

$$I_a = 0.2\left(\frac{1000}{CN} - 10\right) \qquad (3.1)$$

This relationship was developed by the SCS to estimate initial abstraction and is an approximation based upon a scattering of rainfall-runoff data for watersheds less than 10 acres in size.

Infiltration is defined as the entry of water from the surface into the soil profile. It is an important hydrologic process which must be carefully considered in the hydrology of a watershed. Several factors affect infiltration. These include soil properties, the initial water content, rainfall rates, surface sealing and crusting, layered soils, and the porosity of the soil. Many empirical and physical models are available to estimate the infiltration rate.

The SCS method is typically used to determine the infiltration rate after the initial abstraction has been satisfied. Direct runoff is computed by the HEC-1 model in the following manner:

$$Q = \frac{(P - 0.2S)^2}{P + 0.8S}, \qquad (3.2)$$

where

Q = incremental direct runoff in inches;
P = incremental storm rainfall, in inches; and
S = (1000/CN) - 10.

The actual infiltration in any increment of time is equal to $P - I_a - Q$.

E. Unit Hydrographs

Unit hydrographs are used in the planning and design of water control structures. Chow (1964) defined the unit hydrograph of a drainage basin as a hydrograph of direct runoff resulting from 1 inch of effective rainfall generated uniformly over the basin area at a uniform rate during a specified period of time or duration.

Because most watersheds are ungaged, the use of synthetic unit hydrographs is an accepted procedure in the computation of inflow hydrographs into a reservoir. Synthetic unit hydrographs are based on the assumption that watersheds within a homogeneous region have similar rainfall-runoff characteristics. Although this is not the most accurate procedure to use, the lack of gaged data makes the use of synthetic unit hydrographs necessary.

The two most commonly used synthetic unit hydrograph methods in Missouri are the SCS dimensionless unit hydrograph and Gray's (1961) unit hydrograph. The SCS method is shown in Figure 3.5 and is included in many of the commonly used computer models. It is typically used on small watersheds. According to Technical Release 60 (SCS, 1985), the SCS unit hydrograph is valid on watersheds up to 50 square miles in size. Larger watersheds should be divided into subbasins with areas less than 20 square miles. Gray's method was developed using data for the midwestern United States. This unit hydrograph is applicable for watersheds up to 94 square miles. Both methods are acceptable for dam safety analysis.

TABLE 3.1

Runoff Curve Numbers - Urban Areas

Cover Description Cover type and hydrologic condition[1]	Ave % Impervious[2]	Curve Numbers[3] for Hydrologic Soil Group A	B	C	D
Open space (lawns, parks, golf courses, cemeteries, etc):					
Poor condition (grass cover < 50%)		68	79	86	89
Fair condition (grass cover 50% to 75%)		49	69	79	84
Good condition (grass cover > 75%)		39	61	74	80
Impervious areas:					
Paved streets, roads, parking lots, roofs, driveways, etc.	100	98	98	98	98
Paved; open ditches (including right of way)		83	89	92	93
Gravel (including right of way)		76	85	89	91
Urban districts:					
Commercial and business	85	89	92	94	95

[1]Average runoff condition, and $I_a = 0.2S$.

[2]AMC II conditions

[3]Poor; <50% ground cover or heavily grazed with no mulch.
Fair; 50% to 75% ground cover and not heavily grazed.
Good; >75% ground cover and lightly or only occasionally grazed.

[4]Actual curve number is less than 30; use CN=30 for runoff computations.

[5]Poor; <50% ground cover.
Fair; 50% to 75% ground cover.
Good; >75% ground cover.

[6]CN's shown were computed for areas with 50% woods and 50% grass (pasture) cover. Other combinations of conditions may be computed from the CN's for woods and pasture.

[7]Poor; Forest litter, small trees, and brush are destroyed by heavy grazing or regular burning.
Fair; Woods are grazed but not burned, and some forest litter covers the soil.
Good; Woods are protected from grazing, and litter and brush adequately cover the soil.

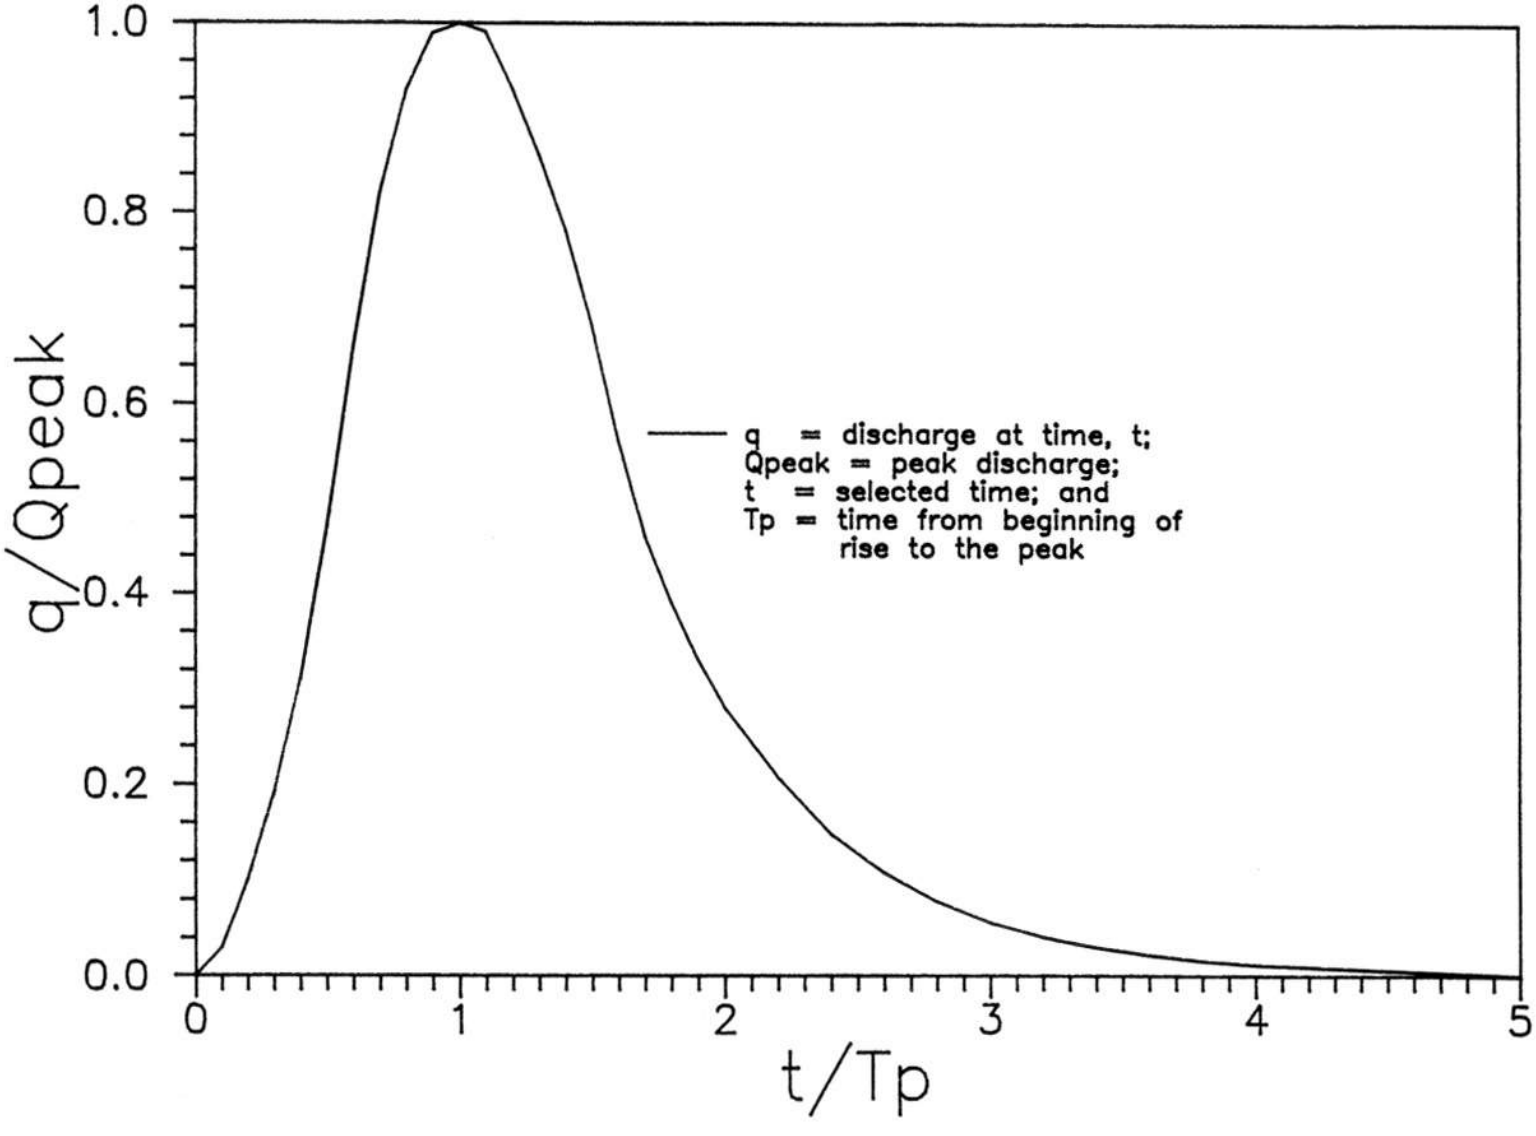

Figure 3.5 SCS Dimensionless Unit Hydrograph

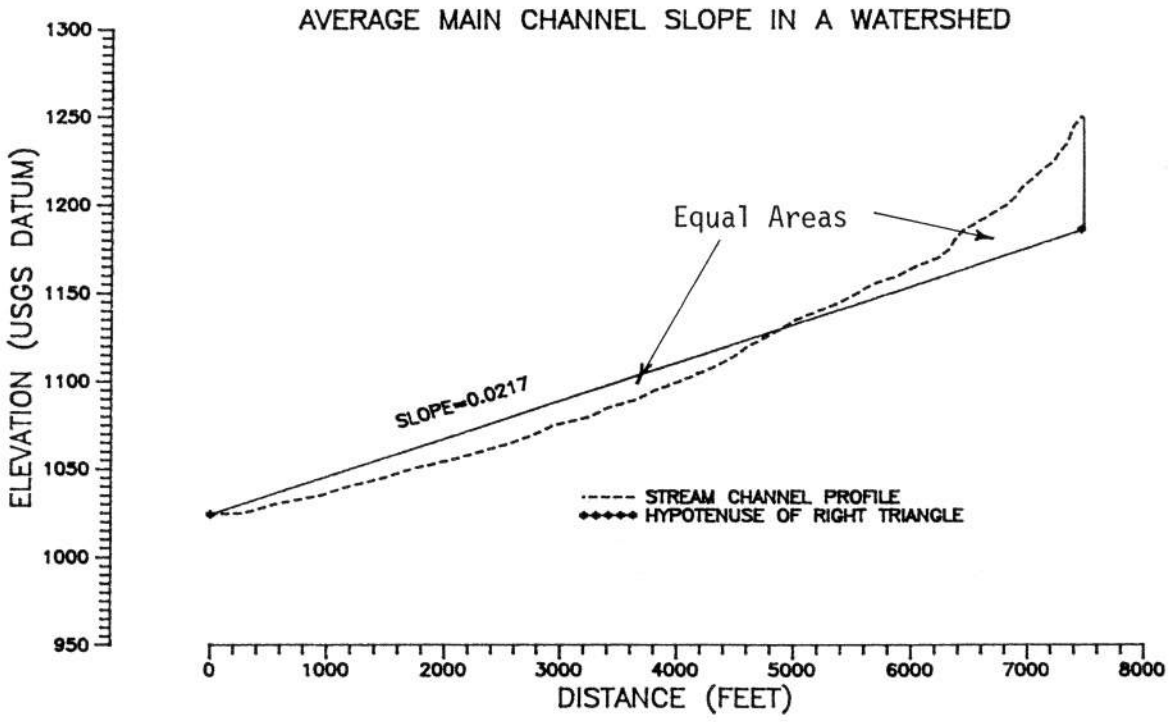

Figure 3.6 Gray's (1961) Method of Computing Channel Slope

The SCS dimensionless unit hydrograph is based upon empirical observations of how natural watersheds "typically" respond to rainfall in excess of the rate at which it can infiltrate. A good description of the method is included in the SCS (1972) National Engineering Handbook, Section 4, Hydrology. The basic input parameters needed to develop a synthetic unit hydrograph for a watershed include the basin lag time, basin area, and the duration of the unit hydrograph. Time to peak, T_P, and the peak flow, Q_{peak}, for each increment of rainfall are computed from these three parameters.

The basin lag time, T_L, should be computed before the unit hydrograph duration, ΔD, is specified. The SCS dimensionless unit hydrograph is based on the relationship, $\Delta D = 0.22 T_L$. According to the SCS, a small variation in ΔD is permissible, however, ΔD should not be greater than 0.25 T_P. This SCS guideline lead the Corps of Engineers to recommend the relationship in Equation 3.3 for selecting the HEC-1 computation interval, Δt.

$$\Delta t \leq .29 T_L, \qquad (3.3)$$

where

Δt = HEC-1 computation interval in minutes; and

T_L = basin lag time in minutes.

Selection of the HEC-1 computation interval is very important because it is also the duration of the SCS dimensionless unit hydrograph.

In Gray's unit hydrograph, a gamma distribution is used to describe a dimensionless unit hydrograph. The length and slope of the main channel upstream of the reservoir and the watershed area are the parameters used to develop the synthetic unit hydrograph. These parameters can easily be obtained from a topographic map. Channel slope is determined as shown in Figure 3.6. The area beneath the channel profile is set equal to the area of a right triangle with the hypotenuse crossing the origin at the elevation of the reservoir. The slope of the hypotenuse is the average channel slope. Gray's unit hydrograph can be computerized to solve for the Unit Hydrograph Ordinates based on an input of watershed area, channel length, and channel slope. A good description of the method is presented by Viessman, Harbaugh, and Knapp (1972).

F. Time of Concentration

The use of synthetic unit hydrographs requires a characterization of watershed response time. This characteristic time is usually taken to be either time of concentration or basin lag time. Both are commonly assumed to be constant and lag time is often considered to be a fraction

of time of concentration so that one is easily converted to the other. Lag time must be computed in order to use the SCS dimensionless unit hydrograph. With Gray's unit hydrograph, the time of concentration is implicitly computed in the determination of the hydrograph ordinates.

The SCS (1972) defined lag time as the time interval between the centroid of effective rainfall and the peak of direct runoff. When used with the SCS unit hydrograph, this definition assumes that lag time is stable and is constant regardless of rainfall duration or intensity. This assumption of linearity is made to simplify computations. Based on their experience on small watersheds, the SCS estimates lag time as

$$T_L = 0.6T_c, \tag{3.4}$$

where

T_C = time of concentration in minutes.

A number of empirical approaches to estimating basin response time have come to be accepted in the field of hydrology for dam safety. Among the most common are the Kirpich formula (1940), the Kerby-Hathaway formula (Kerby, 1959), the SCS Upland method, and the SCS Lag method (SCS, 1985). The SCS methods and the Kerby-Hathaway method consider surface roughness and all four methods recognize the importance of length and slope of the flow path. None of these methods, however, reflect the influence of rainfall characteristics such as rainfall duration and intensity.

The Kirpich formula was developed from data gathered by Ramser (1927) from experiments conducted on a single 112 acre agricultural watershed in Tennessee. The equation is

$$T_c = 0.00013L^{.77}S^{-.385}, \tag{3.5}$$

where

T_C = time of concentration in hours;
L = length of the watershed in feet; and
S = slope in feet/feet.

A version of the Kirpich formula is printed in the U. S. Department of of the Interior (1974) manual entitled Design of Small Dams.

The SCS Lag method is shown in Equation 3.6 and is based on the assumption that the time of concentration equals 1.67 times the lag time. It can be used on watersheds up to 2000 acres in size.

$$T_c = 0.000879L^{.8}\left(\frac{1000}{CN} - 9\right)^{.7}Y^{-.5}, \tag{3.6}$$

where

T_C = time of concentration in hours;
L = hydraulic length of the watershed in feet;
CN = hydrologic soil cover complex no.; and
Y = average watershed land slope, %.

The slope in Equation 3.6 is the average land slope, not the channel slope. It is typically computed from topographic maps and SCS soil survey maps. Horton (1932) published three methods of computing overland slope which are frequently used. These include the contour area method, the mean slope method, and the intersection line method.

The contour area method requires that areas be planimetered between each successive pair of contour lines in a subbasin. Each area is divided by the average contour length for the interval being considered to compute the average distance between contours as shown in Equation 3.7.

$$L_i = \frac{A_i}{\frac{L_1 + L_2}{2}}, \tag{3.7}$$

where

L_i = average distance between contours;
A_i = intermediate area;
L_1 = length of first contour; and
L_2 = length of second contour.

The overland slope of the subbasin is then computed as

$$S_o = \sum \frac{(A_i D)}{A_T L_i}, \tag{3.8}$$

where

S_O = overland flow slope;
D = contour interval; and
A_T = subbasin area.

The mean slope method is a simplified form of the contour area method because it considers the subbasin as a whole. The total length of contours in the subbasin is determined and the mean slope is computed by Equation 3.9.

$$S_o = \frac{D\sum L}{A_T}, \tag{3.9}$$

where

$\sum L$ = total length of contours.

According to Horton (1932), the mean slope method gives good results if the relief is moderate and contours are spaced uniformly.

An average watershed slope can also be computed by weighting the average slopes from the SCS soil map shown in Figure 3.4.

The SCS (1985) Upland Method, shown in Equation 3.10, was developed primarily for flow in upland areas which include overland flow and flow through grassed waterways, paved areas, and small upland gullies.

$$T_c = \frac{L}{3600V}, \qquad (3.10)$$

where

T_C = time of concentration in hours;
L = channel length in feet; and
V = velocity of full bank flow in feet/second.

Travel times for each mode of upland flow and land use are computed from a graph of experience curves (SCS, 1972) showing velocity versus slope for various ground cover conditions. The summation of these travel times equals the time of concentration in the watershed. This method is limited to watersheds less than 2000 acres.

Huggins and Burney (1982) suggested computing time of concentration by adding the channel travel time from the Kirpich equation and the overland flow travel time from the Kerby-Hathaway equation. The basis for the Kerby-Hathaway formula, shown in Equation 3.11, is a study conducted by Hathaway (1945) on overland flow for airfield design and construction.

$$T_c = 0.01377 L_o^{.47} n^{.47} S_o^{-.235}, \qquad (3.11)$$

where

T_C = time of concentration in hours;
L_O = overland flow length;
n = roughness factor; and
S_O = overland flow slope in feet/feet.

When using this method, overland flow lengths should be limited to 500 feet. The roughness factor, n, has the same meaning for overland flow as it does for channel flow, but it is typically higher (0.1 - 0.4) due to the combined resistance effects of the overland flow surface. Kerby (1959) suggested the following values:

TYPE OF SURFACE	n
Smooth impervious surface	.02
Smooth, bare, packed soil	.10
Poor grass, cultivated row crops, or moderately rough bare surface	.20
Pasture or average grass	.40
Deciduous timberland	.60
Conifer timberland, deciduous timberland with deep forest litter, or dense grass	.80

Engman (1986) analyzed data from experimental plots and recommended roughness coefficients of 0.13 for range grass, 0.24 for dense grass, 0.41 for Bermuda grass and 0.45 for bluegrass sod.

This last method, which combines the time of concentration values obtained from the Kirpich and Kerby-Hathaway formulas, is the method generally used by the staff of the Dam and Reservoir Safety Program.

All four methods are acceptable for dam safety analysis, but none of them consider the affects of rainfall. Swenty (1989) conducted a study which showed that lag time is affected by rainfall duration, depth, and intensity. He concluded that the traditional approach of combining the overland and channel flow lag times from the Kerby-Hathaway and Kirpich equations yields reasonable estimates of basin lag time for 100% PMP events on basins less than 1 square mile in size. All four methods were found to underestimate basin lag time for 6-hour and 12-hour rainfall events, less than the 100% PMP.

G. Rainfall Hyetographs

In order to compute an inflow hydrograph, the spillway design flood precipitation value must be distributed over the duration of the rainfall event. Methods are included in the SCS (1974) National Engineering Handbook No. 4 (NEH-4), the U. S. Department of the Interior (1974) Design of Small Dams, and the U. S. Army Corps of Engineers (1987) Flood Hydrograph Package, HEC-1, but the distributions used by the Dam and Reservoir Safety Program are those developed by Huff (1980). Huff published four rainfall distributions for various duration rainfall events. The data used to derive these rainfall distributions were acquired from gaging stations in the state of Illinois. Because of Missouri's close proximity to Illinois, these distributions are acceptable for dam safety projects in Missouri.

The average time distribution of heavy rainfall at a point is shown in Table 3.4 (Huff, 1980). Huff recommended that the point time-distribution relationships shown in Table 3.4 be used with PMP rains extending from a point to 50 square miles.

First and second quartile rainfall distributions should be used for rainfall events less than 12 hours, third quartile rainfall distributions should be used for rainfall durations of 12 to 24 hours and fourth quartile rainfall distributions would be used for rainfall durations greater than 24 hours. Distributions for areas from 50 to 400 square miles were also derived by Huff (1980).

Huff's distributions can also be used to distribute the 50-year and 100-year rainfall events. These rainfall events are typically used to design emergency spillways and to analyze the affect of proposed spillway modifications on discharge rates.

H. Inflow Hydrograph Computation

The inflow design flood hydrograph represents direct runoff from precipitation in the form of rain over a watershed. If hand computations are performed, the procedure outlined in Table 3.5 is recommended.

This procedure should be followed for each duration rainfall event that is analyzed. For a typical small watershed, both a 6-hour and a 12-hour inflow hydrograph will have to be computed. Larger watersheds will require the analysis of longer duration events.

TABLE 3.5

Procedure for Computing an Inflow Hydrograph

Step 1	Determine the size of the drainage area of each basin for which an inflow hydrograph is to be computed.
Step 2	For watersheds less than 10 square miles, determine the PMP values for 6-hour, 12-hour and 24-hour events. For larger watersheds, adjust the PMP value as described in Section B and include 48-hour and 72-hour duration events.
Step 3	Compute the time of concentration for the drainage basin and convert to lag time.
Step 4	Using the lag time, compute the computational time interval, Δt, where $\Delta t \leq 0.29$(lag time).
Step 5	Determine the downstream environmental zone and select the appropriate design precipitation value from Table 5, 10 CSR 22-3.020.
Step 6	Determine the rainfall hyetograph by using Huff's Quartile distributions in Table 3.3. Sum the ordinates to compute an accumulative design rainfall table.
Step 7	Determine the initial abstraction and construct an infiltration model for the watershed. Compute the amount of excess rainfall at each time step. If the SCS curve number method is used, determine the hydrologic soil cover complex number, CN, of the watershed and perform steps 8 and 9.
Step 8	Determine the accumulative direct runoff from Equation 3.2.
Step 9	Convert the accumulative direct runoff table to an incremental table of direct runoff.
Step 10	Construct a synthetic unit hydrograph for the basin.
Step 11	Compute hydrographs for each time increment using the synthetic unit hydrograph (step 10) and either the excess rainfall at each time step (step 7) or the incremental table of direct runoff (step 9). Overlay hydrographs and add ordinates at each time increment. The summation of all ordinates produces the inflow hydrograph to the reservoir.

CHAPTER IV

HYDRAULIC CONSIDERATIONS

The hydraulic calculations that are performed in a dam safety analysis involve the principles of fluid mechanics, and the laws of continuity, conservation of momentum, and specific energy. Many dams have a combination of closed conduit spillways, open channel spillways, and gates and valves for water supply and other uses. It is important that the engineer be familiar with the principles of hydraulic engineering in order to determine the capacity of these spillways.

After the spillways are rated, an overtopping analysis can be conducted. In order to perform an overtopping analysis, the inflow hydrograph must be routed through the reservoir to determine the maximum water surface elevation during the spillway design flood (SDF). This information not only determines whether a dam can safely pass the SDF; it also defines the maximum reservoir loading condition for the slope stability analysis. The purpose of this section is to provide the engineer with the techniques commonly employed by the staff of the Dam and Reservoir Safety Program to perform these computations.

A. Closed Conduit Hydraulics

Closed conduit spillways can either be single structures, such as culverts, or systems consisting of an inlet structure, a closed discharge pipe and an outlet structure. One advantage of this type of spillway is that near maximum capacity is attained at relatively low heads. This characteristic makes the spillway ideal for use where the maximum spillway outflow is to be limited. A disadvantage of conduit spillways is that there is little increase in capacity at higher reservoir levels.

1. Design Considerations for Conduit Spillways

On new dams and modifications to existing dams, the inlet structure should be designed to establish full pipe flow at as low a head as practical and to operate without excessive surging, vibration, or vortex action. This requires the inlet to have a larger cross-sectional area than the main conduit or ventilation.

Trash racks should be placed on inlet risers to exclude trash too large to pass freely through the spillway and outlet structure. General criteria for trash racks is included in the booklet, Maintenance, Inspection, and Operation of Dams in Missouri.

Conduits under earth embankments must support the external loads with an adequate factor of safety. They must withstand the internal hydraulic pressure without leakage under full external load and settlement and convey water at the design velocity without damage to the interior surface of the conduit. The material used for the conduit should be determined by the size of the dam, the economic life of the dam, and the relative ease of replacement.

Conduits should be designed and constructed to remain watertight under maximum anticipated hydrostatic head and maximum joint extension. The analysis should include the effects of joint deflection caused by settlement of the embankment. Corrugated metal pipes are not recommended for use in dams because banded joints are not designed for high pressure flow.

Piping and seepage control around the conduit is an important consideration. For many years, anti-seep collars were required on conduits passing through earth embankment dams. Although no longer used in all dams, anti-seep collars are still an acceptable method for seepage control. When used, the anti-seep collars should be designed to extend the seepage path by 15 percent through the saturated zone. The major disadvantage of anti-seep collars is that it is difficult to compact soil directly against the concrete structure. A large amount of hand compaction is required. An alternative to anti-seep collars is a granular diaphram (sand filter) around a section of conduit downstream of the core. This method is frequently used by the SCS (1986) and is becoming widely accepted by private engineers.

When spillway flows drop from the reservoir pool level to the downstream outlet channel level, the static head is converted to kinetic energy. This energy manifests itself in the form of high velocities, which, if not impeded, results in erosion. Means of returning the flow to the river without serious scour or erosion to the toe of the dam or damage to adjacent structures must be provided. Types of outlet structures include cantilever outlets combined with plunge pools, Saint Anthony Falls (SAF) basins, and impact basins.

2. Shaft Spillways

A shaft spillway is an uncontrolled spillway in which the water enters over a weir and drops through a vertical or sloping shaft into a conduit which discharges into the downstream channel.

The drop-inlet and the morning-glory are the two most common shaft spillways. The drop-inlet spillway is normally a concrete cast-in-place box or a circular sharp crested weir constructed from precast concrete pipe. Figure 4.1 shows a profile of a drop inlet spillway. The morning-glory spillway is a special case of the circular sharp crested weir in which the shape of the weir crest and the upper portion of the shaft are designed to follow the trajectory of the lower nappe.

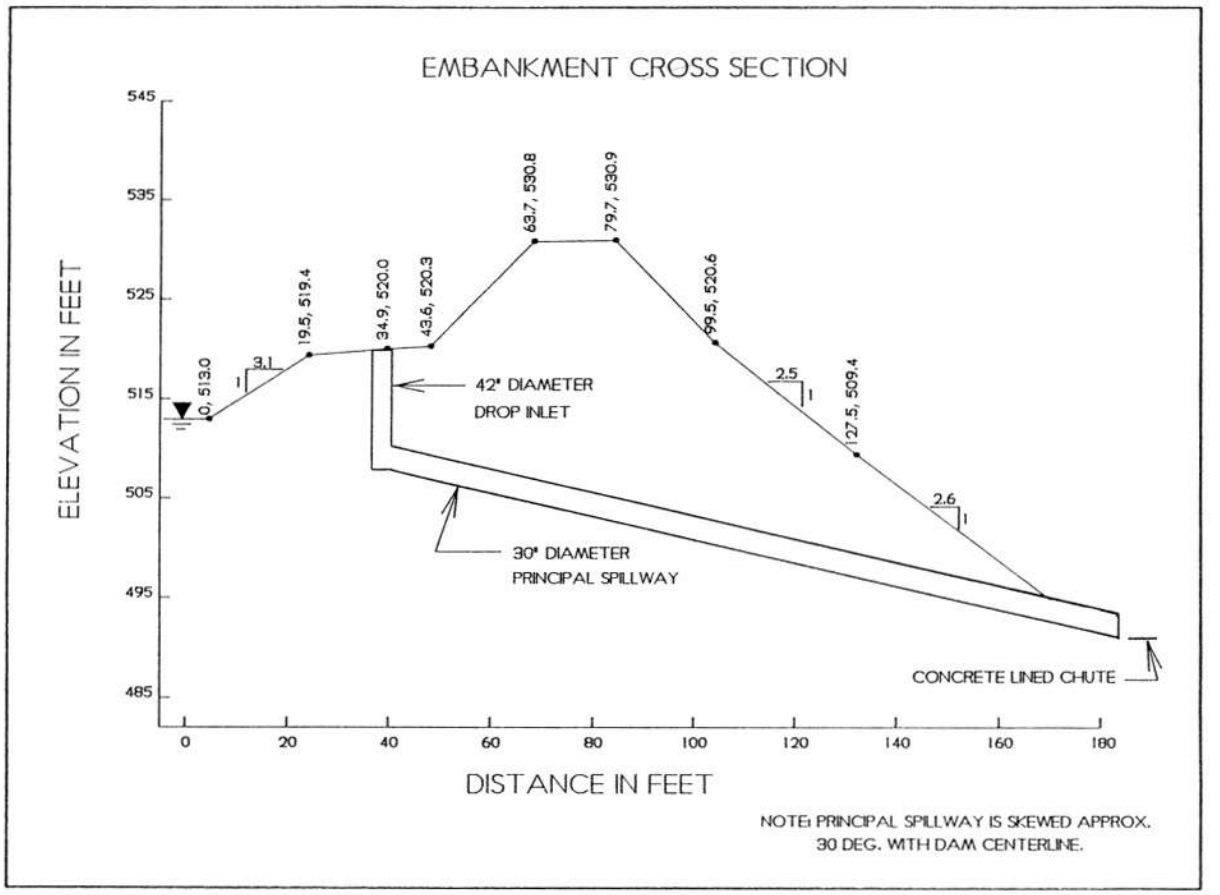

Figure 4.1 Profile of a Drop Inlet Spillway

This section discusses the hydraulic characteristics and the design for a drop-inlet spillway. A discussion of the morning-glory spillway can be found in Design of Small Dams.

The discharge characteristics of a shaft spillway are determined by that portion of the structure which is controlling the discharge. It can be seen in Figure 4.2 that there is the potential for as many as three separate controls and thus three distinct sections in the elevation discharge curve.

The first form of control is weir flow which is described by the weir equation:

$$Q = C_w L_w H^{1.5}, \qquad (4.1)$$

where

Q = discharge in cfs;
C_W = weir coefficient;
L_W = perimeter length of weir in ft.; and
H = depth of water over the weir in ft.

The Portland Cement Association (1964) list the following equations for determining the weir coefficient, C_W, for rectangular drop inlets as a function of the level of the reservoir and the diameter of the outlet pipe:

$$C_w = 3.38\left(1 - \frac{1}{250\frac{H}{D}}\right)^{1.5} \quad for \ \frac{Q}{D^{2.5}} < 4, \qquad (4.2)$$

$$C_w = 4.1\left(1 - \frac{1}{16.7\frac{H}{D}}\right)^{1.5} \quad for \ \frac{Q}{D^{2.5}} > 4, \qquad (4.3)$$

where

H = headwater depth above the inlet in ft.; and
D = diameter of the outlet pipe in ft.

The weir coefficient, C_W, for circular drop inlets is given in Equation 4.4:

$$C_w = 3.60\left(1 - \frac{0.013}{H/D_{rc}}\right)^{1.5}, \qquad (4.4)$$

where

D_{rc} = diameter or riser in ft.

The transition point between weir and orifice flow occurs when the contraction of the flow is fully developed

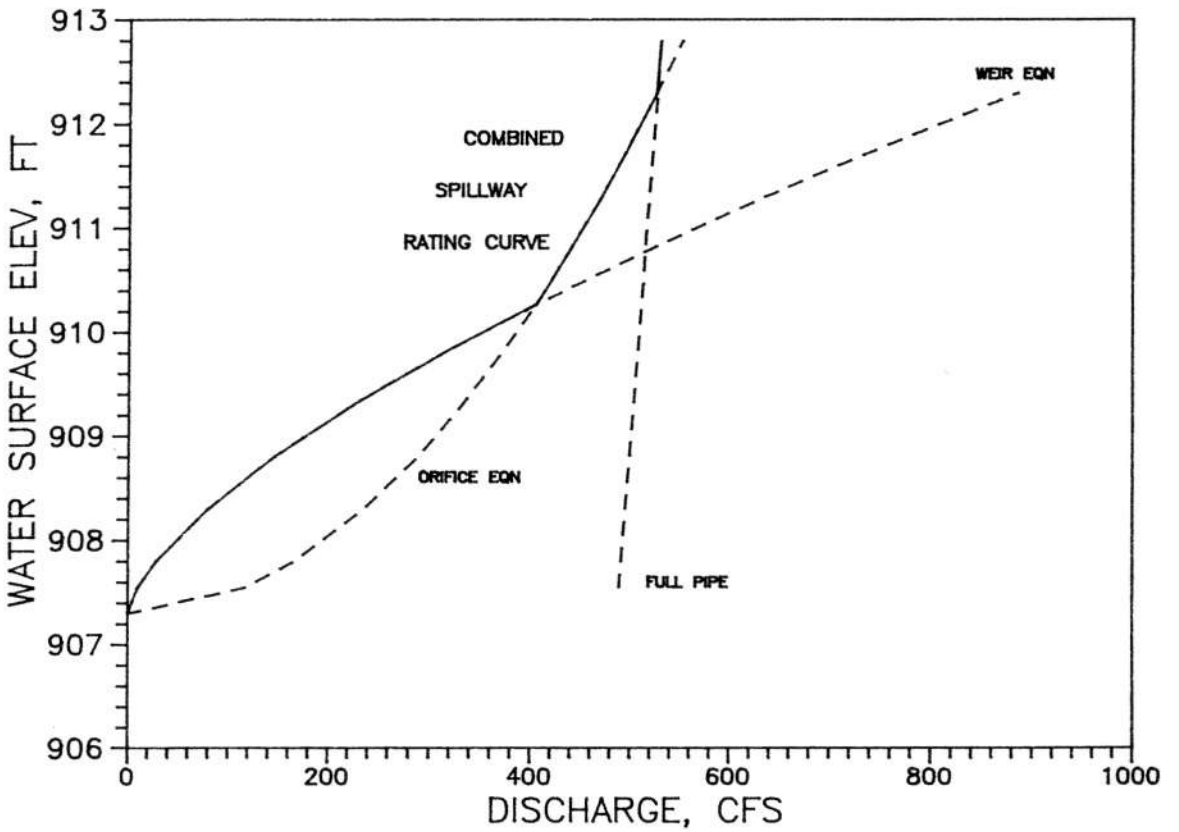

Figure 4.2 Combined Spillway Rating Curve for a Conduit Spillway

at the inlet. The second form of control that must be considered is orifice flow which is discribed in Equation 4.5:

$$Q_o = C_o A\sqrt{(2gH)}, \qquad (4.5)$$

where

Q_O = discharge in cfs;
C_O = contraction coefficient;
A = cross sectional area of inlet in ft^2; and
H = head in feet.

The head is normally taken to be the elevation difference between the top of the inlet and the reservoir surface.

When the depth of water in the vertical riser is above the critical depth for weir flow, the drop inlet will be submerged. Flow is then determined by the relationship in Equation 4.6:

$$Q_p = A_p\sqrt{\frac{2gH_t}{K_c + K_o + \frac{fL}{D}}}, \qquad (4.6)$$

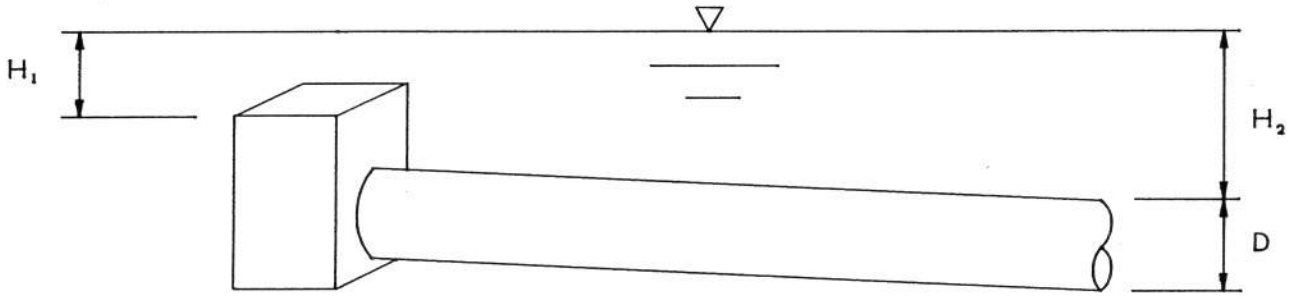
where

Q_p = discharge through pipe in cfs;
A_p = cross sectional area of pipe in square ft;
H_t = total head measured from the headwater surface in the riser to the crown of the pipe outlet in ft;
K_C = total entrance losses, dimensionless coefficient;
K_O = total outlet losses, dimensionless coefficient;
f = Darcy-Weisbach friction factor;
L = length of pipe in feet; and
D = diameter of pipe in feet.

This equation ignores the effect of friction in the riser which, for short risers, is insignificant. Loss coefficients for expansions, contractions, bends, gates, and trashracks are contained in Design of Small Dams. Simon (1986) also provided a good discussion of various loss coefficients.

Figure 4.3 contains a form that can be used to tabulate flow rates under weir, orifice, and full pipe flow conditions. Q_{TOTAL} is determined at each elevation bt taking the minimum of Q_W, Q_O, and Q_P.

This section has not included siphon flow. Unless properly designed to withstand negative pressures, a conduit can be severely damaged by repeated occurrences of siphon flow. A brief explanation of siphon flow follows.



When air is purged from the discharge conduit, large, nearly instantaneous increases in the discharge occur. As the inlet becomes submerged, the high turbulence at the base entrains air and removes portions of the trapped air from the inlet. The pressure inside the inlet becomes negative and creates a pressure differential across the inlet. This is turn increases the discharge through the inlet. The

increased discharge causes the driving head (the depth of water in the inlet) to increase and increases the discharge through the outlet conduit. During this process the unsteady nature of the flow causes waves to travel down the conduit. Usually a wave will seal the conduit. The large negative pressure created by the wave will cause the system to siphon and flow full. The discharge increases abruptly as the flow jumps from inlet to outlet control. Dynamic pressures are created throughout the system. Unless the reservoir rises rapidly, vortexes and other disturbances at the inlet will bring air into the system, break the siphon, and start the cycle over.

Sometimes the siphon action only partially occurs. As the system begins to siphon, the driving head is drawn down in the inlet. The wave, which had sealed the conduit, allows air back up the conduit. The driving head quickly rises and forces the trapped air in the inlet up and through the top "belching" out into the atmosphere. The water at the inlet quickly replaces the belched air as it passes out, and falls into the inlet as a slug causing dynamic pressure surges. These surges can cause damaging vibration throughout the system. Measures must be taken to avoid this problem and insure the proper operation of the system.

3. Culvert Spillways

A culvert spillway ordinarily consists of a simple culvert conduit placed through the dam or along the abutment, generally on a uniform grade with the entrance placed vertically or inclined. The culvert cross section may be round, rectangular, square, or some other shape. Usually, prefabricated pipe materials such as concrete or PVC are utilized.

The factors which combine to determine the nature of flow in a culvert spillway include slope, size, shape, length, roughness of the conduit barrel, and the inlet and outlet geometry. The combined effect of these factors determines the location of the control which in turn determines the discharge characteristics of the conduit. The location of the control dictates whether the conduit flows partly full or full and thereby establishes the head-discharge relationship.

Many nomographs and graphs have been developed for standard size pipe and box culverts. The staff of the Dam and Reservoir Safety Program uses Hydraulic Engineering Circular No. 10 published by the U.S. Department of Transportation (1972) to rate most culverts. Another good reference is Hydraulic Engineering Circular No. 5 published by the U.S. Department of Transportation (1965). Nomographs for determining flow in circular pipes are also included in the appendix of Design of Small Dams.

4. Flow under Bridges

In most cases, flow under bridges should be determined by performing a backwater analysis of the channel over which the bridge is located. However, in some cases, a single span bridge will pass flow as an orifice under low heads.

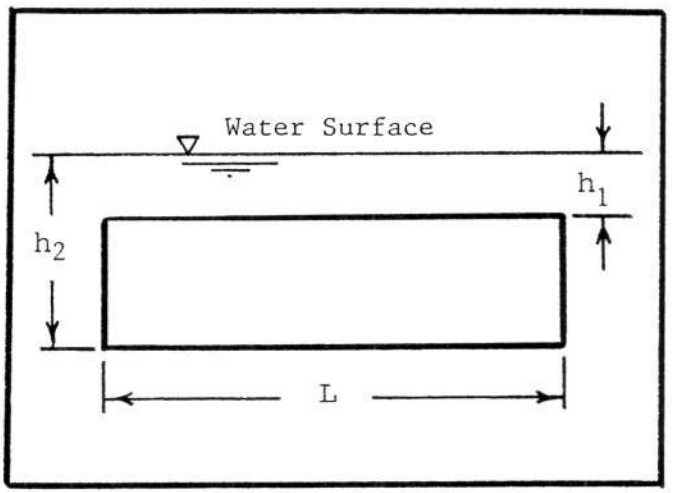

Figure 4.4 Flow Through a Rectangular Orifice

When the head on a vertical orifice is small in comparison with the height of the orifice, there is an appreciable difference between the theoretical discharge and the discharge given by Equation 4.5. Figure 4.4 shows a rectangular orifice of width L and height H. The respective heads on the upper and lower edges of the orifice are h_1 and h_2. Equation 4.7 gives the theoretical discharge for rectangular orifices.

$$Q_t = \frac{2}{3} L\sqrt{2g}(h_2^{1.5} - h_1^{1.5}) \qquad (4.7)$$

When Equation 4.5 is employed for orifices discharging under low heads, the deviation from the theoretical form of the formula must be corrected in the contraction coefficient. Equation 4.7 provides a better means of deriving the rating curve and does not require the estimation of a contraction coefficient.

B. Open Channel Hydraulics

Most dams have open channel principal spillways or emergency spillways which carry the majority of the flow during the design flood. It is important to know how to analyze the capacity of an open channel to determine if a dam will be overtopped. Many open channels have gentle slopes to prevent excessive erosion, but gentle slopes can cause backwater conditions in the channel. Depending on the flow rate, the control can move up or down the channel. Therefore, backwater analyses have to be be performed at several flow rates to determine the capacity of the channel.

Section Factor	Z	Product of the water area and the square root of the hydraulic depth.	$\frac{[(b+zy)y]^{1.5}}{\sqrt{b+2zy}}$

Note y = depth of flow in channel

b = channel base width.

z = sideslope of channel, z:1.

An open channel is a conduit in which the flow has a free surface at all times. This contrasts with closed conduit or pipe flow in which the flow is completely enclosed. The free surface is subject to local atmospheric pressure, thus, the hydraulic grade line of a channel coincides with the water surface. This also has the effect of determining the location of the energy grade line since it is one velocity head $V^2/2g$ above the hydraulic grade line. The driving force which causes water to flow in open channels is the action of gravity along the slope of the channel.

Open channel flow may be classified and described in several ways. One such classification uses time as the criterion. Flow is considered to be steady if a parameter such as velocity or depth of flow at a point does not change over some time interval. The flow is unsteady if there is a change with respect to time.

Table 4.1 illustrates some of the common concepts used in open channel hydraulics. Channel sections are taken perpendicular to the direction of flow. The depth of flow, y, is the vertical distance from the lowest point of a channel section to the free surface. The water area, A, is the cross-sectional area of the flow normal to the direction of flow. The top width, T, is the width of the channel section at the surface. The wetted perimeter, P, is the length of the boundary in contact with the bottom and sides of the channel. The hydraulic radius, R, is the area divided by the wetted perimeter. The hydraulic depth, D, is the area divided by the top width, and is the characterictic length in open channels. Equations for these parameters are listed in Chow (1959) for various channel cross sections.

If space is used as the criterion, the flow is uniform if there is no change in velocity or depth along the length of a reach of channel. If a change does occur the flow is varied. Varied flow may be described as gradually or rapidly varied flow. In gradually varied flow, the rate of change of depth and velocity with respect to distance is relatively small so that some of the assumptions of uniform flow can be used for hydraulic calculations. Flow profiles caused by the backwater effect of a reservoir and changes in channel slope are examples of gradually varied flow.

A channel is prismatic if it has constant cross-section and slope over a reach; otherwise it is nonprismatic.

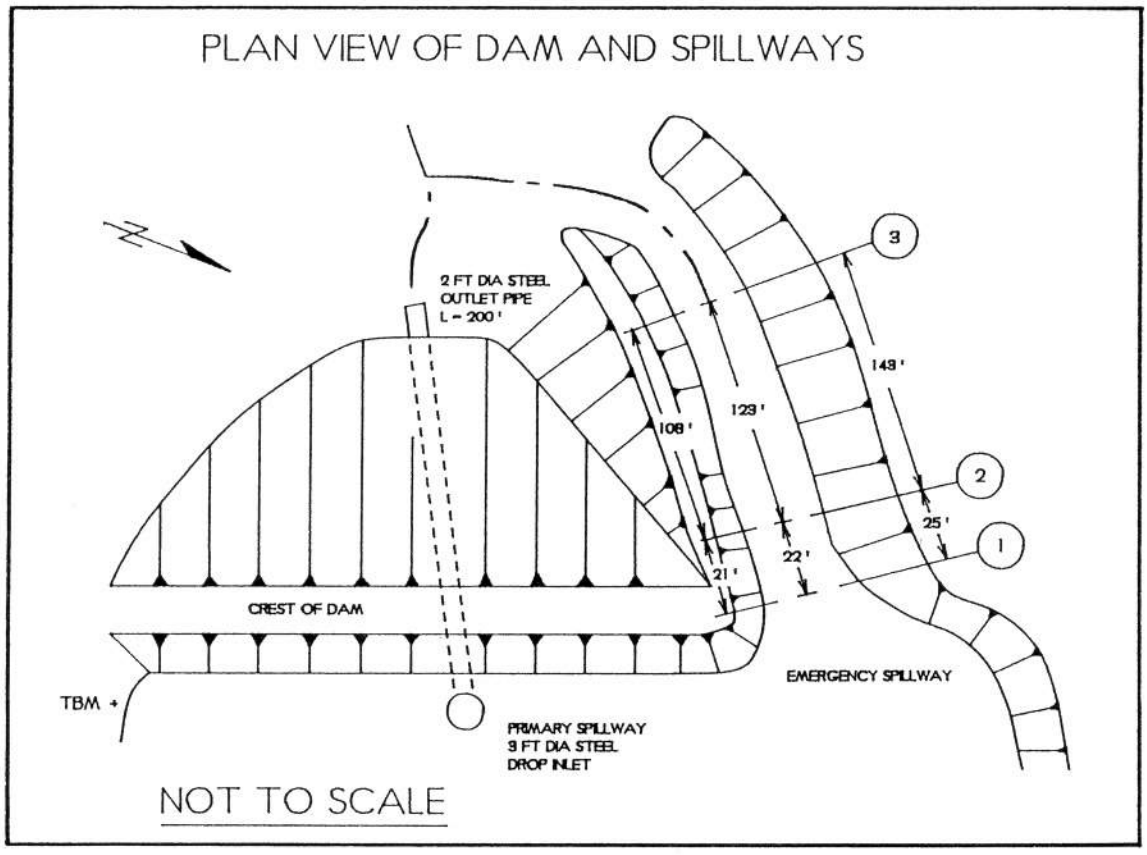

Figure 4.5 Plan View of an Earth Dam and Spillways

1. Water Surface Profiles

When water surface profiles are determined in an open channel spillway, the reservoir surface is assumed to be the elevation of the energy grade line at the upstream most cross section. In surveying an open channel spillway, the engineer should obtain cross sections at several locations both upstream and downstream of the assumed control section. This will ensure that sufficient information will be available to determine the approximate location of the control section. The results of a backwater analysis also allow the engineer to determine if the velocities in the channel are too high and if the training berm is high enough to prevent water from flowing outside the channel. Figure 4.5 shows a typical series of cross sections needed to perform backwater computations.

There are many methods available to compute water surface profiles in an open channel. The staff of the Dam and Reservoir Safety Program utilizes the U.S. Army Corps of Engineers (1982) HEC-2 Water Surface Profiles computer program to perform these calculations. The program calculates water surface profiles for steady gradually varied flow in natural or man-made channels. Both subcritical and supercritical flow profiles can be computed. The effects of various obstructions such as bridges, culverts, weirs, and structures in the channel may be considered in the computations. The computational procedure is based on the solution of the one-dimensional energy equation with energy loss due to friction evaluated with Manning's equation. The computational precedure is generally known as the Standard Step Method.

Figure 4.6 illustrates a short channel reach of length Δx which will be used to explain the basis of the standard step method. Equating the total heads at the two end sections 1 and 2, Equation 4.8 is produced:

$$S_o \Delta x + y_1 + \alpha_1 \frac{V_1^2}{2g} = y_2 + \alpha_2 \frac{V_2^2}{2g} + S_f \Delta x, \qquad (4.8)$$

where

S_O = slope of the channel bottom;
Δx = increment of channel reach;
y = depth of flow;
V = velocity of flow;
g = acceleration of gravity, 32.2 fps^2;
α = energy coefficient; and
S_f = energy gradient.

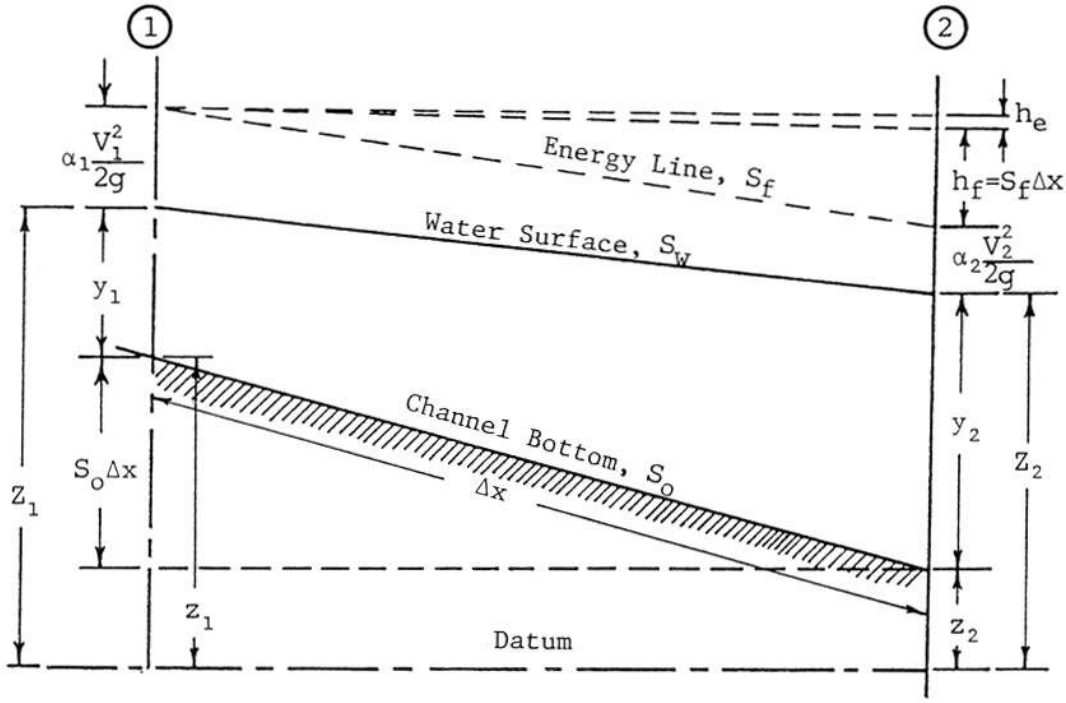

Figure 4.6 Energy in Gradually Varied Open Channel Flow

The water surface elevations at the two end sections are referenced to a horizontal datum as

$$Z_1 = S_o \Delta x + y_1 + z_2 \qquad (4.9)$$

and

$$Z_2 = y_2 + z_2 \qquad (4.10)$$

The friction loss is

$$h_f = S_f \Delta x = \frac{1}{2}(S_{f1} + S_{f2})\Delta x. \qquad (4.11)$$

For ease of computation, the friction slope, S_f, is taken as the average of the slopes at the two end sections, or $\overline{S}_f$. Substituting Equations 4.9, 4.10, and 4.11 into Equation 4.8 yields

$$Z_1 + \alpha_1 \frac{V_1^2}{2g} = Z_2 + \alpha_2 \frac{V_2^2}{2g} + h_f + h_e, \qquad (4.12)$$

where

α = energy coefficient; and
h_e = eddy losses.

The eddy loss depends mainly on the velocity head change and may be expressed as a part of it, or $k\left(\Delta\alpha \frac{V^2}{2g}\right)$ where k is a coefficient. For gradually converging and diverging reaches, k = 0 to 0.1 and 0 to 0.2, respectively. For abrupt expansions and contractions, k is about 0.5.

The total heads at the two end sections are

$$H_1 = Z_1 + \alpha_1 \frac{V_1^2}{2g} \qquad (4.13)$$

$$H_2 = Z_2 + \alpha_2 \frac{V_2^2}{2g} \qquad (4.14)$$

Substituting into Equation 4.12 yields

$$H_1 = H_2 + h_f + h_e \qquad (4.15)$$

Equation 4.15 is the basic equation which is used to develop the procedure used in the standard step method. The standard step computation can be arranged in tabular form and solved as shown in Table 4.2.

The backwater computations must always be carried upstream if the flow is subcritical and downstream if it is supercritical. In computing a flow profile, the following information is generally required:

- The discharge for which the flow profile is desired.
- The water surface elevation at the control section. If this is not available, the comutation may start from an

TABLE 4.2

Standard Step Method of Computation

Station (1)	Z (2)	y (3)	A (4)	V (5)	$\alpha\frac{V^2}{2g}$ (6)	H (7)	R (8)	$R^{\frac{4}{3}}$ (9)	S_f (10)	$\overline{S}_f$ (11)	Δx (12)	h_f (13)	h_e (14)	H (15)

Before the computations begin, the flow rate must be specified as well as the channel roughness, n; slope, S_o; and energy coefficient, α.

Col. 1: Identify channel cross section by station number

Col. 2: Water surface elevation at the station. A trial value is first entered in this column; this will be verified or rejected on the basis of the computations made in the remaining columns of the table. For the first step, this elevation must be given or assumed. When the trial value in the second step has been verified, it becomes the basis for the verification of the trial value in the next step, and so on.

Col. 3: Depth of flow in feet, corresponding to the water surface elevation in column 2.

Col. 4: Water area corresponding to y in column 3.

Col. 5: Mean velocity equal to the given discharge, Q, divided by the water area in column 4.

Col. 6: Velocity head in feet, corresponding to the velocity in column 5.

Col. 7: Total head computed by Equation 4.13, equal to the sum of Z in column 2 and the velocity head in column 6.

Col. 8: Hydraulic radius in feet, corresponding to y in column 3.

Col. 9: Four-thirds power of the hydraulic radius.

Col. 10: Friction slope computed by $S_f = \frac{n^2V^2}{2.22R^{4/3}}$ with V from column 5 and $R^{4/3}$ from column 9.

Col. 11: Average friction slope through the reach between the sections in each step, approximately equal to the arithmetic mean of the friction slope just computed in column 10 and that of the previous step.

Col. 12: Length of the reach between the sections, equal to the difference in station numbers between the stations.

Col. 13: Friction loss in the reach, equal to the product of the values in columns 11 and 12.

Col. 14: Eddy loss in the reach, equal to zero.

Col. 15: Elevation of the total head in feet. This is computed by Equation 4.15, that is, by adding the values of h_f and h_e in columns 13 and 14 to the elevation at the lower end of the reach, which is found in column 15 of the previous reach. If the value so obtained does not agree closely with that entered in column 7, a new trial value of the water-surface elevation is assumed, and so on, until agreement is obtained. The value that leads to agreement is the correct water-surface elevation. The computation may then proceed to the next step.

assumed elevation at a section far enough away from the initial section through which the profile is desired.

- The geometric elements at various channel sections along the reach for all depths of flow within the range expected. Cross sections and reach length between are the two primary elements.

- The channel roughness and losses at each section.

Chow (1959) and Henderson (1966) provide an excellent discussion of the standard step method and procedures to compute backwater profiles.

One of the most difficult assessments that an engineer must make in the performance of a backwater analysis is the estimation of the surface roughness of the channel. Manning's n is a measure of surface roughness and is largely dependent on the material of which the channel boundaries are composed. There are several other factors which affect the value of n, including vegetation, channel irregularity, alignment, silting, scouring, obstructions, size and shape of channel, and depth of flow. Values of n are usually selected from tables for various materials or from pictures of channel for which values of n have been determined empirically. Chow (1959) and the United States Geological Survey (1967) are excellent references which should be used in estimating channel roughness. The following table can be used to estimate roughnesses for channels and closed conduits.

SURFACE	Min. n	Max. n
PVC Pipe	.010	.012
Concrete Pipe	.012	.015
Cast Iron Pipe	.013	.017
Grass Lined Channels	.020	.040
Rock Cut Channels, Smooth	.025	.040
Rock Cut Channels, Irreg.	.030	.045
Natural Streams	.025	.150

Vegetated open channel spillways usually consist of an inlet channel, a control section, and an exit channel. Subcritical flow occurs in the inlet channel and the flow is usually supercritical in the exit channel. Vegetated open channel spillways are typically trapezoidal in cross-section and are protected from erosion by a grass cover. While erosion damage is normally considered to be a maintenance related deficiency, it becomes a safety problem in cases where failure of the discharge channel will cause the flow to impinge on the toe or slopes of the embankment. As a general guideline, channels can be expected to suffer erosion damage when velocities exceed 8 fps.

The amount of erosion that will occur in a channel depends upon the characteristics of the soil, the type and density of the vegetation cover, the discharge velocity, and the duration and frequency of use. To minimize erosion, vegetated open channel spillways should be designed with horizontal or adverse sloped inlet channels and control sections that are located away from the dam. The anticipated average use of a vegetated open channel spillway should be kept to a minimum; it is preferable that the spillway be designed to carry flows only in excess of the 100-year event. In highly erodible soils, concrete sills or weirs should be constructed to stop headward erosion and prevent failure of the spillway.

All spillway flows should be confined to the channel with training berms or levees. Training berms must be high enough to contain the peak flow during the spillway design flood.

2. Critical Flow Computations

When an ogee spillway or a weir is located adjacent to the reservoir, the spillway rating curve can be determined by analyzing critical flow in an open channel. Critical flow is defined as the state of flow at which the specific energy, $y + \frac{V^2}{2g}$, is a minimum for a given discharge, Q. Using Equation 4.16, discharge rates can be computed at various values of critical depth.

$$Q = \sqrt{\frac{A^3 g}{T}}, \qquad (4.16)$$

where

Q = flow rate in cfs;
A = area of flow at critical depth in ft^2;
g = acceleration of gravity, 32.2 ft/sec^2; and
T = top width of water surface.

In order to develop a spillway rating curve, the reservoir elevation, $ELEV_{res}$, must be computed at each value of critical depth, y_c. This can be accomplished using Equation 4.17:

$$ELEV_{res} = ELEV_{sp} + y_c + \frac{V_c^2}{2g}, \qquad (4.17)$$

where

$ELEV_{res}$ = Elevation of the reservoir;
$ELEV_{sp}$ = Spillway crest elevation;
y_c = critical depth in feet; and
$\frac{V_c^2}{2g}$ = velocity head.

The only unknown parameter in Equation 4.17 is the velocity head, $\frac{V_c^2}{2g}$. It can be determined by using the continuity equation to compute the velocity at each value of critical depth, $V_c = \frac{Q}{A}$

Equation 4.16 should only be used to rate control structures such as weirs that will not become submerged by downstream conditions. It is always advisable to perform a backwater analyses of the discharge channel when there are questions about the channel's capacity and erosion resistance, or if training berms must be evaluated.

C. Reservoir Routing

Reservoirs can be routed by any number of level pool techniques. The basic requirements include reservoir elevation-storage information and a spillway rating curve. The beginning reservoir elevation should be the water storage elevation (normal pool) as defined by 10 CSR 22-1.020(62).

After the inflow hydrograph has been computed, the storm hydrograph must be routed through the reservoir. The staff of the Dam and Reservoir Safety Program uses the modified Puls routing method described by Chow (1964). This method assumes an invariable discharge-storage relationship and neglects the variable slope occurring during the passage of a flood wave. It is a satisfactory method for reservoir routing but should not be used for channel routing when unsteady flow conditions exist.

Modified Puls routing requires the solution of the continuity equation which can be expressed as

$$I - O = \frac{\Delta S}{\Delta t}, \qquad (4.18)$$

where

I = inflow into the reservoir;
O = outflow from the reservoir; and
S = water stored in the reservoir.

Equation 4.18 is exact but its application to practical problems involves approximations. The basic assumptions are that the water surface in the reservoir is level at all times and that the average of the inflow and outflow at the beginning and ending of a routing period are equal to the average flow during the period. Using subscripts 1 and 2 to denote the beginning and ending of a routing period gives

$$\frac{I_1 + I_2}{2} - \frac{O_1 + O_2}{2} = \frac{S_2 - S_1}{\Delta t} \qquad (4.19)$$

Arranging Equation 4.19 so that all known values are on the left yields

$$\frac{I_1 + I_2}{2}\Delta t + S_1 - \frac{O_1 \Delta t}{2} = S_2 + \frac{O_2 \Delta t}{2} \qquad (4.20)$$

The assumption that $(I_1 + I_2) / 2$ equals the average inflow during a routing period implies that the inflow hydrograph varies linearly over the time step, Δt. Thus the controlling factor in selecting the routing period Δt is that it be sufficiently short so that this assumption is not seriously violated. The routing period should never be greater than the time of travel through the reservoir and should be chosen to ensure that the peak of the inflow hydrograph will be considered. As a rule of thumb, the routing period should be long enough to consider at least four inflows on the rising limb of the inflow hydrograph.

The two relationships that must be developed to solve Equation 4.20 involve the outflow from the reservoir and storage within the reservoir. This section will consider only storage in the reservoir. The previous sections in this chapter addressed the issue of outflow, which is determined by rating both closed conduit and open channel spillways.

Like basin area, reservoir areas can be determined from a topographic map using a planimeter. The reservoir's water surface area should be determined at each successive contour from the toe to the top of the dam. For dams that have been in existence several years, contour lines may not extend below the normal pool elevation. In this case, only reservoir volumes above normal pool can be computed. Hydrographic surveys are useful to determine the amount of silt in the reservoir but they are not required to perform reservoir routing.

The volume between successive contours can be determined by either of two methods: the average end area method or the conic method. The average end area method averages the area between two successive contours and multiplies the result times the change in elevation as shown in Equation 4.21

$$\Delta Vol = \left(\frac{A_n + A_{n+1}}{2}\right)(E_{n+1} - E_n), \qquad (4.21)$$

where

ΔVol = volume of storage between elevations E_n and E_{n+1};
A_n = water surface area at elevation E_n;
A_{n+1} = water surface area at elevation E_{n+1}; and
E = elevation.

The conic method can be used to compute reservoir volume from surface area versus elevation data as follows:

$$\Delta Vol = (E_{n+1} - E_n)(A_n + A_{n+1} + \sqrt{A_n A_{n+1}})$$

After the reservoir volumes have been computed, a graph of elevation versus storage is developed. Using this graph and the spillway rating curve, a graph of discharge versus storage is created as shown in Figure 4.7. Each point on the curve represents reservoir storage and outflow at a given elevation. Figure 4.8 is a plot of outflow, O, versus $\left(S + \frac{1}{2}O\Delta t\right)$. This graph is obtained by adding to the abscissa of the storage curve, Figure 4.7, one half of the value of $(O\Delta t)$. At the beginning of a routing period, the known values are the inflows for periods 1 and 2 and the outflow at period 1. The goal is to determine the outflow for period 2.

The modified Puls routing procedure involves the following steps:

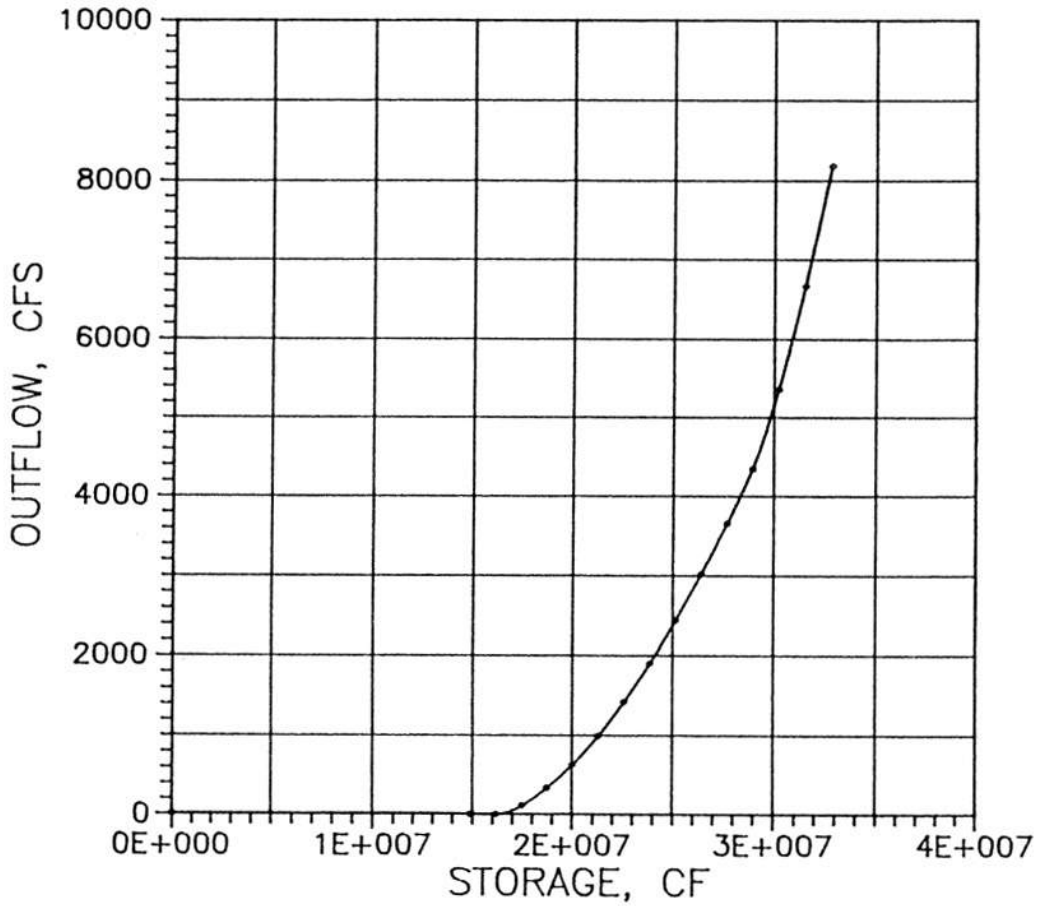

Figure 4.7 Storage Versus Outflow Curve for a Reservoir

Step 1 Compute $(I_1 + I_2)/2$, the average inflow.

Step 2 For an initial outflow, O_1, the storage S_1 is obtained from the storage versus outflow curve, Figure 4.7.

Step 3 Compute the quantity $\left(S_1 - \frac{1}{2}O_1\Delta t\right)$.

Step 4 Using Equation 4.18, determine the quantity $\left(S_2 + \frac{1}{2}O_2\Delta t\right)$ by adding the average inflow plus the quantity $\left(S_1 + \frac{1}{2}O_1\Delta t\right)$.

Step 5 Determine the outflow O_2 corresponding to $\left(S_2 + \frac{1}{2}O_2\Delta t\right)$ from Figure 4.8.

Several iterations of these computations are performed to construct the outflow hydrograph which is a plot of time versus outflow, O_2. The maximum water surface elevation during the design flood is then determined from the peak rate of outflow.

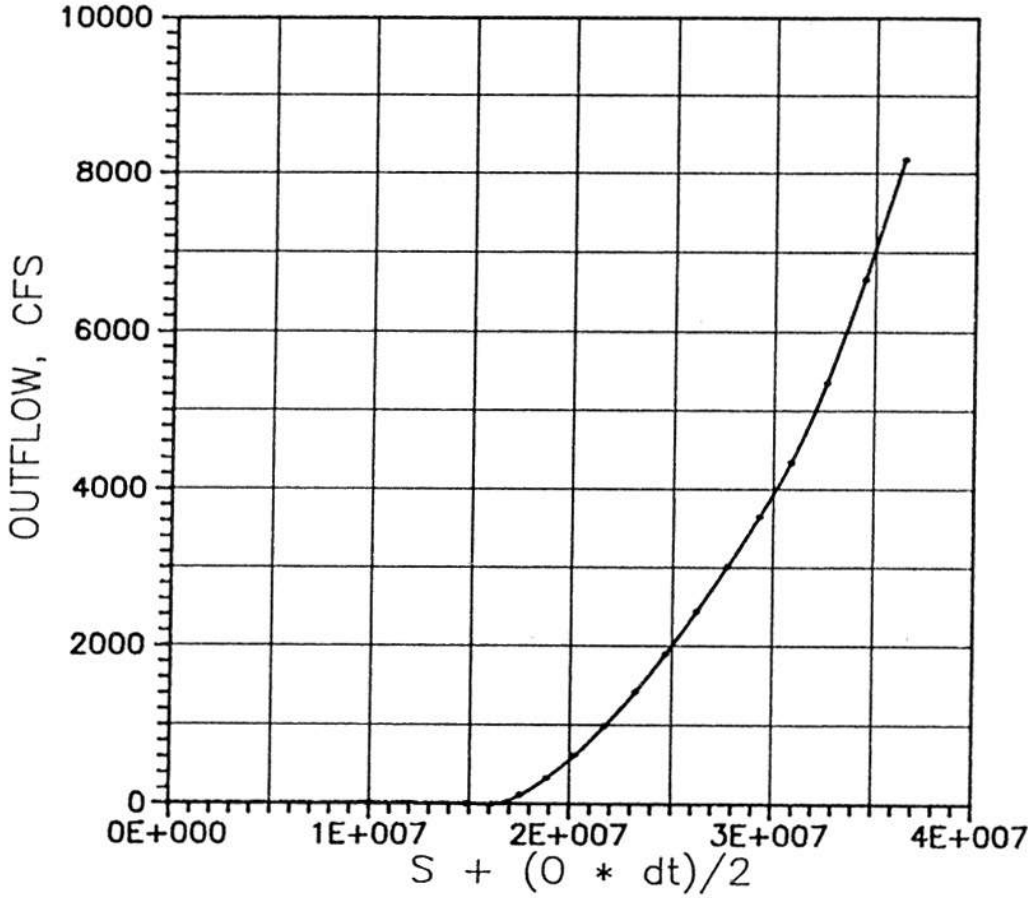

Figure 4.8 S + (O · dt)/2 Versus Outflow Curve for A Reservoir

CHAPTER V

GEOTECHNICAL CONSIDERATIONS

The geotechnical considerations in this chapter will focus on earth, rockfill and tailings dams. Figure 5.1 illustrates the differences between the three types of dams.

Rolled earthfill dams are constructed in successive mechanically compacted layers. They can be constructed as homogeneous embankments or as zoned dams with an impervious core. Homogeneous dams are constructed entirely or almost entirely of a single embankment material. They are so named to distinguish them from zoned dams, which contain different materials in different parts of the embankment. The downstream slope of a homogeneous dam on an impervious foundation will theoretically develop seepage to a height of roughly one-third the depth of the reservoir pool. Sometimes, homogeneous and zoned embankments are constructed with internal drains to control seepage. Chimney, blanket and trench drains are three of the more common types of internal drains used in Missouri. Internal drains serve two important purposes. They control seepage and reduce the pore pressure in the downstream portion of the dam thereby improving the stability of the dam.

Rockfill dams usually have an impervious core which is flanked by zones of material considerably more pervious. The pervious zones enclose, support, and protect the impervious core; the upstream pervious zone affords stability against rapid drawdown; and the downstream pervious zone acts as a drain to control the line of seepage. To prevent internal erosion of the impervious core, a filter is placed between the core and the downstream rock shell.

Tailings or industrial water retention dams are used by mining companies to store waste rock from mining. All tailings dams greater than 35 feet in height are regulated under the dam safety law. The three types of tailings dams currently in existence in Missouri are lead, barite, and iron tailings. Each of these dams typically includes a clay starter dam which is normally constructed as a homogeneous earthfill embankment.

Lead tailings used in dam construction are typically ground limestone and dolomite. The silty sand tailings have a gradation ranging from a #40 to a #200 sieve. On-dam cycloning (Vick, 1983) is the primary method used to disposit lead tailings in Missouri. Underflow sand from each hydro-cyclone is discharged toward the embankment face, and overflow slimes are discharged into the impoundment. A wide zone of slimes adjacent to the upstream slope of the dam helps restrict the flow of seepage through the dam.

Barite tailings used in dam construction consist of well graded gravel. Barite slimes have low permeability and consist of red and dark brown clay.

Iron tailings dams are built with crushed rock that ranges in size from 1/4 to 5/8 inch. In order for iron tailings dams to retain water, a clay blanket or an impermeable liner must be placed on the upstream slope.

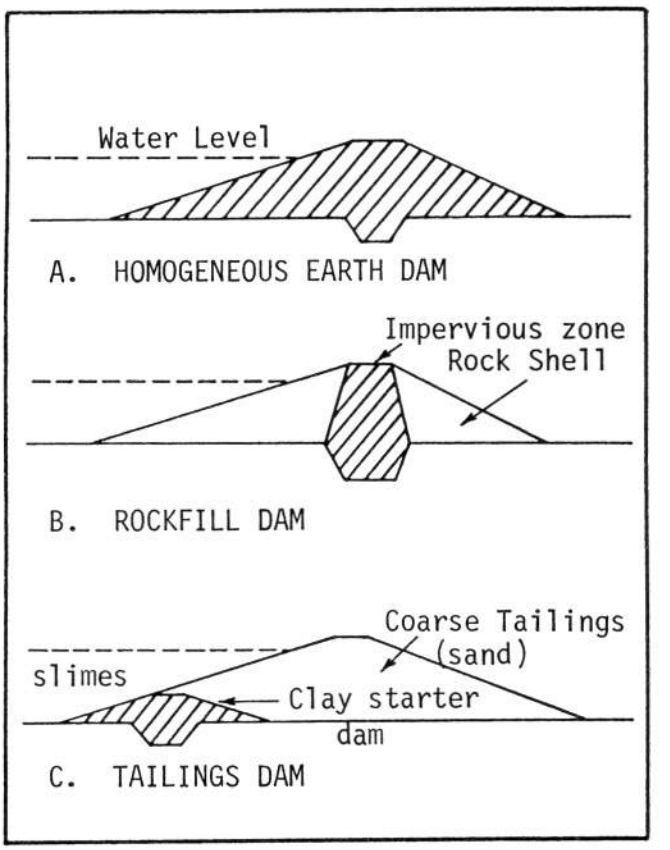

Figure 5.1 Types of Dams in Missouri

Tailings dams can be constructed by the upstream, centerline and downstream methods as shown in Figure 5.2.

The geotechnical analysis of industrial water retention dams involve seepage, slope stability and seismic response computations. The design for all new dams built in Missouri after August 13, 1981 must include a geotechnical analysis to show that the dam will meet the criteria in 10 CSR 22-3.020. A geotechnical analysis is not required for dams that were in existence prior to August 13, 1981 unless the height, slope or reservoir elevation is being modified.

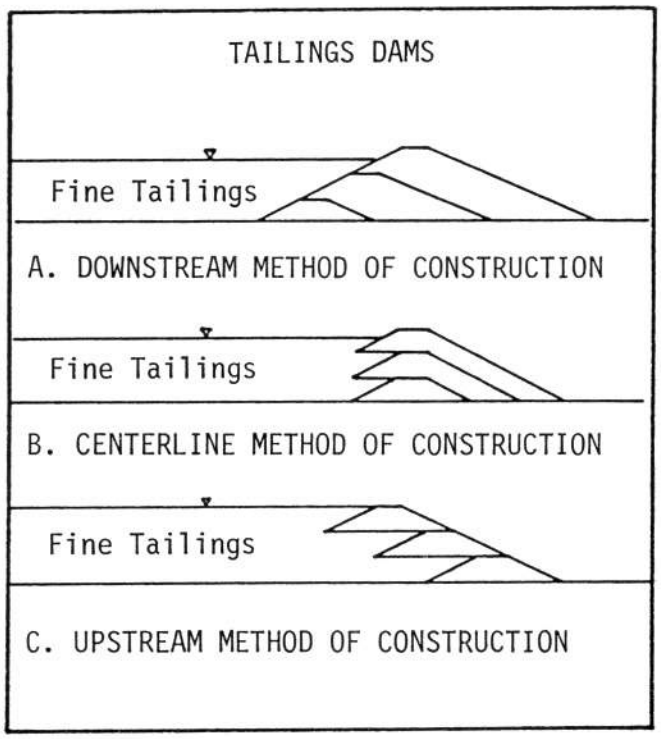

Figure 5.2 Methods of Constructing Tailings Dams

A. Soil Classification

Knowledge of soil classification, including typical engineering properties of soil groups, is essential when investigating earth materials or foundations for structures. Soil classification can be used to estimate engineering characteristics of soils for use in the analysis of small dams.

The Unified Soil Classification System is recommended for use in the classification of soils. Figure 5.3, the Unified Soil Classification Chart, is the basis for soil classification under this system.

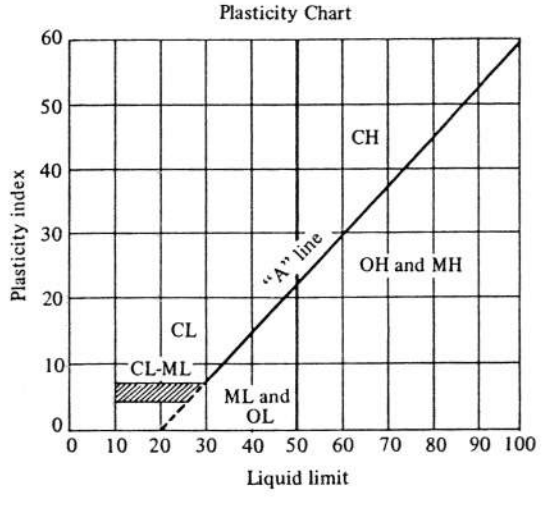
In addition to proper classification, it is important to include an adequate description of the soil in reports or logs of explorations. The classification chart contains the information required for describing soils, citing several examples.

B. Foundation Cutoffs

Many dam sites have a foundation consisting of alluvial deposits of permeable sand and gravel, silt, or weathered rock at or near the surface with an impervious (less permeable) stratum of rock, clay, or shale at a greater depth. For these sites, a positive cutoff is recommended to assure a successful and stable dam. The cutoff should intersect the impervious stratum and be an extension of the core of the embankment. A positive cutoff is particularly important where the water in storage is used for irrigation or water supply.

Where a positive cutoff is impractical because of the depth to an impervious stratum, a partial cutoff may provide foundation stability and reduce seepage losses to acceptable levels. Regardless of the foundation conditions, the only way to determine the economical feasibility of a positive cutoff or partial cutoff is to make a seepage analysis and water balance.

C. Foundation and Embankment Drainage



The impervious portion of an earthfill dam provides resistance to seepage, which creates the reservoir. Soils vary in permeability, and even the tightest clays can transmit seepage. Therefore, seepage control is a major concern in dam design. Filter and drainage systems must have adequate capacity but still control the movement of fine grained soil particles through the embankment. Internal erosion of fine grained soil can lead to a condition known as "piping" in which a conduit or pipe forms within the embankment. If allowed to continue, the erosion can eventually migrate upstream to the reservoir and cause a total failure of the dam.

The movement of reservoir water through the dam depends on the reservoir level, the degree of permeability of the embankment material in the horizontal and vertical directions, the amount of remaining pore-water pressures caused by compressive forces during construction, and the distance over which the seepage travels. The upper surface of seepage is called the phreatic surface; in a cross section, it is referred to as a phreatic line. Although the soil may be saturated by capillarity above this line, giving rise to a "line of saturation," seepage is limited to the portion below the phreatic line.

Drains are included in embankments and foundations for two basic reasons: to prevent piping by controlling migration of soil particles under seepage flow; and to control pressure build-up by allowing free drainage of seepage flow. There are no hard and fast rules for selecting a margin of safety for the capacity of internal drains. Cedergren (1977), recommends that drains be designed to carry at least ten times as much seepage as expected due to difficulty in estimating permeability of the drain material and seepage rates. Judgement is required and should be related to past experience with similar materials and an evaluation of the data obtained during the site investigation and testing program.

In recent years, many engineers have opted to use geotextiles as filters for granular drains. Geotextiles can be either woven or nonwoven. They are used in subsurface drainage systems as a permeable separator to keep soil

Major Divisions			Group Symbols	Typical Names	Laboratory Classification Criteria	
Coarse-grained soils (More than half of material is larger than No. 200 sieve size)	Gravels (More than half of coarse fraction is larger than No. 4 sieve size)	Clean gravels (Little or no fines)	GW	Well-graded gravels, gravel-sand mixtures, little or no fines	Determine percentages of sand and gravel from grain-size curve. Depending on percentage of fines (fraction smaller than No. 200 sieve size), coarse-grained soils are classified as follows: Less than 5 per cent: GW, GP, SW, SP. More than 12 per cent: GM, GC, SM, SC. 5 to 12 per cent: *Borderline* cases requiring dual symbols[b]	$C_u = \frac{D_{60}}{D_{10}}$ greater than 4; $C_c = \frac{(D_{30})^2}{D_{10} \times D_{60}}$ between 1 and 3
			GP	Poorly graded gravels, gravel-sand mixtures, little or no fines		Not meeting all gradation requirements for GW
		Gravels with fines (Appreciable amount of fines)	GM[a] d / u	Silty gravels, gravel-sand-silt mixtures	Atterberg limits below "A" line or P.I. less than 4	Above "A" line with P.I. between 4 and 7 are *borderline* cases requiring use of dual symbols
			GC	Clayey gravels, gravel-sand-clay mixtures	Atterberg limits below "A" line with P.I. greater than 7	
	Sands (More than half of coarse fraction is smaller than No. 4 sieve size)	Clean sands (Little or no fines)	SW	Well-graded sands, gravelly sands, little or no fines	$C_u = \frac{D_{60}}{D_{10}}$ greater than 6; $C_c = \frac{(D_{30})^2}{D_{10} \times D_{60}}$ between 1 and 3	
			SP	Poorly graded sands, gravelly sands, little or no fines		Not meeting all gradation requirements for SW
		Sands with fines (Appreciable amount of fines)	SM[a] d / u	Silty sands, sand-silt mixtures	Atterberg limits above "A" line or P.I. less than 4	Limits plotting in hatched zone with P.I. between 4 and 7 are *borderline* cases requiring use of dual symbols
			SC	Clayey sands, sand-clay mixtures	Atterberg limits above "A" line with P.I. greater than 7	
Fine-grained soils (More than half material is smaller than No. 200 sieve)	Silts and clays (Liquid limit less than 50)		ML	Inorganic silts and very fine sands, rock flour, silty or clayey fine sands, or clayey silts with slight plasticity		
			CL	Inorganic clays of low to medium plasticity, gravelly clays, sandy clays, silty clays, lean clays		
			OL	Organic silts and organic silty clays of low plasticity		
	Silts and clays (Liquid limit greater than 50)		MH	Inorganic silts, micaceous or diatomaceous fine sandy or silty soils, elastic silts		
			CH	Inorganic clays of high plasticity, fat clays		
			OH	Organic clays of medium to high plasticity, organic silts		
	Highly organic soils		Pt	Peat and other highly organic soils		

[a]Division of GM and SM groups into subdivisions of d and u are for roads and airfields only. Subdivision is based on Atterberg limits; suffix d used when L.L. is 28 or less and the P.I. is 6 or less; the suffix u used when L.L. is greater than 28.
[b]Borderline classifications, used for soils possessing characteristics of two groups, are designated by combinations of group symbols. For example: GW-GC, well-graded gravel-sand mixture with clay binder.

Figure 5.3 Unified Soil Classification Chart (ASTM D-2487)

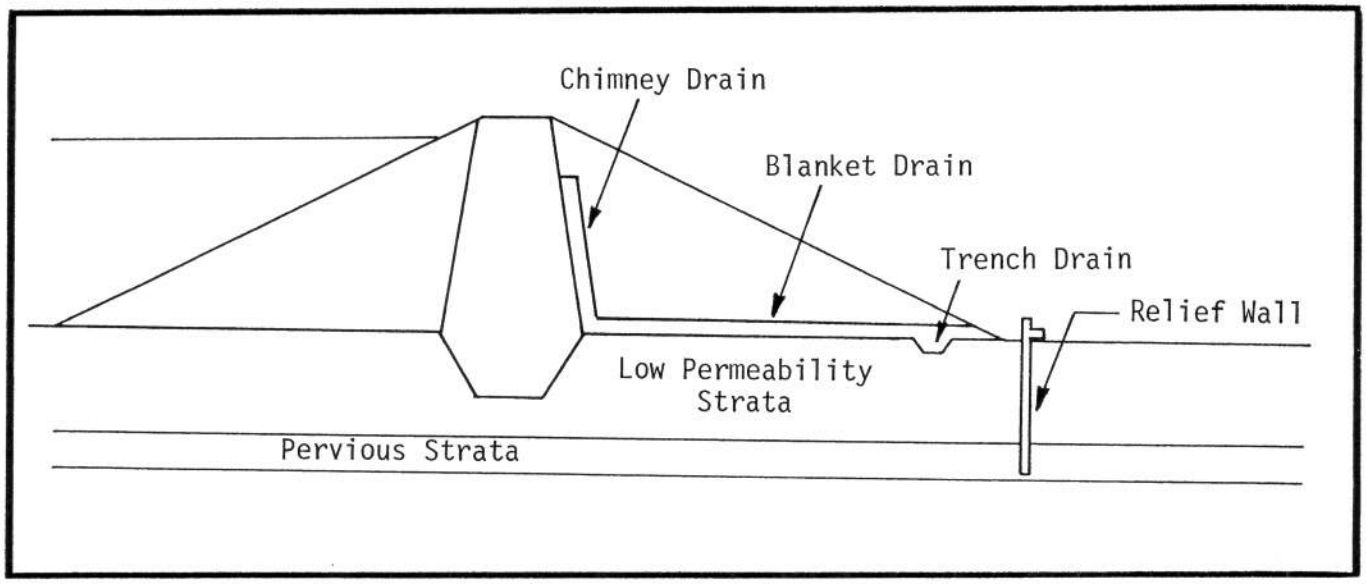


Figure 5.4 Types of Drains

out of the drainage media and permit water to pass freely. Permittivity (capacity to pass water) and pore size (opening size) are critical characteristics of geotextiles. Nonwoven geotextiles are frequently used in dam construction because of their high flow capacity and small pore size. Care should always be taken to assure an effective installation.

Four types of drains will be discussed: chimney drains, blanket drains, trench drains and relief wells. These are shown in Figure 5.4. It should be noted that the selection of the drainage media is a very important consideration. Crushed limestone should not be used. Instead, river run gravel or sand (quartz and chert material) should be selected to ensure the long term success of the drain.

1. Chimney Drains

Chimney drains are primarily interceptors that provide positive control of embankment seepage. With a chimney drain, water that percolates through the soil is intercepted to prevent seepage in the materials downstream from the drain. Chimney drains are applicable where the downstream embankment material cannot be allowed to become saturated and where the horizontal permeability of the fill is significantly higher than the vertical permeability. It may be more economical to place poor materials in a "random fill" zone downstream from a chimney drain than to waste them. Chimney drains are also applicable where embankment materials are susceptible to cracking.

2. Blanket Drains

Horizontal blanket drains occasionally are used in new dams in Missouri. They are primarily used to intercept foundation seepage and prevent saturation of the dam. Horizontal blanket drains are applicable where there is no significant difference between the vertical and horizontal permeability of the embankment or the foundation; where bedrock is pervious (if the drain is placed directly on bedrock); or where a good bond cannot be obtained between bedrock and the embankment and underseepage is a problem.

3. Trench Drains

Trench drains are used more frequently then the other drain types in both new dams and modifications to existing dams. They can be used to provide drainage to the foundation, embankment or abutments. Trench drains are typically excavated with a back hoe and lined with geotextile filter fabric. River run gravel works well as a drainage medium.

Prefabricated drainage composites can also be used as a trench drain, especially in modifications to existing dams. They provide consistent in-place drainage and can reduce the material cost, installation time, and design complexity in some applications. Prefabricated drainage composites typically are two-component materials consisting of a three-dimensional drain core or net with a fabric attached. Water passes through the fabric and into the core. The core acts as a collector and transporter of seepage while the fabric acts as a filtering medium.

4. Relief Wells

Relief wells are generally located near the downstream toe of an embankment. They are particularly adapted for control of pressures from confined and alluvial aquifers

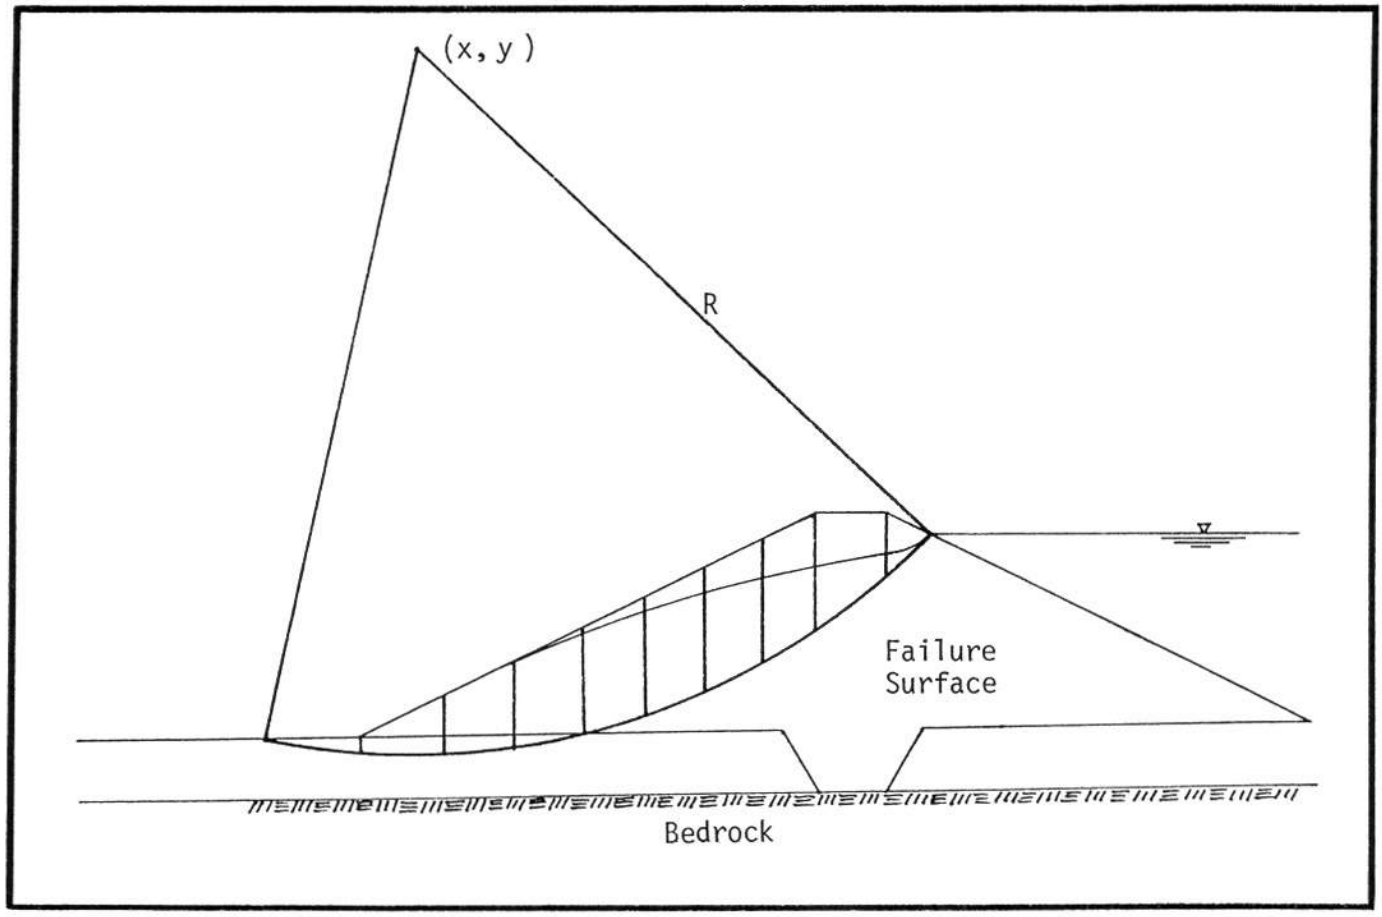

Figure 5.5 Circular Failure Surface in an Earthfill Dam

that are too deep to be drained with foundation drains. They are often used in conjunction with other types of drains.

Drain outlets are needed to conduct the accumulated seepage from all internal drains to a controlled discharge point. PVC pipe works well and provides the dam owner with a outlet location at which to measure the seepage rate.

Two excellent discussions on the subject of internal drains and filters were written by Sherard, Dunnigan, and Talbot (1984).

D. Structural Stability

The potential for failure from sliding, sloughing and rotation must be analyzed, documented and incorporated in the design of all new dams. Embankment and foundation design and geotechnical exploration should be consistent with the complexity of the site and the potential for failure. Anticipated settlement, seepage, and cracking should be considered and documented.

The slope stability criteria used in this manual is that contained in 10 CSR 22-3.020, Tables 1, 3, and 4. Various procedures are available for calculating the factors of safety of embankment sections. The basic methods include the circular arc and the sliding wedge methods.

The staff of the Dam and Reservoir Safety Program use the ICES LEASE and STABL computer programs to perform slope stability analyses. Both programs employ the simplified Bishop Method which divides potential failure surfaces into slices for analysis. Figure 5.5 depicts a circular failure surface in an embankment dam. The factor of safety is the ratio of the moment of shear strength (resisting forces) along the failure surface to the moment of the weight of the failure mass (driving forces). To determine the minimum factor of safety for a dam requires the analysis of several failure surfaces.

The simplified Bishop Method uses a basic moment equilibrium equation for the summation of forces on each

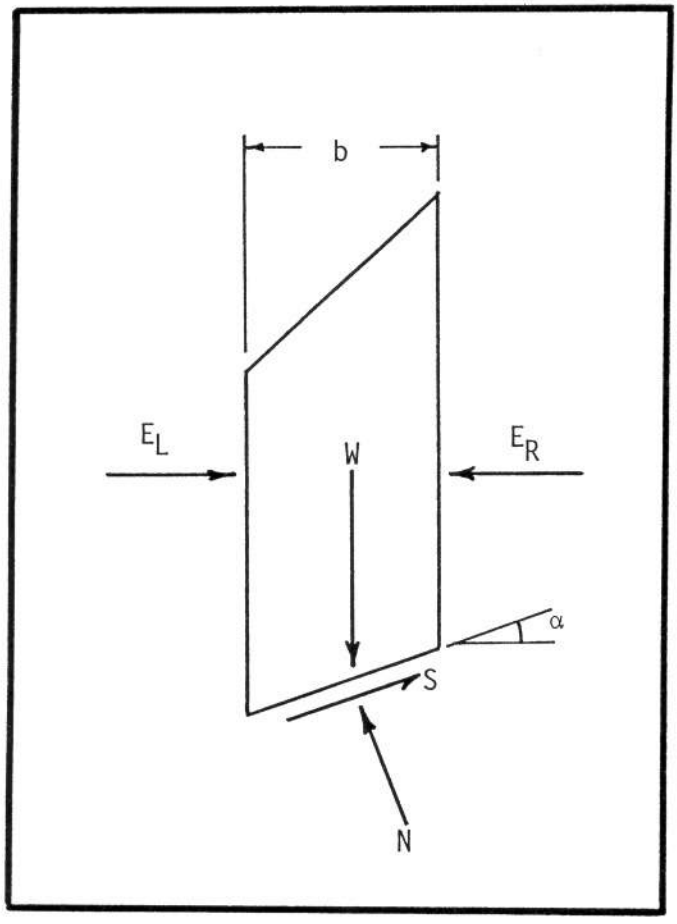

Figure 5.6 Free Body Diagram - Simplified Bishop Method

slice as shown in Figure 5.6. Symbols and definitions are given below.

W = total weight of slice, soil plus water;
b = width of slice;
E_L = Force acting on left boundary of slice;
E_R = Force acting on right boundary of slice;
S = resultant of friction and cohesion forces;
N = effective normal force;
α = angle between the base of each slice and horizontal.

The method sums the vertical components of the forces. The side forces are assumed to be equal, horizontal, and colinear. The factor of safety is computed by Equation 5.1:

$$F = \frac{\sum\left[c + \left(\frac{W}{b} - u\right)\tan\phi\right]b\left(\frac{1}{M_\alpha}\right)}{\sum(W\sin\alpha)}, \qquad (5.1)$$

where

c = cohesion of soil at the bottom of the slice;
W = total weight of slice, soil plus water;
b = width of slice;
u = hydrostatic pressure on the bottom of the slice;
ϕ = angle of frictional resistance of soil;
$M_\alpha = f(F) = \left[1 + \frac{\tan\alpha\tan\phi}{F}\right]\cos\alpha$; and
α = angle between the base of each slice and horizontal.

Except for M_α, all of the parameters in Equation 5.1 are based on the physical characteristics of the failure surface and the soil. Once these parameters are determined, Equation 5.1 can be solved iteratively. This is necessary because the factor of safety term, F, is on both sides of the equation.

A trial factor of safety value can be computed from Equation 5.2:

$$F_1 = \frac{\sum(cb + W\tan\phi)}{\sum(W\sin\alpha)} \qquad (5.2)$$

The parameter, F_1, is used to calculate M_α and solve Equation 5.1. The result of Equation 5.1 is used in the next iteration and the process is repeated until convergence occurs. Lambe and Whitman (1969), Perloff and Baron (1976), and Huang (1983) have provided a good description of the simplified Bishop procedure in detail.

Analyses are to be made for the loading conditions that are most critical during the design life of the structure. For new dams, the following conditions must be considered: (1) end of construction; (2) steady seepage - full reservoir; (3) steady seepage - maximum reservoir; (4) sudden drawdown; and (5) earthquake. When modifications are made to the slopes, height or water storage elevation of dams built before August 13, 1981, only the steady seepage and sudden drawdown cases must be analyzed.

Selection of the soil strength parameters is the most important facet of the slope stability analysis. Unlike steel and concrete, soil strengths vary widely, depending on the type and location of the soil. When testing a soil, the soil strength depends upon consolidation (effective confining) pressure, drainage during shear, volumetric history, disturbance, and strain rate. In most cases, the strength of a soil can be expressed by Equations 5.3 and 5.4:

$$\bar{\tau} = \bar{c} + (\sigma - u)\tan\bar{\phi}, \qquad (5.3)$$

where

$\bar{\tau}$ = effective shear stress on the surface at failure;
$\bar{c}$ = cohesion intercept based on effective stresses;
σ = total normal stress acting on the failure surface;
u = pore water pressure;
$\bar{\phi}$ = friction angle based on effective stresses;

and

$$\tau = c + \sigma \tan\phi, \qquad (5.4)$$

where

τ= shear stress on the surface at failure;

c= cohesion intercept;

σ= total normal stress acting on the failure surface; and

ϕ= friction angle.

As depicted in Equations 5.3 and 5.4, two basically different approaches to the stability problem can be used by the engineer: the effective stress method and the total stress method. Drained strength parameters are used in an effective stress analysis while undrained strength parameters are used in a total stress analysis. According to Sherard et. al. (1963), there are two advantages of the effective stress method: the analysis is carried out with a somewhat more fundamental definition of the shear strength; and pore pressures assumed in the design can later be compared with those which develop in the dam and foundation as measured by piezometers.

In preparation for performing the stability analysis, the engineer should develop a cross section of the dam at the maximum section. The cross section should show all soil zones and their respective properties. Internal drains should be clearly delineated. The phreatic surface must be estimated using analytical methods or piezometric data. The estimated phreatic surface should be depicted on the cross section.

1. End of Construction Case

In the end of construction case, both the upstream and downstream slopes of a dam must be examined for stability. The most conservative condition assumes that the compacted soil does not consolidate under the weight of the soil layers above it and is sheared before drainage can occur. In reality, some dissipation of pore pressures occurs, with an increase in strength of the soil. Estimation of such dissipation of pressure with gain in strength is inexact. A pore pressure instrumentation system may be installed to verify the dissipation of pressures; however this is generally not economically feasible for small to medium sized dams. Soil strength values for the instantaneous end of construction condition can be obtained from the unconsolidated-undrained (UU) triaxial test.

In analyzing the end of construction factor of safety for the downstream slope, the staff of the Dam and Reservoir Safety Program examines all failure surfaces that would result in the release of water from the reservoir. The upstream slope is analyzed by examining all failure surfaces that intercept the crest.

2. Steady Seepage Cases

The two steady seepage conditions that must be analyzed are characterized by the completion of two processes. First, the soil in the dam has been consolidated by the overlying soil and second, all pore pressures have dissipated to values determined by the position of the phreatic surface. These cases are normally critical for the downstream slope because the seepage forces act in the downstream direction and the reservoir supports the upstream slope.

To determine the shear strength parameters, a representative soil sample is compacted to the design density, consolidated under a representative overburden stress, and fully saturated. It is then sheared under fully drained conditions. An alternative is to use the results of a consolidated-undrained (CU) triaxial test with pore pressure measurements. With either method, drained strength parameters are determined. Pore pressures within the dam are estimated from a flow net or as a function of the depth below the phreatic surface. The phreatic surface for a homogeneous dam on an impervious foundation can be estimated as shown in Figure 5.7.

Following Casagrande's (1937) procedure, it is assumed that the theoretical line of seepage starts from the pool level at a distance of $0.3\triangle$ from the dam, where $\triangle$ is the horizontal distance from the upstream toe to the point where the reservoir elevation meets the upstream slope of the dam. Utilizing an x,y coordinate system with the origin at the downstream toe, the exit point of the phreatic surface can be computed from the known values of h and d in Figure 5.7. As an approximation, the y coordinate of the exit point can be taken as 0.33h and the phreatic surface can be drawn as a smooth curve between the entrance and exit points. The phreatic surface is thus assumed to be a parabola tangent to the downstream slope.

Huang (1983) developed tables to compute the exit and mid points as a function of d and h for downstream slopes ranging from s = 1.5 to 5.0. Huang's method can be used in embankment sections on an impervious base and without internal drains. Other methods of approximating the shape of the phreatic surface must be used when internal drains are located in the dam. In most cases, the staff of the Dam and Reservoir Safety Program estimates the shape of the phreatic surface in Figure 5.7 as 2-3 chords which connect the entrance and exit points.

Piezometric data from an existing embankment can also be used to develop the phreatic surface for use in the stability analysis.

In analyzing the steady seepage cases, the staff of the Dam and Reservoir Safety Program examines all failure surfaces that would result in the release of water from the reservoir. The cross section of the dam at the maximum section is analyzed. For the steady seepage-maximum reservoir case, the phreatic surface is assumed to be in the same location as the steady seepage-full reservoir condition unless the dam has an upstream pervious zone.

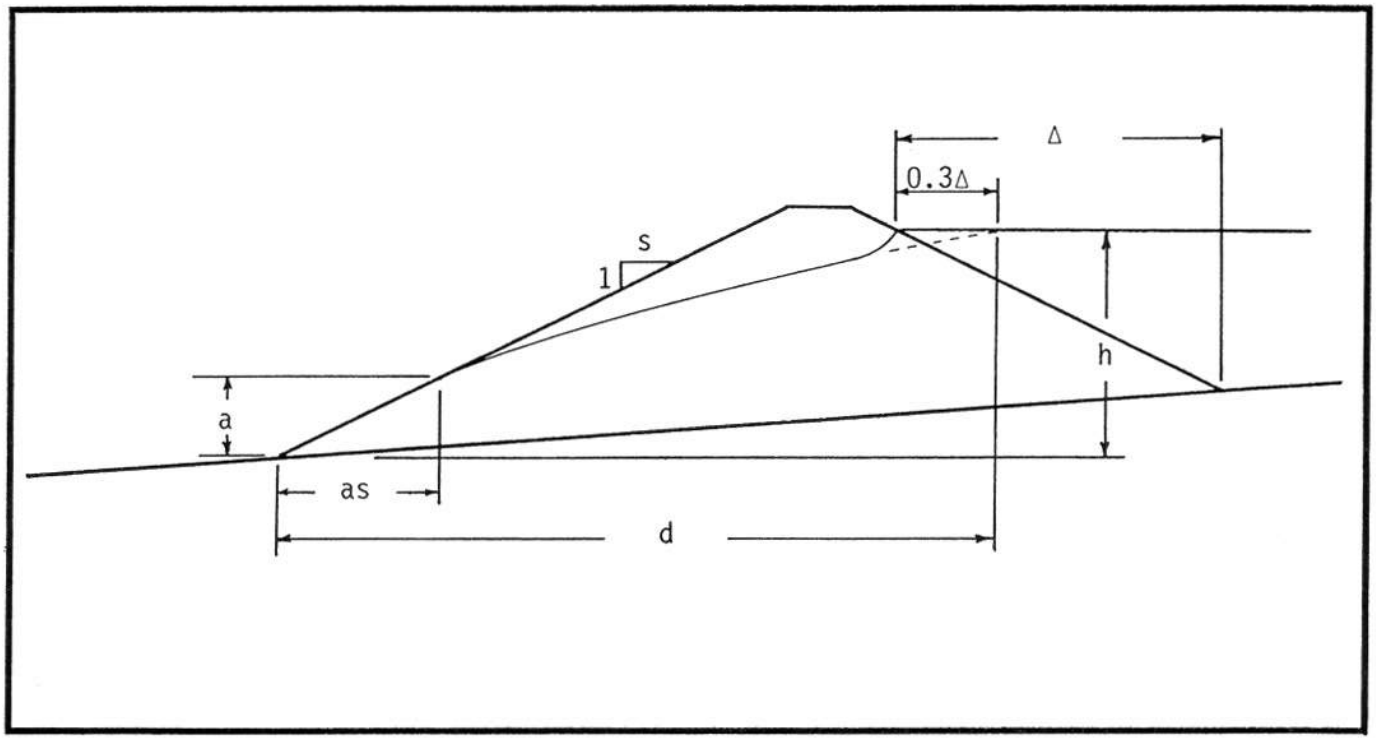

Figure 5.7 Phreatic Surface in an Earthfill Dam

3. Sudden Drawdown

The sudden, or rapid drawdown condition can be critical for the upstream slope of any dam where the reservoir elevation can be drawn down by a lake drain pipe or by other means. If the reservoir level cannot be drawn down quickly, this condition does not have to be analyzed.

In the sudden drawdown case, the soil is fully consolidated under the weight of the overlying material, and saturation with a static water level or a steady seepage condition is established. As the drawdown occurs, buoyancy forces are eliminated in the soil zone above the lowered reservoir elevation. The soil is sheared under undrained conditions by the increased weight of the saturated soil above the lowered reservoir elevation. The shear strength, however, is still governed by the consolidation that occurred before drawdown. The effective normal stress before drawdown should be used to calculate frictional resistance at the assumed failure surface.

The information and shear strength parameters required for the sudden drawdown analysis are obtained from the consolidated, undrained (CU) triaxial tests. The cross section of the dam at the maximum section should be used and the phreatic surface assumed to be in the same location as the steady seepage-full reservoir condition. The staff of the Dam and Reservoir Safety Program examines all failure surfaces that intercept the crest of the dam.

4. Earthquake

The required accelerations for earthquake design are listed in Table 4, 10 CSR 22-3.020. They are termed the Probable Maximum Acceleration and are dependent upon the location of the dam and the downstream hazard classification. These accelerations should be used with the cross section analyzed in the steady-seepage, full reservoir condition to determine the seismic stability of the embankment. The acceleration imparts a horizontal force to each slice which increases the moment of weight of the failing mass. As in the steady seepage cases, effective stress parameters should be used in the analysis.

Earthquake loading may result in the build-up of pore water pressures and a loss of strength for new dams constructed wholly or partially of cohesionless materials (such as sand and silt) or having a foundation of cohesionless materials. Engineers shall take this pore pressure increase and loss of strength into account when performing their stability analysis. The degree to which liquefaction may affect the factor of safety for slope stability is left up to the engineer's best judgement. Dynamic analyses of earth embankments are not required. Typically, a pseudo-static

analysis can be conducted to determine the likelihood of failure. In conductin g the analysis, very low strength parameters are assumed for the liquefaction zones.

E. Protection of Upstream Slopes

It is generally necessary to protect the upstream face of a dam from wave erosion. The orientation and length of the permanent pool, the purpose of the reservoir, and the duration of stages in flood control pools all affect the need for and the type of embankment protection. Embankments in northern Missouri that are constructed of friable, or loessial, soils are particularly susceptible to upstream slope erosion. Minor water level fluctuations lift soil particles from exposed surfaces and leave vertical banks along the water line.

Upstream slope protection usually consists of rock riprap, either dumped or handplaced. As a minimum, rock riprap should consist of hard durable rock, well graded, placed at a minimum thickness of 18 inches on 6 inches of well-graded gravel or a layer of geotextile (filter cloth). On dams with small reservoirs, a properly designed beaching slope can be used instead of riprap.

Judgement is required in the design of the vertical height of riprap. Protection should be provided both above and below the water storage elevation. The protection below the normal pool elevation is dependent upon several factors including the purpose of the reservoir and the base flow of the inflow stream. A water supply reservoir will generally have a wide range of stages during the year due to withdrawals. A recreation dam on a stream with a year round base flow normally only requires a minimal amount of riprap below the normal pool elevation. Maximum protection can be obtained by placing riprap on the upstream face of the dam from the toe to the crest; however, this is expensive and is normally not justified on smaller dams. As a general rule, riprap should be placed a few feet above and below the water storage elevation.

A recommended reference for the design of riprap slope protection is Riprap for Slope Protection Against Wave Action, (SCS, 1983).

F. Instrumentation

Instrumentation can significantly improve the overall safety of a dam by providing continuous surveillance of the structure. Instrumentation is normally associated with large high hazard dams, but it is also used in dams with unusual design features.

Instrumentation refers to the method and equipment used to make physical measurements of dams. Instrumentation is not, however, a substitute for inspection. It is a supplement to visual observations and inspections. Visual examinations are aided by monitoring instruments that measure seepage and leakage through and around the embankment, movements of the embankment and foundation, and water levels and pressures within the embankment and the foundation. Where instrumentation exists, adequate records of measurements, along with the visual observations, should be maintained. To be effective, these records should be continuous and periodically reviewed by a professional engineer experienced in the design and operation of embankment structures. Any change in behavior of the dam would signal a need for further review and analysis.

There are three general types of instruments used to monitor dams. These include seepage monitoring instruments, embankment movement instruments and water pressure instruments (piezometers). An excellent discussion of instrumentation is included in the Training Aids for Dam Safety (TADS) module entitled, Instrumentation for Embankment and Concrete Dams.

1. Seepage and Leakage

All dams seep to varying degrees and all seepage should be monitored and recorded. If there is visible flow, the quantity of water should be measured by channelizing the seepage and installing a pipe, weir, or a flume. A record should be kept of the discharge rate, the temperature of the seepage, and the reservoir elevation. Toe and/or foundation drains should also be monitored and data recorded along with the reservoir elevation. Any wet spots should be noted and the location, size, and condition recorded.

2. Embankment Movements

Considerable movement of embankment dams can be anticipated during and immediately after construction. Much of the movement may be attributed to foundation settlement under the load of the embankment. The embankment will also move as the reservoir is filled for the first time and may periodically experience cyclic movements as the reservoir is emptied and filled in succeeding seasons. Movements are determined by periodic measurements of monuments placed in or on the structure and abutments. For existing dams, monumentation to measure movements is usually limited to the crest and downstream slopes. The monuments are anchored in the embankment below the depth of normal seasonal volume change. Abutment monuments usually consist of steel rods or surveyor's markers embedded in concrete and placed in excavations in the abutments. Differences in elevation and location of the monuments are measured by transit and level surveys of the monuments.

Measurements of the locations of monuments on the surface of the embankment should be such that changes in both vertical and horizontal locations are measured. The measurements should be reduced to graphical displays of changes in vertical location, changes in horizontal

location along the axis of the embankment, and changes in horizontal location transverse to the axis of the embankment (upstream and downstream). The water surface elevation in the reservoir at the time of measurement of the monument is important and should be recorded along with the monument location data. The monuments should be tied to a bench mark that is outside the influence of the dam and reservoir. Monuments should be located in areas where they will not be damaged by normal traffic or operations.

3. Piezometric Pressures

A primary indicator of the performance of an embankment is the pore pressure distribution within the structure and its foundation. Pore pressures in embankments are measured by piezometers. There are basically three types of piezometers in common usage: (1) a hydraulic piezometer (open system) in which the water pressure is obtained directly by measuring the elevation of water standing in a pipe or vertical tube; (2) an electronic piezometer (closed system) in which the water pressure deflects a calibrated membrane and the deflection is measured electronically to give the water pressure; and (3) a gas pressure unit (diaphragm system) in which the water pressure is measured by balancing it with pressurized gas in a calibrated unit.

In large high hazard dams, piezometers should be installed to determine the location of the phreatic line and the pressure distribution along a potential failure surface. Piezometers should be installed so that the porous tip is located in the zone of interest within the dam. The line of piezometers should be perpendicular to the longitudinal axis of the embankment. In large structures, there may be several lines of piezometers, while in smaller structures and existing dams perhaps one line of 3-5 piezometers would be adequate.

CHAPTER VI

ANALYSIS OF CONCRETE GRAVITY STRUCTURES

This section applies only to small concrete gravity dams, overflow weirs, sills, and walls on the crest of a dam. It does not apply to concrete gravity dams greater than 50 feet in height, arch dams, or buttress dams. These topics are beyond the scope of this booklet.

A concrete gravity dam is a structure that is designed so that its own weight provides the major resistance to the forces exerted upon it. If the foundation is adequate, and the dam is properly designed and constructed, a solid concrete dam is a permanent structure which requires little maintenance. It is generally constructed of unreinforced blocks of concrete with flexible seals in the joints between the blocks. The most common types of concrete gravity dam failure are overturning or sliding on the foundation.

The foundation for a gravity dam must be capable of resisting the applied forces without overstressing the dam. The horizontal forces on the dam tend to make it slide in a downstream direction, which results in horizontal stresses at the base of the dam. These in turn may try to induce shear failure in the concrete at the base, along the concrete-foundation contact, or within the foundation. Overturning moments result in stresses which may cause crushing of the rock along the toe.

Table 2, 10 CSR 22-3.020 lists stability criteria for conventional concrete dams. The failure mechanisms that must be analyzed include overturning, sliding, structural integrity, and seismic.

A. Forces Acting On The Dam

To analyze the safety of gravity dams, it is necessary to determine the forces which may be expected to affect the stability of the structure. The forces which must be considered are those due to:

1) external water pressure (reservoir and tailwater);
2) internal water pressure (pore pressure or uplift) in the dam and foundation;
3) silt pressure;
4) ice pressure;
5) earthquake;
6) weight of the structure; and
7) forces from gates and other appurtenant structures.

When analyzing the crest of an overflow section, the possibility of subatmospheric pressure developing between the overflowing sheet of water and concrete should be considered. This phenomenon is known as cavitation and can cause serious damage to concrete.

Figure 6.1 shows a nonoverflow concrete section loaded with reservoir water and tailwater. Symbols and definitions for this loading are given below.

Ψ = angle between face of element and the vertical.

T = horizontal distance from upstream edge to downstream edge of section.

I = moment of inertia of base of section 1-foot wide about its center of gravity, equal to $T^3/12$.

w_c = unit weight of concrete.

w = unit weight of water.

h or h' = vertical distance from reservoir water or tailwater, respectively , to base of section.

P or P' = reservoir water or tailwater pressure, respectively, at base of section. It is equal to wh or wh'.

W_o = dead load weight above base of section under consideration including the weight of the concrete, w_c, plus such appurtenances as gates and bridges.

W_w or W'_w = vertical component of reservoir water or tailwater load, respectively, on face above base of section.

M_o = moment of W_o, about center of gravity of base of section.

M_w or M'_w = moment of W_w or W_w' about center of gravity of base of section.

V or V' = horizontal component of reservoir water or tailwater load, respectively, on face above base of section. This is equal to $\frac{wh^2}{2}$ for V and $\frac{w(h')^2}{2}$ for V'.

M_p or M'_p = moment of V or V' about center of gravity of base of section, equal to $\frac{wh^3}{6}$ for M_p and $\frac{w(h')^3}{6}$ for M'_p.

$\sum W$ = resultant vertical force above base of section.

$\sum V$ = resultant horizontal force above base of section.

$\sum M$ = resultant moment of forces above base of section about center or gravity of base of section.

e = distance from midpoint of base of section to point where resultant

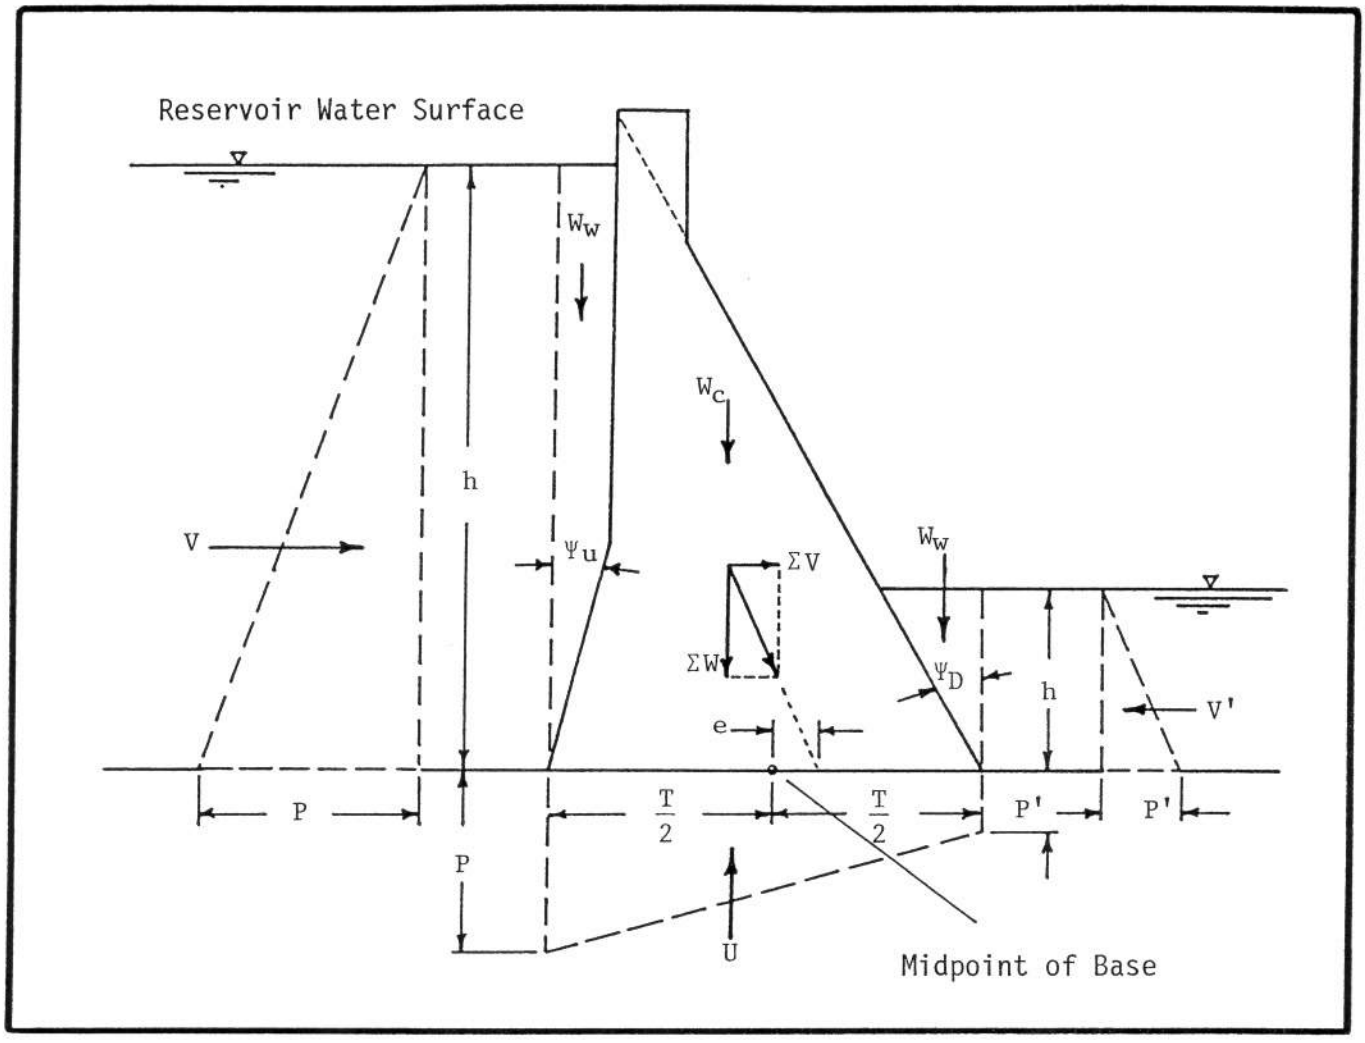

Figure 6.1 Forces Acting on a Concrete Gravity Dam (From Design of Small Dams)

of $\sum W$ and $\sum V$ intersects base of section. It is equal to $\sum M / \sum W$.

U = total uplift force on horizontal section, equal to $T\left(\frac{P+P'}{2}\right)$

The loadings have been summed into horizontal and vertical components, which implies that the foundation or potential failure plane is horizontal or nearly horizontal. If the foundation or potential failure plane is substantially sloped, the loads should be resolved into components normal and parallel to that plane.

1. External Water pressure

External water pressure must be considered on both overflow and nonoverflow sections. Figure 6.1 illustrates water pressure on a nonoverflow section. On the upstream face, the horizontal force is **V** and the vertical force is $\mathbf{W_W}$. The weight of water is generally accepted as 62.4 pounds per cubic foot.

On overflow dams without control features, the total horizontal water pressure on the upstream face is represented by the trapezoid abcd in Figure 6.2. The unit pressures at the top and at the bottom are $62.4h_1$ and 62.4h, respectively. The resultant force passes through the center of gravity of the trapezoid.

The vertical pressure component of water flowing over the top of the spillway is not used in the analysis because most of the total head has changed to velocity head. The sheet of water flowing on the downstream face generally does not exert enough pressure on the dam to warrant consideration. Where tailwater or backwater ponds against the downstream face, it is treated in the same manner as the tailwater in Figure 6.1. The only exception is during major flows when the tailwater pressures are

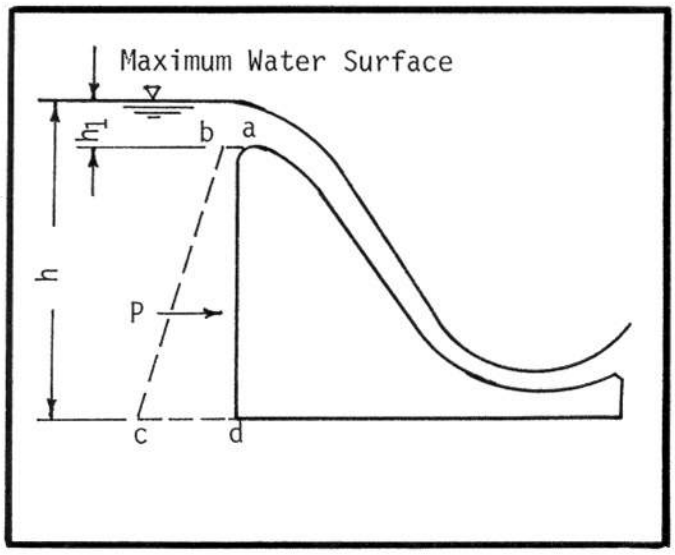

Figure 6.2 Water Pressure on an Overflow Concrete Dam (From Design of Small Dams)

involved in dissipating energy. During this condition, they may contribute only minor stabilizing forces on the dam.

2. Internal Water Pressure

Internal water pressure is an important factor which must be considered on both rock and soil foundations. The intensity of uplift pressure under a concrete dam on a rock foundation is difficult to determine. If the base of the concrete section is not instrumented, it is generally assumed that pore pressures in rock or concrete act over the entire base of the section. It is evident that under sustained loading the uplift pressure at the upstream face is equal to the full reservoir pressure. Its distribution approaches a straight-line variation from this point to the tailwater pressure at the downstream face, or zero if there is no tailwater. This is true not only at the contact between the dam and foundation but within the body of the dam itself. Even if drains are provided to relieve excess hydrostatic pressure, it is still common practice to assume a straight-line pressure distribution from the upstream to downstream toe.

Uplift pressures under a concrete dam on a pervious foundation are related to seepage through permeable materials. Water percolating through pore spaces in the foundation material is affected by frictional resistance in much the same way as water flowing through a pipe. The magnitude and distribution of seepage pressures in the foundation and the amount of underseepage for a given coefficient of permeability can be obtained from a flow net. An excellent reference for flow net construction is given by Cedergren (1977). The intensity of the uplift can be controlled by construction of properly placed aprons, cutoffs, and other devices.

3. Silt pressure

Nearly all streams carry an appreciable amount of silt during flood flows. This is especially true in northern and western Missouri. Where silt is present in a stream on which a concrete dam is built, it will eventually find its way to the reservoir and be deposited adjacent to the dam. If allowed to accumulate against the upstream face of the dam, the saturated silt exerts pressure greater than the hydrostatic pressure of water due to its heavier unit weight. In the absence of reliable test data, a rather common assumption of the magnitude of saturated silt pressure is to consider the horizontal pressure as equivalent to that of a fluid weighing 85 pounds per cubic foot and the vertical weight as 120 pounds per cubic foot.

Many small gravity dams and spillway structures have been designed without regard to silt load. In general, the silt load against storage dams will be a small factor. Against diversion dams, however, it is likely to be more important. In either case there is some basis for neglecting the silt load, especially in the design of concrete spillway weirs and sills.

4. Ice Pressure

Ice pressure is produced by thermal expansion in the ice sheet and by wind drag. The necessary allowance to be made for ice load in the design of a concrete dam is difficult to determine. Data concerning the physical characteristics of ice such as its crushing strength, its modulus of elasticity, and the effects of plastic flow are inadequate and approximate. The thrust exerted by expanding ice depends on the thickness of the sheet, the rate of temperature rise in the ice, fluctuations in the water surface, character of the reservoir shore line, wind drag, and other factors. The rate of temperature rise in the ice is a function of rate of rise of the air temperature and the amount of snow cover on the ice. Lateral restraint of the ice sheet depends on the character of the reservoir shore line.

Because of all these variables, the engineer is faced with a difficult task in estimating the amount of ice pressure acting against a structure. Rose (1947) developed several charts to analyze ice pressure. His charts were reprinted by the U. S. Department of the Interior (1974) in Design of Small Dams and show the thrust in kips for ice thicknesses up to 4 feet and for air temperature rises of 5^{o}, 10^{o}, or 15^{o} F. per hour.

5. Earthquake

Earthquakes impart accelerations to the dam which usually increase the effective loadings on the dam. An allowance for earthquake effects must therefore be made in the analysis of concrete gravity dams and appurtenant structures.

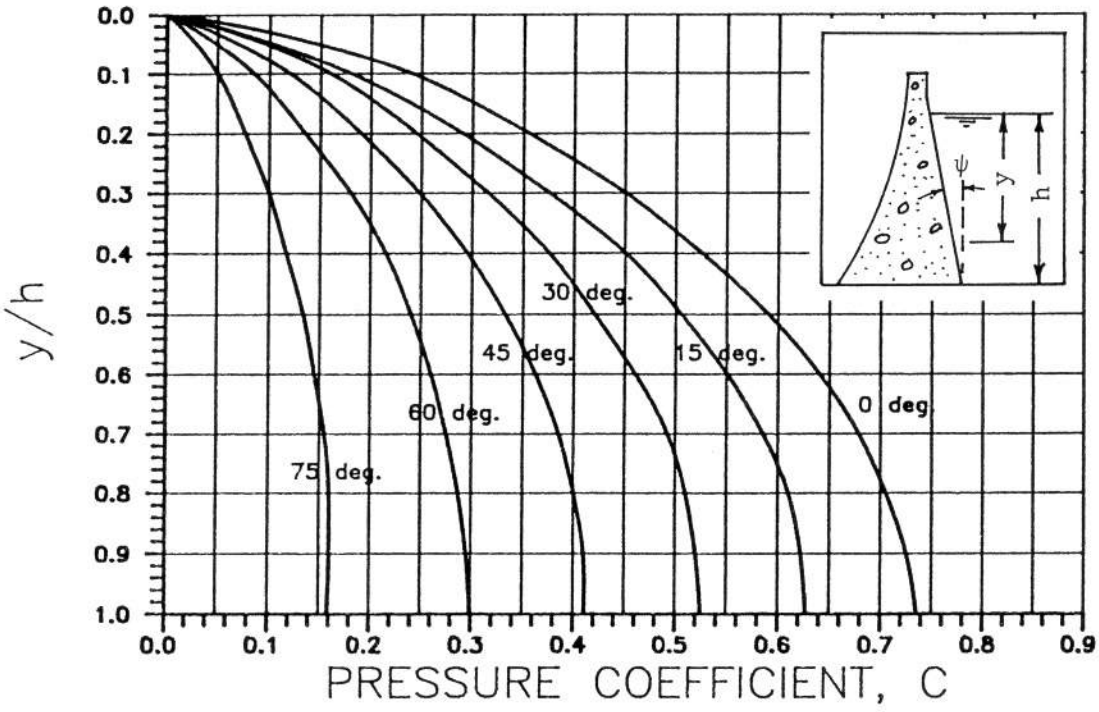

Figure 6.3 Coefficient for Pressure Distribution for Constant Sloping Surfaces

Both vertical and horizontal earthquake loads should be applied in the direction which produces the least stable structure. For the condition of full reservoir this will be a foundation movement in the upstream direction and a foundation movement downward. The upstream movement increases the downstream force of the water and silt loads and produces a downstream inertial force from the mass concrete in the dam. The downward movement decreases the effective weight of the water above a sloping face and of the concrete in the dam. Increasing the horizontal loads in a downstream direction and decreasing the effective weights tend to decrease the stability of the structure. In order to determine the total forces due to an earthquake, the earthquake acceleration must be determined from Table 4, 10 CSR 22-3.020. Table 4 contains horizontal accelerations. Vertical accelerations should be approximated as 50% of the horizontal acceleration.

a. Horizontal Earthquake Force

The effect of inertia on the concrete should be applied at the center of gravity of the mass, regardless of the shape of the cross section. For dams with vertical or sloping upstream faces, the increase in water pressure, P_e, in pounds per square foot, at any elevation due to horizontal earthquake loading is given by Equation 6.1:

$$P_e = C\lambda w h, \qquad (6.1)$$

where

C = a dimensional coefficient giving the distribution and magnitude of pressures;

λ = earthquake intensity (% of gravity);

w = unit weight of water, pcf; and

h = total depth of reservoir at section being studied in feet.

Values of C for various degrees of slope and relations of h and the vertical distance from the reservoir surface to the elevation in question may be obtained from Figure 6.3. The total horizontal force, V_e, above any elevation y distance below the reservoir surface is given by Equation 6.2:

$$V_e = 0.726 P_e y, \qquad (6.2)$$

where

y = the vertical distance from the reservoir surface to the elevation in question in feet.

The total overturning moment, M_e, above elevation y is determined by Equation 6.3:

$$M_e = 0.299 P_e y^2 \qquad (6.3)$$

For dams and structures with a combination vertical and sloping face, the procedure to be used is governed by the relation of the height of the vertical portion to the total height of the dam. If the height of the vertical portion of the upstream face of the dam is equal to or greater than one-half the total height of the dam, it should be analyzed as if it is vertical throughout. If the height of the vertical portion of the upstream face of the dam is less than one-half of the total height of the dam, the pressures should be determined on a sloping line connecting the point of intersection of the upstream face of the dam and reservoir surface with the point of intersection of the upstream face of the dam and the foundation.

b. Vertical Earthquake Force

On sloping faces of dams the weight of the water above the slope should be modified by the appropriate acceleration factor. The weight of the concrete also should be modified by this acceleration factor.

6. Weight of Structure

The weight of the structure includes the weight of the concrete plus appurtenances such as gates and bridges. For most low dams and other concrete structures, only the dead load due to the weight of the concrete is used in the analysis. The unit weight of concrete is considered to be 150 pounds per cubic foot. The total weight acts vertically through the center of gravity of the cross section.

B. Requirements for Stability

A concrete gravity structure must be designed to resist, with ample factor of safety, three failure conditions: overturning, sliding, and overstressing.

1. Overturning

There is a tendency for a gravity structure to overturn about the downstream toe at the foundation or about the downstream edge of any horizontal section. If the vertical stress at the upstream edge of any horizontal section computed without uplift exceeds the uplift pressure at that point, the dam is considered safe against overturning. The most critical condition for inducing overturning is when, at the upstream face, the uplift pressure exceeds the vertical stress at any horizontal section. To perform an analysis of this condition, a combined pressure diagram must be developed.

Under stable conditions the resultant of the horizontal and vertical loads on the structure will be balanced by an equal and opposite force which constitutes the reaction of the foundation. The vertical reaction of the foundation, computed without uplift, is represented by the trapezoid A12B in Figure 6.4B. The vertical normal stresses A1 and B2 are determined by the use of eccentric loading formulas as shown in Equations 6.4 and 6.5:

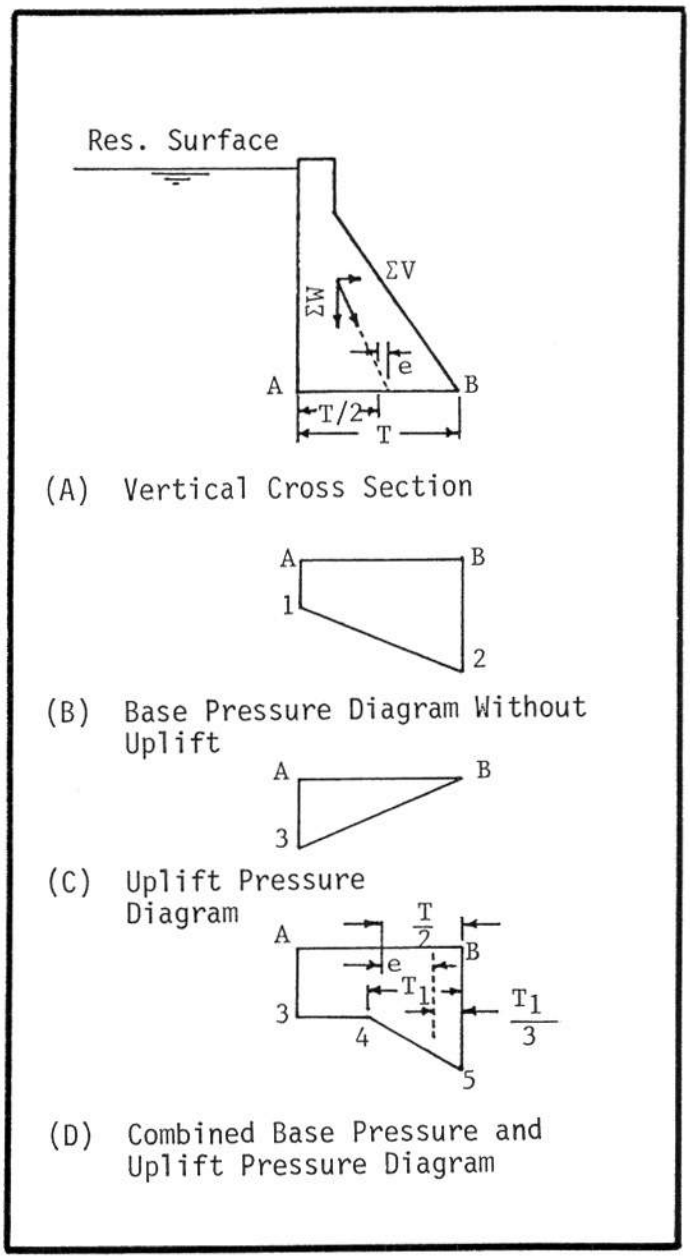

Figure 6.4 Foundation Base Pressures for a Concrete Gravity Dam (From Design of Small Dams)

$$A1 = \frac{\sum W}{T}\left(1 - \frac{6e}{T}\right) \qquad (6.4)$$

$$B2 = \frac{\sum W}{T}\left(1 + \frac{6e}{T}\right) \qquad (6.5)$$

When uplift is introduced and the uplift pressure at the upstream face is less than A1, compression exists on the

upstream face. When the uplift at A is greater then A1, the upstream face is in tension and cracking will occur. To analyze this condition, the foundation pressure diagram must be revised. The following procedure is used:

(1) A horizontal crack is assumed to exist and extend from the upstream face toward the downstream face to a point where the vertical stress of the adjusted diagram is equal to the uplift pressure at the upstream face. This is point 4 in Figure 6.4D.
(2) Taking moments about the center of gravity of the base, the following equations are obtained:

$$e' = \frac{\sum M}{\sum W - A3 \cdot T}, \qquad (6.6)$$

$$T_1 = 3\left(\frac{T}{2} - e'\right), \qquad (6.7)$$

$$B5 = \frac{2(\sum W - A3 \cdot T)}{T_1} + A3, \qquad (6.8)$$

where

e' = eccentricity of the stress diagram after cracking;
$\sum M$ = summation of moments of all forces;
$\sum W$ = summation of vertical forces;
$A3$ = internal hydrostatic pressure at the upstream face;
T = thickness of section at base; and
T_1 = remaining uncracked portion of the structure.

If B5 is less than the allowable stress for the concrete in any horizontal section or less than the allowable stress in the concrete and foundation for a horizontal section at the foundation, the dam is considered to be safe against overturning.

2. Sliding

The horizontal force, $\sum V$, in Figure 6.4A tends to displace the dam in a horizontal direction. This tendency is resisted by the shear resistance of the concrete or the foundation.

The shear friction factor of safety is the sliding stability criterion for all concrete dams and should generally be used for other structures on rock foundations. The shear friction factor of safety, Q, is shown in Equation 6.9:

$$Q = \frac{cA + (\sum W - U)\tan\phi}{\sum V}, \qquad (6.9)$$

where

c = cohesion value of concrete or foundation;
A = area of base considered; and
$\tan\phi$ = coefficient of internal friction of concrete or foundation.

The values of cohesion and internal friction of the rock or rock-concrete contact must generally be determined by special laboratory tests. For certain rock types, free from adverse geologic structures, cohesion and internal friction can be estimated from published test data. Rock with infilled jointing or lamination and other adverse geologic structures require investigation and testing of the properties of the rock surfaces and infilling material.

3. Structural Integrity

The unit stresses in the concrete and foundation must be kept within prescribed maximum values. Normally, the stresses in the concrete of small gravity dams will be so low that a concrete mix designed to meet other requirements such as durability and workability will attain sufficient strength to insure a reasonable factor of safety.

The foundation should be investigated and the maximum allowable stress established. When the foundation consists of soils, the engineering properties of the material should be determined along with the allowable bearing pressure. If there is any doubt as to the proper classification and adequacy of the foundation materials, laboratory tests should be made to determine the allowable bearing pressures.

CHAPTER VII

GEOLOGICAL CONSIDERATIONS

Careful evaluation of geologic conditions at potential lake sites and sound design and construction practices can greatly enhance lake development. It can also save the owner money during the life of the dam.

All dams seep, and below normal rainfall, combined with a high rate of seepage can cause wide fluctuations in lake levels at some reservoirs. When dams are constructed without any borings or consideration for the geological conditions of the lake site, the likelihood that the dam will experience seepage and safety problems increases dramatically. Unfortunately, many owners discover that a geological investigation should have been performed after the dam is built. Seepage and stability problems are frequently linked to geologic conditions. To reduce seepage, it is sometimes necessary to grout the abutments or foundation, construct a new cutoff trench, or construct an impermeable earthern blanket in the reservoir basin. These are all expensive options, particularly if the work is done after the dam is built.

A surface geological evaluation of the proposed lake site should be made by a qualified geologist. The purpose of the visual investigation is to observe geologic conditions that are not evident from maps or reports of previous studies. At the same time, observations can be made of the presence or absence of springs or seeps, the type and thickness of soil, the characteristics of exposed bedrock outcrops, the presence of karst features, and whether the stream is losing or gaining. An excellent source of information for evaluating potential lake sites in Missouri is a booklet entitled, A guide for the geologic and hydrologic evaluation of small lake sites in Missouri, written by Dean, Barks, and Williams (1976).

The Rules and Regulations of the Missouri Dam and Reservoir Safety Council require engineers to submit exploration records and test results for all new dams that will be regulated under the dam safety law. The exploration records are normally in the form of boring logs which detail the strata and composition of the foundation and abutments at the lake site. The regulations do not specify the type or number of borings.

Typically, an owner will request his engineer to obtain borings at 100-200 foot intervals along the proposed dam centerline across the valley. The actual interval will depend on local conditions and the length of the proposed dam. There should be at least one hole in each abutment and two of the valley holes should extend 10 to 20 feet into bedrock. Backhoe pits can be excavated in potential borrow areas to determine the type and quantity of material available to construct the dam. Care must be taken in obtaining samples from the borrow areas to determine the strength of the soil that will be used in the dam. As pointed out in Chapter V, soil does not have predictable strength properties like concrete or steel. It must be tested at the density at which it will be placed to determine its strength. Construction permits issued by the Dam and Reservoir Safety Program require that density testing of the fill be performed during construction. This requirement is made to insure that the material is placed in accordance with the design specifications.

A. Core Trench Requirements

It is common practice to construct a core trench to control seepage beneath new dams. Subsurface borings give the engineer an indication of how deep the core trench will have to be and how much material must be removed. If the core trench extends to bedrock, the engineer should evaluate the rock strata to insure that the trench has penetrated all weathered rock and the underlying material is free from undesirable geological features.

An understanding of the weathering process is important. Rock at the earth's surface is continually being broken down by weathering. One of the most common weathering processes is the freezing of water in cracks accompanied by expansion of the ice and subsequent fracturing of the rock. Numerous cycles of freezing and thawing can produce extensive weathering.

The flow of water through rock can weaken some minerals and leave the remainder susceptible to wind or water erosion. The broken particles resulting from the weathering process are often transported by air, ice, water, or gravity and redeposited. The modes of deposition can be extremely variable and can cause considerable differences in the successive layers of the deposited or sedimentary material. Hence, sedimentary rocks are often characterized by the great variety in the material in the successive layers. Except for the St. Francois mountain region, Missouri's surface bedrock is almost exclusively sedimentary rock.

There are several types of defects that exist in bedrock. Some of the potential defects in a rock foundation include faults, joints, fractures, and bedding planes. An inspection of the core trench during construction can identify problems and insure that they are corrected before the trench is backfilled.

Faults are common in Missouri, but few are active. Faults are ruptures in rock formations and are caused by high-magnitude tectonic forces. Joints in sedimentary

rock are formed as a result of weathering. The primary difference between faults and joints is the method by which they are formed. When portions of a formation move with respect to each other, the discontinuity produced is termed a fault. If there is a discontinuity but no movement has occurred, the break would be called a joint or fracture. The term fracture can refer to a joint or a fault but always denotes a discontinuity in the rock mass.

Water percolating through fractures can alter the mineral of the adjacent rock and in some cases actually dissolve portions of it. This process occurs in many of the carbonate rock formations in southern Missouri and results in a weak, altered material. The solution joint that is produced can be open, closed, or filled with some type of secondary material. In many cases, the secondary material found in the joint is weak clay. Joints generally tend to be more weathered and open near the surface and narrow with increasing depth. Regardless of whether the joints are filled, it is necessary to identify them during the core trench inspection. Foundation leakage can be reduced by washing and then grouting the joints and fractures. Large clay seams and sand zones in the bedrock need to be excavated and backfilled with compacted clay.

Separations between bedding planes are a type of joint primarily associated with sedimentary rock. The shale and sandstone region of west central Missouri has distinct bedding planes. During construction of the core trench, all weathered shale should be removed.

Faulting and jointing in carbonate rocks may contribute to the development of karst conditions. Deposited clay material along such discontinuities may be washed away with increased head. A severe increase in abutment seepage can sometimes occur during the initial filling of the reservoir. This can be associated with the erosion of clay in abutment joints. It is therefore important to construct a good core trench up the abutment walls as well as along the base of the valley.

Glacial materials deposited by Pleistocene continental ice sheets are prevalent in northern Missouri. Varying thicknesses of till and loess characterize this area. The soils are highly erodible and contribute to siltation problems. Common core trench problems include sand-gravel alluvium and buried channels. Unconsolidated, permeable drift soils in foundations and in reservoir areas are likely to create defects in a dam and must be removed. Because of wide variations in the glacial deposits, proposed dam sites should be thoroughly investigated.

Depending on the region of the state, many different types of soil and bedrock may be encountered. It is important to review detailed published geologic and soil maps before beginning an exploration program or excavating a core trench. Maps and other published reports on Missouri geology are available from the Division of Geology and Land Survey, 111 Fairgrounds Road, P.O. Box 250, Rolla, Missouri 65401.

B. Spillways

Open channel spillways can be located in rock or soil. Borings should be conducted to determine the extent of bedrock and soil in the proposed spillway location. Rock cut spillways are generally erosion resistant and require less maintenance than grass lined soil spillways. Excavation of the rock frequently requires the use of explosives. A well trained, experienced blasting contractor should be retained to perform all blasting at new dams and to enlarge rock cut spillways at existing dams. Overblasting can result in the creation of new joints in the underlying bedrock which can lead to seepage and weathering problems during the life of the dam. An experienced blasting contractor can produce rock from the spillway excavation that can be used as riprap for slope protection, discharge channel erosion protection, and toe berms.

A pre-blast and post-blast survey should be conducted when using explosives at an existing dam when homes and other structures are located nearby. In addition, the staff of the Dam and Reservoir Safety Program requires the owner of an existing dam to monitor slope movement and seepage as part of any construction permit which authorizes blasting.

Where bedrock is deep, the spillway channel should either be lined, retaining walls should be constructed, or the soil cut slopes should be designed to be stable. Many different types of soil can be encountered. Soils may be classified by their origin or mode of deposition. The broadest divisions are residual soils and transported soils. Residual soils are formed by in place chemical and physical decomposition of parent rock or soil material. The deeply weathered clays in southern Missouri are an example of residual soils. Transported soils are moved from their original site of deposition by water, gravity, wind, or ice. They can be deposited in water or on land. The loess soils in northern and western Missouri were transported and deposited by wind. Loess is highly erodible and care should be exercised when designing open channel spillways in it.

Colluvium is soil that has been transported downslope on hillsides primarily by the influence of gravity. In addition to gravity, movement of the soil is aided by ice heave, overturning of tree roots, and water. Abutments that are characterized by bent tree trunks, hummocky or irregular slopes, landslide scars, or heterogeneous soil mixtures likely have colluvial materials at their base. Colluvium can be particularly hazardous to existing dams where landsliding may impact the reservoir, spillways, or other appurtenant structures. This is especially true in open channel spillways.

A stability analysis should be conducted of all spillway cut slopes in soil. A slope failure can result in a spillway becoming blocked by slide debris.

CHAPTER VIII

ENGINEERING SURVEYS

Engineering surveys for dam safety include the study and selection of sites for new dams, construction surveying, and the procurement of data for design and analysis. For new construction, engineering surveying is closely allied to the various stages of project development. The American Society of Civil Engineers (1985) published a manual on engineering surveys, which includes a chapter on dam construction. It is a good reference for practicing engineers to use in planning preliminary and design surveys.

A. Site Selection Survey

An engineering survey program for a dam generally originates as a preliminary or reconnaissance study of one or more sites. The preliminary study does not determine the feasibility of a project; it does, however, provide an important source of data for planners and designers of the project to use in making siting and preliminary design determinations.

The preliminary survey and siting procedure begins with the best available contour maps, such as the U.S. Geological Survey 1 in. = 2000 ft (1:24000) scale quadrangle maps. If the maps used are from two or more sources, care must be taken to insure that the vertical datums are compatible. Possible site locations can then be noted on these maps and a limited amount of field work performed to verify the accuracy of the maps at the published scale. Any changes which have taken place subsequent to development of the maps can be noted during a field reconnaisance.

Care must be exercised when using old maps. Several years are involved in the compilation of mass-produced maps, and many years may pass before the maps are revised. Significant changes may have taken place in the area since the maps were compiled, which could seriously impair the accuracy and usefulness of the maps.

10 CSR 22-3.040(1)(A)12 requires engineers to submit topographic surveys with the construction permit application. Once a site has been selected, additional exploration and testing will usually be performed. Unless the project is very small in scope, photogrammetric mapping probably will be the most economical and expedient means for obtaining the necessary large scale, detailed topographic maps for the engineering design and construction operations. The optimum time for obtaining the photography for mapping is the time interval from January through early April. This is primarily due to the better sun angle and absence of foliage on the trees. The project may have areas obscured by dense tree or underbrush cover in the summer and early fall. Information derived from the geological investigation of the site should be plotted on the photogrammetric map. This includes the location of borings and test pits for future reference.

It is important to establish baselines and temporary benchmarks at an early stage of the design. A horizontal and vertical control survey net should control all five survey programs: preliminary, engineering design, property acquisition, construction, and post-construction. Adequate horizontal and vertical control survey monumentation should be provided to carry the project through the construction stage. Vertical control should be based on the North American Vertical Datum of 1929 where possible. Location of the monumentation on or near the final right-of-way lines generally will serve best to preserve them from disturbance or destruction during construction. In addition, the monumentation should be designed to accommodate post-construction maintenance and control needs such as monitoring the performance or movement of the structure throughout its useful life.

Information obtained from the engineering design survey will be used to layout the core trench, the dam, the spillways, and all appurtenant works in the drawings and during construction staking. Borrow pit location, access roads, material and equipment storage areas, and diversion channels will be delineated on the plans and tied to established baselines. Suitable map scales for reservoir areas and large dam sites will vary with the size of the reservoir areas and roughness of the terrain. Maps for design drawings and structural details may be needed at scale ratios of 1 in. = 10 ft. (1:120) to 1 in. = 100 ft. (1:600). Aerial photography of these particular structural design areas, at the proper altitude for the desired special photogrammetric mapping, should be obtained at the same time as the photography for the overall mapping.

In planning the survey program for the engineering and design phase of project development, consideration must also be given to property acquisition, construction, and post-construction survey programs. This will avoid expensive resurveys or even more costly redesign or correction of already completed portions of the project.

The Rules and Regulations of the Dam and Reservoir Safety Council do not require owners to submit boundary surveys of the reservoir or the dam site. Flood easements are the sole responsibility of the owner. Before building a dam, it is advisable for the owner to obtain the written consent of all persons, agencies, or authorities owning property which may be inundated by the dam on a temporary or permanent basis. This will require a determination

of the impoundment area below the top of dam elevation.

B. Construction Surveying

Upon completion of the engineering design for the project, location and construction surveys and monumentation will be required. Dam site centerlines are usually staked for the convenience of the design engineers, but offset reference monuments will be needed to reestablish the centerline location as construction proceeds. These offset reference monuments should carry both horizontal and vertical positions.

If the area is heavily wooded, the control reference line may be located along a roadway, railway, or electric power transmission line clearing which roughly parallels the stream. Offset traverses to the reference line can then be computed in the office and surveyed in the field. Construction control requirements usually involve more than the basic establishment of centerlines and strategically located bench marks. Supplemental control may also be required at many locations around and on a structure for activities such as setting concrete forms and aligning pipes.

Before the embankment is started, original and final excavated topography of the foundation and the core trench should be obtained to prepare as-built drawings following construction. During construction, survey checks should be made from time to time of monuments to detect any horizontal or vertical disturbance which may have been caused by construction equipment.

The execution of the construction surveys may be the responsibility of the owner, the contractor, or it may be a divided responsibility in accordance with the specifications. In some cases, the owner may establish and maintain principal centerline and grade references while the construction contractor performs required layout work and detailed referencing of the construction.

The reference line monumentation should be preserved for use in postconstruction maintenance and control surveys. The location of the core trench, all internal drains, and pipes should be tied to a reference line. The design may include provisions for the contractor to install monitoring instruments in the dam to detect internal changes and horizontal and vertical movement.

Another aspect of construction surveys is height data. Vertical control must be established to determine the elevation of the crest of the dam and the toe. Because the dam safety law only applies to dams that are over 35 feet in height, care must taken to establish the elevation of the toe of the dam for future reference. This is especially true at sites where the owner plans to build a dam less than 35 feet in height. Post-construction grading can obscure the toe and old creekbed after the dam is complete.

In order to obtain a construction permit to build a dam greater than 35 feet in height, hydrological information must be analyzed and submitted. This includes the flow elevation of all spillways, channel profiles and cross sections, the water storage elevation, inlet and outlet works elevations, and stage-storage information for the reservoir. This information is normally included on the plans. It is necessary to know the topography of the dam site to design a spillway system that will keep the dam from being overtopped during the design flood.

C. Analyzing Existing Dams

Dam safety inspections include an engineering survey to obtain data to perform a hydrologic and hydraulic analysis of the dam and to determine the slope of the embankment faces. The survey includes a profile of the crest, a cross section of the embankment at the maximum section, invert elevations of pipes, cross sections of open channel spillways, location and top elevation of dikes along the discharge channel, and dimensions of inlet and outlet structures.

The two most common methods employed by the staff of the Dam and Reservoir Safety Program are stadia surveys and level and tape surveys. The primary benefit of performing a stadia survey is to develop a plan of the dam and spillways. The location of observable defects such as slides, uncontrolled seepage exit points, and cracks can be determined and plotted on a plan view. It also gives the engineer analyzing the dam additional information concerning the location of the spillways and discharge channels in relation to the dam. With the widespread use of electronic distance measuring equipment, this information can be determined in a few hours. Level and tape surveys are adequate for most dams. Because elevations are the most important data for the hydrologic and hydraulic analysis, a level traverse should be completed and closed on the beginning benchmark.

Stationing for the crest profile must be close enough to determine the lowest elevation on the dam. This elevation is the location where water will first overtop the crest. Stations should extend far enough to include all spillways, except in the case of tailings dams where spillways are typically located several hundred feet upstream. Elevations should be rounded off to the nearest 0.05 ft. A higher degree of accuracy is not needed because the results of the overtopping analysis are normally rounded off to the nearest .1 ft. If the crest is crowned or if the crest slopes from one shoulder to the other, the elevations should be taken at the highest point.

The engineer should attempt to tie the survey to a National Geodetic Vertical Datum (NGVD) but that is not always possible. When an assumed elevation is used, a temporary benchmark should be established near the dam at a location that will remain undisturbed if modifications are required. A nail or spike in a tree near the dam works well. All references to the benchmark should be labeled "local datum". Because the stage-storage curve will be derived from USGS maps, the survey should include the local normal pool elevation which can be related to a reservoir elevation on the map. It is good practice to include an

equation in the inspection report for converting local survey elevations to the elevations on the topographic map.

The engineer should obtain a cross section of the embankment at the maximum section to establish the height of the dam and determine the upstream and downstream slopes. At dams where the old steambed has been covered, it may be necessary to take several elevations along the toe to determine the lowest point in accordance with 10 CSR 22-1.020(59). The station of the embankment cross section should be noted and the engineer should obtain enough points to plot the cross section in the inspection report.

The invert elevations or flow lines of all pipes, inlet structures, and outlet structures should be determined. This information will be used to rate the spillways and establish the water storage (normal pool) elevation. Dimensions and elevations of inlet structures are very important. It may be necessary to make soundings in a deep drop inlet structure to determine the upstream flow line of the discharge pipe.

The final phase of the engineering survey involves open channel spillways. Figure 4.5 shows a plan of a typical open channel emergency spillway. In order to determine the capacity of the channel and derive the water surface profile, a backwater analysis is required. The purpose of the backwater analysis is to rate the channel, determine the location of the control, determine the velocities expected in the channel, and compute the depth of water throughout the channel during the design flood. The term "control" applies to the channel section that regulates discharge. This cannot be determined visually. In fact, the location of the control can change with increasing discharge. Therefore, enough cross sections must be obtained to rate the channel at several discharges.

After the highest elevation in the channel is determined, cross sections should be laid out on the ground. Elevations should be taken at every break in slope and distances measured between each point. The left bank, right bank, and center of channel distances must be determined between each cross section. The bank elevations should extend to the top of dam elevation or to the top of training berms and dikes. The training berm information will be used to determine if it will be overtopped during the spillway design flood.

The survey notes should include information about the type of surface in the spillway. The information should be sufficient to estimate the roughness of the channel at each cross section.

REGISTRATION PERMIT APPLICATION

DAM NAME _____ ID # MO _____

COUNTY _____ DATE _____

☐ **ENGINEER CERTIFICATION**

I hereby certify that I have inspected the _____ _____(Name of Dam) on _____ (Date) in accordance with the law.

☐ **ENGINEER CERTIFICATION**

I hereby certify that the owner of the _____ _____(Name of Dam) has complied with my recommendations to correct observed defects as required by law.

☐ **JUDGEMENT OF STABILITY**

At the time of my inspection, there were no observable indications that the dam was unsafe.

_____

(Name of Firm)

_____

(Registered Engineer and P.E. #)

(Engineer's Seal)

10 CSR 22-1.030	Immunity of Officers	5

Title 10—DEPARTMENT OF NATURAL RESOURCES
Division 22—Dam and Reservoir Safety Council
Chapter 1—Organization, Definitions and Immunity

10 CSR 22-1.010 General Organization

PURPOSE: This rule complies with section 536.023, RSMo which requires each agency to adopt as a rule a description of its operation and the methods where the public may obtain information or make submissions or requests.

(1) Section 236.410, RSMo established a Dam and Reservoir Safety Council of Missouri. The council consists of seven (7) members appointed by the governor with the advice and consent of the senate. The council holds a minimum of four (4) regular meetings each year and special meetings and hearings as the council chairman may deem necessary.

(2) The Missouri dam and reservoir safety law, rules, regulations, guidelines and standards provide for the construction management and operation of dams and reservoirs in a manner which will provide adequate protection of public safety, life or property. To achieve this purpose the council has statutory powers as listed in sections 236.405 and 236.415, RSMo for policy making, adopting rules, standards and guidelines and issuing of permits.

(3) The Department of Natural Resources is authorized under section 236.405, RSMo to administer and enforce all rules, standards and guidelines adopted by the council and to assist the council in achieving its statutory duties. The department has designated the dam and reservoir safety program as the agency within the department responsible for administering the dam and reservoir safety law. The director of the Department of Natural Resources appoints a chief engineer who is the dam and reservoir safety program director and a staff, as provided in section 236.405, RSMo. The chief engineer and staff provide day-to-day operation of the dam and reservoir safety program.

(4) The dam and reservoir safety program performs administrative and technical functions including: review permit applications and recommend approval or denial of applications; inspect dams and reservoirs; enforce the law and all rules, standards and guidelines adopted pursuant to Chapter 236, RSMo; employ necessary staff; develop facts as may be required by the council; recommend rules, standards and guidelines required by Chapter 236, RSMo; mitigate or eliminate unsafe dam or reservoir conditions; and other functions as described in sections 236.420 to 236.500, RSMo.

(5) Requests for permit applications, requirements or other permit information, copies of these rules and the dam and reservoir safety law, dam inspections and technical information and assistance, requests for public hearings and any other submissions are to be made to the Department of Natural Resources, Dam and Reservoir Safety Program, P.O. Box 250, Rolla, MO 65401.

AUTHORITY: Chapter 236, RSMo 1986. Original rule filed April 14, 1981, effective Aug. 13, 1981.

Original authority: 236.405, RSMo 1979 and 236.415, RSMo 1979.

10 CSR 22-1.020 Definitions

PURPOSE: The following terms when used in rules, standards and guidelines adopted by the Dam and Reservoir Safety Council pursuant to the dam safety law shall have the meaning respectively ascribed to them by this section.

PUBLISHER'S NOTE: The secretary of state has determined that the publication of the entire text of the material which is incorporated by reference as a portion of this rule would be unduly cumbersome or expensive. Therefore, the material which is so incorporated is on file with the agency who filed this rule, and with the Office of the Secretary of State. Any interested person may view this material at either agency's headquarters or the same will be made available at the Office of the Secretary of State at a cost not to exceed actual cost of copy reproduction. The entire text of the rule is printed here. This note refers only to the incorporated by reference material.

(1) Agency engineer means an experienced engineer, not necessarily registered as a professional engineer in Missouri, who works for an engineering division of a state or federal agency regularly engaged in dam and reservoir design and construction for soil and water conservation or irrigation or relating to wildlife conservation.

(2) Agricultural dam means any dam, the primary use of which is to impound water for use in irrigation, livestock watering or commercial fish rearing and sale.

(3) Alterations, repairs, or either means alterations or repairs as affect the safety of a dam or reservoir, or public safety, life or property.

(4) Appurtenant works means the structures or materials incident to or annexed to dams which are built or maintained in connection with dams and which are used primarily in connection with their proper operation, maintenance or functioning. This includes, without limitation, structures as spillways, either in the dam or separate therefrom; the reservoir rim; low level outlet works; and water conduits such as tunnels, pipelines or penstocks, either through a dam or its abutments.

(5) Area capacity curves means graphic curves which show the relationship between reservoir surface area and the storage capacity of the reservoir at given elevations.

(6) Chief engineer means the head of the dam and reservoir safety program of the Department of Natural Resources or his/her representative.

(7) Commercial fish rearing reservoir means a reservoir which was designed specifically for fish rearing purposes and the primary use is to provide water for commercial fish rearing and sale to other parties in a for profit venture. This does not include activities such as sport fishing.

(8) Construction permit means a written authorization issued by the council giving the owner the right to construct, alter, enlarge, reduce, repair or remove a dam or reservoir or appurtenances thereto, with conditions that are necessary to adequately protect the public safety, life, property, the dam or reservoir.

(9) Conventional dam means any dam other than an industrial water retention dam.

(10) Council delegate or authorized representative means an individual, usually the chief engineer, authorized by the council to act in its behalf.

(11) Crest or dam crest means the top surface of the dam.

(12) Crest elevation or dam crest elevation means the lowest elevation of the crest exclusive of the spillway(s).

(13) Dam means any artificial or man-made barrier which does or may impound water and which impoundment has or may have a surface area of fifteen (15) or more acres of water at the water storage elevation or which is thirty-five feet (35') or more in height from the natural bed of the stream or watercourse or lowest point on the toe of the dam (whichever is lower) up to the crest elevation, together with appurtenant works. Sections 236.400 to 236.500 shall not apply to any dam which is not or will not be in excess of thirty-five feet (35') in height or to any dam or reservoir licensed and operated under the Federal Power Act.

(14) Dam and Reservoir Safety Council referred to as the council means seven (7) members appointed by the governor for purposes of implementing the dam safety law.

(15) Dangerous dam or reservoir is a dam or reservoir which is in an advanced state of deterioration so that if deterioration continues, the threat of dam failure and flooding would be substantial.

(16) Department means the Department of Natural Resources.

(17) Downstream environment zone means the area downstream from a dam that would be affected by inundation in the event the dam failed when filled to the emergency spillway crest elevation or to the dam crest elevation, in the absence of an emergency spillway.

(18) Earthquake intensity means Modified Mercalli intensity which is used to describe the degree of shaking a dam will experience.

(19) Enforcement order means a written directive issued by the council or the chief engineer to the owner of a dam for correction of defects in the dam or reservoir which have been determined to make the structure a threat to public safety, life or property. The order will contain specific actions with which the owner must comply to remove the threat the dam or reservoir poses to public safety, life or property.

(20) Enlargement means any change in or addition to an existing dam or reservoir, which raises the height of the dam, increases the watershed for the reservoir or raises the water storage elevation of the water impounded by the dam or reservoir.

(21) Environmental class means a classification of the downstream environment zone based on the contents of that zone (see 10 CSR 22-2.040(1)). Class I represents the most severe threat to public safety, life or property and Class III represents the least threat.

(22) Factor of safety means the resultant of the summation of the forces resisting failure divided by the summation of the driving forces tending to cause failure.

(23) Freeboard means the difference in elevation between the dam crest elevation and the water storage elevation in the reservoir.

(24) Height or height of dam means the difference in the elevation of either the natural bed of the stream or watercourse or the lowest point on the toe of the dam (whichever is lower) and the dam crest elevation.

(25) Industrial building means a permanent, enclosed structure used by groups of workers usually involved in some type of manufacturing, processing or industrial related process.

(26) Industrial water retention dam means a dam used to retain the solids transported as water-borne industrial byproducts and the associated water. This includes, but is not limited to, tailings dams, slime impoundments and settling ponds.

(27) Inundation means water, two feet (2') or more deep, over the general level of the submerged ground affected outside the stream channel.

(28) Inspection means scheduled and unscheduled examinations of a dam and reservoir with the primary objective of making safety observations and recording them in a written description.

(29) Irrigation reservoir means a reservoir whose primary use is to provide water for the irrigation of agricultural lands for the production of grains, hay, pasture, fruits, vegetables and animal feeds which are for sale or to be used by the owner.

(30) Law means the dam and reservoir safety law, as contained in Chapter 236, RSMo and all rules, standards and guidelines adopted thereto.

(31) Liquefaction is a condition where a soil will undergo continued deformation at a constant low residual stress or with low residual resistance, due to the build-up and maintenance of high pore water pressures, which reduce the effective confining pressure to a very low value.

(32) Livestock watering reservoir means a reservoir whose primary use is to provide water for livestock which are raised for breeding or marketing purposes.

(33) Maintenance means the proper keeping of all aspects of a dam or reservoir and appurtenances thereto, that pertain to safety, in a state of repair and working order as necessary to comply with the law and any permit issued thereunder and to protect public safety, life or property.

(34) Modification(s) means changes or revisions to the design, construction, maintenance, operation or repair or the alteration, enlargement, reduction, removal or natural physical changes that may occur to a dam or reservoir that were not included in the approved plans for the construction permit, or changes or revisions to a dam or reservoir where a registration or safety permit is in effect or required hereunder, if the changes or revisions would endanger public safety, life or property as a result of creating a potential failure in the dam or reservoir; except that modification(s) do not mean or include approved anticipated enlargements, outlined by design plans and specifications submitted and approved with the original application for a construction, safety or registration permit for industrial water retention dams and reservoirs.

(35) Observable defects are those defects which would be detectable by an experienced professional engineer making an on-site visual inspection of the dam in accordance with current engineering, geologic and construction practices.

(36) Owner or dam owner means a person who owns, controls, operates, maintains, manages or proposes to construct a dam or reservoir including: the state and its departments, institutions, agencies and political subdivisions, but not the United States government; a municipal or quasi-municipal corporation; a district; a public utility; a natural person, firm, partnership, association, corporation, political subdivision or legal entity; the duly authorized agents or leasees, or trustees of any of the foregoing; or receivers or trustees appointed by any court for any of the foregoing.

(37) Permanent dwelling means a dwelling occupied at least ninety (90) days a year.

(38) Permit means construction, safety or registration permit.

(39) Permit applicant or applicant means an owner who applies for a construction, safety or registration permit.

(40) Probable maximum acceleration means the horizontal acceleration developed at a dam as a result of an earthquake with a probability of occurrence similar to the probable maximum precipitation. The probable maximum acceleration is readily available from a Corps of Engineers Report entitled Earthquake Potential of the St. Louis District—Ground Motion Supplement which is on file with the chief engineer of the Dam and Reservoir Safety Program.

(41) Probable maximum precipitation or PMP means the precipitation that may be expected from the most severe combination of critical meteorologic conditions that are reasonably possible in an area. The PMP is readily available from the National Weather Service in Hydrometeorological Report 51, Probable Maximum Precipitation Estimates, United States East of the 105th Meridian.

(42) Public building means a permanent, enclosed structure used by groups of the general public but not necessarily owned by the public.

(43) Registration permit means a permit issued for a period not to exceed five (5) years by the council to the owner of a dam or reservoir in existence or in the progress of construction on August 13, 1981 or which becomes subject to the law for the dams and reservoirs by a change in factors or circumstances subsequent to that date. Permits shall only be issued for dams which are in a properly maintained condition or which have made and complied with recommendation for corrections of observed defects of the dam or reservoir and have been examined and approved in accordance with the law.

(44) Reservoir means any basin, including the water, which contains or will contain the maximum amount of water impounded by a dam.

(45) Safety permit means a permit issued to the owner of a dam for a period of five (5) years, or less if safety considerations so require, by the council indicating that the dam meets the requirements of the law, and containing conditions as to operations, maintenance and repair as are necessary to adequately protect public safety, life and the dam or reservoir.

(46) Seepage means the migration of water through a dam or foundation.

(47) Significant modification means changes, alteration or modifications to an existing dam or changes to the construction documents for a new dam. Those include, but are not limited to: changes in the location of the dam or reservoir, changes in the storage capacity or drainage area, changes in the capacity of the spillway system, modification of the embankment slopes, changes in the height of the dam or structure, or the use of different construction methods or procedures than those submitted with the permit application.

(48) Spillway means any passageway, channel or structure, open or closed or both, designated expressly or primarily to discharge excess water from a reservoir after the water storage elevation has been reached.

(49) Spillway design flood or SDF means the specified flood discharge that may be expected from the most severe combination of critical meteorologic and hydrologic conditions that are reasonably possible in an area and for which the dam and reservoir are designed. The SDF is derived from the rainfall values given in Table 5.

(Editor's Note: For Table 5 see 10 CSR 22-3.020)

(50) Stability means the properties of a dam or reservoir that cause it when disturbed from a condition of equilibrium to develop forces or moments that restore the original condition.

(51) Starter dam means a pervious or impervious dam constructed as the first phase in the building of an industrial water retention dam and reservoir.

(52) Storage means the volumetric capacity of the reservoir below the water storage elevation or other selected reference on the dam.

(53) Stream means any river, creek or channel, having well-defined banks, in which water flows for substantial periods of the year to drain a given area.

(54) Tailings means the material generated by a mining/milling operation which is deposited in slurry form in an impoundment for storage, disposal, or both.

(55) Tailings dam means an existing dam or reservoir used for the impoundment or retention of tailings or a proposed, existing or newly constructed dam and reservoir for which the anticipated or contemplated use is the impoundment or retention of tailings.

(56) Toe or toe of slope means the line of the fill (dam embankment) slope where it intersects the natural ground.

(57) Water means water, other liquids or tailings.

(58) Watercourse means a valley, swale, depression or other low place in the topography occupied by flowing water during conditions of runoff.

(59) Water storage elevation means that elevation of water surface at the principal spillway which could be obtained by the dam or reservoir were there no outflow and were the reservoir full of water.

(60) Watershed means the area that contributes or may contribute surface water to a reservoir.

AUTHORITY: sections 236.405, RSMo Supp. 1993 and 236.415, RSMo 1986. Original rule filed April 14, 1981, effective Aug. 13, 1981. Amended: Filed June 14, 1984, effective Jan. 1, 1985. Amended: Filed Sept. 1, 1993, effective May 9, 1994.*

**Original authority: 236.405, RSMo 1979, amended 1933 and 236.415, RSMo 1979.*

10 CSR 22-1.030 Immunity of Officers

PURPOSE: The purpose of this rule is to restate the immunity from damages provided in section 236.475, RSMo (1986).

(1) In the absence of willful and wanton misconduct, no action shall be brought against the council, the chief engineer or his/her agents, department employees or private individuals employed as consultants by the department for the recovery of damages caused by the partial or total failure of any dam or reservoir or through the use or operation of any dam or reservoir upon the ground that the person is liable by virtue of any of the following: the approval of a dam or reservoir or permits therefore; the issuance or enforcement of orders relating to maintenance, operation or repair of a dam or reservoir; control or regulation of a dam or reservoir; measures taken to protect against failure during an emergency; or denial of a permit.

AUTHORITY: section 236.475, RSMo 1986. Original rule filed April 14, 1981, effective Aug. 13, 1981.*

**Original authority: 236.475, RSMo 1979.*

Title 10—DEPARTMENT OF NATURAL RESOURCES
Division 22—Dam and Reservoir Safety Council
Chapter 2—Permits

10 CSR 22-2.010 Who Needs a Permit

PURPOSE: This rule identifies those persons who need to obtain a permit for their dam and reservoir and to identify those persons who do not need to obtain a permit for their dam and reservoir.

(1) The owner of a proposed new dam thirty-five feet (35') or more in height is required to obtain a construction permit and a safety permit for his/her dam and reservoir. The owner of an existing dam thirty-five feet (35') or more in height is required to obtain a registration permit within the time set forth in 10 CSR 22-2.020(2).

(2) By definition, the United States government is not considered an owner. Therefore, no federal dam and reservoir is regulated by sections 236.400—236.500, RSMo and no permits are required.

(3) Agricultural dams are exempted from all permit requirements as long as the agricultural dam and reservoir continue to be used primarily for agricultural purposes (see 10 CSR 22-1.020(2)). The owners of agricultural dams and reservoirs over thirty-five feet (35') in height must notify the council of their reliance on this exemption and their basis for application of this exemption to their dams. If an agricultural dam and reservoir is constructed after the effective date of the law, but subsequently becomes subject to the provisions of the law, the owner shall provide, prior to obtaining a registration permit, evidence that the dam meets the construction permit criteria in effect at the time the dam was constructed.

(4) Dams and reservoirs licensed and operated under the Federal Power Act are exempted from all permit requirements.

(5) Dams and reservoirs that were designed by and the construction monitored by an agency engineer (see 10 CSR 22-1.020(1)) do not need a construction permit but a set of plans shall be filed with the chief engineer prior to the initiation of any construction activity. These dams and reservoirs are required to have a registration or safety permit subsequent to construction.

(6) Industrial water retention dams (see 10 CSR 22-1.020(27)) and reservoirs regulated by another state agency or federal agency are exempted from all permit requirements. For the exemption to apply, the industrial water retention dam and reservoir must be subject to safety inspections by the other state agency or federal agency and standards used must be at least as stringent as those required by the law. In addition, the owner must notify the council that another agency is regulating his/her dam and reservoir and explain the basis for the exemption to apply.

AUTHORITY: sections 236.400, 236.415, 236.435, 236.440 and 236.465, RSMo 1986 and 236.405, RSMo Supp. 1993. Original rule filed April 14, 1981, effective Aug. 13, 1981. Amended: Filed June 14, 1984, effective Jan. 1, 1985. Amended: Filed Sept. 1, 1993, effective May 9, 1994.*

**Original authority: 236.400, 236.415, 236.435, 236.440 and 236.465, RSMo 1979 and 236.405, RSMo 1979, amended 1993.*

10 CSR 22-2.020 Types of Permits

PURPOSE: This rule describes the three types of permits and their uses that the Dam and Reservoir Safety Council will issue.

(1) There are three (3) types of permits—registration permits, construction permits and safety permits and each one is intended to regulate a separate and distinct type of activity. A dam and reservoir will have only one (1) type of permit in effect at any given time although they may have more than one (1) type of permit during their existence.

(2) Registration permits (see 10 CSR 22-1.020(44)) apply to and are required for the continued operation of a dam and reservoir that was in existence or in the process of being constructed on the effective date of this section, August 13, 1981. A registration permit also applies to and is required for structures which become subject to the provisions of the dam and reservoir safety law that were in existence prior to the date that they became subject to the law. Registration permits may be issued for a time period up to five (5) years. The owner of a dam and reservoir on the effective date of the law shall obtain his/her first registration permit in accordance with the height of his/her dam. For dam heights of thirty-five feet (35') to less than fifty feet (50'), fifty feet to seventy feet (50'–70') and over seventy feet (70 + '), the maximum time to obtain the first registration permit is respectively within nine (9) years, four (4) years and two (2) years from the effective date of this section, August 13, 1981.

(3) Construction permits (see 10 CSR 22-1.020(8)) apply to the construction of a new dam and reservoir, the alteration, enlargement, reduction, repair or removal of a new or existing dam, reservoir or appurtenances. New dams are dams for which construction commences after the effective date of this section, August 13, 1981. For dams which were under construction on August 13, 1981, construction must be completed by August 13, 1987 or the owner will be required to obtain a construction permit. If completed prior to August 13, 1987, the owner will be required to obtain a registration permit as outlined in 10 CSR 22-2.020(2). A construction permit may be issued for any reasonable length time period required to complete construction and it may contain appropriate restrictions placed on the owner for construction and operation of the dam and reservoir during that period. At the conclusion of construction, a safety or registration permit shall be obtained by the owner.

(4) Safety permits (see 10 CSR 22-1.020(48)) apply to the operation of a dam and reservoir constructed pursuant to a construction permit. The safety permit is not a guarantee of the dam and reservoir's safety and does not alter the owner's liability; it is simply an operating permit. If a dam and reservoir were not subject to the provisions of the law when they were constructed but subsequently become subject to the provisions of the law, the owner shall obtain a registration permit, not a safety permit. Safety permits may be issued for a time period up to five (5) years, and they may contain appropriate conditions for the operation and safety of the dam and reservoir.

AUTHORITY: sections 236.400, 236.415, 236.435, 236.440 and 236.465, RSMo 1986 and 236.405, RSMo Supp. 1993. Original rule filed April 14, 1981, effective Aug. 13, 1981. Amended: Filed June 14, 1984, effective Jan. 1, 1985. Amended: Filed May 15, 1987, effective Sept. 15, 1987.*

**Original authority: 236.400, 236.415, 236.435, 236.440 and 236.465, RSMo 1979 and 236.405, RSMo 1979, amended 1993.*

10 CSR 22-2.030 Types of Dams and Reservoirs

PURPOSE: This rule describes the two fundamentally different types of dams and reservoirs that will be required to obtain permits from the Dam and Reservoir Safety Council.

(1) There are two (2) types of dams and reservoirs, conventional dams and reservoirs and industrial water retention dams and reservoirs. The two (2) types of dams and reservoirs are distinguished on the basis of their reservoir contents and the length of the time period during which active dam building occurs.

(2) Conventional dams and reservoirs (see 10 CSR 22-1.020(9)) are dams and reservoirs used for purposes other than tailings, slime, settling or other similar industrial water retention purposes. A conventional dam is constructed in one (1) relatively continuous operation over a short time span (compared to the design life of the reservoir). Filling and use of the reservoir occurs after construction is completed.

(3) Industrial water retention dams and reservoirs (see 10 CSR 22-1.020(27)) are dams and reservoirs used for the purpose of storing solids and the water associated with the particular industrial process such as tailings, slime and other similar industrial materials. An industrial water retention dam may be constructed in phases and steps or continuously, over a long period of time (compared to the design life of the reservoir). Filling and use of the reservoir may occur during most phases of construction. An industrial water retention dam and reservoir in existence or under construction on the effective date of 10 CSR 22-2.020(2), August 13, 1981, shall obtain a registration permit which may include approval to make enlargements. The owner of any such dam and reservoir shall apply for and obtain new construction and/or registration permits for any modifications to that dam and reservoir other than enlargements covered by an existing permit. A construction permit is required and shall be obtained by the owner, for the initial construction phase of any new industrial water retention dam and reservoir built after the effective date of 10 CSR 22-2.020(3), August 13, 1981. Upon completion of the initial construction phase, the owner shall apply for a safety permit for the operation and enlargement of the new dam and reservoir.

AUTHORITY: sections 236.405, RSMo Supp. 1993 and 236.415, 236.435, 236.440 and 236.465, RSMo 1986. Original rule filed April 14, 1981, effective Aug. 13, 1981. Amended: Filed June 14, 1984, effective Jan. 1, 1985.*

**Original authority: 236.405, RSMo (1979), amended 1993 and 236.415, 236.435, 236.440 and 236.465, RSMo (1979).*

10 CSR 22-2.040 Classes of Downstream Environment

PURPOSE: This rule describes the three environmental classes for the downstream environmental zone that will be used by the Dam and Reservoir Safety Council when considering permits.

(1) The downstream environment zone is the area downstream from a dam that would be affected by inundation in the event the dam failed. Inundation is defined as water, two feet (2') or more deep over the general level of the submerged ground affected outside the stream channel. Based on the content of the downstream environment zone, three (3) environmental classes are defined. They are: class I, which contains ten (10) or more permanent dwellings or any public building; class II, which contains one to nine (1–9) permanent dwellings, or one (1) or more campgrounds with permanent water, sewer and electrical services or one (1) or more industrial buildings; and class III, which is everything else.

(2) Spillway design standards are based on the environmental class of the downstream environment zone of a dam and reservoir. The standards become more stringent for lower environmental class numbers. If conditions change in the downstream environment zone and it becomes necessary to change the environmental class of the dam and reservoir, the owner must then meet the standards and criteria for the new environmental class of the dam and reservoir. A dam and reservoir may be in only one (1) environmental class at a given time.

(3) Inundation, the downstream environmental zone and the associated environmental class are analyzed, assuming the dam fails with the reservoir at the emergency spillway crest elevation or the dam crest elevation in the absence of an emergency spillway. If the spillway standards for class I are used, the failure analysis does not have to be performed. If a failure analysis is made, the contents of the downstream environment zone used to determine the environmental class are only the features that would be inundated by the flooding resulting from the dam failure.

AUTHORITY: sections 236.405, RSMo Supp. 1993 and 236.415, 236.435, 236.440 and 236.465, RSMo 1986. Original rule filed April 14, 1981, effective Aug. 13, 1981. Amended: Filed June 14, 1984, effective Jan. 1, 1985.*

**Original authority: 236.405, RSMo 1979, amended 1993 and 236.415, 236.435, 236.440 and 236.465, RSMo 1979.*

10 CSR 22-2.050 Issuing First Permit

PURPOSE: This rule describes the procedure for issuing the first permit to a dam and reservoir owner for a particular dam and reservoir.

(1) A permit will be issued or a letter will be sent to the owner with comments within forty-five (45) days after the receipt of a properly prepared application or after the completion of any hearings or record period conducted by the council in connection with the application, whichever is later. The council, upon hearing the recommendations of the chief engineer, shall approve or deny the permit application.

(2) A permit will be issued if a complete and proper application has been submitted and the dam and reservoir comply with the law.

(A) A registration permit may be denied if it is determined that the owner has not complied with the experienced professional engineer's or agency engineer's inspection recommendations.

(B) A construction permit may be denied if there is insufficient information to determine that the proposed construction, alteration, enlargement, reduction or removal of a dam or reservoir would not endanger public safety, life or property or otherwise would comply with the law.

(C) A safety permit may be denied if it is determined that there are violations of the construction permit or the law.

(D) If revisions have been made which vary substantially from the provisions of the construction permit, the owner must show that the revisions do not endanger public safety, life or property before a safety permit will be issued.

(3) Conditions contained in a construction permit shall include that the construction work must be under the responsible charge of an experienced professional engineer and the records be kept and made available as

required by the chief engineer including, without limitation, for the foundation excavation and inspection and placement of backfill in the core trench. It is not necessary for the engineer in responsible charge to be on-site continuously. During construction, the council or its delegate, the chief engineer, may make periodic site inspections the purpose of inspecting and securing conformity of construction with the approved plans and specifications and the owner shall permit, upon reasonable notice, the person entry upon its property to make such inspections. The owner may be required to perform, at its own expense, reasonable work or tests as are necessary to provide sufficient information to enable the council to determine that there is conformity. Usually, testing will be limited to verification of embankment compaction, concrete strengths and other similar requirements. It is expected that the tests will be required where the owner's inspection records are lacking.

(4) Any significant modifications from a construction permit or approved plans makes the permit void and requires the owner to obtain a new permit. Significant modification to the plans and specifications must be prepared by an experienced professional engineer. The council or its delegate will follow the same evaluation procedures for the modifications as used with issuance of the original construction permit. Special attention will be given to these modification requests to provide a quick decision.

(5) The owner of a dam and reservoir that is removed under a construction permit must notify the council or its delegate when this work is completed and in conformity with the provisions of the construction permit. The council or its delegate will then issue a final approval to relieve the owner of the requirement to have a permit upon a showing that the requirements of the law for removal have been satisfied.

(6) Approval by the council for a construction permit becomes invalid within one (1) year, unless work on the construction has begun within that period, except that the owner may be excused from beginning work for a period of time that the work is prevented by flood, shortage of materials or regulation of government which cannot be met for reasons over which the owner has no control or other causes beyond the owner's control. The same applies to construction of approved modifications contained in the conditions of a registration or safety permit for industrial water retention dams unless the conditions specify a different time schedule.

AUTHORITY: sections 236.400, 236.415, 236.435, 236.440 and 236.465, RSMo 1986 and 236.405, RSMo Supp. 1993. Original rule filed April 14, 1981, effective Aug. 13, 1981. Amended: Filed June 14, 1984, effective Jan. 1, 1985.*

**Original authority: 236.400, 236.415, 236.435, 236.440 and 236.465, RSMo 1979 and 236.405, RSMo 1979, amended 1993.*

10 CSR 22-2.060 Issuing Permit Renewals

PURPOSE: This rule describes the procedure for renewing a permit.

(1) The owner of a permitted dam and reservoir must apply for the renewal of the permit not less than sixty (60) days prior to expiration of that permit. Before any permit may be renewed, the chief engineer must determine that the dam and reservoir are essentially as described in the latest permit and approved plans; they satisfy the law; and that no inspection conducted in connection with the permit renewal reveals any defect which would threaten public safety, life or property. The council, or its delegate will issue another permit within forty-five (45) days of the receipt of a complete and proper application unless it is determined that the dam and reservoir are not as described in the latest permit and approved plans; not properly maintained; do not satisfy the law; or that the defects are not corrected.

(2) The council may require the owner to furnish a certification by an experienced professional engineer or an agency engineer that the dam and reservoir are as described in the latest permit and approved plans; are properly maintained; satisfy the law; and have all defects corrected.

AUTHORITY: sections 236.405, RSMo Supp. 1993 and 236.415, 236.440 and 236.465, RSMo 1986. Original rule filed April 14, 1981, effective Aug. 13, 1981. Amended: Filed June 14, 1984, effective Jan. 1, 1985.*

**Original authority: 236.405, RSMo 1979, amended 1993 and 236.415, 236.440 and 236.465, RSMo 1979.*

10 CSR 22-2.070 Modifications not Requiring Permit Changes
(Rescinded January 1, 1985)

AUTHORITY: sections 236.405, 236.415, 236.435, 236.440, and 236.465, RSMo Supp. 1980. Original rule filed April 14, 1981, effective Aug. 13, 1981. Rescinded: Filed June 14, 1984, effective Jan. 1, 1985.

10 CSR 22-2.080 Revoking Permit

PURPOSE: This rule describes the reasons for revoking a permit.

(1) Approval of the council or its delegate, the chief engineer, shall be obtained for modifications that substantially alter or adversely affect the safety or stability of the dam or reservoir. Modifications, without the approval of the council or its delegate, the chief engineer, are cause for suspension or revocation of any permit. If the chief engineer finds that the condition of the dam and reservoir has deteriorated substantially from those conditions present when the permit was issued, or that has defects which adversely affect the safety or stability of the dam and reservoir or threatens public safety, life or property, s/he shall revoke the permit. If a permit is suspended or revoked, the dam owner will be in violation of the law and may be subject to prosecution for a misdemeanor.

(2) If the chief engineer determines that a dam or reservoir constitutes a threat to public safety, life or property, s/he may order its removal or take any other actions necessary to reduce or eliminate the threat. Failure of a dam owner to alter or remove his/her dam and reservoir as directed, when it is found to be a threat to public safety, life or property, will result in revocation of the permit and, if necessary, removal of the dam or any other action necessary to reduce or eliminate the threat to public safety, life or property by the state at the owner's expense.

AUTHORITY: sections 236.405, RSMo Supp. 1993 and 236.415, 236.445, 236.495 and 236.500, RSMo 1986. Original rule filed April 14, 1981, effective Aug. 13, 1981. Amended: Filed June 14, 1984, effective Jan. 1, 1985.*

**Original authority: 236.405, RSMo 1979, amended 1993 and 236.415, 236.445, 236.495 and 236.500, RSMo 1979.*

10 CSR 22-2.090 Transferring Permit

PURPOSE: This rule describes the procedure for transferring a permit when ownership changes.

(1) Permits issued pursuant to 10 CSR 22-2.050 and 10 CSR 22-2.060 are transferable only as provided in section 236.460, RSMo.

If ownership or other transfer of interest in the dam and reservoir changes, the former owner must notify the chief engineer of the sale or transfer and the permit will be transferred to the new owner after determination that the transfer will not endanger the public safety, life, property, the dam or reservoir. The permit holder of record will be held responsible for maintaining compliance with these rules and standards. If the former owner does not have the permit transferred, the new owner may submit the appropriate application and documents necessary to obtain a new permit. The new owner, in this case, must also show proof of ownership. The old owner's responsibilities of ownership under the law will not be extinguished until the permit is transferred to an eligible owner. Nothing in these regulations shall be construed to eliminate the liability of the previous owner for damages or injuries caused by a dam failure, nor a new operator who has not obtained a permit nor had an existing permit transferred to his/her name.

AUTHORITY: sections 236.405, RSMo Supp. 1993 and 236.415, and 236.460, RSMo 1986. Original rule filed April 14, 1981, effective Aug. 13, 1981. Amended: Filed June 14, 1984, effective, Jan. 1, 1985.*

**Original authority: 236.405, RSMo 1979, amended 1993 and 236.415 and 236.460, RSMo 1979.*

10 CSR 22-2.100 Appeal of Action on Permits

PURPOSE: This rule describes the procedure for appealing the results of any action taken with regard to a permit.

(1) Permits revoked or denied are subject to council appeal. All parties shall be afforded an opportunity for hearing before the council for review of denial or revocation decisions, if request is made within thirty (30) days after notice is served personally or by certified or registered mail upon the parties or their agents. Except for emergency action, further legal action shall not be taken until after the hearing and council decision.

(2) The record of hearing shall include all written testimony, data, records, etc., as well as all oral proceedings recorded stenographically or by other means that will preserve the testimony. Rules of discovery, evidence and privilege as applied in civil cases in the circuit courts shall be followed.

(3) A final decision will be in writing, and the party or its agents will be notified personally or by registered or certified mail of the final decision. A copy of any opinion in support of this decision will be furnished upon request. Decisions are subject to judicial review pursuant to provisions of section 236.480, RSMo.

AUTHORITY: sections 236.405, RSMo Supp. 1993 and 236.415, 236.425, 236.440, 236.445, 236.470 and 236.480, RSMo 1986. Original rule filed April 14, 1981, effective Aug. 13, 1981. Amended: Filed June 14, 1984, effective Jan. 1, 1985.*

**Original authority: 236.405, RSMo 1979 amended 1993 and 236.415, 236.425, 236.440, 236.445, 236.470 and 236.480, RSMo 1979.*

Title 10—DEPARTMENT OF NATURAL RESOURCES
Division 22—Dam and Reservoir Safety Council
Chapter 3—Permit Requirements

10 CSR 22-3.010 General Information

PURPOSE: The purpose of this rule is to provide general information about permit requirements.

(1) Requirements for existing or proposed dams and reservoirs must allow for variations in conditions and materials from site-to-site. Therefore, this rule and 10 CSR 22-3.020—10 CSR 22-3.050 describe the minimum general requirements which are consistent with current engineering, geologic, construction, operation and maintenance practices, necessary to obtain permits from the Dam and Reservoir Safety Council.

(2) These rules are not intended to define the only requirements for a dam and reservoir to comply with the law or sound engineering, geologic and construction practices, to be used in detailed site investigation or in the specific design and construction of individual dams. The detailed and specific information that outlines current and prudent engineering, geologic and construction practices is available in technical literature. Determinations by the Dam and Reservoir Safety Council, after hearing the recommendations of the chief engineer of the acceptability of a design and adequacy of plans, specifications and construction must be made, by necessity, on a case-by-case basis. Therefore, it is recommended that applicants unfamiliar with the way these rules are applied contact the council or the chief engineer prior to commencing extensive work or plan development.

(3) Adherence to the law does not guarantee the safety of any dam or reservoir or relieve the owner of any liability in the event of dam failure.

(4) A permit application form along with a copy of the laws, rules, standards and guidelines relating to dam and reservoir safety can be obtained free from the Department of Natural Resources, Division of Geology and Land Survey, Dam Safety Program, P.O. Box 250, Rolla, MO 65401. Persons seeking this and/or other information on dams in Missouri should address their inquiry to the chief engineer.

AUTHORITY: sections 236.400, 236.405, 236.415, 236.435, 236.440 and 236.465, RSMo 1986. Original rule filed April 14, 1981, effective Aug. 13, 1981.*

**Original authority: 246.400, RSMo 1979; 236.405, RSMo 1979, amended 1993, 1995; 236.415, RSMo 1979, amended 1995; 236.435, RSMo 1979; 236.440, RSMo 1979; and 236.465, RSMo 1979.*

10 CSR 22-3.020 General Requirements

PURPOSE: The purpose of this rule is to itemize the basic requirements and standards that apply to all permits.

(1) The permit application must contain information required by the council and the chief engineer including, but not limited to, the following information: type of permit being applied for; name of owners; mailing address of owners; telephone number(s) of owners; name of dam; name of reservoir; coordinate location of the dam centerline at the maximum section; purpose or use of dam and reservoir; name, address and telephone number of the experienced professional engineer or agency engineer who has provided or will provide required technical assistance; and the downstream environment zone environmental class for the dam and reservoir. The owners must complete all applicable investigations required in 10 CSR 22-3.0202–10 CSR 22-3.050 before filing a permit application. All permit applications must be filed with the chief engineer at the address listed in 10 CSR 22-3.010(4).

(2) The owner must provide a determination of an environmental class for each dam and reservoir. The method, data and assumptions used by the owner to determine environmental class shall conform to practices reputable and in current use in the engineering, geologic and construction professions or the chief engineer may reject the owner's classification. If an owner chooses not to have this done by an experienced professional engineer or an agency engineer, the chief engineer will assign the dam and reservoir to environmental class I or s/he may assign the dam and reservoir to another environmental class if s/he has justification to do so.

(3) The anticipated consequences of a dam failure with respect to public safety, life and property damage are important considerations in establishing acceptable methods for specific investigations and sites. Methods used in exploration design, construction and maintenance must be in accordance with good engineering practices reputable and in current use in the engineering, geologic and construction professions.

(4) When the owner is applying for a construction permit, the required design factors of safety for slope stability for earth and rock conventional dams which are given in Table 1 shall be met. The required design factors of safety for concrete conventional dams are given in Table 2. The required design factors of safety for slope stability for industrial water retention dams are given in Table 3. Owners shall meet these requirements in the design of new dams prior to the issuance of the permit. Owners shall also meet these requirements when substantial changes are proposed to the height or slope of an existing conventional dam or structure prior to the issuance of the construction permit (see the following tables).

(5) For new dams constructed wholly or partially of cohesionless materials (such as sands and silts) or having a foundation of cohesionless materials, earthquake loading may result in the build-up of pore water pressures and a loss of strength. Engineers shall take this pore pressure increase and loss of strength into account when performing their stability analysis, but the degree to which liquefaction may affect the factor of safety for slope stability shall be left up to the engineer's best judgment. Bedrock accelerations and earthquake intensities are listed in Table 4.

(6) New dams constructed wholly of cohesive materials (such as clays) and having a foundation of cohesive materials or rock, can be expected to withstand significant earthquake shaking if it can be shown that other required design factors of safety for slope stability are met. Therefore, only new dams located in Bollinger, Butler, Cape Girardeau, Dunklin, Mississippi, New Madrid, Pemiscot, Ripley, Scott, Stoddard and Wayne Counties must meet the requirements for slope stability during earthquake loading while dams located in other counties do not unless 10 CSR 22-3.030(5) applies to them. Bedrock accelerations and earthquake intensities are listed in Table 4.

Table 1—Required Design Factors of Safety for Slope Stability Earth and Rock Conventional Dams

Loading Condition	Factor of Safety
End of construction, full reservoir*	1.4
Steady seepage, full reservoir*	1.5
Steady seepage, maximum reservoir**	1.3
Sudden draw down, from full to empty reservoir (if applicable)	1.2
Earthquake***, steady seepage, full reservoir*	1.0

*Full reservoir means water level is at the water storage elevation.

**Maximum reservoir means water level is at maximum water level attained during the spillway design flood or at the dam crest elevation, whichever is lower.

***Earthquake loading will vary according to dam location in relation to seismic source zones and downstream environmental zones. (See Table 4).

Table 2—Required Design Factors of Safety Concrete Conventional Dams

Failure Mode	Loading Condition	Factor of Safety
Overturning	full reservoir*	1.5
	maximum reservoir**	1.3
Sliding	full reservoir*	1.5
	maximum reservoir**	1.3
Structural integrity	full reservoir*	1.5
	maximum reservoir**	1.3
Earthquake*** any mode	full or maximum reservoir* & **	1.0

*Full reservoir means water level is at the water storage elevation.

**Maximum reservoir means water level is at maximum level attained during the spillway design flood.

***Earthquake loading will vary according to dam location in relation to seismic source zones and downstream environmental zones. (See Table 4).

Table 3—Required Design Factors of Safety for Slope Stability Industrial Water Retention Dams

Loading Condition	Factor of Safety
Starter dam, end of construction, full reservoir*	1.4
Any other stage of construction, full reservoir*, steady seepage	1.3
Any other stage of construction, maximum reservoir*, steady seepage	1.0
Completed dam, full reservoir*, steady seepage	1.5
Completed dam, maximum reservoir**, steady seepage	1.3
Earthquake***, steady seepage, full reservoir*	1.0

*Full reservoir means water level is at the water storage elevation.

**Maximum reservoir means water level is at the maximum level attained during the spillway design flood or at the dam crest elevation, whichever is lower.

***Earthquake loading will vary according to dam location in relation to seismic source zones and downstream environmental zones. (See Table 4).

(7) The required spillway design flood, which shall allow for flood storage in the reservoir, is to be derived by using the precipitation values given in Table 5 and shall apply to both new and existing dams.

Table 4—Required Design Acceleration For Earthquake Design

Dam Type	Stage of Construction	Special Descriptions	Environmental Class I	II	III
Conventional or Industrial	Completed	New dams less than 50 feet in height	.75PMA*	.5PMA*	.25PMA*
		New dams greater than 50 feet in height**	.75PMA*	.5PMA*	.4PMA*
Industrial	Starter dam	New dams**	.5PMA*	.2PMA*	.1PMA*
	dam is completed	After starter dam is finished and before final New dams**	.75PMA*	.5PMA*	.2PMA*

Zone	PMA*	Intensity**

10 CSR 22-3.030 Registration Permit Requirements

PURPOSE: The purpose of this rule is to itemize the requirements for a registration permit.

(1) In addition to the basic requirements for all permits listed in 10 CSR 22-3.020(1), (2), (3) and (7), the registration permit application for a conventional dam and reservoir must include certification by an experienced professional engineer or an agency engineer that the dam and reservoir have been inspected in accordance with the law and that the owner has compiled engineer's recommendations to correct the observed defects and an inspection report, as required by the law. The engineer must further show that the spillway can safely pass the spillway design flood derived from Table 5 and submit a report describing the correction of all observed defects and the description of an operation and maintenance program to be followed while the registration permit is in effect.

(A) The inspection of a dam and reservoir for a registration permit is intended to detect observable defects. The procedure to determine observable defects normally will be a surface examination by an experienced professional engineer or an agency engineer. The inspection must include all surface examinations necessary to determine if observable defects exist that affect the stability of the dam and reservoir or the adequacy of the spillway. Judgment of the structural stability and an evaluation of the spillway capacity must be made. Judgment shall be based upon the engineer's experience, training and knowledge of similar dams and in accordance with practices reputable and in current use in the engineering, geologic and construction professions.

1. Observed defects which may require correction, evaluated on the basis of current engineering, geologic and construction practices, include but are not limited to: slides; slopes as steep as or steeper than those on similar types of dams and constructed of similar materials which have experienced slope stability problems; piping of fines; seepage that exits in an uncontrolled fashion on the downstream slope of or from the downstream foundation of the dam; unusual zones of softness and irregular settlement; erosion on the upstream or downstream slope of the dam; spillways that are calculated to be inadequate for the design flood; spillways that are eroded or otherwise in poor condition and cracks in the embankment or structure.

2. Observed defects that are in an advanced state of deterioration must be immediately reported by the inspecting engineer to the owner and to the chief engineer.

(B) Proper maintenance and operation of a dam and reservoir are critical to the continuing safety of a dam and reservoir and to public safety, life and property. A maintenance program shall be required and shall include the following items: erosion control on the embankment; monitoring emergency spillway flow rates; vegetation control; spillway maintenance; emergency action plans; maintenance and monitoring of seepage observation devices, if any; and maintenance and monitoring of instruments used, if any, to observe the stability of the dam.

(C) Visits for the purpose of observation of maintenance and operation may be made by the council, the chief engineer or a member of the chief engineer's staff. Visits will be at any reasonable time following reasonable notice, except that in the case of an emergency threatening public safety, life or property, no notice shall be required and inspection may be at any time. Owners shall permit entry to its property for persons to perform the inspections.

(D) The application need not state, nor is it necessary to show, that the dam is a safe dam. The intent of the registration permit is to show that the dam is performing adequately and that there are no observable indications that the dam is unsafe.

(2) In addition to the basic requirements for all permits listed in 10 CSR 22-3.020(1), (2), (3) and (7), the registration permit application for an industrial water retention dam and reservoir shall include certification by an experienced professional engineer or an agency engineer that the dam and reservoir have been inspected in accordance with the law and that the owner has complied with the engineer's recommendations to correct observed defects and an inspection report, as required by the law. The engineer must further show that the spillway can safely pass the spillway design flood derived from Table 5 and submit a report describing the correction of any observed defects, the operation and maintenance program to be made a part of the registration permit and the phased, stepped and/or continuous construction of the dam.

(A) The inspection of an industrial water retention dam and reservoir for a registration permit is intended to detect observable defects. The procedure to determine observable defects normally will be a surface examination by an experienced professional engineer or an agency engineer. The inspection must include all surface examinations necessary to determine if observable defects exist that affect the stability of the dam and reservoir or the adequacy of the spillway. Judgment of the structural stability and an evaluation of the spillway capacity must be made. Judgment shall be based upon the engineer's experience, training and knowledge of similar dams and in accordance with practices reputable and in current use in the engineering, geologic and construction professions.

1. Observed defects which may require correction, evaluated on the basis of current engineering, geologic and construction practices, include but are not limited to slides; slopes as steep as or steeper than those on similar types of dams and constructed of similar materials which have experienced slope stability problems; piping of fines; seepage that exits in an uncontrolled fashion on the downstream slope of or from the downstream foundation of the dam; unusual zones of softness and irregular settlement; erosion on upstream or downstream slope of the dam; spillways that are calculated to be inadequate for the design flood; spillways that are eroded or otherwise in poor condition and cracks in the embankment or structure.

2. Observed defects that are in an advanced state of deterioration must be immediately reported by the inspecting engineer to the owner and to the chief engineer.

(B) Proper maintenance and operation of a dam and reservoir are critical to the continuing safety of a dam and reservoir and the protection of public safety, life and property. A maintenance program shall be required and shall include the following items: erosion control on the embankment; monitoring of storm runoff; vegetation control; spillway maintenance; emergency action plans; maintenance and monitoring of seepage observation devices, if any; and maintenance and monitoring of instruments used, if any, to observe the stability of the dam.

(C) The council or chief engineer may require the owner to submit a report describing the phased, stepped and/or continuous construction of an industrial water retention dam and reservoir, containing information on

the materials used, method of transport and placement of materials, the sequence and placement location of materials, spillway changes to be made, the anticipated final dimensions and configuration of the dam and the name, address and telephone number of the person(s) in responsible charge of this work.

(D) Visits for the purpose of inspecting during construction or enlargement or observation of maintenance and operation may be made by the council, the chief engineer or a member of the chief engineer's staff. Visits will be at any reasonable time following reasonable notice, except that in the case of an emergency threatening public safety, life or property, no such notice shall be required and inspection may be made at any time. Owners shall permit entry to its property for persons to perform inspection.

(E) It shall not be necessary for the owner to retain an experienced professional engineer or an agency engineer continuously during the entire permit period unless there is modification(s) in the construction method described in the permit application. However, personnel with adequate supervision and training in methods of safe construction, maintenance and operation of dams must be provided to insure that the construction maintenance and operation of the dam and reservoir are carried out as described.

(F) The registration permit will be the only permit required for an industrial water retention dam and reservoir that was in existence prior to the effective date listed in 10 CSR 22-2.020(2) unless it is to be reduced or removed. If the dam or reservoir is to be reduced or removed, a construction permit will be required. Other changes will require the owner to obtain a new registration permit.

(G) The applicant need not state, nor is it necessary to show, that the dam is a safe dam. The intent of the registration permit is to show that the dam is performing adequately and that there are no readily observable indications that the dam is unsafe and that phased, stepped and/or continuous construction of the dam will meet the requirements of the law.

AUTHORITY: sections 236.400, 236.405, 236.415, 236.420, 236.425, 236.440 and 236.465, RSMo 1986. Original rule filed April 14, 1981, effective Aug. 13, 1981. Amended: Filed June 14, 1984, effective Jan. 1, 1985.*

**Original authority: 236.400, RSMo 1979; 236.405, RSMo 1979, amended 1993, 1995; 236.415, RSMo 1979, amended 1995; 236.420, RSMo 1979; 236.425, RSMo 1979; 236.440, RSMo 1979; and 236.465, RSMo 1979.*

10 CSR 22-3.040 Construction Permit Requirements

PURPOSE: The purpose of this rule is to itemize the requirements for a construction permit.

(1) In addition to the basic requirements for all permits listed in 10 CSR 22-3.030, the construction permit application for a conventional dam and reservoir shall be prepared under the direction of and certified by an experienced professional engineer and shall be in accordance with practices reputable and appropriate in the engineering, geologic and construction professions.

(A) The following requirements shall apply to and the following information shall be provided by the owner:

1. Up-to-date topographic map(s) showing the location of the proposed or existing dam, the upstream watershed, the reservoir and the downstream environment zone. The topographic map(s) of the project area must be at a scale appropriate to the size of the project area. An up-to-date United States Geological Survey topographic map is considered a minimum;

2. Exploration records and results including the location of all exploration, especially in the area of the core trench, the method(s) used to explore the site, a record of what was found, the method(s) used to obtain samples and the number of samples taken;

3. Testing records and results including information on the care and treatment of samples, types of tests performed on samples or in situ, reference(s) to or the procedures used in testing and the test results. Physical and mechanical properties of foundation and construction materials must include the information source for these values especially if they are not the results of testing;

4. The geotechnical design procedure(s) or method(s) shall be identified and referenced or described so that they may be reviewed and the applicability verified. This shall include all assumptions made. The geotechnical procedure(s) or design results shall include the minimum computed factors of safety and they must meet or exceed the required design factors of safety (see 10 CSR 22-3.020(4)). The geotechnical design information shall be presented for the foundation, core trench and dam embankment. Earthquake loading must be analyzed as outlined in 10 CSR 22-3.020(5) and (6);

5. The structural design procedure(s) or method(s) shall be identified and referenced or described so that they may be reviewed and their applicability verified. Design results for concreted dams and concrete structures appurtenant to embankment dams shall provide for and show an adequate factor of safety for normal and maximum loading conditions of compression, tension, shear, torsion, buckling, sliding and overturning;

6. Hydrologic information used to evaluate the watershed, reservoir, spillway and downstream environment zone including the watershed area, rainfall rate and duration, antecedent moisture conditions, time of concentration, area capacity curves, description of spillway elevation(s), type(s), dimensions, locations, cross section and profiles, dam crest elevation and the downstream valley cross sections;

7. The hydrologic/hydraulic design procedure(s) or method(s) used shall be identified and referenced or described so that they may be reviewed and their applicability verified. This shall include all assumptions made. The hydrologic/hydraulic procedure(s) or design results shall include the reservoir inflow hydrograph, the reservoir outflow hydrograph, the spillway discharge capacity, the freeboard at the maximum water storage elevation and the environmental class of the dam. The dam shall be capable of safely containing or discharging the required design flood (see 10 CSR 22-3.020(5));

8. Location and design of diversion channels or other structures to control stream flow during or after construction shall be provided if failure of these channels or other structures would affect hydrologic conditions of the dam. Stream diversion systems used during construction shall be designed to provide protection to the dam and the safety of the public;

9. Construction control and inspection procedures shall be used during the construction of a new dam and reservoir or modification of an existing dam and reservoir. Construction control and inspection procedures should include compaction testing and density testing;

10. Procedures shall be used for recordkeeping and monitoring throughout the construction or modification process to provide information about any construction progress and conditions that may cause difficulties during construction;

11. The location of and protective measures used in conjunction with all drain lines, sewer lines, utilities or other structures that pass through or under the dam;

12. Topographic surveys showing the location of baselines, centerlines and other horizontal and vertical control points sufficiently accurate to locate the proposed construction and to define the volume of storage in the reservoir;

13. Two (2) sets of plans and specifications including—

A. Graphic scales shall be provided for all scaled drawings;

B. The title, which shall be identical on the plans and the specifications, shall include: the name of the dam; the name of the owner; whether the work shows an existing dam, a proposed dam or an enlargement, repair or alteration of the dam or reservoir; the county(ies) the dam and reservoir are in; the location of the dam by quarter section, section, township and range or by geodetic coordinates; and each sheet shall have in an appropriate title block the name of the dam as well as the sheet number in relation to the total, for example, sheet one (1) of twelve (12); and

C. Certifications by the experienced professional engineer and the owner shall be placed near the lower right-hand corner of the title sheet (first sheet) of the drawings. The certifications shall be similar to those presented in figures 1 and 2 (see figures 1 and 2); and

Figure 1

14. If a construction permit is requested to convert a dam to a retaining or retarding structure, the procedure to be followed in making the conversion shall be described by the owner; and

15. The procedures set up for regular inspection by the owner. The owner shall develop an emergency action plan, inspect his/her dam regularly and as necessary to protect public safety, life and property. A list of items to be inspected, a time schedule for these inspections and a form for reporting the results shall be established.

(B) The council or chief engineer may require the following action and information from the owner:

1. Procedures set up to provide regular maintenance and minor repairs to the dam and reservoir after construction and to continue or start recordkeeping and monitoring work so that the dam and reservoir are maintained in a safe condition and a complete history of its performance is available;

2. Location and types of instrumentation, drainage and/or seepage control facilities. Monitoring equipment and drainage and seepage control facilities are recommended for all dams and reservoirs, however, depending on conditions, they may be mandatory items if necessary to accomplish the purposes of the law;

3. The downstream environment zone warning procedure to be used if dam failure is a threat. A downstream environment zone warning system is recommended for all dams and reservoirs, however, depending on conditions, it may be necessary to accomplish the purposes of the law. This would consist of the current name(s) of the dam and reservoir owners representative(s) responsible for giving notification of a threat of failure and the current phone numbers of appropriate local police and other persons having emergency assistance authority;

4. Upstream slope protection from wave action; and

5. Additional actions or information as required to protect public safety, life and property and to accomplish the purposes of the law.

(C) Visits for the purpose of inspecting during or after construction or observation of operation and maintenance may be made by the council, the chief engineer or a member of the chief engineer's staff. Visits will be at any reasonable time following reasonable notice, except that in the case of an emergency threatening public safety, life or property, no notice shall be required and inspection may be made at any time. Owners shall permit entry to their property for persons to perform inspections.

(2) In addition to the basic requirements for all permits listed in 10 CSR 22-3.020, the construction permit application for an industrial water retention dam and reservoir shall be prepared under the direction of and certified by an experienced professional engineer and shall be in accordance with practices reputable and appropriate in the engineering, geologic and construction professions.

(A) The engineer who plans and designs an industrial water retention dam and reservoir or its modification shall assess the sequence, timing, method of placement and stability control program during construction from the beginning of the starter dam or modification through the life of the structure and after operation ceases or until the dam and reservoir no longer need a permit.

(B) Adequate records, as required by best practices in the geologic and engineering professions, shall be kept and made available to the council or chief engineer for the construction, maintenance and operation procedures. Adequate instrumentation and monitoring of seepage water shall be provided where necessary. Any significant settling or movement in the foundation of the dam should be measured if possible. Trained personnel and adequate supervision shall be provided to insure the construction and operation of the dam and reservoir are carried out to specifications.

(C) The following requirements shall apply to and the following information shall be provided by the owner:

1. A description of the system used to deposit tailings on the dam;

2. Up-to-date topographic map(s) showing the location of the proposed dam, the upstream watershed, the reservoir and the downstream environment zone. The topographic map(s) of the project area must be at a scale appropriate to the size of the project area. An up-to-date United States Geological Survey topographic map is considered minimum;

3. The location(s) of surface and underground mine workings if these workings would cause, would contribute to the cause or would be affected in the event of failure;

4. Exploration records and results including the location of all exploration, especially in the area of the core trench, the method(s) used to explore the site, a record of what was found, the method(s) used to obtain samples and the number of samples taken;

5. Testing records and results including information on the care and treatment of samples, types of tests performed on samples or in situ, reference(s) to or the procedures used in testing and the test results. Physical and mechanical properties of foundation and construction materials must include the information source for these values especially if they are not the results of testing;

6. The geotechnical design procedure(s) or method(s) shall be identified and referenced or described so that they may be reviewed and their applicability verified. This shall include all assumptions made. The geotechnical procedure(s) or design results shall include the minimum computed factors of safety and they must meet or exceed the required design factors of safety (see 10 CSR 22-3.020(4)). The geotechnical design information shall be presented for the foundation core trench and dam embankment. Earthquake loading must be analyzed as outlined in 10 CSR 22-3.020(5) and (6).

7. Type and physical properties of the liquid and solid materials to be used in construction of the dam and contained in the reservoir;

8. The changes created in the downstream environment zone as the dam and reservoir become incrementally larger;

9. The embankment changes and new factors of safety for stability as the dam and reservoir become incrementally larger;

10. If a starter dam is used, whether it will be pervious or impervious;

11. The expected crest elevation, dam configuration, spillway elevation and the size and configuration of each successive stage of the dam shall be included;

12. Anticipated storage volume of solid or semisolid materials and of liquids at the completion of the dam;

13. The structural design procedure(s) or method(s) shall be identified and referenced or described so that they may be reviewed and their applicability verified. Design results for concrete dams and concrete structures appurtenant to embankment dams shall provide for and show an adequate factor of safety for normal and maximum loading conditions of compression, tension, shear, torsion, buckling, sliding and overturning;

14. Hydrologic information used to evaluate the watershed, reservoir, spillway and downstream environment zone including the watershed area, rainfall rate and duration, antecedent moisture conditions, time of concentration, area capacity curves, description of spillway elevation(s), type(s), dimensions, locations, cross sections and profiles, dam crest elevation and the downstream valley cross sections;

15. Hydrologic/hydraulic design procedure(s) or method(s) used shall be identified and referenced or described so that they may be reviewed and their applicability verified. This shall include all assumptions made. The

hydrologic/hydraulic procedure(s) or design results shall include the reservoir inflow hydrograph, the reservoir outflow hydrograph, the spillway discharge capacity, the freeboard at the maximum water storage elevation and the environmental class of the dam. The dam shall be capable of safely containing or discharging the required design flood (see 10 CSR 22-3.020(5));

16. The hydrologic changes, the spillway alterations proposed and the freeboard changes as the dam becomes incrementally larger;

17. Location and design of diversion channels or other structures to control stream flow during or after construction shall be provided if failure of these channels or other structures would affect the stability or hydrologic conditions of the dam. Stream diversion systems used during construction shall be designed to provide protection to the dam and to protect public safety, life and property;

18. Location and design of any diversion channels or other structures to control runoff or reclaimed water;

19. Construction control and inspection procedures shall be determined by the engineer and used during the construction of a new dam and reservoir or modification of an existing dam and reservoir. Construction control and inspection procedures shall include compaction testing and density testing and any other quality control measures used to insure compliance with the construction specifications;

20. Procedures shall be used for recordkeeping and monitoring throughout the construction, enlargement or modification process to provide information about any construction progress and conditions that may cause difficulties during construction;

21. The location of and protective measures used in conjunction with all drain lines, sewer lines, utilities or other structures that pass through or under the dam;

22. Topographic surveys showing the location of baselines, centerlines and other horizontal and vertical control points sufficiently accurate to locate the proposed construction and to define the volume of storage in the reservoir at each planned stage of construction;

23. Two (2) sets of plans and specifications including:

A. Graphic scales shall be provided for all scaled drawings;

B. The title, which shall be identical on the plans and the specifications, shall include: the name of the dam; the name of the owner; whether the work shows an existing dam, a proposed dam or an enlargement, repair or alteration of the dam and reservoir; the county(ies) the dam and reservoir are in; the location of the dam by quarter section, section, township and range or by geodetic coordinates; and each sheet shall have in an appropriate title block the name of the dam as well as the sheet number in relation to the total, for example, sheet one (1) of twelve (12); and

C. Certification by the experienced professional engineer and the owner shall be placed near the lower right-hand corner of the title sheet (first sheet) of the drawing. The certifications shall be as presented in figures 1 and 2 (see figures 1 and 2 preceding);

24. If a construction permit is requested to convert a dam to a retaining or retarding structure, the procedure to be followed in making the conversion shall be described by the owner; and

25. The procedure set up for regular inspection by the owner. The owner shall develop an emergency action plan, inspect his/her dam and reservoir regularly and as necessary to protect public safety, life and property. A list of items to be inspected, a time schedule for these inspections and a form for reporting the results shall be established by the council or chief engineer. Items that shall receive maintenance to and/or inspections on a daily basis during periods of active dam enlargement include: the spigots or cyclones; the decant lines; the position of the water pool in relation to the spillway, decant intake and crest of the tailings dam; drain lines checked for quantity of water and sediment; the embankment observed for visual defects such as slides or significant seepage changes; the spillway shall be checked to verify that it has not become blocked.

(D) The council or chief engineer may require the following action and information from the owner:

1. Procedures set up to provide regular maintenance and minor repairs to the dam and reservoir during construction and enlargement so that the dam and reservoir are maintained in a safe condition and a complete history of its performance is available;

2. Location and types of instrumentation, drainage and/or seepage control facilities. Monitoring equipment and drainage and seepage control facilities are recommended for all dams and reservoirs, however, depending on conditions they may be mandatory items if necessary to accomplish the purposes of the law; a list of items to be inspected, a time schedule for these inspections and a form for reporting the results shall be established by the council or chief engineer;

3. The downstream environment zone warning procedure to be used if dam failure is a threat. A downstream environment zone warning system is recommended for all dams and reservoirs, however, depending on conditions, it may be necessary to accomplish the purposes of the law. This would consist of the current name(s) of the dam and reservoir owners representative(s) responsible for giving notification of a threat of failure and the current phone numbers of appropriate local police and other persons having emergency assistance authority;

4. Upstream slope protection from wave action; and

5. Additional actions or information as required to protect public safety, life and property and to accomplish the purposes of the law.

(E) Visits for the purpose of inspecting during or after construction or observation of operation and maintenance may be made by the council, the chief engineer or member of the chief engineer's staff. Visits will be at any reasonable time following reasonable notice, except that in the case of an emergency threatening public safety, life or property, no notice shall be required and inspection may be made at any time. Owners shall permit entry to their property for the persons to perform inspections.

(F) Drawings to show changes shall be submitted when changes are made to the original plans including, without limitation, changes in incremental dam crest heights, spillway locations and cross sections.

AUTHORITY: sections 236.400, 236.405, 236.415, 236.420, 236.425, 236.435, 236.440 and 236.465, RSMo 1986. Original rule filed April 14, 1981, effective Aug. 13, 1981. Amended: Filed June 14, 1984, effective Jan. 1, 1985.*

10 CSR 22-3.050 Safety Permit Requirements

PURPOSE: The purpose of this rule is to itemize the requirements for a safety permit.

(1) In addition to the basic requirements for all permits listed in 10 CSR 22-3.020, the safety permit application for a conventional dam and reservoir shall include:

(A) Notification of the completion of construction and application for the first safety permit for the dam and reservoir shall be provided by the owner. The experienced professional engineer or agency engineer who was

in responsible charge of the construction work shall certify that the construction was substantially in accordance with the approved plans and specifications. If revisions have been made which vary considerably from the provisions of the construction permit, it must be shown that the revisions do not endanger public safety, life or property. This subsection shall not be construed to excuse any person from the requirement to notify the council or chief engineer of modifications or revisions prior to commencing the actions and to obtain the required permits or authorization thereof;

(B) Notification of completion shall be within two (2)-months' time after completion of construction; and

(C) As-built drawings shall be submitted.

(2) In addition to the basic requirements for all permits listed in 10 CSR 22-3.020, the application for a safety permit for an industrial water retention dam and reservoir shall include:

(A) Notification of completion of the starter dam or the initial phase of construction shall be prepared by or under the supervision of an experienced professional engineer and shall indicate that construction was performed in accordance with the provisions of the construction permit.

(B) Notification of the completion of construction and application for the first safety permit for the dam and reservoir shall be provided by the owner. The experienced professional engineer who was in responsible charge of the construction work shall certify that the construction was substantially in accordance with the approved plans and specifications. If revisions have been made which vary considerably from the provisions of the construction permit, it must be shown that the revisions do not endanger public safety, life or property. This subsection shall not be construed to excuse any person from the requirement to notify the council or chief engineer or modifications or revisions prior to commencing the actions and to obtain the required permits or authorization therefore;

(C) Notification of completion shall be within two (2)-months time after completion of construction; and

(D) As-built drawings shall be submitted.

(3) Visits for the purpose of observation of operation and maintenance procedures may be made by the council, the chief engineer or a member of their staff. Visits will be at any reasonable time following reasonable notice, except that in the case of an emergency threatening public safety, life or property, no notice shall be required and inspection may be made at any time. Owners shall permit entry to their property for such persons to perform the inspections.

AUTHORITY: sections 236.400, 236.405, 236.415, 236.420, 236.425, 236.440 and 236.465, RSMo 1986. Original rule filed April 14, 1981, effective Aug. 13, 1981. Amended: Filed June 14, 1984, effective Jan. 1, 1985.*

**Original authority: 236.400, RSMo 1979; 236.405, RSMo 1979, amended 1993, 1995; 236.415, RSMo 1979, amended 1995; 236.420, RSMo 1979; 236.425, RSMo 1979; 236.440, RSMo 1979; and 236.465,RSMo 1979.*

Rules of
Department of Natural Resources
Division 22—Dam and Reservoir Safety Council
Chapter 4—Action Taken by Council and Chief Engineer

Title		Page
10 CSR 22-4.010	Emergency Action	3
10 CSR 22-4.020	Enforcement Orders and Enforcement Procedures	3

Title 10—DEPARTMENT OF NATURAL RESOURCES
Division 22—Dam and Reservoir Safety Council
Chapter 4—Action Taken by Council and Chief Engineer

10 CSR 22-4.010 Emergency Action

PURPOSE: The purpose of the rule is to define the way emergency action is taken.

(1) In performing his/her duties, the chief engineer shall determine by inspection whether a dam or reservoir constitutes a threat to public safety, life or property. If it is determined that a dam is in an advanced state of deterioration and in such condition that continued deterioration could cause failure of the dam, the chief engineer may classify the dam as dangerous to public safety, life or property. If the chief engineer or council further determines that there is not sufficient time to issue an enforcement order to the owner to correct the hazard, or to take other legal action, the chief engineer may take any appropriate action necessary for emergency protection of public safety, life or property. The type of action depends upon the state of progression of the deterioration, the physical layout of the dam, reservoir and inundation zone below the dam, and the resources available to the chief engineer or council at the time of the emergency.

(2) The chief engineer or council, upon determining that a dam or reservoir is dangerous and constitutes a substantial threat of failure and flooding, may request the attorney general or a prosecuting attorney to take any legal steps necessary for the protection of public safety, life or property. Action may be brought in any county where the defendant or defendant's principal place of business is located or where the dam or reservoir is located. Nothing in this section shall preclude the chief engineer or council from taking immediate action under 10 CSR 22-4.010(1) with respect to any dam or reservoir that has been classified as dangerous to public safety, life or property.

AUTHORITY: sections 236.400, 236.405, 236.420, 236.425 and 236.455, RSMo 1986. Original rule filed June 14, 1984, effective Jan. 1, 1985.*

**Original authority: 236.400, RSMo 1979; 236.405, RSMo 1979, amended 1993, 1995; 236.420, RSMo 1979; 236.425, RSMo 1979; and 236.455, RSMo 1979.*

10 CSR 22-4.020 Enforcement Orders and Enforcement Procedures

PURPOSE: The purpose of this rule is to identify the procedure to be taken for the issuance of enforcement orders.

(1) Enforcement orders shall be prepared by the chief engineer or council in cases where a dam or reservoir contains serious defects which pose a threat to public safety, life or property. Enforcement orders shall be sent to a dam owner by certified mail or served personally.

(2) If an owner does not initiate corrective actions to his/her dam and reservoir within thirty (30) days of the issuance of an enforcement order by the chief engineer or council, the council may request the attorney general or a prosecuting attorney to apply to the circuit court having jurisdiction to enforce compliance. Nothing in this section shall preclude the chief engineer from taking immediate action under 10 CSR 22-4.010(1) with respect to any dam or reservoir s/he has classified as dangerous to public safety, life or property.

AUTHORITY: sections 236.400, 236.405, 236.410, 236.415, 236.445 and 236.450, RSMo 1986. Original rule filed June 14, 1984, effective Jan. 1, 1985.*

**Original authority: 236.400, RSMo 1979; 236.405, RSMo 1979, amended 1993, 1995; 236.410, RSMo 1979, amended 1992; 236.415, RSMo 1979, amended 1995; 236.445, RSMo 1979; and 236.450, RSMo 1979.*

Missouri Revised Statutes

Chapter 236
Dams, Mills and Electric Power

August 28, 2010

Dams across nonnavigable streams--who may erect.

236.010. Any person or corporation chartered and organized to construct, operate and maintain mills, electric power and light works, or other machinery, may erect a dam across any watercourse, not being a navigable stream, if such person or corporation is the proprietor of the land through which the watercourse runs at the point where it is proposed to erect such dam, by proceeding as herein provided.

(RSMo 1939 § 10286)

Prior revisions: 1929 § 9157; 1919 § 7399; 1909 § 5456

Owner of land on one side of stream may erect dam.

236.020. Any person or corporation chartered and organized to construct, operate and maintain mills, electric power and light works, or other machinery, being the owner, in fee simple, of the land on one side of such watercourse, including a part of the bed of the stream, at a point where it is proposed to erect a dam, may, nevertheless, erect such dam by proceeding as herein provided.

(RSMo 1939 § 10287)

Prior revisions: 1929 § 9158; 1919 § 7400; 1909 § 5457

Petition to be filed in circuit court--contents.

236.030. In the case supposed in section 236.010, the person or corporation proposing to erect a dam shall file a petition in the circuit court of the county in which it is proposed to erect such mill, electric power and light works, or other machinery, in connection with the dam, and shall therein set forth:

(1) A description of the land and an abstract of the title thereto;

(2) The name of the watercourse, and a description of the point at which it is proposed to erect such dam;

(3) The altitude of the dam which it is proposed to erect; and

(4) The kind of mill, electric power and light works, or other machinery, which it is proposed to connect with the dam.

(RSMo 1939 § 10288)

Prior revisions: 1929 § 9159; 1919 § 7401; 1909 § 5458

Additional information to be set out.

236.040. In the case supposed in section 236.020, the person or corporation proposing to erect a dam shall file a petition as provided in section 236.030, and in addition thereto shall set forth:

(1) The name and place of residence of the owner of the land on the other side of the watercourse whereon to abut such dam;

(2) On what side of the watercourse it is proposed to erect such mill, electric power and light works, or other machinery in connection with the dam; and

(3) A prayer that the title to one acre of the land on the opposite side of such watercourse, to include the place where to abut such dam, may be decreed to such person or corporation, and that the same may be set apart by metes and bounds.

(RSMo 1939 § 10289)

Prior revisions: 1929 § 9160; 1919 § 7402; 1909 § 5459

Petition, where filed.

236.050. Such petition shall be filed in the circuit court of the county within which the petitioner proposes to erect such mill, electric power and light works, or other machinery.

(RSMo 1939 § 10290)

Prior revisions: 1929 § 9161; 1919 § 7403; 1909 § 5460

Writ of ad quod damnum.

236.060. Upon filing the petition, it shall be the duty of the court to cause a writ of ad quod damnum to be issued, under the seal of the court, directed to the sheriff, commanding him to summon twelve fit persons of his county to meet at the place where it is proposed to erect a dam, on a day to be named in the writ, then and there to inquire, by the said jury, touching the matters contained in the petition a copy of which shall accompany the writ.

(RSMo 1939 § 10291)

Prior revisions: 1929 § 9162; 1919 § 7404; 1909 § 5461

Duty of sheriff in executing writ.

236.070. The sheriff shall attend the jury on the day and at the place appointed, and upon full examination, inquire by such jury:

(1) What damage each proprietor will sustain by reason of inundation consequent upon the erection of the dam, as proposed;

(2) Whether the mansion house of any such proprietor, or the outhouses, curtilages or gardens thereto

immediately belonging, or orchard, will be overflowed thereby;

(3) Whether and to what extent ordinary navigation and the passage of fish will be obstructed by such erection, and whether and by what means the same may be prevented or diminished; and

(4) Whether the health of the neighborhood will be materially affected in consequence of such erection.

(RSMo 1939 § 10292)

Prior revisions: 1929 § 9163; 1919 § 7405; 1909 § 5462

Acre of ground to be set apart, when.

236.080. In the case supposed in section 236.020, the sheriff shall further inquire by the jury the value of the acre of land mentioned in the prayer of the petition, and set apart the same by metes and bounds.

(RSMo 1939 § 10293)

Prior revisions: 1929 § 9164; 1919 § 7406; 1909 § 5463

Proprietor to be notified of the inquest.

236.090. In such case the sheriff shall give the proprietor of the land whereof one acre is prayed for, a reasonable notice of the time and place when and where he will take the inquest of the jury, if such proprietor be in his county, and if not, he shall set up notice at the house of the tenant of such land, and if there be no actual tenant thereof, he shall set up such notice at some conspicuous place on the land.

(RSMo 1939 § 10294)

Prior revisions: 1929 § 9165; 1919 § 7407; 1909 § 5464

Sheriff and jury may act in adjoining county.

236.100. The sheriff and jury may enter and act in an adjoining county when necessary to the discharge of their duties.

(RSMo 1939 § 10295)

Prior revisions: 1929 § 9166; 1919 § 7408; 1909 § 5465

Inquest to be in writing.

236.110. The inquest of the jury shall be reduced to writing, signed by each of the jurors, and returned by the sheriff, together with the writ and a statement of the manner in which he executed it, into the court whence it issued, without delay.

(RSMo 1939 § 10296)

Prior revisions: 1929 § 9167; 1919 § 7409; 1909 § 5466

Proceedings on return of inquest.

236.120. Upon the return of such inquest and writ, any person aggrieved by the verdict of the jury may file his objections to the proceedings under such writ, and to the verdict, and show cause why the proceedings should be quashed and the verdict set aside.

(RSMo 1939 § 10297)

Prior revisions: 1929 § 9168; 1919 § 7410; 1909 § 5467

Issues to be tried as in civil cases.

236.130. The court may thereupon direct issues to be made up and tried as in other civil cases, and if good cause be shown therefor, the court shall quash the proceedings and set aside the verdict.

(RSMo 1939 § 10298)

Prior revisions: 1929 § 9169; 1919 § 7411; 1909 § 5468

Costs, how adjudged.

236.140. The costs attending the trial of such issues shall be adjudged against the unsuccessful party, as in other civil cases.

(RSMo 1939 § 10299)

Prior revisions: 1929 § 9170; 1919 § 7412; 1909 § 5469

Court may order new writ.

236.150. The court, on motion, may order a new writ of ad quod damnum to issue, for the purpose of having the damages assessed according to law.

(RSMo 1939 § 10300)

Prior revisions: 1929 § 9171; 1919 § 7413; 1909 § 5470

Court may enter order to erect dam, when.

236.160. If no objections be filed to the proceedings under the writ or to the verdict of the jury, and it shall appear to the court, upon a view of the inquest, that the mansion house of any proprietor, or the outhouse, curtilages or gardens thereto belonging, or orchard, will not be overflowed, and that the health of the neighborhood will not be materially affected by the stagnation of water consequent upon the proposed erection, the court shall thereupon grant or refuse the permission prayed for, according to its judgment of what would be most reasonable and just under all circumstances.

(RSMo 1939 § 10301)

Prior revisions: 1929 § 9172; 1919 § 7414; 1909 § 5471

Court shall include in its order, what.

236.170. When the party petitioning prays for an acre of land whereon to abut his dam, the court shall include in its order, if the petition is granted, a judgment vesting the title of such acre of land in the party petitioning, his heirs and assigns forever.

(RSMo 1939 § 10302)

Prior revisions: 1929 § 9173; 1919 § 7415; 1909 § 5472

Privilege to erect subject to certain conditions.

236.180. The judgment and order authorized by sections 236.160 and 236.170, and the rights and privileges thereby granted, shall, in all cases, be upon and subject to the conditions following:

(1) Such conditions in reference to the obstructions to the passage of fish and ordinary navigation, as the court shall think proper to impose;

(2) That all damages and valuations assessed and made by the jury shall be paid;

(3) That the dam and mills, electric power and light works, or other machinery, shall be commenced within one year, and finished and ready for business within three years from the date of the order of permission;

(4) That whenever the dam or mill, electric power and light works, or other machinery, shall be destroyed or materially impaired, the same shall be built or repaired within three years thereafter; but if the owner of such dam or mill, electric power and light works, or other machinery, shall be an infant, or of unsound mind, or imprisoned at the time such dam or mill, electric power and light works, or other machinery, shall be destroyed or materially impaired, then within three years after such disability is removed.

(RSMo 1939 § 10303, A. 1949 S.B. 1080)

Prior revisions: 1929 § 9174; 1919 § 7416; 1909 § 5473

CROSS REFERENCE:

Dam owners to maintain fishways--fish hatchery in lieu of fishway, 252.150

Land decreed for mill privileges to revert, when.

236.190. In case of noncompliance with any of the conditions concerning the building, rebuilding or repairing, where the land of another shall have been adjudged by the court for the purpose of an abutment, the same shall revert to and revest in the original owner, his assigns or legal representatives.

(RSMo 1939 § 10304)

Prior revisions: 1929 § 9175; 1919 § 7417; 1909 § 5474

Height of dam, how increased.

236.200. Any owner of any dam or mill, electric power and light works, or other machinery, erected by virtue of this or any previous law, may increase the altitude of his dam by permission of the court, under and by the same proceedings, regulations and conditions herein provided.

(RSMo 1939 § 10305)

Prior revisions: 1929 § 9176; 1919 § 7418; 1909 § 5475

Inquest not to bar right of action, when.

236.210. The inquest of the jury, or the order and permission of the court founded thereupon, shall not bar any prosecution or action for injuries caused by the erections herein contemplated, except such as were actually foreseen and estimated by the jury.

(RSMo 1939 § 10306)

Prior revisions: 1929 § 9177; 1919 § 7419; 1909 § 5476

Power of court to prevent erection of dam.

236.220. The circuit court of the proper county shall have power, upon petition, to prevent the erection or raising of any dam, stoppage, or obstruction across any stream which shall operate as a nuisance and be injurious to any mill, electric power and light works, or other machinery erected, or which shall dam up and render impure or unwholesome or unhealthy the waters of said stream at any point where water is or may be taken from said stream to supply the inhabitants of any city or town or village in the state with water, or of any dam, the erection of which has been authorized by the order of any competent tribunal, of a date earlier than that permitting the erection and raising of such first mentioned dam, stoppage or obstruction; and such court may, upon a final hearing of such petition, order and adjudge that such dam, stoppage or obstruction be abated by the sheriff of the proper county.

(RSMo 1939 § 10308)

Prior revisions: 1929 § 9179; 1919 § 7421; 1909 § 5478

Dams without chutes declared nuisances.

236.230. Every person who shall erect or maintain, or cause to be erected or maintained, in or across any of the waters of this state, unless said waters be wholly upon his own premises, any dam or other obstruction, no matter for what purpose, and shall not place and maintain thereon an apron or chute not less than fifteen feet wide, and sloping from each side to the center, so that the center shall be at least six inches lower than either edge, and having an inclination of not more than forty-five degrees, and so situated that the main current of water, impeded in its natural flow by the dam or other obstruction, shall pass over the same, or who shall not so construct or arrange such dam or other obstruction that it shall be lowest at the point where the apron or chute shall be placed, and low enough for the free passage of fish over the same each way, whenever the stream in which the same shall be situate shall be swollen beyond its ordinary size, shall be guilty of a misdemeanor, and shall be held to be guilty of a distinct offense each day he shall be in default as aforesaid; and every dam or other obstruction erected or maintained in violation of this section, shall be a public nuisance, and may be abated as such.

(RSMo 1939 § 10312)

Prior revisions: 1929 § 9183; 1919 § 7425; 1909 § 5482

Dams deemed public nuisances, when.

236.240. All dams, stoppages and obstructions not made according to law shall be deemed to be public nuisances, and may be dealt with as such.

(RSMo 1939 § 10309)

Prior revisions: 1929 § 9180; 1919 § 7422; 1909 § 5479

Forfeiture of rights, when.

236.250. If any person or corporation, or his or its legal representatives, to whom permission to erect a dam by virtue hereof shall have been given, shall fail to build, rebuild or repair the same, together with the mill, electric power and light works, or other machinery connected therewith, according to the requirements of law or the conditions of the permission, it shall be lawful for any person owning the land on one side of the watercourse, at the point where such dam is erected, or below, to build a dam and mill, electric power and light works, or other machinery thereon, as if no such permission had been given, without incurring any liability on account of backing the water on such dam.

(RSMo 1939 § 10310)

Prior revisions: 1929 § 9181; 1919 § 7423; 1909 § 5480

Dam reconstructed and maintained when used for other purposes.

236.255. In any case where a dam has been erected for a period of thirty years or more, and property above the dam within one mile of the point where the dam is situated has been developed for use of the impounded waters above the dam, the owner of the land on either side of the stream at the point where the dam is located shall have the right and authority to repair, maintain or reconstruct the dam, even though the dam is not used for the operation of any mill, electric power and light works, or other machinery.

(L. 1953 p. 669)

Privilege to construct dam to cease, when.

236.260. If the improvement of the navigation of any stream shall be undertaken by the state, or by any county, or other lawful authority under the state, then the privilege of keeping any dam across such stream, the right to construct which may be hereafter granted, shall cease, if the same would prevent or obstruct the making of such improvement; and it shall be the duty of the owner or owners of such dam, either to remove it or to make such change in the same as will render the navigation safe and convenient, according to the plan of such improvement; said change or alteration in such dam shall be so constructed as to be approved of by the proper officers or agents who shall have the superintendence of the improvement of such stream.

Prior revisions: 1929 § 9182; 1919 § 7424; 1909 § 5481

Penalty for building without permission.

236.270. Any person who shall build or heighten any dam, or any other stoppage or obstruction on or across any watercourse, without first obtaining permission from the court of the proper county, according to law, and shall thereby work any injury to any other person, shall forfeit to the party injured double damages for such injury, to be recovered by civil action.

(RSMo 1939 § 10307)

Prior revisions: 1929 § 9178; 1919 § 7420; 1909 § 5477

Right to divert stream through tunnel--conditions.

236.280. Any person or persons, firm or firms, corporation or corporations, owning lands extending across the neck of any bend in any of the rivers of this state where a tunnel through such bends would create a waterfall to create electric power, that such owner or owners shall have the right to tunnel through such bends in such neck, on his or their or its own land or lands, and take up and divert and transmit and use the waters of said river (leaving enough water in said river at the point where said diversion shall be made to meet the wants of stock and the families below such point of diversion), and use the waters so diverted to create electric power for transmission and sale to the public, and then return such waters to said river again, without the consent of the riparian owners thereof owning shore lands on the inside and outside of said bend, between the intake and output points of said tunnel, by the use of the usual condemnation proceedings in the circuit court of the county of this state in which said lands, or a part thereof, are, or may be situated, to ascertain and establish the damage that will accrue to such owner or owners of said riparian rights by reason of the use and license aforesaid, and after this has been established and decreed, and that the judgment so awarded shall be paid before diverting and using said waters.

(RSMo 1939 § 10313)

Prior revisions: 1929 § 9184; 1919 § 7426; 1909 § 5483

Definitions.

236.400. As used in sections 236.400 to 236.500, standards, rules and regulations promulgated hereunder, unless the context otherwise requires the following words and terms mean:

(1) "Agricultural dam", any dam constructed to impound water for use in irrigation, livestock watering, or commercial fish rearing and sale;

(2) "Alterations", "repairs", or either of them, such alterations or repairs as affect the safety of a dam or reservoir, or public safety, life or property;

(3) "Chief engineer", the head of the dam and reservoir safety program of the department of natural resources or his representative;

(4) "Construction permit", a written authorization issued by the council giving the owner the right to construct, alter, enlarge, reduce, repair or remove a dam or reservoir or appurtenances thereto, with such conditions as are necessary to adequately protect the public safety, life, property, the dam or reservoir;

(5) "Dam", any artificial or manmade barrier which does or may impound water, and which impoundment has or may have a surface area of fifteen or more acres of water at the water storage elevation, or which is thirty-five feet or more in height from the natural bed of the stream or watercourse measured at the downstream toe of the barrier or dam, if it is not across a streambed or watercourse, together with appurtenant works. Sections 236.400 to 236.500 shall not apply to any dam which is not or will not be in excess of thirty-five feet in height or to any dam or reservoir licensed and operated under the Federal Power Act;

(6) "Dam and reservoir safety council", as designated by sections 236.400 to 236.500 and referred to as the "council" shall consist of seven members appointed by the governor according to the provisions of sections 236.400 to 236.500;

(7) "Director", the director of the department of natural resources of the state of Missouri;

(8) "Enlargement", any change in or addition to an existing dam or reservoir which raises the height of a dam, increases the watershed for a reservoir, or raises the water storage elevation of the water impounded by a dam or reservoir;

(9) "Experienced professional engineer", an engineer registered in the state of Missouri and experienced in hydraulics, hydrology and civil engineering as applied to dam design and construction;

(10) "Maintenance", the proper keeping of all aspects of a dam or reservoir and appurtenances thereto, that pertain to safety, in a state of repair and working order as necessary to comply with sections 236.400 to 236.500, any permit hereunder, and protect public safety, life and property;

(11) "Natural physical changes", those changes not directly or indirectly caused by man which affect the safety of the dam or reservoir;

(12) "Operation", the physical changes, natural or manmade that occur or are made to a dam or reservoir, or operation of the mechanisms or appurtenances of the dam or reservoir, which affect or may affect public safety, life or property;

(13) "Owner", a person who owns, controls, operates, maintains, manages, or proposes to construct a dam or reservoir including:

(a) The state and its departments, institutions, agencies, and political subdivisions, but not the United States government;

(b) A municipal or quasi-municipal corporation;

(c) A district;

(d) A public utility;

(e) A natural person, firm, partnership, association, corporation, political subdivision, or legal entity;

(f) The duly authorized agents, lessees, or trustees of any of the foregoing;

(g) Receivers or trustees appointed by any court for any of the foregoing;

(14) "Permit", a construction, safety or registration permit;

(15) "Permit applicant", an owner who applies for a construction, safety or registration permit;

(16) "Reduction", any decrease in the height of a dam, watershed size, or water storage elevation of the water

impounded by a dam or reservoir;

(17) "Registration permit", a permit issued for a period not to exceed five years by the council to the owner of a dam or reservoir in existence on September 28, 1979, or which becomes subject to the provisions of sections 236.400 to 236.500 for such dams and reservoirs which are in a properly maintained condition or which have made and complied with recommendations for corrections of observed defects of the dam or reservoir and have been* examined and approved in accordance with sections 236.400 to 236.500 and standards, rules and regulations and guidelines issued pursuant to sections 236.400 to 236.500;

(18) "Reservoir", any impoundment which results from a dam as defined in sections 236.400 to 236.500;

(19) "Safety permit", a permit issued to the owner for a period of five years, or less if safety considerations so require, by the council indicating that the dam meets the requirements of sections 236.400 to 236.500 and the guidelines, standards, rules and regulations issued pursuant to sections 236.400 to 236.500, and containing such conditions as to operations, maintenance and repair as are necessary to adequately protect public safety, life and the dam or reservoir;

(20) "Water", water, other liquid or tailings;

(21) "Water storage elevation", that elevation of water surface at the principal spillway which could be obtained by the dam or reservoir were there no outflow and were the reservoir full of water;

(22) "Watershed", the area, usually expressed in acres of square miles, that contributes or may contribute surface water to a reservoir.

(L. 1979 H.B. 603 § 1)

*Words "have been" not in original rolls.

Employment of engineer and assistants--records--rulemaking, procedure.

236.405. 1. There is hereby created a dam and reservoir safety program in the department of natural resources. The council shall promulgate rules, regulations, guidelines, and standards relating to the determination of whether a dam or reservoir constitutes a danger to public safety, life or property to be effective upon approval by the director.

2. The director of the department of natural resources shall employ an experienced professional engineer as chief engineer and assistants to administer the activities of the dam and reservoir safety program.

3. The chief engineer shall be selected under the state merit system on the basis of professional experience directly related to the design and construction of dams and reservoirs.

4. The findings, opinions, and orders of the council and the chief engineer shall be kept as permanent public records in the offices of the department of natural resources.

5. No rule or portion of a rule promulgated under the authority of sections 236.400 to 236.500 shall become effective unless it has been promulgated pursuant to the provisions of section 536.024.

(L. 1979 H.B. 603 § 2, A.L. 1993 S.B. 52, A.L. 1995 S.B. 3)

Council established--members, terms, qualifications, officers--meetings--quorum--

compensation.

236.410. 1. There is hereby created a "Dam and Reservoir Safety Council", whose domicile for the purposes of sections 236.400 to 236.500 shall be the department of natural resources of the state of Missouri, for the regulation of dam and reservoir safety. The council shall consist of seven members, no more than four of whom shall be members of the same political party, appointed by the governor with the advice and consent of the senate.

2. The members of the council shall have a background of academic training or professional experience directly related to the design of dams and reservoirs. At least two members of the council shall be professional engineers registered in the state of Missouri, one of whom shall represent the general public; at least one member shall be an engineering geologist; at least one member, in addition to the professional engineer, shall be a representative of the general public; two members shall be from industry, one of whom shall be earthmoving contractors; and one member shall be the owner of a dam or reservoir. The members shall serve for a term of two years; except, of the first appointments three shall be appointed for one year. The governor shall fill any vacancy on the council and may remove any appointed member for cause. The council shall annually elect a chairman and vice chairman from among its members. The council shall meet regularly but not less than quarterly. Special meetings and hearings may be called upon delivery of written notice to each member of the council signed by the director, the chief engineer, the council chairman or four of the council members. Four members of the council shall constitute a quorum to transact the business of the council. The council shall decide all questions by a majority vote of those present and constituting a quorum. The members of this council shall not receive any compensations other than for actual travel and subsistence when acting officially as members of the council.

(L. 1979 H.B. 603 § 3, A.L. 1992 H.B. 1634)

Council's powers and duties--public hearings required--adoption of rules and regulations, procedure.

236.415. 1. The council considering recommendations of the chief engineer shall, subsequent to a public meeting, adopt, subject to the approval of the director, the general technological guidelines and the standards, guidelines, rules and regulations applicable to permits, the design, construction, maintenance, operation, alteration, repair, enlargement, reduction, removal or natural physical changes that may occur to a dam or reservoir. Violations of guidelines, standards, rules and regulations are violations of sections 236.400 to 236.500 permitting the revocation, suspension, or refusal to issue any permit required by sections 236.400 to 236.500. No standards, guidelines, rules, or regulations shall be adopted, or any amendment or repeal thereof shall be effective, except after a public hearing to be held after thirty days' prior notice by advertisement or press release, and publication as required in chapter 536 of the date, time and place of the hearing and opportunity given to the public to be heard.

2. At the hearing, opportunity to be heard by the council with respect to the subject thereof shall be afforded any interested person upon written request to the council, addressed to the chief engineer, received not later than seven days prior to the hearing and may be afforded to other persons if convenient. In addition, any interested person, whether or not heard, may submit, within seven days subsequent to the hearings, a written statement of his views. The council may solicit the views, in writing, of persons who may be affected by, or interested in, proposed rules and regulations, standards or guidelines. Any person heard or represented at the hearing or making written request for notice shall be given written notice of the action of the council with respect to the subject thereof.

3. The council upon hearing the recommendations of the chief engineer and reviewing the application for a construction or registration permit shall approve or deny the permit application. The council may delegate authority to approve or deny permit applications to the chief engineer, whose actions shall be subject to appeal to the council as provided in subsection 2 of section 236.425.

4. No standard, rule or regulation or guideline, or amendment or repeal thereof, adopted by the council shall be in force and effect until it has been approved in writing by the director and the requirements of chapter 536 are satisfied. The affirmative vote of at least four members of the council shall be required for adoption.

(L. 1979 H.B. 603 § 4, A.L. 1995 S.B. 3)

Inspection of dams and reservoirs, when--report on conditions.

236.420. The council, with the advice and assistance of the chief engineer, shall carry out a state program of inspection of dams and reservoirs in accordance with regulations adopted by the council. All dams and reservoirs in this state shall be inspected on a periodic basis to determine if they constitute a threat to public safety, life or property. The chief engineer shall submit reports to the director and the council concerning the condition of each dam or reservoir inspected, and recommendations as to any alterations or repairs needed.

(L. 1979 H.B. 603 § 5)

Chief engineer's duties--search warrants--council to hear certain appeals.

236.425. 1. The chief engineer shall administer the provisions of sections 236.400 to 236.500 by:

(1) Recommending general technological guidelines that pertain to the design, construction, maintenance, operation, use, alteration, repair, enlargement, reduction, or natural physical changes of, or that may occur to, a dam or reservoir including their removal; except that, detailed technical specifications shall not be promulgated to regulate the design, construction, operation, maintenance, use, alteration, repair or removal of a dam or reservoir. Such guidelines shall not be effective until adopted by the council and approved by the director at a public meeting, after notice requirements set forth in subsection 1 of section 236.415 herein have been satisfied;

(2) Making* recommendations concerning the issuing, continuing in effect, revoking, modifying, suspending, or denying, under such conditions as prescribed by sections 236.400 to 236.500 and such rules as may be adopted to protect public safety, life, property, dams and reservoirs, construction permits for the construction, alteration, enlargement, reduction, repair or removal of dams or appurtenances thereto, and safety and registration permits to insure continuing protection of public safety, life, property, dams and reservoirs, for all dams subject to the provisions of sections 236.400 to 236.500;

(3) Making such investigations, including hearings, as are proper to protect public safety, life and property from an unsafe dam or reservoir, and to determine whether any permits should be issued, continued, revoked, modified, suspended, or denied or whether any violations of sections 236.400 to 236.500, standards, or rules or regulations have occurred or are occurring;

(4) Entering, at any reasonable time, any private or public premises as necessary to make an investigation or inspection of a dam or reservoir, or records kept, pertaining thereto, and such inspection shall follow reasonable notice to the owner given prior to such investigation or inspection except in the case of an emergency threatening public safety, life or property, in which case such inspection or investigation may be made without prior notice. A suitably restricted search warrant, upon a showing of probable cause in writing and upon oath, shall be issued by any judge having jurisdiction, to the chief engineer or his representative for the purpose of enabling him to make the inspection.

2. The council shall meet with or hear the appeal of a permit applicant and his representative upon request of the permit applicant if the chief engineer has rejected the application for a construction, safety or registration permit.

(L. 1979 H.B. 603 § 6)

*Words "To make" appear in original rolls.

Employees, council to provide for.

236.430. The council shall retain, employ, provide for and compensate within appropriations available therefor, such consultants, assistants, and other employees on a full- or part-time basis as may be necessary to carry out the provisions of sections 236.400 to 236.500 and prescribe the times at which they shall be appointed and their powers and duties.

(L. 1979 H.B. 603 § 7)

Permits required, when, procedure to obtain--chief engineer to make recommendation--exemptions--plans to be filed.

236.435. 1. Prior to the commencement of the construction, alteration, enlargement, reduction or removal of a dam or reservoir, the owner shall apply to the council and upon satisfying the requirements of sections 236.400 to 236.500 and the rules, regulations and standards promulgated pursuant hereto, obtain a construction permit.

2. The application for a construction permit shall bear the seal and signature of an experienced professional engineer registered in Missouri or employed by a qualified engineering division of a state or federal agency regularly engaged in dam construction for soil and water conservation, or irrigation or relating to wildlife conservation and shall be accompanied by the design report and plans and specification of the proposed design, alteration, enlargement, reduction, repair or removal of the dam or reservoir.

3. Any person constructing or owning a dam or reservoir, or living or owning property in an area affected, or whose safety may be affected by such dam or reservoir may consult with the chief engineer concerning such dam or reservoir.

4. The council upon hearing the recommendation of the chief engineer shall approve or deny an application for a construction permit within forty-five days after its receipt or the completion of any hearings in connection with such application, whichever is later. The permit shall be issued upon the receipt of the application if, in the judgment of the council, requirements of sections 236.400 to 236.500 and all standards, rules and regulations hereunder are satisfied and the design will be adequate to protect the public safety, life and property.

5. The council upon hearing the recommendation of the chief engineer may reject the application if it decides that there is insufficient information to determine the safety of the proposed construction, alteration, enlargement, reduction or removal of the dam or reservoir or that the construction, alteration, enlargement, reduction or removal of the dam or reservoir would endanger public safety, life or property, or otherwise not comply with sections 236.400 to 236.500 and any rules, standards, guidelines and regulations adopted hereunder.

6. A landowner who now owns or proposes to construct an agricultural dam or reservoir which will be used primarily for agricultural purposes will be exempt from all provisions of sections 236.400 to 236.500. If the council with the advice of the chief engineer, determines that the dam or reservoir is no longer used primarily for agricultural services, it shall become subject to the provisions of sections 236.400 to 236.500.

7. Dams or their construction, alterations, enlargements, reductions or removals designed by, and their construction, alteration, enlargement, reduction or repair or removal monitored by, a qualified engineer regularly engaged in dam construction for soil and water conservation or irrigation or relating to wildlife conservation are for the purposes of such construction or other listed actions exempt from the provisions of this section except that the plans for the dam shall be filed with the chief engineer prior to construction, or other listed action. Amended plans shall be filed at the completion of construction or other listed action if there have been significant

deviations from the previously filed plans.

(L. 1979 H.B. 603 § 8)

Owner to notify council, when--council to issue safety permit--registration of existing dams, when--violations.

236.440. 1. The owner shall notify the council upon completion of construction, alteration, enlargement, or reduction of the dam or reservoir. This notification shall bear the seal and signature of an experienced professional engineer and shall be accompanied by an application for a safety permit. The owner of any dam or reservoir subject to the provisions of sections 236.400 to 236.500 shall obtain a safety permit following completion of construction.

2. Upon receipt of complete and proper application for a safety permit, including notification of completion by the owner and certification by an experienced professional engineer that the new construction, alteration, enlargement or reduction has been completed in accordance with the provisions of the construction permit and sections 236.400 to 236.500, the council shall upon receipt of the application issue a safety permit. The council upon advice of the chief engineer may deny the application if it determines that violations of the construction permit or sections 236.400 to 236.500 exist. If revisions have been made which vary substantially from the provisions of the construction permit, it must be shown that the revisions do not endanger public safety, life or property. The safety permit for dams constructed pursuant to a construction permit issued under sections 236.400 to 236.500, may contain conditions the council upon advice of the chief engineer determines are necessary for the protection of public safety, life and property and a schedule and timetable for the dam and reservoir to achieve compliance with the construction permit and provisions of sections 236.400 to 236.500, standards, rules and regulations promulgated hereunder, but such conditions shall not be more stringent or restrictive than those contained in the construction permit.

3. Owners of dams and reservoirs in existence on September 28, 1979, shall obtain registration permits for dams of fifty to seventy feet in height within four years, and for dams up to fifty feet in height within six years of September 28, 1979, or as otherwise required by the provisions of sections 236.400 to 236.500 and rules and regulations adopted hereunder. A registration permit shall be issued by the council upon the advice of the chief engineer for dams and reservoirs only after it is determined that the dam meets the standards of sections 236.400 to 236.500 and rules and regulations hereunder, and any recommendations made by the inspecting engineer pursuant thereto.

4. Upon complete and proper application for a registration permit, on forms provided by the department of natural resources, by the owner of a dam in existence upon September 28, 1979, including a certification by an experienced professional engineer or an engineering division of a state or federal agency regularly engaged in dam construction for soil or water conservation, irrigation, or relating to wildlife conservation, that the dam has been inspected in accordance with sections 236.400 to 236.500, standards, rules and regulations and guidelines promulgated hereunder, and that the owner has complied with the inspecting engineer's or agency's recommendations necessary to correct observed defects of the dam or reservoir, the council shall, upon receipt of the application, issue a registration permit. The council upon hearing the recommendations of the chief engineer may deny the application if it determines that the owner has not complied with the inspecting engineer's or agency's recommendations.

5. For dams for which construction was completed prior to the effective date of the construction permit requirements hereunder, the registration permit may contain conditions the council upon hearing recommendations of the chief engineer determines to be necessary to bring the dam and reservoir into compliance with sections 236.400 to 236.500 and standards, rules and regulations promulgated hereunder.

6. If a dam or reservoir has been removed by the owner, the council shall issue a final approval upon notification by the owner and receipt of certification by an experienced professional engineer that the removal has been

carried out in accordance with the provisions of the construction permit issued for such removal. Failure to obtain final approval shall be a violation of sections 236.400 to 236.500.

7. The council shall issue safety permits for dams or their construction, alterations, enlargements, reductions or removals designed by, and their construction or other listed actions monitored by, a state or federal agency engaged in dam construction for soil and water conservation, irrigation or relating to wildlife conservation provided the owners obtain from such agency and file with the chief engineer a statement upon completion of the construction or other listed actions and at not greater than five year intervals, and with every application for renewal of a safety permit, that the dam conforms to the plans on file with the chief engineer and is in a safe, properly maintained condition.

8. The owner shall apply for renewal of a safety or registration permit not less than sixty days prior to expiration of the previously issued permit. The chief engineer shall determine if the dam and reservoir are essentially as described in the latest permit issued for that dam and reservoir, whether they satisfy the requirements of sections 236.400 to 236.500 and any rules, regulations, standards and guidelines adopted pursuant to sections 236.400 to 236.500 and whether any inspection conducted in connection with the permit renewal reveals any defect in the dam or reservoir which would threaten public safety, life or property. Unless the chief engineer determines that the dam and reservoir are not properly maintained, do not satisfy the requirements of the permit, act* or rules, regulations, standards and guidelines promulgated hereunder, or that defects revealed by the inspection are not corrected, the council upon hearing the recommendations of the chief engineer shall issue or renew the safety or registration permit upon forty-five days of the receipt of a complete and proper application. The council may require the owner to furnish a certification, as a part of an application to renew a permit hereunder, by an experienced professional engineer or a qualified engineering division of a state or federal agency regularly engaged in dam construction for water conservation, irrigation or relating to wildlife conservation that the dam is in a properly maintained condition and that any recommendation for correction of defects which violate sections 236.400 to 236.500, guidelines, rules, regulations and standards hereunder or which threaten public safety, life or property have been complied with and that the engineer detected no other such defects which have not been corrected.

9. If a barrier or water impoundment becomes a dam or reservoir through alteration or enlargement as defined herein, it shall be subject to the provisions of sections 236.400 to 236.500.

10. Failure to obtain and comply with a permit as required in this section is a violation of sections 236.400 to 236.500.

(L. 1979 H.B. 603 § 9)

*Word "act" apparently refers to "this act", now §§ 236.400 to 236.500.

Permit may be suspended--alteration or removal may be required--violation.

236.445. 1. If it is found that a dam or reservoir presents a threat to public safety, life or property, or that the safety of the dam or reservoir is threatened, the permit for the dam or reservoir shall be suspended and shall be reinstated only when the owner at his expense has completed the necessary alteration or has established such operational procedures as the council upon hearing the recommendations of the chief engineer deems necessary for protection of the public safety, life, property, the dam or reservoir. If necessary for such protection, the council may require the owner at his expense to remove the dam or reservoir, or if the owner refuses or neglects to act, the state may alter or remove the dam or reservoir, and the chief engineer may recover the costs of such action as provided in section 236.450.

2. If the owner refuses to alter or remove a dam or reservoir as directed when found to be a threat as set forth in sections 236.400 to 236.500, he shall be in violation of sections 236.400 to 236.500 and the permit requirements hereunder, and such action shall subject the owner to the enforcement provisions contained herein and revocation

of the permit.

(L. 1979 H.B. 603 § 10)

Removal or repair of abandoned dam--recovery of expenses.

236.450. An existing dam or reservoir which the chief engineer determines to be abandoned and considered to be a threat to public safety, life, or property may be altered, repaired, or removed upon such determination at the expense of the state of Missouri, and the chief engineer may request either the attorney general or a prosecuting attorney to bring an action in the name of the people of the state of Missouri to recover such expenses from the owner through appropriate legal processes. Such action may be brought in any county where the defendant or defendant's principal place of business is located or where the dam or reservoir is located.

(L. 1979 H.B. 603 § 11)

Emergency action authorized.

236.455. If it is determined at any time that the condition of a dam or reservoir is an imminent and substantial threat, and so dangerous to public safety, life or property as not to permit time for issuance of an enforcement order to correct the hazard, the chief engineer may take any appropriate action not prohibited by the constitution or laws of this state he deems necessary for emergency protection of public safety, life or property, and may request the attorney general or a prosecuting attorney to take any legal steps necessary to accomplish such action and to recover the cost of such measures from the owner by appropriate legal action.

(L. 1979 H.B. 603 § 12)

Transfer of ownership, notice required.

236.460. The owner shall notify the chief engineer upon the sale or other transfer of interest in a dam or reservoir, either existing or under construction, alteration or removal. The construction, safety or registration permit shall be transferred to the successive owner upon receipt of this notification and upon determination that such transfer will not endanger public safety, life, property, the dam or reservoir.

(L. 1979 H.B. 603 § 13)

Industrial water retention structures subject to provisions of sections 236.400 to 236.500--inspection--changes.

236.465. Irrespective of any other provisions of sections 236.400 to 236.500, the following provisions shall apply to the construction, alteration or enlargement of tailing, slime and settling ponds and to other similar industrial water retention structures included within the definitions of dam or reservoir in section 236.400:

(1) Applications for construction, safety or registration permits shall be submitted as provided in section 236.435 and section 236.440 except that design plans and specifications which outline any anticipated enlargement of the industrial water retention structure shall be included;

(2) It shall not be necessary to reapply for a permit each time the structure is enlarged if the enlargement plans

have been submitted in and approved with the original application, and the provisions of subdivision (3) of this section have been satisfied;

(3) Upon notification of the chief engineer, bearing the seal and signature of an experienced professional engineer, that the initial phase of construction has been completed in accordance with the provisions of the construction permit and sections 236.400 to 236.500, or if a registration permit has been issued as provided in subdivision (1) of this section, and before any enlargement is begun, and if no violation of sections 236.400 to 236.500 can be shown, a safety permit or a registration permit with special provisions that authorize the planned enlargement to the initially constructed structure shall be issued, on application, if enlargement plans were included and approved in the original application;

(4) It is not necessary to retain continuously a professional engineer after the initial stage of construction;

(5) The dam shall be inspected by an experienced professional engineer registered in the state of Missouri as required to renew the safety permit or registration permit at five-year intervals unless safety of the public, life and property require a shorter period of time;

(6) The chief engineer shall make inspections of these structures as necessary to insure adequate protection for public safety, life and property;

(7) Where it is shown that a tailings, slime and settling pond, or other similar water retention structure is subject to inspection for safety, using standards at least as stringent as those required under sections 236.400 to 236.500, by a federal or state agency and the owner notifies the council that the structure is subject to such inspection, such structures shall be exempt from the provisions of sections 236.400 to 236.500.

(L. 1979 H.B. 603 § 14)

Conduct of hearings--subpoenas--approval of final orders.

236.470. 1. At any public hearing all testimony taken before the council, or a hearing officer appointed by the council chairman, shall be under oath and recorded stenographically. The transcript so recorded shall be made available to any person upon payment of the usual charge therefor.

2. In any such hearing, any member of the council or the hearing officer shall issue in the name of the council notice of hearing and subpoenas. Subpoenas shall be issued and enforced as provided in section 536.077. The rules of discovery that apply in any civil case apply to hearings held by the council.

3. All hearings to approve, amend or repeal guidelines, standards or rules and regulations shall be held before at least four members of the council.

4. All other hearings may be held before one council member designated by the council chairman or a hearing officer who shall be a member of the Missouri bar and appointed by the council chairman. The hearing officer or council member shall preside at the hearing and hear all evidence and rule on the admissibility of evidence. The hearing officer or council member shall make recommended findings of fact and may make recommended conclusions of law to the council.

5. All final orders or determinations or other final actions by the council shall be approved in writing by at least four members of the council. Any council member approving in writing any final order or* determination or other final action, who did not attend the hearing, shall do so only after reviewing all exhibits and reading the entire transcript.

(L. 1979 H.B. 603 § 15)

*Word "of" appears in original rolls.

Immunity of officers.

236.475. In the absence of willful and wanton misconduct, no action shall be brought against the council, the chief engineer or his agents, or department employees or private individuals employed as consultants by the department for the recovery of damages caused by the partial or total failure of any dam or reservoir or through the use or operation of any dam or reservoir upon the ground that such person is liable by virtue of any of the following:

(1) The approval of a dam or reservoir or permits therefor;

(2) The issuance or enforcement of orders relating to maintenance, operation or repair of a dam or reservoir;

(3) Control and regulation of a dam or reservoir;

(4) Measures taken to protect against failure during an emergency.

(L. 1979 H.B. 603 § 16)

Judicial review of actions--administrative review required--interpretation of administrative actions.

236.480. 1. All final decisions, orders, actions or determinations made pursuant to the provisions of sections 236.400 to 236.500 are subject to judicial review pursuant to the provisions of chapter 536. No judicial review shall be available, however, until all administrative remedies are exhausted.

2. In any suit filed pursuant to section 536.050 concerning the validity of the standards, rules, guidelines and regulations promulgated hereunder, the court shall review the record made pursuant to their adoption to determine the validity and reasonableness of such standards, rules, guidelines and regulations and may hear such additional evidence as it deems necessary.

(L. 1979 H.B. 603 § 17)

Water rights preserved.

236.485. The provisions of sections 236.400 to 236.500 do not grant or diminish any right to that water entering, discharged from or impounded by a dam or contained in a reservoir.

(L. 1979 H.B. 603 § 18)

Enforcement of act.

236.490. All duly constituted officers of the law of this state or any political subdivision thereof shall aid in the enforcement of the provisions of sections 236.400 to 236.500.

(L. 1979 H.B. 603 § 19)

Legal actions for enforcement available, procedure.

236.495. 1. In carrying out the provisions of sections 236.400 to 236.500 and to the extent not inconsistent with chapter 491, the chief engineer or council may subpoena witnesses and compel their attendance, and may also require the submission of books, papers, documents or other pertinent data in any hearing or enforcement proceedings hereunder or in any case wherein a violation of this chapter is alleged. Upon failure or refusal to comply with such order or upon failure to honor a subpoena, as herein provided, the council may request the attorney general or a prosecuting attorney to apply to the circuit court having jurisdiction to enforce compliance.

2. The council may request the attorney general or a prosecuting attorney, in the name of the state, to institute a suit for injunctive relief to stop or prevent violations of the provisions of sections 236.400 to 236.500, permits, standards, orders and rules and regulations promulgated hereunder, which shall be violations of sections 236.400 to 236.500, or to restrain any violation thereof, or after written notification of violation by the council, and a reasonable time to correct such violation, for the assessment of a penalty of up to one thousand dollars per day, for each day or part thereof the violation continues to occur after such notice. Such action may be brought in any county where the defendant's principal place of business is located, where the dam or reservoir is located, or the violation does or may occur.

(L. 1979 H.B. 603 § 20)

Penalties.

236.500. 1. Any person who willfully violates any of the provisions of sections 236.400 to 236.500 is guilty of a misdemeanor and, upon conviction, shall be punished by a fine of not less than five hundred dollars nor more than ten thousand dollars, or by confinement in the county jail for a term of not less than thirty days nor more than one year, or by both such fine and confinement.

2. In the event of a continuing violation, each day that the violation continues shall constitute a separate and distinct offense.

3. Any person who willfully obstructs, hinders or prevents the council, the chief engineer or his agents or employees from performing the duties imposed by sections 236.400 to 236.500 and rules and regulations promulgated hereunder or who willfully resists the council, the chief engineer or his agents in the performance of the duties imposed on them by sections 236.400 to 236.500 and rules and regulations promulgated hereunder is guilty of a misdemeanor and, upon conviction, shall be punished as provided in subsection 1 of this section.

4. Any owner who willfully engages in the construction, repair, alteration or removal of any dam or reservoir without a construction permit or in violation of a construction permit or willfully violates the requirements of or for a safety or registration permit is guilty of a misdemeanor and, upon conviction, shall be punished as provided in subsection 1 of this section.

E.25. Montana

Is Your Dam Above Homes, Highways, or Other Structures?

Do you own or plan to build a dam above homes, highways, or other structures?

If you own or plan to build a dam, it's important to know whether the dam presents a hazard to the people and property downstream. A high hazard dam is any dam that impounds 50 acre-feet of water or more and could cause loss of life downstream in the event of a dam failure. "High-hazard" is not a description of the dam's condition. "High-hazard" refers to the potential for the loss of life downstream if the dam were to fail.

There are over 3,500 dams in Montana that impound 50 acre-feet of water or more. Of these dams, approximately 150 are classified as high-hazard.

Montana's Dam Safety Law

In 1985, Montana became one of 48 states to adopt regulations for high-hazard dams. The Montana Dam Safety Act implements a permitting process requiring that construction, maintenance, and operation of high-hazard dams be conducted in a safe manner.

It is beneficial for a high-hazard dam to be in compliance with Montana's Dam Safety Act. If a high-hazard dam is permitted under the act, a dam owner is not, in the absence of negligence, liable for damages resulting from discharges from the dam or reservoir that

continued...

exceed the 100 year flow. This provision reduces the risk of liability to a high- hazard dam owner.

Exempt from the Dam Safety Act are:

- Dams that are owned by the federal government,
- Dams inspected by the Federal Energy Regulatory Commission,
- Dams included in a mine operating permit issued by the Montana Department of Environmental Quality,
- Dams associated with facilities certified under the Major Facility Siting Act.
- Private dams on federal property, including dams on U.S. Forest Service property.

These dams are already required to meet safety standards established by other state or federal law and are exempt to prevent instances of dual jurisdiction or conflicting standards.

Hazard Classification

Construction of a new dam or alteration of an existing dam, with an impoundment capacity of 50 acre-feet or more, requires an application to the Department of Natural Resources and Conservation (DNRC) Dam Safety Program for a hazard classification. The ***impoundment capacity*** is measured to the maximum normal operating pool, which is usually the crest of the spillway. The requirements for hazard classification also apply to flood control structures that have the potential for impounding 50 acre-feet or more.

Construction Work on Deadman's Basin Dam

Construction Permit

If determination is reached that a high-hazard potential exists downstream from a dam, a construction permit is necessary before construction. ***Construction*** includes construction of a new high-hazard dam or major repair, alteration, enlargement, or removal of an existing high-hazard dam. An application for a construction permit must be accompanied by construction plans and specifications as well as an engineering design report.

The plans, specifications, and report must be prepared by a licensed professional engineer experienced in dam design and construction. Within 60 days of receiving a completed application, DNRC will issue or deny a construction permit. There is no fee associated with a construction permit application.

A construction permit is not required for performing minor and routine repairs, maintenance, or emergency repairs on a high-hazard facility.

The determination of hazard involves an evaluation of the area downstream from the dam that would be flooded in the event of dam failure. If the flood would have the potential to cause a loss of life, the dam is classified as a high-hazard structure. The hazard classification is based on the potential loss of life downstream; ***it is not an assessment of the safety of the structure.*** DNRC will make a hazard classification determination within 60 days after a complete application is received. The cost of the hazard classification determination is $125.

Painted Rocks Dam

Operation Permit

It may be necessary to obtain an operation permit from DNRC if you own or plan to own a high-hazard dam. An operation permit application must include an operation plan and an engineer's inspection report. The permit is effective for a period of no longer than 5 years. After 5 years renewal of the permit is required. The ***operation plan*** consists of reservoir operation procedures, maintenance procedures for the dam and appurtenant works, and the emergency procedures. The plan must be updated whenever the permit is renewed. Preparation of and adherence to the plan will aid in the safe operation and maintenance of the high-hazard dam. A more detailed description of an operation plan can be found in Administrative Rules of Montana Chapter 36.14.101-803. A sample of an operation plan is available from DNRC.

A periodic inspection of the high-hazard dam is necessary when the operation permit is first applied for or renewed. The minimum frequency for inspection is stated in the operation permit and is at least once every five years. The inspection must be arranged by the dam owner and conducted by a licensed professional engineer. A report of the inspection must accompany the permit application.

If, after reviewing the application, operation plan, and inspection report, DNRC determines that the high-hazard dam meets or exceeds minimum safety standards and can be safely operated and maintained, an operation permit is issued. There is no fee associated with an operation permit application. DNRC will issue or deny the permit within 90 days after receiving a complete application.

Civil Penalty

A civil Penalty of up to $1,000 per day can be assessed against a dam owner, for non-compliance with the Montana Dam Safety Act.

Eureka Dam Failure

Emergency

If a dam is in danger of failing due to structural deficiencies or severe flood conditions and poses a life threatening emergency, a dam owner may proceed with the necessary repairs or breaching without the previously described construction permit. ***DNCR must be notified immediately of any proposed emergency repairs or breaching.*** If a dam owner fails to act, DNRC may take any action necessary to safeguard downstream life and property. Costs incurred by DNRC's action during an emergency must be paid by the owner of the dam.

Complaints - Unsafe Dam or Reservoir

If you have a concern that life or property is being endangered by a dam, regardless of the capacity of the reservoir, a complaint may be filed by submitting an affidavit to DNRC. DNRC may then inspect or order an inspection of the dam unless the data, records, and inspection reports are adequate to determine that the complaint has no merit.

If the inspection discloses defects in the dam or reservoir that, in the judgment of DNRC, constitute an immediate hazard to life or property, DNRC can order the reservoir be drained, limiting its use, or taking other steps to ensure the safety of the dam. DNRC may require the owner to pay all or part of the inspection expenses.

Toston Dam

Ackley Dam

Laws, Rules and Forms

For copies of the Montana Dam Safety Act, the administrative rules, or application forms, you may write or call DNRC at the address below.

Other Information

Numerous publication are available concerning inspection guidelines, emergency and early warning plans, and other areas that may be of interest or assistance to owners of dams. Contact DNRC for more information.

TECHNICALLY SPEAKING… MONTANA'S TECHNICAL NOTES FOR RISK-BASED DAM SAFETY ANALYSES

Gary Fischer, P.E., Hydrometrics, Inc. and Carroll College
and
Michele Lemieux, P.E., Montana Dam Safety Program, Montana Department of Natural Resources and Conservation

Introduction

In 1999, the Montana Dam Safety Program adopted spillway design standards based on risk-based criteria and moved away from standards based on percentages of the probable maximum flood (PMF) keyed only to dam height and reservoir volume. This propelled the program into an era where spillway standards are determined by the risk of loss of life (LOL) due to dam failure, instead of just the size of the impounded reservoir. This was a good thing for some dam owners who were penalized for owning a large dam even though the dams were located in rural areas with sparse population where the chance for LOL due to failure was rare. However, since the new standards are based on breach inundation modeling and runoff hydrology of storms with very low exceedance probabilities, they have also required engineers to have a thorough understanding of storm hydrology and to be adept at computer modeling of storm routing and breach failures. The myriad of data available to engineers to conduct such modeling can be overwhelming and it is sometimes hard for engineers to stay abreast of the latest techniques and available information. In response to this relatively new approach to dam safety analyses, the Montana Dam Safety Program has contracted with Hydrometrics, Inc. to initially develop three Technical Notes designed to assist and provide guidance to professionals for dam safety analyses. This paper provides a description of the first two Technical Notes, with a look ahead at the anticipated features of the third.

What Would Washington State Do?

The Montana Dam Safety Program has long held a close working relationship with the Washington Dam Safety Office. The two states share similar geographical features, both having mountainous terrain in the western third of each state with the eastern two-thirds comprised of mostly high elevation plains. While Washington experiences roughly 2 to 3 times the annual precipitation and much higher population in the western third of their state compared to Montana, the eastern plains areas of both states are similar in meteorology and population. Holding similar philosophies in terms of risk-based standards, Montana in the late 1990s developed spillway standards using Washington's risk-based standards as examples. Montana's state-specific extreme storm studies were conducted using the same statistical analyses as Washington. Similar in concept to the Washington State Dam Safety Office Guidance Documents (1), the Montana Dam Safety Program is in the process of developing technical notes that provide information for professionals and engineers to conduct spillway capacity analyses, LOL determinations, and simplified evacuation mapping.

The Evolution of Spillway Standards in Montana

In Montana, a dam is regulated as “high hazard” if its failure has the potential for causing LOL. The original Dam Safety Rules established spillway hydrologic standards for high hazard dams based on reservoir volume and dam height. It became evident that in many cases the required spillway size was disproportionate to the level of downstream development. This was particularly true for large dams located in rural areas or, on the other end of the scale, for smaller dams that had dense downstream development but still posed significant threats to downstream populations.

To help address this discrepancy, the Montana Dam Safety Program within DNRC in 1999 developed new hydrologic standards that provide a uniform level of downstream protection by relating the required spillway size to the consequences of a dam failure, or estimated LOL, rather than to the size of the dam. The minimum inflow design flood, or IDF, is the storm runoff that enters a reservoir impounded by a dam and is routed through the spillway. The magnitude, or relative size, of the IDF is determined by LOL, which in turn dictates the spillway capacity to safely pass the routed IDF.

Current standards require that an IDF for LOL of 0.5 or less must have a minimum recurrence interval of 500-years. For LOL greater than 0.5 and less than or equal to 5, the minimum recurrence interval used for calculating the IDF is determined by multiplying the LOL by 1,000. In other words, for a dam with LOL potential of 3, the IDF would have a recurrence interval of 3,000 years. For LOL greater than 5 and less than 1,000, the minimum IDF is based upon the amount of runoff that is predicted to occur from an amount of precipitation calculated using equations that interpolate rainfall depths between the 5,000-year event (LOL = 5) and the probable maximum precipitation (PMP). The full PMP is used to determine the IDF, called the PMF, when the LOL is greater than or equal to 1,000. (2)

Montana-Specific Hydrologic Data

Since the new standards require estimates of runoff for precipitation storms having recurrence intervals up to 5,000 years, it was important to obtain meteorological and hydrological data to match. In anticipation of the new risk-based spillway standards, the Montana Dam Safety Program initiated two studies that provided methods for determining precipitation depths and temporal hyetograph development up to a recurrence interval of 5,000 years. Both studies were conducted by the U.S. Geological Survey (USGS) Water Science Center in Helena, Montana. The first study, completed in 1997, uses precipitation gage data from three meteorologically similar regions in Montana to develop procedures for estimating precipitation depths for 2-, 6- and 24-hour duration storms having recurrence intervals up to 5,000 years (3). The second study, completed in 1998, provides methodologies to construct synthetic rainfall hyetographs using precipitation depths estimated by the 1997 report (4). In the 1998 report, storm temporal characteristics are estimated from Montana precipitation gage data using the same three homogeneous regions as the 1997 study.

A third USGS study provides procedures for estimating unit hydrographs for large runoff events in Montana at ungaged sites (5). Based on Montana stream gage data, this report provides methodologies for estimating unit hydrographs using Clark’s Method and the Soil Conservation Service (SCS) Dimensionless Unit Hydrograph Method.

The three USGS studies described above can be used for spillways whose dams have the potential for LOL equal to or less than five. For LOL greater than 5, spillway IDF will

determined either by runoff produced by the PMP or an interpolated precipitation amount between the 5,000-year depth and the PMP. In Montana, PMP estimates are determined by two National Oceanic and Atmospheric Administration (NOAA) reports: Hydrometeorological Report (HMR) 55a (6) for areas east of the Continental Divide; and HMR 57 (7) for areas west of the Continental Divide.

Armed with these studies, Montana engineers and hydrologists have the ability to reasonably estimate precipitation and runoff events for very large and infrequent storms.

Technical Note 1 – Analysis of Spillway Capacity in Montana

Even with the wealth of information available to conduct hydrologic analyses in Montana, professionals are still faced with the complicated task of piecing together both relatively new spillway hydrologic standards and technical information provided by the USGS and NOAA. The Montana Dam Safety Program provided a spillway adequacy decision tree (8), shown in Figure 1, to help in determining steps needed in conducting a spillway analysis. The procedures shown in Figure 1 reflect the risk-based spillway hydrological standards for Montana. Technical Note 1 (TN1), *Analysis of Spillway Capacity in Montana* (9) was developed to expand the procedures in Figure 1, providing a logical, comprehensive guide for determining spillway capacity for Montana high hazard dams. TN1 incorporates the technical references specific to Montana with guidance on developing a hydrologic model using the computer program HEC-HMS (Hydrological Modeling System) (10) for spillway analysis. TN1 is a guidance document for professionals with at least some knowledge of spillways and hydrological modeling. While other references and procedures are accepted by the Dam Safety Program, TN1 references and procedures are recommended because of their direct applicability to Montana dams and because of the experience gained by the Dam Safety Program in dealing with spillway analyses.

Technical Note 2 – Loss of Life Determination

Since Montana spillway hydrologic standards are risk-based, or dependent on the estimated LOL due to dam failure, it was necessary for the Montana Dam Safety Program to develop more standardized guidance for the determination of LOL. To do this, the Dam Safety Program contracted with Hydrometrics, Inc. to develop Technical Note 2 (TN2), *Loss of Life Determination for Spillway Capacity Analysis* (11). TN2 is currently in draft form and is in the process of Dam Safety Program review. TN2 is intended as a dynamic publication that will be modified as necessary to incorporate the latest and best references for estimating LOL from dam failures. At this time, the Montana Dam Safety Program recommends procedures developed by Graham of the U.S. Bureau of Reclamation (12) for determining LOL from dam failures. Graham studied data from “every U.S. dam failure that resulted in more than 50 fatalities and every dam failure that occurred after 1960 resulting in any fatalities” (ibid). Data was evaluated with regard to warning time, population at risk (PAR) and LOL. Graham concluded LOL from dam failures is greatly influenced by three main factors: the PAR or population occupying the area inundated by a dam failure flood; the warning time given to PAR exposed to the failure flood; and the severity of the flooding. Graham provides procedures and empirical equations to estimate LOL for various combinations of the three factors mentioned previously. In general, LOL is much less than PAR, particularly in low force areas, where flood depth and flow velocity are relatively low, and with sufficient warning time.

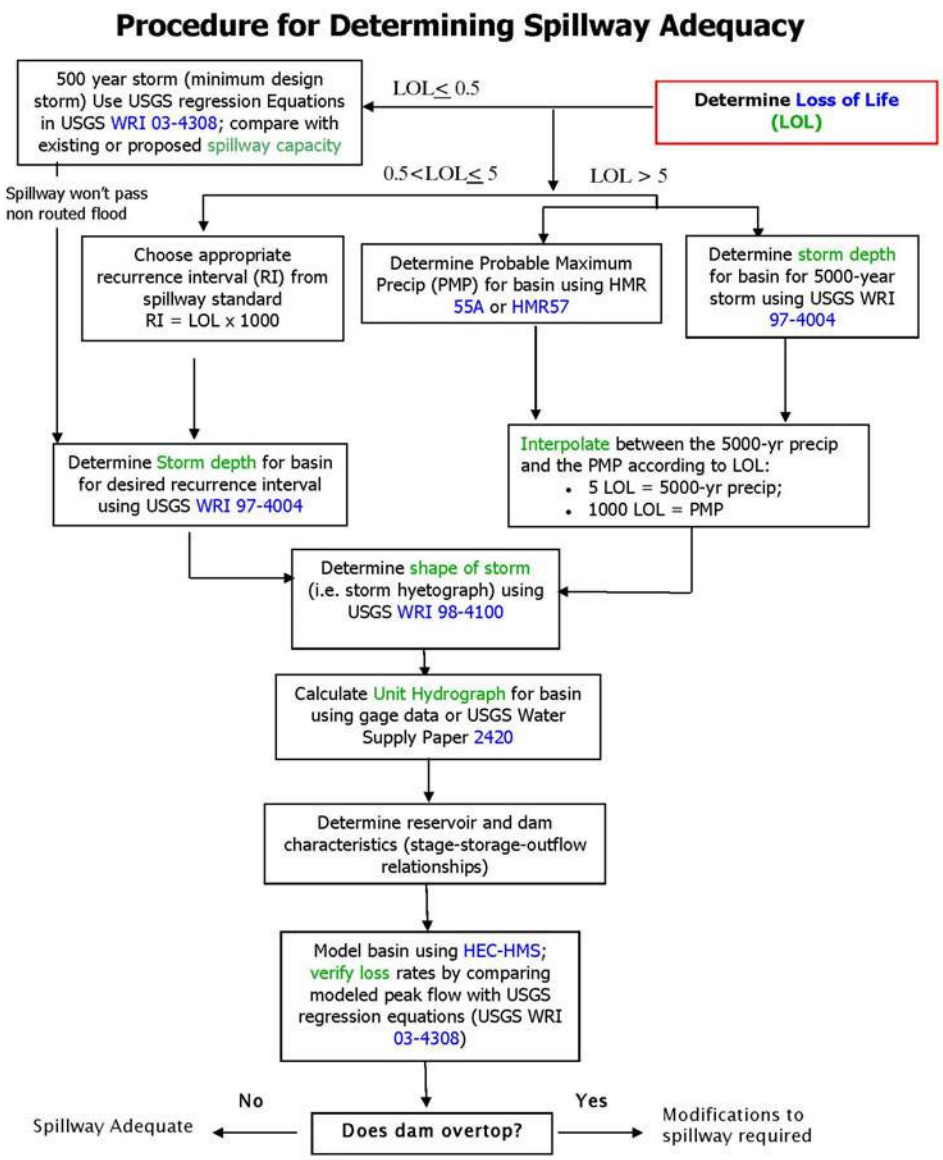

Figure 1. Procedure for Determining Spillway Adequacy for Montana Dams (8).

The Montana spillway hydrologic standards specify that the LOL determination be conducted using a simulated “spillway failure” flood (2). The Montana Dam Safety Program interprets spillway failure as the point where the spillway has exceeded its ability to discharge outflow, i.e. the spillway fails when the reservoir has reached a level at the low point of the dam crest. The modeled failure flood for an LOL determination is a result of a dam breach with the reservoir level at the crest of the dam. The failure flow does not include spillway discharge. PAR within the failure flood boundary is determined by the number of structures, roads, recreational areas and other features where humans could congregate and assigning average numbers for human occupancy. LOL is estimated using the PAR estimates, warning time, and judgment on flood severity. Flood severity according to Graham can be categorized in three levels: low severity occurs when no buildings are washed off their foundations; medium severity occurs when homes are destroyed but trees or mangled homes remain for people to seek refuge in or on; and high severity occurs when the flood sweeps the area clean and nothing remains. Obviously, professional judgment is required in assigning a severity rating. Graham recommends assigning low severity if “most of the structures will be exposed to depths of less than 10 feet and medium severity if most of the structures will be exposed to depths of 10 feet or more” (12). A final factor recommended by Graham in determining LOL is flood severity understanding. Flood severity understanding can fall within one of two categories: vague, where the issuers give the warning prior to dam failure or they are not truly aware of its potential for damage; or precise, where issuers of warnings have either seen the flooding or have relayed accurate information from others who are aware of the flooding. Figure 2 contains Graham’s table for estimating LOL based on the factors described above.

Technical Note 3 – Simplified Breach Analysis

With the need for standardizing guidance for technical evaluations using the risk-based spillway standards in Montana, the Montana Dam Safety Program also realized the need for consistent evacuation mapping and breach modeling. According to an informal survey of emergency and disaster response personnel in Montana, many emergency action plan evacuation maps tend to be confusing, especially during an emergency or emergency simulation. Evacuation maps contain at least two flood inundation boundaries, one for a clear-weather (piping) breach, and another for a storm-induced (overtopping) breach.

While these boundaries differed significantly in some cases, it was left to the emergency responder to decifer the correct boundary on the map to match the type of failure. In true emergencies, time used to read and understand maps could be time better used in issuing warnings and conducting evacuations. Other information often placed on maps, such as peak discharge travel time and flood wave height, was either ignored or misunderstood much of the time.

In an attempt to simplify evacuation maps and the engineering required to develop them, the Dam Safety Program has encouraged simplified evacuation mapping and procedures. To better explain how simplified mapping is accomplished, the Dam Safety program has tasked Hydrometrics, Inc. with developing Technical Note 3 (TN3), *Simplified Evacuation Mapping for Emergency Action Planning*. At this time, a draft version of TN3 has been written (13) and is currently being reviewed by the Dam Safety Program.

Table 7 Recommended Fatality Rates for Estimating Loss of Life Resulting from Dam Failure				
Flood Severity	Warning Time (minutes)	Flood Severity Understanding	Fatality Rate (Fraction of people at risk expected to die)	
			Suggested	Suggested Range
HIGH	no warning	not applicable	0.75	0.30 to 1.00
	15 to 60	vague	Use the values shown above and apply to the number of people who remain in the dam failure floodplain after warnings are issued. No guidance is provided on how many people will remain in the floodplain.	
		precise		
	more than 60	vague		
		precise		
MEDIUM	no warning	not applicable	0.15	0.03 to 0.35
	15 to 60	vague	0.04	0.01 to 0.08
		precise	0.02	0.005 to 0.04
	more than 60	vague	0.03	0.005 to 0.06
		precise	0.01	0.002 to 0.02
LOW	no warning	not applicable	0.01	0.0 to 0.02
	15 to 60	vague	0.007	0.0 to 0.015
		precise	0.002	0.0 to 0.004
	more than 60	vague	0.0003	0.0 to 0.0006
		precise	0.0002	0.0 to 0.0004

Figure 2. From Graham, Table for Estimating Loss of Life Resulting from Dam Failure (12)

TN3 defines the procedures to develop simplified evacuation maps. One breach flood boundary will be placed on the map to avoid confusion by emergency response personnel. The breach model will begin with a breach of the dam with the reservoir level at the low point of the dam crest. Maps will be developed in consultation with local emergency personnel in order to identify affected structures, escape routes and potential areas of backwater where additional boundaries may be added to the breach boundary. The Montana Dam Safety Program recommends breach routing modeled with the computer program HEC-HMS (10) because of its ease of use and adequate accuracy for evacuation map purposes. HEC-HMS uses pseudo-unsteady flow computational methods for flood routing, such as kinematic wave or Muskingum-Cunge, which are simplified but computationally robust. Other computer models may be used that are more sophisticated unsteady flow models, such as HEC-RAS (14) and FLDWAV (15), but to date these models can be difficult to refine in order to maintain computational consistency without program errors. The Dam Safety Program has concluded HEC-HMS provides results well within the accuracy bounds of any breach flood model, especially with the potential for uncertainty of large flood waves that may verge on non-Newtonian flow by carrying large percentages of debris and mud. HEC-HMS also tends to take less time for engineers to develop a breach model as compared to HEC-RAS or FLDWAV, reducing the cost to owners for engineering analysis.

Summary

Since the introduction of risk-based spillway standards for Montana high-hazard dams, the Montana Dam Safety Program has searched for methods to provide guidance for professionals to conduct analyses related to spillway adequacy. In 2008, the Dam Safety Program developed Technical Note 1, *Analysis of Spillway Capacity in Montana*, which is available for use by engineers and professionals, engaged in spillway analyses. Technical Note 2, *Loss of Life Determination for Spillway Capacity Analysis*, is currently in draft form and should be ready for use by professionals by mid-2010. A draft of Technical Note 3, *Simplified Evacuation Mapping for Emergency Action Planning*, has been developed and is in the process of being reviewed by the Dam Safety Program.

36.14.502 HYDROLOGIC STANDARD FOR EMERGENCY AND PRINCIPAL SPILLWAYS

(1) Spillway conveyance for high-hazard dams will be based on estimated loss of life downstream from the dam caused by spillway failure.

(2) The minimum inflow design flood for an estimated loss of life of 0.5 or less shall be the 500-year recurrence interval flood.

(3) The minimum inflow design flood recurrence interval for estimated loss of life greater than 0.5 and less than or equal to 5 shall be determined by multiplying the estimated loss of life by 1,000.

(4) The minimum inflow design flood for estimated loss of life greater than 5 and less than 1,000 shall be determined from the design precipitation derived using the following equations:

$$P_s = P_{5,000}\ (10^{rd}) \text{ where}$$

$$r = -0.304 + .435 \log_{10} (lol)$$

$$d = \log_{10} (PMP) - \log_{10} (P_{5,000})$$

lol = estimated loss of life

PMP = probable maximum precipitation

$P_{5,000}$ = 5,000-year recurrence interval precipitation

P_s = design precipitation to meet spillway standard

(5) The minimum inflow design flood for estimated loss of life greater than or equal to 1,000 shall be the probable maximum flood.

(6) The reservoir and spillway must safely store and pass the runoff resulting from the minimum inflow design flood.

(7) As a minimum, the reservoir will be assumed at normal operation pool before the minimum inflow design flood begins.

(8) The spillway capacity may be smaller if an analysis shows that there is no additional loss of life expected from the dam failure flood than that observed for the minimum inflow design flood.

DAM SAFETY PROGRAM TECHNICAL NOTE 1 (TN1)
ANALYSIS OF SPILLWAY CAPACITY IN MONTANA

Overview

Technical Note 1 (TN1) provides guidance to engineers and professionals engaged in the analysis and design of spillways for Montana high hazard dams. TN1 is intended for analyses related to high hazard dams regulated by the Montana Dam Safety Program, but the guidance provided can be used on other dams. The appropriate guidelines for specific dams are typically determined by the dam's regulating agency. The procedures in TN1 are intended for analyzing spillway capacity using the hydrologic computer model HEC-HMS (Hydrologic Modeling System). TN1 addresses only spillway capacity analysis. It does not provide guidance on armoring or erosion control design, energy dissipation, or maintenance and operation procedures.

TN1 is organized to lead the user through logical steps of spillway capacity analysis. TN1 first provides a clear explanation of spillway hydrologic standards according to Montana Dam Safety rules. Then the user is led through analysis methods to estimate factors that are used to develop a hydrologic model, such as basin characteristics, routing techniques, precipitation estimates, and reservoir and spillway characteristics. Next, TN1 provides information for the user to model precipitation and runoff with HEC-HMS as well as methods to verify the model is providing reasonable results. Finally, the appendices of TN1 provide valuable information such as design standards and flowcharts to properly analyze a spillway, model input factors and an example of a spillway capacity analysis.

TN1 is not a regulatory requirement for spillway analysis. Other methods may be used by engineers and professionals. But the guidance provided in TN1 is accepted by the Montana Dam Safety Program and the methods suggested are common in engineering practice.

We welcome comments on TN1 and contact information is provided in Section 1. We hope you find TN1 helpful and that it will serve as a reasonable approach to spillway capacity analysis.

DAM SAFETY PROGRAM
TECHNICAL NOTE 1
ANALYSIS OF SPILLWAY CAPACITY IN MONTANA

1.0 INTRODUCTION

The **Montana Dam Safety Program** is pleased to provide this **Technical Note 1 (TN1), Analysis of Spillway Capacity in Montana**. We hope this publication is helpful in providing technical guidance to professionals engaged in the analysis and design of spillways for high hazard dams in Montana. Our intent is to make available relevant and up-to-date information, references and procedures, much of which is unique to Montana, which will aid engineers and professionals in conducting spillway analyses.

This is the first Technical Note developed by the Montana Dam Safety Program and, as such, we are interested in making it the best we possibly can. We welcome and encourage your feedback on its contents. Please send your comments to:

Montana Dam Safety Program
Department of Natural Resources and Conservation (DNRC)
PO Box 201601
Helena, MT 59620-1601
mlemieux@mt.gov

The Montana Dam Safety Program operates within the DNRC Water Resources Division's Water Operations Bureau.

DNRC would like to acknowledge Hydrometrics, Inc. of Helena, Montana for the development and preparation of Technical Note 1 and Mr. Rob Kingery of the DNRC State Water Projects Bureau for his review and technical guidance.

TN1 will be revised as updated technical references are made available.

1.1 PURPOSE

The purpose of TN1 is to assist and provide guidance to engineers and professionals engaged in the analysis and design of spillways for Montana high hazard dams. TN1 is not a regulatory document and the references and procedures provided can be modified to suit the needs of the user. TN1 references technical resources that are recognized as applicable to Montana dams and most often used by the Dam Safety Program in analyzing and designing spillways. The Dam Safety Program intends for TN1 to provide a consistent means of conducting spillway analyses, but recognizes that professionals may prefer other technical resources that are not used in TN1.

1.2 FOCUS AND LIMITATIONS

TN1 is intended for use on high hazard dams regulated by the Montana Dam Safety Program. Several of the technical references are specific to Montana hydrology. Guidance for federal dams may come from other sources developed for their appropriate regulations.

TN1 provides a methodology for analyzing spillway capacity using the HEC-HMS (Hydrologic Modeling System) (USACOE, 2008) rainfall-runoff model, for which data collection and input are accomplished manually. Other methods can be used to come to similar results. Where digital data is available, the use of geographical information systems (GIS) is becoming an increasingly popular and useful tool in conducting a multi-element spatial runoff model, and several available software packages and models can be used in this application.

TN1 is applicable to larger, undeveloped drainage areas, usually at least one square mile. Smaller watersheds and urban watersheds can best be modeled using other methods.

TN1 assists in evaluation of spillway capacity, but does not provide guidance on armoring or erosion control design. It also does not address energy dissipation of flows or maintenance and operation procedures.

1.3 TARGET AUDIENCE

TN1 is for use by engineers and professionals experienced in hydrologic analyses and familiar with design and rehabilitation of spillways and dams. Professional judgment is required and expected regardless of guidance provided by TN1. Users of TN1 are expected to be familiar with common hydrologic and hydraulic computer programs and their appropriate use. DNRC and the Dam Safety Program are not responsible for the use and interpretation of TN1 contents.

2.0 DESIGN STANDARDS AND PROCEDURES

Montana Dam Safety Administrative Rules govern the design, operation and maintenance of high hazard dams (dam safety rules are part of the Administrative Rules of Montana (ARM) and can be viewed at h*ttp://dnrc.mt.gov/wrd/water_op/dam_safety/*.)As described in this section, standards for Montana dams came about through a growing awareness of the potential danger of dams and the need for regular maintenance and operation procedures. This awareness started at the federal level and has become the responsibility of state agencies. The Dam Safety Program currently maintains spillway hydrologic standards based on the estimated loss of life downstream of a dam.

2.1 HISTORY OF SPILLWAY STANDARDS

The development of current spillway hydrologic standards began as an organized effort to identify potentially hazardous dams and to implement appropriate design, maintenance and operation procedures to protect downstream citizens. In the United States, the first federally-funded effort to address the safety of dams was initiated in 1972 by the National Dam Inspection Act, Public Law 92-367, which authorized the Secretary of the Army, through the Corps of Engineers, to conduct safety inspections of non-federal dams throughout the United Sates. The Corps of Engineers developed guidelines for safety inspections of dams in 1975. The guidelines recommended a two-phased study for investigating and evaluating dams. Phase 1 inspections of high hazard and other significant dams were conducted in the late 1970s and early 1980s. Results of the Phase 1 inspections were presented to state agencies responsible for dams and reservoirs. States were responsible for implementing Phase I recommendations. Phase II of the study consisted of more detailed investigations and evaluations of dams to better identify specific safety concerns. Except in special cases, the Phase II investigations were the responsibility of states.

In response to the Phase 1 reports for Montana dams, the Montana Legislature passed the Montana Dam Safety Act in 1985. The Act is currently part of the Montana Code Annotated (MCA), Title 85 (Water Use), Chapter 15 (Dam Safety Act). The Act

authorizes the DNRC to administer and implement dam safety rules and regulations. In 1988, DNRC developed the Dam Safety Rules in the Administrative Rules of Montana (ARM) Chapter 36.14.

The original Dam Safety Rules established spillway hydrologic standards for high hazard dams based on reservoir volume and dam height. The minimum inflow design flood for an existing dam impounding less than 100 acre-feet and less than 20 feet in height was the 100-year flood. The inflow design flood increased in magnitude for larger impoundments by fractions of the Probable Maximum Flood (PMF) to a maximum of the full PMF for dams impounding 50,000 acre-feet or greater and with heights of 100 feet or higher.

It became evident that in many cases the required spillway size was disproportionate to the level of downstream development. This was particularly true for large dams located in rural areas or for smaller dams that had dense downstream development. In response, DNRC searched for new hydrologic standards that would provide a uniform level of downstream protection by relating the required spillway size to the consequences of a dam failure, rather than to the size of the dam.

DNRC organized a Montana Spillway Standards Committee to develop risk-based hydrologic standards for spillways of high hazard dams and in 1999 the Committee released *Technical Decisions for Minimum Design Inflow for High Hazard Dams (Appendix B)*. The Committee recommendations were incorporated into the current Dam Safety Rules in 1999. The hydrologic standards generally require spillway capacity for high-hazard dams to be based on an estimate of the number of lives that may be lost downstream from the dam due to a spillway failure, which is called the estimated loss of life or LOL. The minimum inflow design flood, or IDF, is the storm runoff that enters a reservoir impounded by a dam and is routed through the spillway. The magnitude, or relative size, of the IDF is determined by LOL, which in turn dictates the capacity of the spillway. The IDF for an LOL of 0.5 or less must have a minimum recurrence interval of 500-years. For an LOL greater than 0.5 and less than or equal to 5, the minimum

recurrence interval used for calculating the IDF is determined by multiplying the LOL by 1,000. For an LOL greater than 5 and less than 1,000, the minimum IDF is based upon the amount of runoff that is predicted to occur from an amount of precipitation calculated using equations that interpolate rainfall depths between the 5,000-year event and the probable maximum precipitation (PMP). The full PMP is used to determine the IDF, called the probable maximum flood (PMF), when the LOL is greater than or equal to 1,000. Details of calculating IDF magnitudes are given in the following sections.

2.2 DETERMINING REQUIRED INFLOW DESIGN FLOOD

Central to the evaluation of spillways is the determination of LOL and its impact on the determination of IDF and spillway size.

2.2.1 Estimated Loss of Life Determination

One of the most subjective and misunderstood components of dam safety is the determination of LOL from dam failure. Yet this determination is the deciding factor in determining the size of the IDF for spillway design in Montana. Because of the varying approaches to calculating LOL, the Montana Dam Safety Program has provided **Technical Note 2 (TN2), Estimated Loss of Life Determination for Spillway Design**. Procedures from TN2 should be used to estimate LOL from a dam failure prior to continuing with the analysis procedures in this technical note.

2.2.2 Inflow Design Flood Determination

The method of determining the IDF for spillway adequacy depends on whether the LOL is greater, equal to or less than 5. For an LOL less than or equal to 5, the spillway IDF magnitude is calculated as a return interval, or exceedance probability of occurrence. An LOL greater than 5 requires the IDF magnitude to be calculated by equations that interpolate precipitation depths between the 5,000-year recurrence interval and the PMP.

2.2.2.1 Design Storm Frequency or Return Period for LOL ≤ 5

If the estimated LOL is equal to or less than 0.5, the minimum IDF is the 500-year recurrence interval. (Yes, LOL can be a fraction! This is part of the reason for some of the misunderstanding surrounding LOL and the need for using the procedures in TN2.)

If the LOL is greater than 0.5 and less than or equal to 5, the minimum IDF recurrence interval is determined by multiplying the LOL by 1,000.

The general equation for the return interval of the minimum IDF for LOL ≤ 5 is:

Inflow Design Flood (IDF) Return Interval = LOL x 1,000

The IDF is usually determined by applying precipitation that corresponds to the appropriate return interval to a rainfall-runoff model. Methods of determining this precipitation are described in Section 5.0. It is also feasible to determine a hydrograph for the IDF with the required return interval by conducting statistical analyses on stream gage data. However two conditions have to be met: 1) the reservoir must exist on a stream that has a nearby gage with a long-term record; and 2) the gage record must be long enough to statistically estimate peak discharges for the return interval required for dam safety purposes. For dams with LOL less than or equal to 0.5, an inflow hydrograph could be developed for the 500-year flood by first estimating the peak flood discharge using regional regression equations for ungaged basins (USGS, 2003).

Use caution when calculating the IDF based upon runoff from precipitation of a given return interval. The precipitation event with a given return interval rarely produces a flood of the same return interval. Even if two precipitation storms have identical total rainfall depths, they rarely produce equal runoff hydrographs because of differences in the temporal and spatial distribution of precipitation and variability in other basin parameters. Therefore, the user should verify rainfall-runoff model results, to the extent

possible, with established runoff statistical estimates or regional regression equations for equal return interval estimates. Section 8.0 discusses this issue in greater detail.

2.2.2.2 Design Storm Precipitation Interpolation for LOL > 5

If the LOL is greater than 5 and less than 1,000, the precipitation depth for determining the IDF is calculated with equations that effectively interpolate between depths for the 5,000-year storm and the PMP. The equations are found in the Dam Safety Administrative Rules of Montana, but are provided here also:

$$P_S = P_{5,000}\left(10^{rd}\right) \text{ where}$$

$$r = -0.304 + 0.435\log_{10}\left(LOL\right)$$

$$d = \log_{10}\left(PMP\right) - \log_{10}\left(P_{5,000}\right)$$

PMP = probable maximum precipitation depth (inches)

$P_{5,000}$ = 5,000-year return interval precipitation depth (inches)

P_s = design precipitation depth for the spillway standard (inches)

The IDF for an LOL greater than or equal to 1,000 is the probable maximum flood, or PMF. The PMF is runoff produced by the PMP.

3.0 BASIN CHARACTERISTICS

Basin characteristics include all physical features of the rainfall watershed contributing to the reservoir on which the dam and spillway are located. These characteristics affect the volume and timing of the resulting hydrograph from a precipitation event, and must be defined in a rainfall runoff model.

3.1 PHYSICAL ATTRIBUTES

Each drainage basin has unique physical attributes. The following sections provide insight and sources of data for each of the attributes that affect runoff.

3.1.1 Area

The area of the drainage basin is measured along the watershed boundaries or divides. A watershed is the catchment for rainfall from which runoff will flow into the reservoir. For input to HEC-HMS, the area is measured in units of square miles.

3.1.2 Subbasins

If the drainage basin has sub-areas with distinctly different characteristics or which contain separate tributaries leading to a main drainage, it can be divided into subbasins. Each subbasin can be treated as a separate rainfall-runoff unit, but the connection of each subbasin to successive subbasins or routing channels must be done in a proper sequence to model as close as possible the actual runoff flow patterns.

3.1.3 Soils

Accurate identification of soil types in the basin is essential to accurately predicting runoff. In most cases it is impractical to conduct comprehensive physical soil sampling and testing to determine soil types. If soil data are not available, some soil sampling and testing, including infiltration measurements, may be warranted as verification of estimated parameters. Soil data may not be available, especially in mountainous terrain. However, the USDA Forest Service may have unpublished data for some areas of National Forests. We advise you contact the soil scientist for the National Forest where

the drainage basin resides. For much of Montana, including state, federal and private land, there are Soil Surveys produced and published by the USDA Natural Resources Conservation Service (NRCS). The following sections describe some of the sources available for soil data.

3.1.3.1 NRCS Web Soil Survey

The NRCS provides a *Web Soil Survey* site to assist in determining soil properties for a specified "area of interest", which is in this case is a drainage basin or subbasin. The link for accessing the *Web Soil Survey* is http://websoilsurvey.nrcs.usda.gov. This site contains most of the available soil survey information for the state and is a convenient way to determine composite hydrologic soil groups. The site includes most federal land in its inventory.

3.1.3.2 NRCS Soil Surveys

NRCS Soil Surveys are published for most counties in Montana and are available. A listing of soil surveys and their availability is shown on the following web site: http://soils.usda.gov/survey/printed_surveys/state.asp?state=Montana&abbr=MT.

3.1.3.3 Other Data Sources

Soil data can be obtained from a variety of sources. It is up to the user to determine the best available data. Common sources include counties, federal and state land management agencies, colleges and agricultural research centers.

3.1.4 Land Use and Ground Cover

While soil is important in determining infiltration rates and water holding capacity, it is equally important to determine the predominant plant cover and land uses for the subject basin. These factors greatly influence precipitation loss parameters, as in determining an appropriate NRCS curve number (see Section 3.3.2.1). Commonly, thick vegetation and healthy forests create abstractions that either trap rainfall or effectively delay the runoff response, creating runoff hydrographs that have relatively low peak discharges and runoff volumes. Conversely, urbanization and human development produce impervious areas

that prevent or delay infiltration, resulting in more runoff than in a natural setting. The general effect is to produce higher runoff volumes and peak discharges in a basin.

3.1.5 Hydrologic Condition and Antecedent Moisture Condition

Hydrologic condition, according to the NRCS, refers to the factors that affect infiltration and runoff, including density of vegetative areas and surface toughness. Poor hydrologic condition indicates impaired infiltration and increased runoff, while good hydrologic condition is the opposite. Antecedent moisture condition is a measure of the soil moisture just prior to a storm event. Estimating hydrologic condition and antecedent moisture of a drainage basin depends on how much conservatism the user intends for the rainfall-runoff model. Hydrologic condition of a basin can typically be estimated based on the factors listed above. However, soil moisture constantly changes and predicting the water holding capacity of a soil just prior to a given precipitation event is not usually possible. If a basin is relatively dry, and has not experienced rainfall for a period of time, there will typically be a fairly high capacity for infiltration and the ability to retain or retard rainfall for the design storm. High soil moisture or saturated soils may be present if antecedent storms have occurred prior to the design storm. If the basin is already wet and the soil has little additional water holding capacity, more precipitation will become runoff and the resulting hydrograph will be larger than dry antecedent conditions. Hydrologic condition and antecedent moisture condition are typically accounted for in a hydrologic model by infiltration variables, which are discussed in Section 3.3.

3.2 UNIT HYDROGRAPH ESTIMATION

The most common method to define the unique shape and timing of a direct runoff hydrograph for a given drainage basin is to determine its unit hydrograph. As a review, unit hydrograph theory will be briefly described. First introduced by Sherman (1932), the unit hydrograph is defined as a hydrograph of 1 inch of rainfall excess or direct runoff (the portion of rainfall that is available for runoff after losses) for a specified rainfall duration. It is also assumed that the rainfall is distributed uniformly over the entire basin. The unit hydrograph is considered to be a function of basin characteristics. The theory of a unit hydrograph is that runoff is linearly related to rainfall excess. Therefore, direct

runoff from complex storms of any duration with sequential increments varying in depth can be estimated by superimposing and adding unit hydrographs. There are numerous hydrology reference texts available to assist the user with further details on the theory and application of unit hydrographs.

3.2.1 Hydrograph Analysis

For a reservoir on a watershed with streamflow and rainfall gage records, a unit hydrograph can be derived by a trial-and-error procedure that involves analyzing recorded runoff hydrographs and rainfall hyetographs. Users are encouraged to follow standard published methodologies if this situation applies to their project.

3.2.2 Synthetic Unit Hydrograph Development

Most applications in dam safety will involve developing a synthetic unit hydrograph on an ungaged basin. Many methods have been developed for estimating synthetic unit hydrographs, but because of the work accomplished by the USGS specifically for Montana, this technical note will focus on two related methods and include just a brief discussion of other common methods.

3.2.2.1 Montana Procedures (USGS WSP 2420)

USGS published *Water-Supply Paper 2420, Procedures for Estimating Unit Hydrographs for Large Floods at Ungaged Sites in Montana* (1996). This paper presents procedures for determining unit hydrograph parameters for two methods: the Clark unit hydrograph and the dimensionless unit hydrograph. The USGS study was initiated because of the subjectivity in determining unit hydrographs in dam safety applications. The Dam Safety Program recognizes *WSP 2420* as a reliable source for unit hydrograph development for dams in Montana.

WSP 2420 presents procedures derived from Montana streamflow and rainfall records. Unit hydrographs are developed for physiologically similar regions of the state. Examples in *WSP 2420* provide procedures for unit hydrograph development. Unit hydrograph parameters can be easily input into HEC-HMS for rainfall-runoff modeling.

Clark (1945) developed a method to define unit hydrographs using three components: the time of concentration (Tc); a basin storage coefficient (R); and a time-area curve. Using regression analysis of rainfall and runoff gage data, the USGS developed equations to calculate the Tc and R for the Clark unit hydrograph. Although the time-area curve may be developed independently, it is most common to utilize the default time-area curve from Figure 3 of *WSP 2420*.

The dimensionless unit hydrograph is a versatile tool when comparing drainage basins with varying characteristics. In the USGS study, unit hydrographs were made dimensionless by dividing the discharge at each time step by the "standard lag" time, as defined by Snyder (1938). This is the same procedure developed by Cudworth (1989) for the U.S. Bureau of Reclamation.

The tables and equations for using *WSP 2420* dimensionless unit hydrograph methods to calculate unit hydrographs are too extensive for this technical note, however DNRC has available a spreadsheet that will perform the calculations. This spreadsheet is available from the Dam Safety Program.

It is necessary for the user to become familiar with the concepts and procedures presented in *WSP 2420* to properly use the publication for dam safety applications. While the parameters for determining unit hydrographs were developed from Montana hydrological data, there is scatter in the data used to derive the variable regression equations and the user is encouraged to review and understand the reliability of the equations prior to unit hydrograph development. *WSP 2420* fully explains the limitations and design considerations of the study. Several limitations are as follows:

- Unit hydrograph characteristics were generally derived from general (or long duration) rainfall events instead of local (thunderstorm) events. These were some of the largest storms recorded in Montana, so they should represent the "worst-case" conditions.

- Lag time estimates in the report are not valid for use in other dimensionless unit hydrographs, such as those of the U.S. Bureau of Reclamation.
- The unit hydrograph duration needs to be small enough to reasonably estimate the peak discharge. Rules for calculating the unit duration are given in the study.
- The methods are applicable for basins small enough that variations in areal runoff do not affect the hydrograph shape. If the calculated unit duration is greater than 7 hours, the basin may require subdividing with separate unit hydrographs for each subbasin. Likewise, it is recommended that basins over 500 square miles be subdivided for the same reasons.
- Equations for adjusting the peak and shape of dimensionless unit hydrographs are invalid when the desired dimensionless peak discharge is less than 8.0.
- The study estimation methods are valid only within the range of variables used. Figures 15-19 should be reviewed to insure that the basin parameters are within the range of data used in *WSP-2420*.
- The methods are intended for use at ungaged sites where no site-specific information is available.

3.2.2.2 Other Methods

Hydrology texts describe various other methods for determining synthetic unit hydrographs. Here are brief descriptions of several of the most common methods, whose reference citations are included in the text by Viessman and Lewis (2003):

Gamma Distribution – Because the shapes of most hydrographs closely match a two-parameter gamma function, this method can be used to develop synthetic unit hydrographs. The advantage of this method is the volume under the curve can be determined to exactly equal one inch of runoff from a basin, plus it produces a line that is continuous rather than relying on the calculation of only several points to draw a curve.

Snyder's Method – Commonly employed by the US Army Corps of Engineers, this method is used in the USGS dimensionless unit hydrograph procedure to determine

standard lag time. But the full use of the method results in calculations of lag time, time base, unit hydrograph duration, peak discharge, and hydrograph time widths at 50 and 75 percent of peak flow to construct a unit hydrograph. Some coefficients vary according to types and locations of streams and drainage basins.

Espey-Altman Method – For use in primarily urban settings, this method uses a set of regression equations developed from a regional analysis of relatively small watersheds to calculate seven points on a 10-minute unit hydrograph.

NRCS Dimensionless Unit Hydrograph – Using the same general concept as in WSP 2420, the NRCS used the results of an analysis on a large number of natural unit hydrographs to develop dimensionless time and discharge coordinates for a dimensionless unit hydrograph. In order to determine the unit hydrograph coordinates, the method requires calculations of the hydrograph time from the beginning of rainfall to peak discharge and the peak discharge.

3.3 RAINFALL LOSSES

Not all rainfall becomes surface runoff. Understanding how rainfall infiltrates, is intercepted, or is stored in small ground depressions is key to determining the volume and timing of runoff. Reasonably accurate estimates of rainfall losses are difficult to determine and are probably the most subjective parameters in surface hydrology. The following sections provide guidance on some of the methods for determining rainfall losses.

3.3.1 Initial Abstraction

As defined by the NRCS, initial abstraction is the portion of rainfall that is lost before it becomes excess rainfall or surface runoff. Initial abstraction includes interception (rainfall that is held by vegetation or structures before reaching the ground), infiltration (rainfall lost into the soil before becoming saturated and reaching a point where rainfall intensity is greater than the soil infiltration rate), and depression storage (surface storage

areas that do not release trapped water during the rainfall event). Initial abstraction can be estimated by several different methods.

The most common equation for determining initial abstraction is empirical and used in conjunction with the NRCS curve number method (2007) (see Section 3.3.2.1of this technical note), which is

$I_a = 0.2S$ where I_a = initial abstraction, inches

S = potential maximum retention after runoff begins, inches = 1000/CN -10

CN = soil complex curve number

HEC-HMS offers many different methods of determining rainfall loss and initial abstractions are generally included with each method. Note that when using the NRCS curve number method (see section 3.3.2.1), if an initial abstraction of zero is entered, HEC-HMS automatically calculates an initial abstraction based on the curve number. The user is encouraged to estimate initial abstraction with whatever method is familiar, but to justify the parameters chosen.

Initial infiltration loss is included with methods on infiltration (Section 3.3.2). Other resources are available for estimating interception, such as Horton (1919) and Woodall (1984). Depression storage can be estimated from other sources as well, including Chin (2006).

Initial abstraction can be a useful tool in calibrating a surface runoff model such as HEC-HMS. Please refer to Section 8.0 of this technical note for a discussion on model verification.

3.3.2 Infiltration

Infiltration in this application refers to rainfall lost to the soil after initial abstraction, once surface runoff has started. Infiltration rates vary with soil texture. In general terms,

infiltration rates in coarse grained or sandy soils are much higher than fine grained or clayey soils. Infiltration rates for a given soil are not linear over time when water is continuously ponded at the surface. Given enough time with water ponded over the soil column, infiltration will approach a steady, constant rate. Infiltration rates can be estimated by several different methods, briefly described below:

3.3.2.1 NRCS Curve Number

The USDA Natural Resources Conservation Service (NRCS) developed the curve number model through empirical research on a broad range of soil types and cover combinations. It is probably the most popular method of determining excess rainfall, or direct surface runoff, because of its ease of application and extensive database of parameters. The curve number model divides rainfall into three components: rainfall excess (runoff), initial abstraction, and retention. Through a series of computational relationships between all three components, the NRCS developed hydrologic soil-cover complexes. Each complex was assigned a curve number, or CN, which indicates the runoff potential of a complex during periods when the soil is not frozen. High curve numbers indicate high potential for runoff. The highest possible CN is 100, which means that all rainfall becomes runoff and there are no abstractions.

In order to use the CN method, the user has to know the soil and cover types for the basin being considered. The user also has to determine the hydrologic condition of the cover vegetation (whether it is thick or sparse), and assume an antecedent soil moisture condition. Appendix C of this technical note contains tables for estimating CN for a basin.

While this method is empirically-based and has been shown to be less accurate than some physically-based infiltration models, it is one of the most widely used methods. It provides a relatively easy method to estimate rainfall losses, especially over large basins, and it is backed by the NRCS, who use this method extensively. To the extent possible, the user should verify the results of a rainfall-runoff model based on the CN method with

an independent analysis of peak discharge values and adjust CN values appropriately, as described in Section 8.0 of this technical note.

Note that curve numbers can give a quick estimate of direct runoff volume from a basin using the following NRCS equation:

$$Q = \frac{(P - 0.2S)^2}{(P + 0.8S)}$$

Where Q = direct runoff in inches (which can be converted to volume by multiplying by the basin area)

P = total precipitation in inches

S = potential maximum retention of precipitation = (1000 – CN)/10

CN = curve number

3.3.2.2 Constant Loss Rate

The constant loss rate for infiltration is used when the assumption is that the soil is saturated and infiltration has reached a minimum, steady value. Use of this method also indicates that initial infiltration abstractions are zero. Various tables are available with estimated constant loss rate values for different soil types. The Technical Reference Manual for HEC-HMS has such a table with ranges of constant loss values for soil types used for CN estimations.

3.3.2.3 Other Methods

Other infiltration models are appropriate and, when properly used, provide very accurate estimates of rainfall infiltration. There are general input parameters available for these methods, but most require actual infiltration data to be effective. Data collection may be cumbersome in most applications, but these methods can precisely predict infiltration if data are available. References for the following infiltration models are included in the HEC-HMS Technical Reference Manual.

Horton Model – Derived empirically but based on physical relationships, the Horton Model is an exponential relationship that defines infiltration rate over time assuming water is continuously ponded over the soil. Infiltration declines exponentially until it asymptotically approaches a minimum constant rate.

Green-Ampt Model – Also called the delta function model, it was derived as both a physical and empirical model that assumes water is constantly ponded on the soil surface and that as the water moves downward in the soil, there is a sharp interface where wet soil meets dry soil. Infiltration is affected by soil hydraulic conductivity, wetting front suction head and porosity.

3.3.3 Percent Impervious Area

If a basin contains areas that prevent infiltration, such as frozen ground, open water bodies, pavement, rock, etc., these surfaces are accounted for in the model as "percent impervious area". This factor is used in conjunction with CN or other loss methods to estimate runoff in a storm event. Greater percentages of impervious areas produce higher runoff volumes. Therefore, if the user desires conservative (high) runoff values, then high percent impervious values are used. Percent imperious area can also be used as a calibration parameter when verifying model results.

4.0 CHANNEL ROUTING METHODS

If there is a component to the hydrologic model that requires flow of runoff in an established channel, such as a stream, river, or prismatic channel, the model will need a method specified to route the hydrograph. Channel routing is a means of transporting flow in a channel and adjacent floodplain overbanks. Routing starts with a runoff hydrograph determined from overland flow of excess rainfall, or direct surface runoff, from a subbasin. The upstream hydrograph is routed down the channel by a specified method to a known downstream point, resulting in a downstream hydrograph. Travel time through the specified reach is an indication of the hydrograph translation. Attenuation of the hydrograph (reduction of peak discharge and flattening of the hydrograph curve) occurs because of energy loss and storage as it travels downstream.

As described in Section 4.2, there are several models available for computing a downstream hydrograph using a program such as HEC-HMS. Each of these models solves, in various degrees of simplification, the fundamental equations of open channel flow: the continuity and momentum equations. Combined, the two equations are known as the St. Venant, or unsteady (dynamic wave), equations. HEC-HMS methods are simplified to the point of approximating unsteady flow using simplified approximations. These approximations typically combine the continuity equation with a simplified momentum equation that includes only relevant and significant terms. The justification for not using the solution of the full unsteady equations in HEC-HMS is that approximations of the full equations are adequate for typical flood routing needs and the approximations provide faster and more stable computational processes.

It may be necessary for some problems to use the full unsteady equations. Section 4.3 provides a brief summary of some of the models available for this application.

4.1 BASEFLOW

A runoff hydrograph is generally separated into two types of flow: direct runoff from excess precipitation and baseflow. Baseflow is usually the "normal" flow of a water course, consisting of runoff from prior precipitation or groundwater inflow that was stored temporarily in the watershed. Baseflow can also be the delayed subsurface runoff from the current storm. Some modelers try to account for the contribution of snow melt by approximating it as baseflow.

Some models of watersheds use extensive computations to account for baseflow storage and subsurface flow. This approach is appropriate for long-term watershed modeling and hydrologic budgeting. However the impact of baseflow on a short-term flood event, such as for dam safety applications, may be not as significant. HEC-HMS uses three methods for estimating baseflow, each with simplified approximations that are more appropriate for storm runoff applications:

- Constant, monthly-varying value
- Exponential recession model
- Linear-reservoir volume accounting model

Selection of the appropriate method is left to the user.

4.1.1 Considerations for Snow Melt and Rain-on-Snow

While most extreme runoff events are triggered by and modeled for only rainfall, there is the potential for significant runoff caused by snowmelt in Montana. Spring and early summer storms may occur on snowpack, creating rain-on-snow events that have the potential to be severe. Mostly notably, the June 1964 storm along the northern Rocky Mountain front that caused nearly 20 fatalities and several dam failures was a rain-on-snow event. Given the right meteorological conditions, high elevation watersheds have the potential for significant runoff from only snowmelt.

However, effective and accurate modeling of snowmelt is difficult and tends to be very data intensive. HEC-HMS offers two methods for predicting snowmelt: the gridded temperature index and the temperature index. Both methods use atmospheric conditions to determine snow accumulation and snowmelt rates. Runoff is the result of availability of liquid water at the soil surface.

Snow's contribution in hydrologic modeling can be simplified to at least estimate that portion of runoff resulting from snowmelt. If some data are available to determine reasonable estimates of runoff by snowmelt, they can be used to enhance the rainfall runoff. A typical method is to account for the snowmelt by increasing base flow by an average snowmelt discharge. Total discharge would combine the rainfall runoff and the enhanced base flow.

The NRCS maintains SNOTEL sites, which are remote, high mountain snow data collection locations, for providing snowpack runoff data that is transmitted telemetrically. SNOTEL stands for SNOwpack TELemetry. In addition to providing data that may be used to determine average or typical rates snowmelt runoff for a basin, SNOTEL sites may provide data that can be used to confirm that a spillway is sized adequately to handle the largest snowmelt event of record in addition to the spillway design inflow. For some small, high mountain dams, this maximum snowmelt rate may be larger than the spillway design inflow calculated from precipitation events.

4.2 HEC-HMS ROUTING METHODS

As mentioned previously, HEC-HMS offers routing methods that provide approximations of full unsteady flow equations. Methods should be selected based on specific uses and conditions of the routing channel and parameters of the project, and familiarity of the user with a specific method. The following are brief descriptions of the methods offered in Version 3.2 of HEC-HMS and, for some of the following methods, their applicability for routing hydrographs along channels:

Kinematic Wave Routing – This process ignores the inertial and pressure forces of the full unsteady flow equations. It is better suited for relatively steep streams and channels

that can be approximated by regular shapes and slopes, such as man-made channels. Five options are provided for determining the channel cross sectional shape: circle (for open channel flow in circular channels – not for pressure flow in a pipe), deep (for shapes where depth is approximately equal to width), rectangle, trapezoid, and triangle.

Lag Routing – This method is used only for the translation of a flood wave, or hydrograph. It does not account for attenuation or diffusion of the flood wave. It can be effectively used in short stream segments where travel time and flow depth are known and do not vary. The only input parameter for lag routing is lag time, which is the travel time for the hydrograph to move from the upstream end to the downstream end of the stream segment. It is best suited to short stream segments with a predicable travel time that doesn't vary with flow depth. This method may be overly conservative, as some attenuation always occurs.

Modified Puls Routing – Also called storage or level pool routing, this method uses a relationship between water storage in a stream reach and discharge from the reach to route flow. It is through calculated storage and delayed release of retained water that attenuation is determined. It can be used to calculate backwater from channel constrictions, as long as the backwater is contained in the stream reach. The process requires input of a storage-discharge function for each reach. This can be obtained from hydrograph analysis or by conducting a HEC-RAS analysis of the reach to determine a storage-discharge relationship. The user also determines an initial flow condition by one of three options: initial discharge; outflow equals inflow; and an elevation-discharge relationship.

Muskingum Routing – Using a basic conservation of mass computation, this method determines a water surface that is linear but is not level. By this approximation, Muskingum routing accounts for increased water storage in the rising limb of the hydrograph and decreased storage in the falling limb. By adding a travel time component, K, and an X variable that expresses the weighting between inflow and outflow in the specified reach, this method approximates hydrograph attenuation.

Muskingum-Cunge Routing – This method combines the conservation of mass and an approximation of diffusion in the conservation of momentum equation. Sometimes referred to as the variable coefficient method, it recalculates parameters at each time step with new depth and channel properties. It is sometimes referred to as a variable coefficient method because the routing parameters are recalculated every time step based on channel properties and the flow depth. It represents attenuation of flood waves and can be used in reaches with a mild slope. The user has a choice of five types of cross sections to enter into the routing procedure: rectangular, trapezoidal, triangular, circular or an eight-point section. The eight-point section makes this method useful for natural channels and is based on an average stream and floodplain cross section for the selected reach. Reaches should be determined on the basis of each having similar cross sectional properties. Manning's 'n' values for channel and left and right overbanks are to be input by the user. Manning's 'n' values should be average numbers for each reach. Note that when using HEC-HMS it often is necessary to include a baseflow when using the Muskingum-Cunge method, in order for the computations to work.

Straddle Stagger Routing – This method uses empirical representations of translation and attenuation to route flow through a specified reach. Two parameters are entered into the model: lag and duration. Lag is the approximate travel time of the hydrograph through the reach; duration defines the amount of spread in the hydrograph peak, or the amount of attenuation.

4.3 OTHER ROUTING METHODS

For more precise estimation of hydrograph routing in a channel reach, it is recommended that a hydraulic model be used to incorporate the full solution of St. Venant's equations. At this time, the most widely used and accessible computer program for accomplishing this is HEC-RAS (River Analysis System, USACOE, 2008). The advantage of unsteady flow estimation in HEC-RAS is that the physically-based equations more accurately represent floodplain storage and energy dissipation while a flood wave travels in a natural channel and floodplain corridor, as well as defining backwater profiles at channel

constrictions. At this time, HEC-RAS computational modeling of unsteady flow tends to be somewhat unstable in cases of rapidly varied flow, such as a flood wave, and the user is required to make model adjustments based on professional judgment to overcome the program instability.

The National Weather Service (NWS) developed two computational models to help forecast hydrograph routing in rivers. The first, DWOPER (Dynamic Wave Operation Model) (1984), was intended as a tool to model unsteady flow in major rivers where mild bottom slopes and backwater created problems in hydrologic routing models. The second is DAMBRK (Dam Break Model) (1988), used primarily to predict flood wave routing specifically for dam failures. Each model has limitations unique to their intended function. The NWS sought to combine features of each into one model, called FLDWAV (Generalized Flood Wave Routing Model) (1998), but at this time, access to the program is limited and utilization is primarily for NWS projects.

The United States Geological Survey (USGS) has available for public use a program titled Full Equations Model (FEQ) (1996), which is a computer model for simulation of one-dimensional unsteady flow in open channels and through control structures. According to the USGS, FEQ can be applied to simulate a wide range of stream configurations including loops and lateral-inflow conditions.

All of the programs mentioned above are one-dimensional unsteady flow models. Applications of flood flow simulation in wide, flat floodplains where flow occurs in two directions may require the use of two-dimensional models such as FLO-2D® (FLO-2D, 2007) or MIKE FLOOD® (DHI, 2008). Both models are approved by the Federal Emergency Management Agency (FEMA) for floodplain modeling and use dynamic computations for complex flow interaction. Use of these models requires a technical understanding of the two-dimensional flow regime.

5.0 PRECIPITATION ESTIMATES FOR MONTANA

For use in rainfall-runoff modeling, precipitation is the catalyst for runoff. While basin characteristics have a significant effect on the timing and volume of runoff, precipitation plays a more important role, especially with very large storms that easily saturate soil and fill small depression storage areas. Four components of precipitation need to be determined in order to fully define how runoff will occur: depth, duration, temporal distribution and spatial distribution. Depth and duration are linked by the premise that severe storms of short duration typically have higher rainfall intensities than longer duration storms. Publications specific to Montana have been developed by both the USGS and NWS to assist in precipitation estimates.

In response to the effort by DNRC to base spillway IDF on LOL from dam failure, and move away from standards based solely on reservoir size, the USGS developed methods for determining storm depth and temporal distribution up to a return interval of 5,000 years for the state of Montana. For larger storms, rainfall depths are interpolated between the 5,000-year storm and the probable maximum flood (PMF). As described earlier in this technical note, a PMF is produced by PMP estimates, which in turn are computed by methods developed by the NWS.

5.1 RAINFALL BASED ON OCCURRENCE PROBABILITY

For dams having LOL less than or equal to 5 (determined from a dam breach evaluation), and subsequently a storm return interval of between 500 and 5,000 years, the rainfall storm depth is calculated using methods developed by the U.S. Geological Survey (USGS) for extreme precipitation events. The following sections provide guidance on use of the appropriate references.

5.1.1 Storm Depth and Duration Determination (*USGS WRIR 97-4004*)

The USGS published *Water-Resources Investigations Report (WRIR) 97-4004, Regional Analysis of Annual Precipitation Maxima in Montana* (1997). This document provides methods for determining precipitation depths in Montana for extreme storms having

exceedance probabilities up to one-in-five thousand, or return intervals to 5,000 years. The study utilized statistical procedures that effectively combine record lengths of multiple rainfall gages to make depth estimates for relatively long return intervals. Dimensionless frequency curves for three homogeneous regions within Montana were developed based on physiography and climate. Precipitation depths can be computed for storm durations of 2-, 6-, and 24-hours. Mean storm depth regression equations use site mean annual precipitation, latitude and longitude as variables. The user is encouraged to follow the publication examples in *WRIR 97-4004* to determine storm depths for various applications.

5.1.2 Temporal Distribution (*USGS WRIR 98-4100*)

Following *WRIR 97-4004*, the USGS published *Water Resources Investigations Report 98-4100, Characteristics of Extreme Storms in Montana and Methods for Constructing Synthetic Storm Hyetographs* (1998), which identifies temporal distributions of incremental storm depths for 2-, 6-, and 24-hour duration storms, and their application to analyses or design. The study uses the same homogeneous regions as *WRIR 97-4004*. Starting with total storm depths determined from *WRIR 97-4004*, incremental depths are calculated and distributed to construct hyetographs according to regional statistical analyses. Peak incremental depths are temporally distributed based on historical occurrences within a specified region and the level of conservatism desired. *WRIR 98-4100* offers examples of hyetograph construction for various applications in the homogeneous regions of the state.

5.1.3 Areal Distribution

Specific spatial, or areal, distribution recommendations are not given in *WRIR 97-4004* or *WRIR 98-4100*. Spatial distribution is left to the user. It is possible to use the areal distribution procedures for some PMP estimates, discussed in Section 5.2.4. Section 5.2.4 also provides a brief discussion on the use of areal distribution within a drainage basin.

5.1.4 Areal Reduction Factors

WRIR 98-4100 provides depth-area reduction curves that are adapted from NOAA Atlas-2 (1973). These curves should be utilized to compute a basin-wide areal reduction factor for rainfall depth values derived from *WRIR 97-4004*.

5.2 PROBABLE MAXIMUM PRECIPITATION (NWS HMR 55A AND 57)

The National Oceanic and Atmospheric Administration (NOAA) conducted a nation-wide study of precipitation events mainly to address the need to develop data in support of the growing concern over dam safety issues in the late 1970's. Because of the potentially catastrophic results of dam failures, NOAA developed methods to estimate rainfall events that potentially create the most severe precipitation possible, given optimum meteorological conditions. These storms are defined as probable maximum precipitation, or PMP, events. NOAA conducted PMP studies for specific regions throughout the United States. The PMP studies are called Hydrometeorological Reports, or HMR's. Two HMR's cover the state of Montana: HMR No. 55A (1988), which was developed for the area of the United States between the Continental Divide and the 103rd Meridian (the longitudinal line just east of the Montana-North Dakota border); and HMR No. 57 (1994), which is for the Pacific Northwest States of Idaho, Oregon, Montana and Washington between the Continental Divide and the Cascade Mountains.

5.2.1 Storm Duration

PMP estimates were developed for both short duration ("local") and long duration ("general") events. General storms are defined as a major synoptic weather features that are longer than 6 hours duration and can cover large drainage areas. Local storms are generally shorter than 6 hours in duration (often only 1 or 2 hours long), are separate from general storm patterns, and are confined to smaller drainage areas. Local storms are often related to thunderstorm events.

HMR procedures typically apply to general storms having durations between 1 and 72 hours over areas between 10 and 10,000 square miles, and local storms having durations between ¼ and 6 hours over areas between 1 and 500 square miles. NOAA recommends

that for drainage areas less than 500 square miles, both the general and local storms should be considered.

The goal of estimating IDF for dams is to determine the worst case, or most conservative, scenario if options are available for a given storm event. In general, local storms will produce higher peak discharges and less runoff volume than general storms. Therefore, professional judgment may be needed to determine if a local storm or a general storm will produce the largest routed flood for spillway capacity analysis. Many times both storms need to be routed to determine which is the most severe. Often, spillways for reservoirs on small drainages will experience higher outflows from local storms than from general storms. The opposite is often the case with spillways on reservoirs with large upstream drainage areas. There are exceptions, however, and the user is cautioned to explore all plausible cases because other factors play a role in determining the worst-case scenario for spillway analysis, such as reservoir volume, dam height and drainage basin characteristics

5.2.2 Storm Depth Determination

Each HMR contains step procedures and examples for determining total and incremental depths for a specified storm. Time increments are determined by total storm duration, with shorter increments associated with shorter durations. There are some steps that require user decisions, such as the use of all-season or seasonal PMP estimates, depending on the application. The user is responsible for understanding the appropriateness of such factors.

Other factors in the step procedures will affect the calculated storm depth, such as areal reduction factors that are used to account for spatial variability of storms over larger drainage areas.

5.2.3 Temporal Distribution

HMR publications provide guidance on determining the sequential order of PMP increments. The sequence combinations provided are options for the user to determine the critical distribution for a specific drainage.

Another option is to use the temporal distributions found in *WRIR 98-4100* (described in Section 5.1.2 of this technical note), which are specific to Montana regional extreme storms. Options for determining sequences that fit with the intended purpose of the storm synthesis can allow the user flexibility in computing conservative hyetographs for dam safety purposes.

5.2.4 Areal Distribution

Procedures for areal distribution of the PMP over a basin are only provided for western Montana in HMR No. 57 for local, short-duration storms. If this method is used, the user can then eliminate rainfall adjustments for duration and basin area.

No other specific areal distribution procedures are given in HMR publications for Montana.

Use of areal distributions in a hydrologic model such as HEC-HMS requires special considerations on how the model is set up and developed. For synthetically produced precipitation, the HEC-HMS model distributes rainfall uniformly over the area of an identified subbasin. Areally distributed rainfall can be simulated by use of gage weights, gridded precipitation data or treatment of rainfall on specifically delineated subbasins within the entire drainage area.

5.2.5 Areal Reduction Factors

Both HMR 55A and HMR 57 provide depth area reduction curves which should be utilized to adjust PMP depths based upon total basin area.

5.3 DESIGN PRECIPITATION DEPTH

In Section 2.2 of this Technical Note, descriptions were given of how to compute an IDF for spillway capacity analysis. In general, the size of the IDF is dependent on the LOL downstream of the dam. For LOL less than and equal to 5, the IDF is computed by precipitation based on occurrence probability. For LOL equal to or greater than 1000, the IDF is computed by precipitation based on full PMP estimates. However, it is the case where LOL is between 5 and 1000 that computation of precipitation for the IDF becomes more complicated. The equation for calculating these precipitation depths are given in Section 2.2.2.2.

Provided in this section are three suggested methods for calculating precipitation depths for LOL between 5 and 1000: 1) The Non Areal Reduced Approximate Method, 2) The Areal Reduced Approximate Method and 3) The Incremental Precipitation method.

The Non Areal Reduced Approximate Method for calculating precipitation depths for LOL between 5 and 1000 is as follows:

1. Through previous analyses, determine the storm duration that produces the most severe routed spillway flow from an IDF. If this has not been done, then the steps that follow should be repeated, once for a short duration storm (usually no greater than 6 hours) and again for a long duration storm (usually 24 hours or longer).
2. At the selected storm duration, determine total precipitation depths for two events:
    a. A 5,000-year event using the references and procedures given in Section 5.1 of this Technical Note, without including the aerial reduction factor.
    b. A full PMP event using the references and procedures given in Section 5.2 of this Technical Note, without including the areal reduction factor.
3. Use the equation for Section 2.2.2.2 to compute an interpolated depth. Note that the areal reduction factors in WRIR 97-4004 differ from those utilized for development of the PMP. Leaving the areal reduction factors out of the 5,000

year and PMP precipitation values, avoids combining apples and oranges, so to speak. Note that the interpolated depth is not areally reduced.

4. Use procedures in WRIR 98-4100 (Section 5.2 of this Technical Note) to distribute the interpolated precipitation depth temporally. An areal reduction factor is applied at this time.

The Areal Reduced Approximate Method for calculating precipitation depths for LOL between 5 and 1000 is as follows:

1. Through previous analyses, determine the storm duration that produces the most severe routed spillway flow from an IDF. If this has not been done, then the steps that follow should be repeated, once for a short duration storm (usually no greater than 6 hours) and again for a long duration storm (usually 24 hours or longer).
2. At the selected storm duration, determine total precipitation depths for two events:
    a. A 5,000-year event using the references and procedures given in Section 5.1 of this Technical Note, including the aerial reduction factor.
    b. A full PMP event using the references and procedures given in Section 5.2 of this Technical Note, including the aerial reduction factor.
3. Use the equation for Section 2.2.2.2 to compute an interpolated depth. Since both the 5000 year storm and the PMP are aerial reduced, the interpolated depth is considered to be areally reduced.
4. Use procedures in WRIR 98-4100 (Section 5.2 of this Technical Note) to distribute the interpolated precipitation depth temporally. Since the precipitation is already areal reduced, the areal reduction factor is neglected (assigned a value of 1).

The Incremental Precipitation Method for calculating precipitation depths for LOL between 5 and 1000 is more technically accurate, but significantly more complicated than either Approximate Method. The procedure is as follows:

1. Develop areally reduced depth-duration curves for both the 5,000 year event and the PMP following the procedures given in WRIR 97-4004 and the appropriate HMR, respectively. Note that the areal reduction factors in WRIR 97-4004 differ from those utilized for development of the PMP. The reduction factors will also differ for each incremental duration.
2. Use the equation from Section 2.2.2.2 to compute an interpolated cumulative depth for each duration in the two depth-duration curves. The resulting interpolated depth-duration curve will be the design depth-duration curve.
3. Use procedures in *WRIR 98-4100* to develop a temporal distribution of incremental precipitation depths from the design depth-duration curve.

6.0 RESERVOIR AND SPILLWAY CHARACTERISTICS

Characteristics of the reservoir and spillway are important to identify the reservoir storage volume and spillway outflow characteristics for routing the IDF. Unless the reservoir has a relatively small volume in relation to the upstream drainage area, the reservoir pool is typically effective, at least to a certain degree, attenuating the peak discharge of the inflow design hydrograph. The extent of attenuation is also dependent on the required spillway IDF magnitude.

The term "spillway" in this section refers to a reservoir's principal and auxiliary spillways which are designed to safely convey flood waters past the dam. The capacity of the low-level outlet should typically be ignored in the flood-routing analysis since it is typically much smaller than the spillway capacity. Additionally, flood events often occur unexpectedly and may impair access to the dam, thus making it difficult to operate the gates. There are cases, however, where analysis of the outlet capacity is necessary and methods to assist in determining its stage-discharge relationship are given below.

6.1 RESERVOIR STAGE-AREA/VOLUME

One of the most difficult data features to obtain, the reservoir volume is often approximated unless a recent detailed bathymetric survey has been completed. Often the only reservoir volume information is from original design data, which may be outdated because of sedimentation in the reservoir. However, original design data may be the only reasonable information available. The user may need to exercise judgment or use other available data to determine actual reservoir volume.

As an alternative to existing volume data, there are two relatively easy methods to approximate reservoir volume. The first is to estimate volume using the simplified equation found in ARM 36.14.102, which is

Reservoir volume = 0.4 times the vertical height in feet from the downstream toe of the dam to the crest of the dam times the water surface area at that level in acres.

The above equation more closely approximates volume if the reservoir is fairly circular in surface area.

Another relatively simple method for reservoirs in natural basins is to approximate volume by interpolating an elevation-area relationship of the basin above the normal storage level for the reservoir. This can usually be accomplished with USGS 7.5 minute quadrangle topographic maps. The method involves the following steps:

1. Determine the area for several elevation contours above the normal water level of the reservoir. Assume the dam's location does not change.
2. Plot the contour elevations versus area on graph paper or using a spreadsheet graphing feature.
3. Also plot the elevation of the reservoir outlet, or known low point of the reservoir, at the zero area point.
4. Interpolate the line through the elevation zone of the reservoir, from the normal water surface elevation to zero, using the same shaped curve as for the plotted points, or by using a fitted-curve function of a spreadsheet.
5. Use the interpolated points to calculate volume by the elevation-area method.

6.2 DAM CREST ELEVATION AND WIDTH

The elevation of the low point on the dam crest and the width of the crest can be measured easily in the field, if the information is not already published. It is important to obtain the low-point elevation of the crest to understand when overtopping might occur. The crest width can be used to estimate flow over the dam if overtopping occurs during model routing. Overtopping flow can be approximated by appropriate broad-crested weir equations.

6.3 OUTLET CONDUIT DISCHARGE

For a conservative method of determining the spillway capacity, ignore the low-level outlet flow contribution during flood routing. For most small to medium sized earthen dams, the outlet capacity is much smaller than the spillway capacity, and it is reasonable to ignore outlet flow contribution. This is particularly true since it should not be assumed that the dam operators will be able to access the dam in a timely fashion during an extreme flood event.

6.3.1 Discharge Estimation

Three HEC-HMS methods can be used to estimate elevation-discharge relationships for the outlet if it is used in flood routing. The first method is to choose the 'Outflow Curve' option and calculate the elevation-discharge curve using established hydraulic equations. In HEC-HMS, the outflow curve can be entered as a paired data function. Calculated flow through a gated outlet with a pipe culvert should include the following:

- Discharges at several reservoir levels, accounting for the hydrostatic head above the outlet pipe
- Entrance and exit head losses and any head loss through gates
- Friction loss in the outlet pipe, accounting for pipe length, material on the inside of the pipe, the pipe's age and its condition
- Tailwater levels in the downstream outlet channel for the range of possible discharges

The second method available in HEC-HMS is to choose the 'Outflow Structures' option, which allows the model to compute outlet flow given a standard set of parameters. There are two methods available: orifice and culvert outlets. The orifice method applies to outlets without a culvert pipe, while the culvert method is used for low-level outlets where friction head loss would affect the outflow characteristics. The outflow structures option also computes emergency spillway flow, which is discussed in Section 6.4.

The third method is identified as 'Specified Release' in HEC-HMS. This option is used if actual outflow data has been measured and the gage information is used instead of an outflow curve. The measured flow is entered as a time-series gage and should represent actual measured outflows for time periods in the past and estimated outflows for any time periods in the future.

6.4 SPILLWAY STAGE-DISCHARGE

In most cases, the spillway is used only during runoff events. Also, spillways are typically open channels with relatively prismatic cross sections, or weir structures that have various crest configurations (such as broad-crested or ogee).

As discussed in Section 6.3 for outlets, HEC-HMS offers three ways to defined emergency spillway outflow characteristics: outflow curve; outflow structures; or specified release.

An 'Outflow Curve' is determined by independent calculation of spillway discharge for a range of reservoir elevations. Commonly, this is accomplished by use of a surface water profile model, such as HEC-RAS. Other methods to calculate the open-channel flow is by manual calculations using Manning's equation or by programmed software, such as FlowMaster® (Bentley, 2005), which can estimate flow in prismatic channels. The elevation-discharge or storage-discharge relationship is entered as a paired-data file.

The 'Outflow Structures' option has three methods available for calculating spillway discharges: broad-crested spillway; ogee spillway; or a specified spillway. Broad-crested and ogee methods will prompt the user to input parameters that define the chosen spillway. The specified spillway method is the same as entering an outflow curve, as described in the above paragraph, as a paired-data file.

'Specified Release' is essentially the same as described for principal spillway outlets in Section 6.3, except that flow data is measured for the emergency spillway. The measured data is entered as a time-series gage in HEC-HMS.

7.0 MODELING SURFACE RUNOFF AND FLOOD ROUTING

As indicated previously in this technical note, the most common runoff and flood routing model currently in use is HEC-HMS. While some of its limitations have been pointed out, HEC-HMS is relatively user-friendly and provides reliable results. The model is versatile in being able to route floods through reservoirs and spillways. It is a useful tool for dam safety evaluations to effectively determine spillway adequacy.

HEC-HMS is made available to the public at no cost. However, the Corps of Engineers does not provided technical support to the public and it is up to the user to understand the applicability and limitations of the model. The user is also responsible for upgrading the model as new versions become available.

In this section, we have provided a brief overview on how HEC-HMS is organized and important features that are needed to conduct a spillway capacity analysis. This is not a replacement for the HEC-HMS User's Manual or Technical Reference Manual and the user is responsible for becoming familiar with the program and its use.

7.1 HEC-HMS PROCEDURES

HEC-HMS is separated into components that contain data for use in the model. The components are:

Basin Model	Time-Series Data
Meteorological Model	Paired Data
Control Specifications	Grid Data

The Basin Model is shown graphically and allows the user to place icons for each basin component in the order of flow. Once data is entered into the model, the user prompts the model to perform computations that estimate runoff and routing. Results of the computations are available in tabular or graphical form.

Model features are described below.

7.1.1 Basin Model

All basin, subbasin, channel (or reach, as defined in HEC-HMS), and reservoir information are entered into the Basin Model. Options are also available for junctions on more complex basins, diversions, sources and sinks. The Basin Model is organized with the parameters shown in Table 7-1. Typical information for entering data for spillway capacity models is contained in Sections 3.0, 4.0 and 6.0 of this technical note. Each feature within the basin is connected in order of flow direction. Separate subbasins can be connected at confluence points with the Junction feature in HEC-HMS. There are also options to model diversions, water inflow sources and sinks where no outflow occurs.

7.1.2 Meteorological Model

All rainfall, snowmelt and evapotranspiration information are entered into the Meteorological Model. The Meteorological Model is organized with the parameters shown in Table 7-2. Typical information for entering meteorological data for spillway capacity models is contained in Section 5.0 of this technical note.

7.1.3 Control Specifications

The Control Specifications allow the user to specify the time period of the model. The user is asked to enter a starting date and time and an ending date and time, as well as a model time interval. The time interval usually corresponds to the interval used in time series data, such as precipitation or discharge gages.

TABLE 7-1. BASIN MODEL PARAMETERS FOR HEC-HMS

Component	Method	Parameter

	Temperature Index

7.1.4 Time Series Data

Time series data includes the following type of information:

Precipitation Gages

Discharge Gages

Stage Gages

Temperature Gages

Solar Radiation Gages

Crop Coefficient Gages

Snow water Equivalent Gages

Time series data is information that includes time as a variable. Precipitation is usually the only type of time series data used in spillway analyses unless snowmelt is considered, in which case temperature, solar radiation and snow water equivalent gages may also be included.

7.1.5 Paired Data

Paired data are tables of information that identify relationships or functions between two variables for use in runoff and routing models. Options for paired data include:

Storage-Discharge Functions
Elevation-Discharge Functions
Elevation-Storage Functions
Elevation-Area Functions
Cross Sections
Inflow-Diversion Functions
Diameter-Percentage Functions
Unit hydrograph Curves
Percentage Curves
ATI-Meltrate Functions
ATI-Coldrate Functions
Groundmelt Patterns
Meltrate Patterns

Elevation, storage and discharge data are normally associated with reservoirs and spillways. Cross sections are used in channel routing methods. Most of the remaining paired data could be used in spillway analyses if needed.

7.1.6 Grid Data

Grid data for runoff-routing model is based on data captured during a discrete time frame and utilizes radar-based estimates for simulation. Grid data provides actual spatial data over a basin, whereas other time series data assumes uniform areal distribution over a basin. Therefore, it can be useful for calibration of a specified storm, but data may be hard to obtain. The options for grid data include:

Precipitation Grids
Temperature Grids
Solar Radiation Grids
Crop Coefficient Grids
Storage Capacity Grids
Percolation Rate Grids
Storage Coefficient Grids
Moisture Deficit Grids
Impervious Area Grids
SCS Curve Number Grids
Elevation Grids
Cold Content Grids
Cold Content ATI Grids
Meltrate ATI Grids
Liquid Water Content Grids
Snow Water Equivalent Grids

7.1.7 Simulation Runs and Results

HEC-HMS allows the user to create and run simulations for specified subbasins and meteorological models. Features in HEC-HMS gives the user options to check data prior to computations and messages appear to give the user information about the simulation, such as warnings and errors. Once a run is successfully computed, the user can view a variety of tables and graphs that display the results of the simulation.

7.2 SUGGESTED PHASE APPROACH

Modeling flood routing for evaluating spillway capacity can be a detailed and complex effort. When the cost of conducting such a study is considered, it is a benefit to the user and potential clients to look at ways to expedite the evaluation process and to save time and money where possible. Therefore, in this section we offer suggestions on phasing the evaluation process as an approach to determine spillway adequacy.

If detailed information is available and building a reliable model is relatively easy, then it is always better to use the best available data. Sometimes introducing overly conservative data, such as assuming no infiltration of rainfall, is a way of determining if the spillway exceeds its required capacity and limiting the time to develop more a detailed model. However, this approach does not allow a reasonable estimate of the basin's reaction to rainfall nor does it provide an accurate estimate of the spillway's actual capacity.

The following are steps suggested for building a flood routing model in a phased approach:

- Develop the model with data needed to begin the evaluation process:
    - Reservoir and spillway elevation-storage-discharge paired data.
    - Rainfall/snowmelt time-series data for the required return interval. For dams with estimated large LOL downstream, if it is suspected that the reservoir will pass the PMF, it may be wise to look at the PMF first. If the reservoir passes the PMF, there is no need to estimate the LOL downstream or calculate the IDF.
    - Basic basin characteristics such as drainage area and transform (unit hydrograph) information.
- Make conservative assumptions first to check if spillway capacity is adequate.
    - Conservative assumptions include: reservoir storage that is smaller than actual; larger rainfall storm than required; smaller spillway size than actual, use of lag equation for routing subbasin flows down to reservoir; etc.
- Run the model with conservative soil/infiltration assumptions first and check spillway adequacy.
    - Assume no initial abstraction and little to no rainfall losses. Note that HEC-HMS will calculate initial abstraction when using NRCS Curve number method if an initial abstraction of zero is entered.
- If spillway does not pass the routed flow at each intermediate steps, build a more detailed model with more exact information.

8.0 MODEL VERIFICATION

Any hydrologic model is as "good", or accurate, as the information input to the model. It is crucial to modeling that some form of verification be conducted to assure the model is as accurate as possible. In dam safety, the consequences of inaccurate modeling can be long-lasting and even severe. Underestimating spillway size may have the unfortunate result of dam failure, which can be devastating for the owner, engineer, and the public downstream. Overestimating spillway size is very costly to an owner. Putting effort into verifying the model may cost more in engineering analysis, but usually is a relatively small amount if done in a logical and professional manner, especially compared to the high cost of construction or the overwhelming cost of damages from failure.

This section provides guidance for conducting verification of hydrologic models used for spillway analyses. Actual hydrologic data may be scarce or difficult to obtain, but there are publications available that can assist the user in most cases.

8.1 MODEL UNCERTAINTY

In Montana, hydrologic records have been kept, at best, approximately one hundred years. Some data may have longer records and most are shorter. Streamflow gages exist on many waterways, but are more common on larger rivers. Most small streams are not gaged. Studies have been conducted by the USGS and other agencies that produced regression relationships to help predict flow frequency and magnitude on ungaged streams. While the regression equations developed for ungaged streams are reasonably accurate, they are based on gage data from regional streams, which have limited record lengths, usually no more than about one hundred years. So when spillway hydrologic analyses are conducted for runoff events that exceed a return interval of 500 years and greater the uncertainty associated with the flow estimates can be very significant.

Parameter estimates for basin characteristics tend to be general in nature, especially in larger basins, and are based on best available data or empirical relationships. Parameter selection,

such as soil and ground cover type, infiltration rates and unit hydrograph parameters each introduce uncertainty to the model.

The same is true for meteorological data, where gage data is likely not available for watersheds being considered, and where gage records, if available, are relatively short in length compared to the return intervals required for spillway analyses. User decisions for temporal and spatial distribution are subjective, though there are references for Montana that provide guidance based on statistical analyses of actual gage data. Regardless, rainfall and snowmelt input to a hydrologic model will invariably introduce additional uncertainty.

But any uncertainty introduced into a model is balanced against what should be considered reasonable, when using best available data. The methods included in this technical note provide references to data that are considered to be the best available for Montana. The goal of "reasonable" is reached when model verification is accomplished to within standard error bounds of recorded gage data or regression equations. Variability of model results will still exist among different users and according to differing objectives for specific spillway analyses, but hopefully the procedures for verification mentioned in this section will produce somewhat consistent methodologies.

8.2 MODEL CONSERVATISM

Because of uncertainty of a hydrologic model for spillway analysis, there is sometimes a common reaction for users to intentionally introduce conservatism as an assurance that the model will exceed standards and reduce risk of failure. Being conservative in spillway analyses is a choice that professionals must make depending on the dam, the risk of failure, and input from regulatory agencies, the public and the dam owner.

As briefly mentioned in Section 7.2, introducing overly conservative data as a first step in a phased approach to modeling is an option in determining if a spillway exceeds required capacity and it tends to reduce the time of analysis if the spillway successfully passes the conservative flood flow. This may be effective for only determining if the spillway "passes or fails" the simulated flow. But further analysis is necessary if the spillway does not

successfully pass the conservative flow, or if the analysis will be used to route multiple levels of storm magnitudes as part of the spillway analysis that would require verification that the storm estimates are reasonable.

Introducing conservative assumptions at various points in a hydrologic analysis make it difficult to verify model results. In Section 8.3, where model verification techniques are discussed, the goal is to verify, to the extent possible with available data, the results of the hydrologic model using peak flows established by statistical gage analyses or regional regression equations. If model input is knowingly conservative, verification will not be possible.

By virtue of the spillway standards set for high hazard dams in Montana, at least some conservatism is inherently introduced in the spillway analysis. Section 2.0 of this technical note provides an explanation of standards whereby spillway standards are established on the basis of LOL in the event of dam failure. An IDF is assigned a return interval of 1,000 times the expected LOL up to a 5,000 year return period. Between 5 and 20 LOL, the IDF is interpolated between the 5,000 year return period and the PMF. The PMF is the standard for LOL equal to or greater than 1,000. All of the IDF standards, including the minimum 500-year flood, are very large events established because of the catastrophic consequences, but whose occurrences are very rare. Adding conservatism to already rare events may make the analysis unreasonable, in addition to being unverifiable.

8.3 VERIFICATION METHODS

Because streamflow records are limited, statistical analyses to determine storm frequency peak flows can only estimate up to approximately 100-year, or possibly 500-year, return interval peaks. While these storm peaks may be relatively small in comparison to spillway design peaks, they still represent large, infrequent storms. The response of a Montana drainage basin to a 100- or 500-year rainfall event may be similar to that of a larger event, especially if soil infiltration rates reach the point of saturation and most of the rainfall becomes direct runoff. It is reasonable, then, to use 100- or 500-year peak streamflows to

verify hydrologic models for a spillway IDF. Smaller return intervals may be used for model verification if no other data exists.

In this section, we will discuss methods to conduct verification (sometimes called "pseudo-calibration") of hydrologic models using peak flows developed from streamflow gage data or USGS regression equations for ungaged basins. Adjustment of the model to match estimated peaks usually requires modification of basin characteristics. More specifically, it is common to adjust model parameters such as the unit hydrograph and basin losses so that the modeled peak flows match or exceed peak streamflow estimates from USGS regression equations or flood-frequency analyses. This also means that appropriate return interval rainfall to match the streamflow return interval peaks will need to be input to the model. This is contrary to the concept that rainfall of a specified return period will not always produce peak runoff of the same return period, but it is the closest method available.

8.3.1 Model Parameters

The primary model parameters that may be utilized to pseudo-calibrate the runoff peaks from the model are those associated with the unit hydrograph and basin losses. Although both will affect the runoff peak, changes made to the basin losses will also affect the runoff volume. It is generally more conservative to calibrate by adjusting the unit hydrograph since this will only affect the runoff peak without affecting the total runoff volume.

Unit Hydrograph Parameters: Tc and R (Clark Unit Hydrograph) and tp and qp (Dimensionless Unit Hydrograph) should be estimated using the equations given in *WSP 2420* (Section 3.2.2.1). These two parameters may be utilized to pseudo-calibrate the model, but should remain within one standard deviation of the estimated value.

Basin Infiltration Parameters: The parameters available to pseudo-calibrate the model are the "percent impervious area", "initial abstractions", and the loss rate (typically the curve number or ultimate infiltration rate). Each of these parameters has a range of "reasonable" values that may be estimated utilizing published guidelines (Section 3.3). The model should

be run with various combinations of basin infiltration parameters during the process of verification.

8.3.2 Gage Data

If the drainage basin upstream of a reservoir considered for spillway analysis has one or more streamflow gages near the reservoir or nearby in the basin, the recorded data could be used to determine a desired return period peak flow by a direct frequency analysis or analysis by transposition.

Probably the most common distribution used to conduct a frequency analysis of streamflow gage data is Log Pearson Type III. This distribution has been found to fit well with streamflow data and has wide application in hydrologic studies. Use of Log Pearson Type III analysis was popularized with the publication of Bulletin 17B (USGS, 1981) by the Interagency Advisory Committee on Water Data. Methods developed in Bulletin 17B have become the standard for conducting streamflow frequency analyses. The user can follow Bulletin 17B methods to conduct frequency analyses on streamflow data sets of at least 10 years. It is desirable to estimate flows to the highest return period possible in order to allow reasonable model verification for extreme floods.

Techniques for transposition of flows from a gage that is not located near the location of the reservoir but within the drainage basin being considered can be found other hydrologic technical references.

8.3.3 USGS Regression Equations (USGS WRIR 03-4308)

Approximately every ten years, the USGS publishes an updated version of regression equations that estimate flood frequency for ungaged streams. The latest publication is Water-Resources Investigations Report (WRIR) 03-4308 (2004) which is based on water data through 1998. Regression equations were developed that relate frequency peak flows to various basin and climate characteristics, as well as to bankfull widths. Estimates can be calculated for return intervals of 2, 5, 10, 25, 50, 100, 200, and 500 years.

Methods in WRIR 03-4308 are easy to implement and provide reasonable estimates of frequency flows when no gage data is available.

8.4 CONFIDENCE IN VERIFICATION AND MODEL CONSERVATISM

Since analysis of gage data and the use of regression equations have associated uncertainty, and "best estimates" for parameters have been utilized throughout the development of the model, it is necessary that the model be verified to insure that it's results are reasonable and that an appropriate level of conservatism is applied at this final step. The model results are typically considered to be "reasonably conservative" if they are within a confidence band between the calculated mean value and the mean value plus one standard deviation of the streamflow estimates (whether from gauged data or from the USGS regression equations). Additionally, it is important to verify that the model will continue to yield reasonably conservative results when it is used to estimate flows beyond the 500-year flood. This may best be accomplished by plotting the model results for the 100-year and 500-year peak inflows on the flood-frequency graph that contains the historic (or regression) streamflow estimates. The slope of the line between the 100-year and 500-year model result points should be equal to or greater than the slope between the corresponding streamflow estimate points. If the slope is too flat, it is very likely that the model will underestimate peak flows for larger events.

MINIMUM INFLOW DESIGN FLOOD FOR HIGH HAZARD DAMS (MONTANA SPILLWAY STANDARDS COMMITTEE TECHNICAL DECISIONS, MAY 1999)

MINIMUM INFLOW DESIGN FLOOD FOR HIGH HAZARD DAMS

MONTANA SPILLWAY STANDARDS COMMITTEE

TECHNICAL DECISIONS

May 1999

Introduction

Under current Montana Rule 36.14.502, the Probable Maximum Flood (PMF) or a fraction thereof is often used to calculate the inflow design flood for high hazard dams. It is required that the reservoir and spillway safely store and pass the design flood. Inflow design criteria are based on both reservoir volume and dam height. Some form of the PMF criteria are applied unless a reservoir is less than 100 acre-feet and the dam is less than 20 feet high.

Under the current rule, the required spillway size for existing dams is not related to potential loss of life downstream from the dam. For example, the criteria remains the same regardless if one loss of life or one hundred loss of life would result from spillway failure below a given dam.

A goal of the Montana Department of Natural Resources and Conservation (DNRC), Dam Safety Section, is to implement a hydrologic standard for spillways that is risk based, with dams having a large population below being held to a more stringent criteria than dams having a low population below. Therefore, during the spring of 1997, the Montana Spillway Standards Committee was formed to advise the Dam Safety Section in development of new rules for spillway conveyance requirements. The committee is made up of dam owners, downstream residents of dams, consulting engineers, and government employees. The purpose of this report is to document the recommendations made by this committee.

In support of this effort, the U.S. Geological Survey (USGS), with some financial assistance from DNRC, conducted a study to characterize extreme storms that have a very low probability of occurrence. As a result, we are now able to estimate precipitation depths, throughout Montana, with recurrence intervals as high as 5,000-years. After determination of rainfall depth, the resulting flood is routed through the reservoir to estimate required spillway size.

Discussed in this report are recommendations by the Montana Spillway Standards Committee regarding risk vs. recurrence interval for the design flood and loss of life assessment. This report only addresses spillway requirements and not hydrologic techniques or other structural aspects of dams. Hydrologic techniques used by DNRC to help assess the proposed spillway standards are presented in "Montana Spillway Standards - Hydrologic Analysis", DNRC, May 1999.

Risk vs. Recurrence Interval - Inflow Design Flood

B.C. Hydro has pioneered the development of quantified risk analysis for dam safety evaluations. B.C. Hydro owns and operates 61 dams and is responsible for the production and distribution of electrical energy for the province of British Columbia, Canada. B.C. Hydro has adopted a mathematical annual expected value of loss of life for each dam of 0.001.

The committee recommends that a probability value of .001 (0.1% annually) of loss of one life due to spillway failure is acceptable. The associated recurrence interval for annual probability of .001 is 1,000-year. Therefore, the estimated loss of life due to spillway failure is multiplied by 1,000 to determine the inflow design storm recurrence interval that must be routed in the reservoir and passed by the spillway. For example, if a spillway failure is estimated to result in the loss of 2.4 lives, the spillway and reservoir will need to route the 2,400-year recurrence interval rainfall to be considered safe. If the spillway just meets this criteria, there will be a .042% ({1/2400}x100) chance each year that the 2.4 lives will be lost, and during a 50 year period there will be a 2% ($1-\{1-.00042\}^{50}$) chance that these lives will be lost.

The committee found that once a loss of life can be estimated from spillway failure, an appropriate inflow design storm with an assigned recurrence interval or probability of occurrence must safely be stored in the reservoir and passed by the spillway.

Committee Suggested Criteria

If the estimated loss of life is greater than zero and less than or equal to 0.5, the committee determined that the spillway and reservoir must be able to store and pass the 500-year runoff event. In other words, the minimum standard inflow design flood for high hazard dams is the 500-year flood. A graphical display of spillway standards for five loss of life or less is shown in Figure 1.

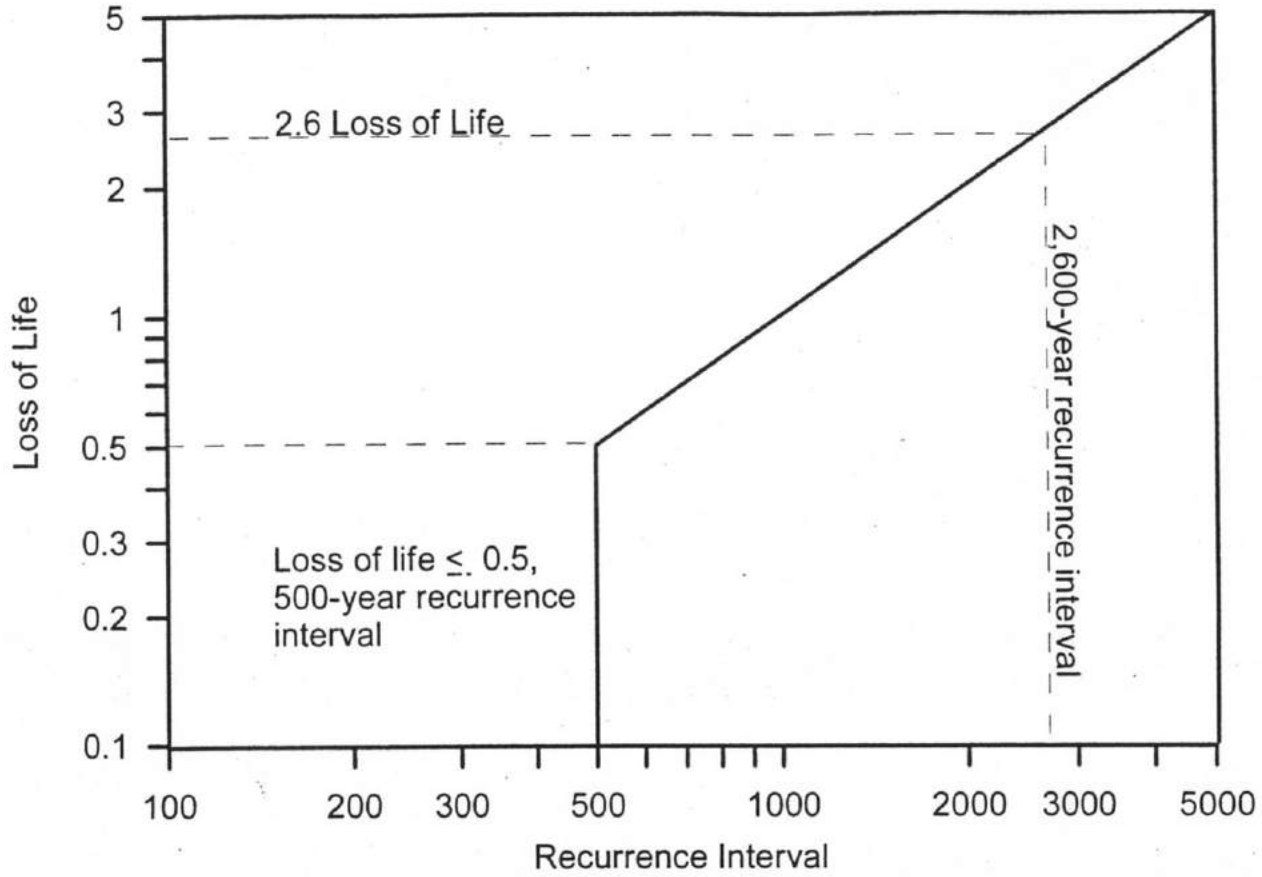

Figure 1. Minimum Standard Inflow Design Flood with an Estimated Loss of Life of Five or Less

If the loss of life is greater than 5, the probability-based approach will no longer be used and the inflow design flood is derived from the precipitation computed using equations 1 through 3. It needs to be emphasized that although no probability is associated with the standard above five loss of life, the standard does become more severe as expected loss of life increases below the dam. The results of the committee's decision on this portion of the standard are shown in Figure 2.

Eq. 1 $P_s = P_{5,000}\,(10^d)$

Eq. 2 $r = -0.304 + .435\,\log_{10}(lol)$

Eq. 3 $d = \log_{10}(PMP) - \log_{10}(P_{5,000})$

lol = *loss of life* ($5 < lol < 1{,}000$)

PMP = *Probable Maximum Precipitation*

$P_{5,000}$ = *5,000-year recurrence interval precipitation*

P_s = *Design precipitation to meet spillway standard*

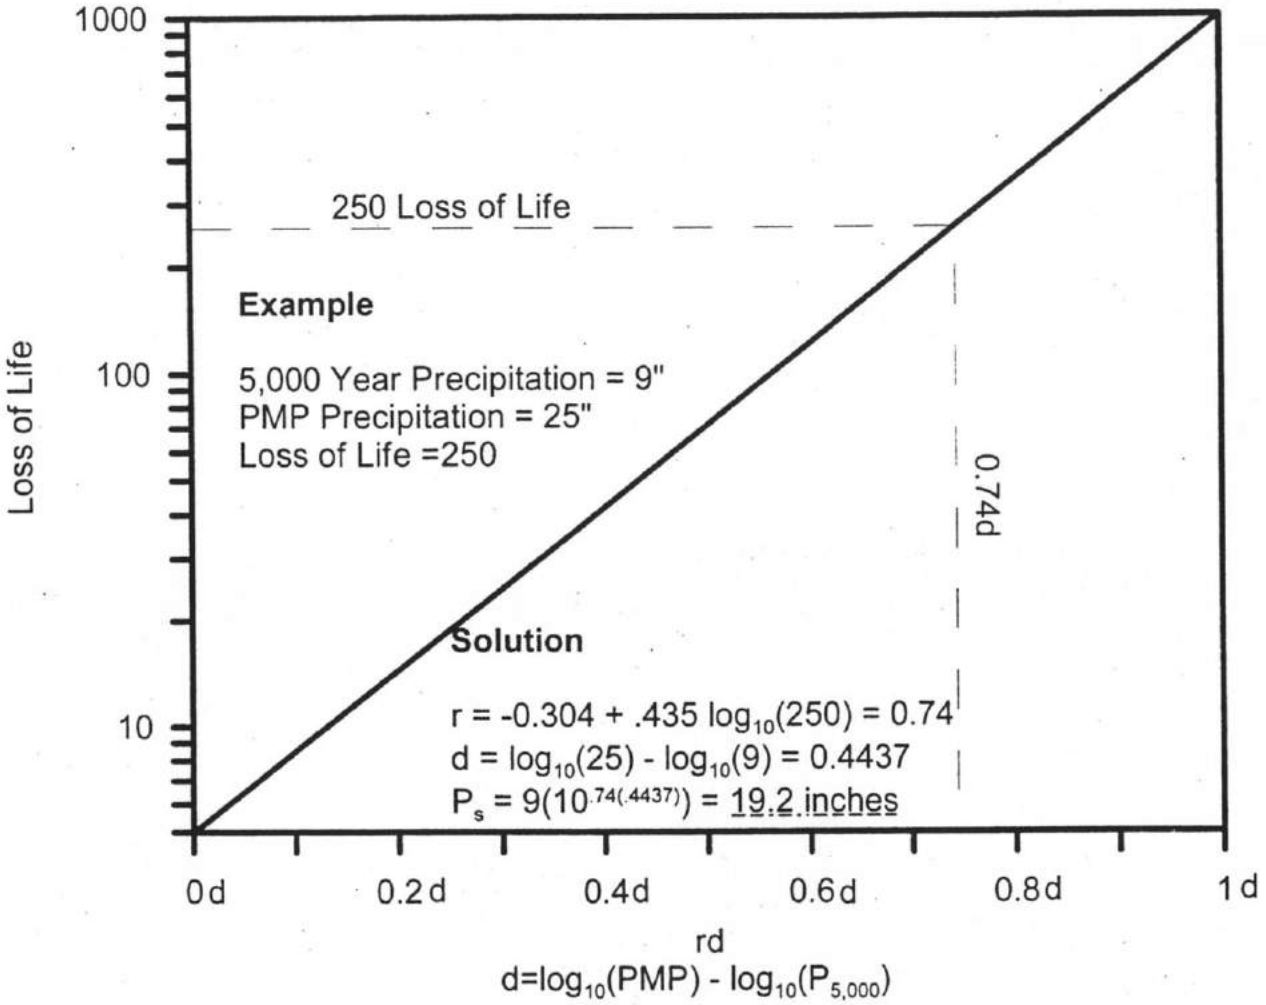

Figure 2. Minimum Standard Inflow Design Flood with an Estimated Loss of Life Between 5 and 1,000

The spillway standard changes for a loss of life greater than 5 not because the overall risk-based approach is no longer acceptable, but there is currently no acceptable way to estimate rainfalls with recurrence intervals greater than 5,000-year events.

For only the purposes of computing the risk factor, which will be discussed shortly, the PMP event is assumed a 1:1,000,000 event for interpolation.

If the loss of life is greater than or equal to 1,000, the reservoir and spillway must safely store and pass the runoff resulting from the PMP storm, often called the probable maximum flood or PMF.

Current design criteria provide for the minimum design storm to be reduced if it can be shown no further loss of life results from spillway failure. This criteria will be kept under the new standard.

Compliance of Existing Dams

For existing dams, the Montana Spillway Standards Committee has decided that it would be unreasonable to expect all existing spillways to come under compliance in a short period of time.

To assist the DNRC Dam Safety Section in prioritizing spillway construction or rehabilitation, the committee suggested using a risk factor developed using both the expected loss of life below the dam and the recurrence interval storm that the existing dam and spillway can safely store and pass. The risk factor is determined using Equation 4.

Eq. 4 $RF = RI_{SW}/LOL$

RF = *Risk Factor*

RI_{SW} = *Flood recurrence interval that the spillway can currently pass*

LOL = *Estimated loss of life associated with spillway failure*

If the RF value is 1,000 or above, the existing spillway meets or exceeds the standard and a larger spillway is not required. The committee has recommended for spillways significantly undersized (RF value below 100) that immediate action be taken. These actions may include reservoir level restrictions or breaching. These dams have a more than 1% probability each year of loss of life due to spillway failure.

For RF values between 100 and 500, proof of diligent effort towards correcting the problem will be required for issuance of operation permits.

For RF values between 500 and 1,000, dams will be evaluated on a case-by-case basis. The committee felt that these dams are sufficiently close to meeting the new standard, and the need for repair is not urgent if the spillway is in good condition.

Loss of Life Assessment

The committee examined several methods to estimate loss of life, caused by spillway

failure, downstream from a dam. Many methods base the loss of life (LOL) from the population at risk (PAR). They found the best current method to come from "Predicting Loss of Life in Case of Dam Failure and Flash Flood," Michael L. DeKay and Gary H. McClelland, Risk Analysis, Vol. 13, No. 2, 1993. In the future, new and better methods may become available. These methods should then be used.

The DeKay and McClelland method is based on an empirical approach that incorporates warning time, PAR, and the force of the flood. It is suggested by DeKay and McClelland that no one who is more than 3 hours travel time below the dam be included in the PAR. It is also strongly recommended that the PAR not be lumped into smaller reaches and zones of inundations since this leads to overestimates of LOL. The following equations are given by DeKay and McClelland to determine loss of life.

Eq. 5

$$LOL_{HF} = \frac{PAR_{HF}}{1 + 13.277(PAR_{HF}^{0.440})e^{(2.982(WT_{HF}) - 3.790)}}$$

Eq. 6

$$LOL_{LF} = \frac{PAR_{LF}}{1 + 13.277(PAR_{LF}^{0.440})e^{(0.759(WT_{LF})}}$$

LOL_{HF} = *Loss of Life in High Force Area*

LOL_{LF} = *Loss of Life in Low Force Area*

PAR_{HF} = *Population at Risk in High Force Area*

PAR_{LF} = *Population at Risk in Low Force Area*

WT_{HF} = *Warning time for High Force Area*

WT_{LF} = *Warning time for Low Force Area*

In most cases the committee recommends that 0 warning time be used. This assumption can be modified if sufficient evidence can be shown that a warning time exists.

The force of flood will often be estimated at site. In general, if the flood will occur in a narrow canyon area, the flood will likely be high force. If the area downstream of the dam is flat and wide, it is likely that much of the areas within the inundation zone will be classified low force.

If more specific information is needed regarding the flood force, the document "Downstream Hazard Classification Guidelines," ACER Technical Memorandum No. 11, U.S. Bureau of Reclamation, 1988 may be useful. Shown in Figures 3-5 are plots of velocity vs. depth for houses, mobile homes, and passenger vehicles. The various zones are high danger, low danger, and judgment.

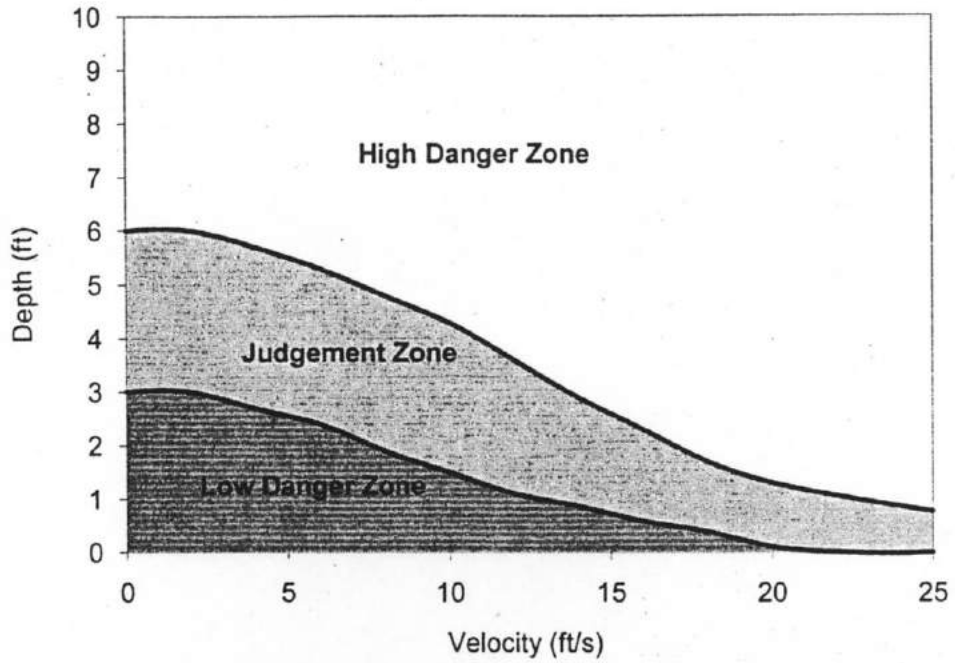

Figure 3. - Depth-Velocity Flood Danger Level Relationships for Houses Built on Foundations

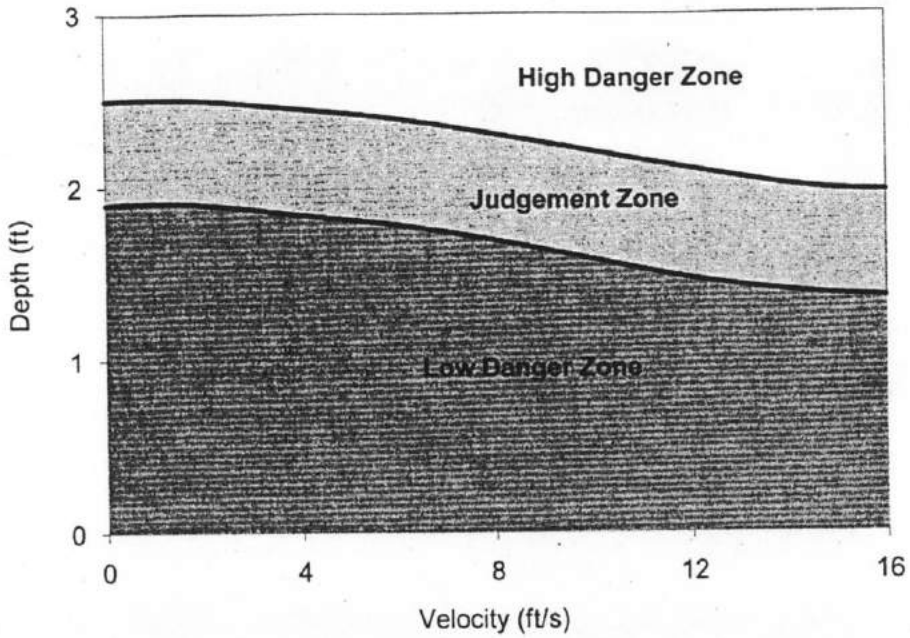

Figure 4. - Depth-Velocity Flood Danger Level Relationship for Mobile Homes

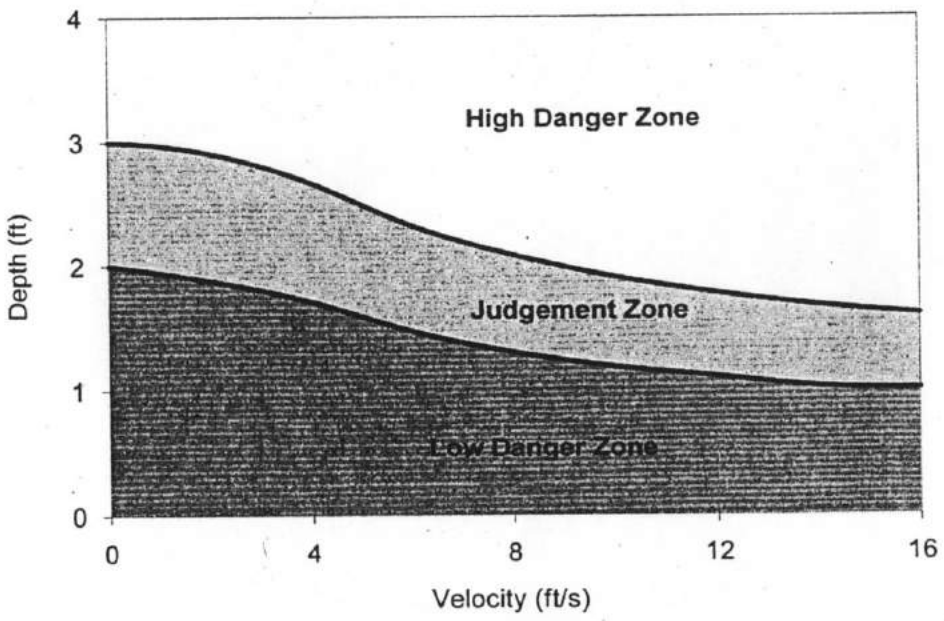

Figure 5. - Depth-Velocity Flood Danger Relationships for Passenger Vehicles

The estimation of PAR in the high force area and the subsequent use of the high force equation has the most significant effect on the LOL. Special attention will be focused on defining the area influenced by the high force wave and the PAR in the area.

Conclusion

The design precipitation used to determine spillway size under the proposed rule is very different from the design precipitation used under the current rule. The proposed rule requires the design precipitation to be based on population level downstream of the dam whereas the current rule requires the design precipitation to be based on the height and volume of water associated with the dam.

Since the population at risk is closely related to whether the force of water is high or low after dam failure, the proposed rule does still indirectly incorporate height of dam within the criteria. The current rule only considers that some population is at risk below the dam. The level of population at risk plays a small to nonexistent role in the spillway conveyance criteria.

For these reasons, dams with large populations at risk downstream, will often have more stringent spillway requirements under the proposed rules. On the other hand, dams with small populations at risk will often have less stringent spillway requirements under the proposed rules. The Montana Spillway Standards Committee has decided that the risk of life downstream should be the overriding factor in determining spillway capacity.

E.26. Nebraska

Nebraska Safety of Dams and Reservoirs Act

Overview

The Department's Dam Safety Program was peer reviewed by the Association of State Dam Safety Officials (ASDSO) in 2002. The peer review found that overall the department had a good program, but one of the deficiencies identified was a lack of clear statutory authority to implement the program. The peer review specifically recommended that the Department consolidate program authorization and legal requirements, provide for civil enforcement authority, update and simplify fee schedules, provide authority to establish dam safety rules and regulations, and incorporate other aspects of FEMA's Model Dam Safety Law.

LB619, the Safety of Dams & Reservoirs Act, was introduced by Senator Schrock on January 19, 2005 and signed by Governor Heineman on April 7, 2005 as part of LB335. LB335 will go into effect on September 3, 2005.

Some of the highlights of LB335:

- Makes it clear that dams that are regulated under a federal dam safety program may continue to be regulated primarily by the federal program provided that the federal program has objectives, standards, and requirements that meet or exceed the purposes of the Act, and the owner has entered into a cooperative agreement with the Department.
- Adds requirement that plans, specifications, and construction supervision be the responsibility of a licensed professional engineer.
- Provides that a city, village, or county may institute overlay zoning precluding construction of structures downstream of a state permitted dam that is classified as having other than a high hazard potential, if a breach inundation study performed by an engineer, in accordance with generally accepted engineering practice, determines that construction of such structures would require that such dam be reclassified as having a high hazard potential. The owners of such dam shall provide such engineering study as a condition to requesting overlay zoning.
- Allows department employees to enter onto private property, as necessary, to perform their official duties.
- Modifies the criteria for a jurisdictional size dam: any dam 25 feet or more in height or having 50 acre-ft or more maximum storage capacity; or any dam in a high hazard location regardless of size. The following exemptions exist; any dam that is less than six feet tall or any dam with less than 15 acre-ft total storage is exempt; also canal control structures and highway and railroad embankments are exempt unless they are intended to be dams.

- Removes requirements for repair, operation, and maintenance from the law because these types of work are not, and have not been regulated by the Department in the past.
- Changes the fee structure from the current one dollar per foot in height of dam to a flat fee to be established by rule and regulation of not to exceed two hundred dollars for dams less than twenty-five feet in height, three hundred dollars for dams twenty-five feet in height to not more than fifty feet in height, and four hundred dollars for dams in excess of fifty feet in height.
- Adds a civil penalty provision that provides that any person who violates the Act or an application approval, an approval to operate, a rule, a regulation, an order, or a requirement of the department under the Act may be assessed a civil penalty in an amount not to exceed five hundred dollars per day. The Department would have to bring an action in the court in the jurisdiction in which the violation occurred.
- Adds "no fault" language with respect to the state, department, its employees and agents.
- Adds provision for the appointment of a consulting board to report on safety matters when requested by the owner.
- Expands on the authority of the department to investigate or require the owner to investigate, gather data, study, etc. as necessary for safety.
- Restates and expands on department authority to adopt rules and regulations.
- Expands on and strengthens the construction completion certification requirement for new or reconstructed dams.
- Adds requirement for the department to issue an approval to operate prior to the dam going into service.
- Expands on the department's action and authority upon receipt of a complaint relative to a dam.
- Expands on the owner's responsibilities and actions during emergencies. Also, provides the department authority to take control of a dam during an emergency.
- States requirements for dams completed prior to the enactment of LB 335.
- Expands on requirements for emergency action plans.

Laws 2005, LB 335, § 10
Effective date September 4, 2005.

~ Revised Statutes Supplement 2005

Section 46-1611

Dam, defined.

(1) Dam means any artificial barrier, including appurtenant works, with the ability to impound water, wastewater, or liquid-borne materials and which (a) is twenty-five feet or more in height from the natural bed of the stream or watercourse measured at the downstream toe of the barrier, or from the lowest elevation of the outside limit of the barrier if it is not across a stream channel or watercourse, to the maximum storage elevation or (b) has an impounding capacity at maximum storage elevation of fifty acre-feet or more, except that any barrier described in this subsection which is not in excess of six feet in height or which has an impounding capacity at maximum storage elevation of not greater than fifteen acre-feet shall be exempt, unless such barrier, due to its location or other physical characteristics, is classified as a high hazard potential dam.

(2) Dam does not include:

(a) An obstruction in a canal used to raise or lower water;

(b) A fill or structure for highway or railroad use, but if such structure serves, either primarily or secondarily, additional purposes commonly associated with dams it shall be subject to review by the department;

(c) Canals, including the diversion structure, and levees; or

(d) Water storage or evaporation ponds regulated by the United States Nuclear Regulatory Commission.

Section 46-1625

Owner, defined.

Owner includes any of the following who or which owns, controls, manages, or proposes to construct, reconstruct, enlarge, alter, breach, remove, or abandon a dam:

(1) The United States Government and its departments, agencies, and bureaus;

(2) The state and its departments, institutions, agencies, and political subdivisions;

(3) A municipal or quasi-municipal corporation;

(4) A public utility;

(5) A district;

(6) A person;

(7) A duly authorized agent, lessee, or trustee of any person or entity listed in this section; and

(8) A receiver or trustee appointed by a court for any person or entity listed in this section.

Section 46-1636

Applicability of other law.

The Safety of Dams and Reservoirs Act does not relieve the owner or operator of a dam or reservoir from obtaining any necessary approvals from the department under sections 46-233 to 46-241 or from any other local, state, or federal regulatory authority.

Laws 2005, LB 335, § 36
Effective date September 4, 2005.

~ Revised Statutes Supplement 2005

Section 46-1637

Regulation by political subdivisions; restrictions; conditions.

(1) Except as provided in subsections (2) and (4) of this section, no city, village, or county may, by ordinance or resolution enacted by the legislative body thereof or adopted by the people, (a) regulate, supervise, or provide for the regulation or supervision of any dams and associated reservoirs or the construction, reconstruction, enlargement, repair, alteration, operation, breach, removal, or abandonment thereof or (b) limit the size or the impounding capacity of a dam if such action would conflict with the power and authority vested in the department pursuant to the Safety of Dams and Reservoirs Act.

(2) A city, village, or county may adopt ordinances or resolutions (a) regulating, supervising, or providing for the regulation or supervision of dams and reservoirs that are not within the state's jurisdiction and are not subject to regulation, owned, or operated by another public agency or body or (b) which apply only to adjacent structures not germane to the safety of the dam, such as, but not limited to, roads and fences.

(3) A city, village, or county may institute overlay zoning precluding construction of structures downstream of a state-permitted dam that is classified as having other than a high hazard potential if a breach-inundation study performed by an engineer, in accordance with generally accepted engineering practice, determines that construction of such structures would require that such dam be reclassified as having a high hazard potential. The owners of such dam shall provide such engineering study as a condition to requesting such overlay zoning.

(4) The Safety of Dams and Reservoirs Act does not preempt or supersede any local zoning ordinances, resolutions, rules, or regulations regarding special use permits enacted by a political subdivision with respect to permit applications for livestock waste control facilities.

Laws 2005, LB 335, § 38
Effective date September 4, 2005.

~ Revised Statutes Supplement 2005

Section 46-1639

Immunity from liability; when.

(1) No action shall be brought against the state, the department, or its agents or employees for the recovery of damages caused by the partial or total failure of any dam by reason of control and regulation thereof pursuant to the Safety of Dams and Reservoirs Act, including, but not limited to, any of the following:

(a) Design and construction application approval of the dam or approval of interim flood routing plans during construction, reconstruction, enlargement, alteration, breach, removal, or abandonment;

(b) The issuance or enforcement of orders relative to maintenance or operation of the dam;

(c) Control and regulation of the dam;

(d) Measures taken to protect against failure of the dam during an emergency, except for negligent acts of the department in assuming control of a dam during an emergency; or

(e) Failure to act.

(2) The Safety of Dams and Reservoirs Act does not relieve an owner or operator of a dam of the legal duties, obligations, or liabilities incident to the ownership or operation of the dam.

Laws 2005, LB 335, § 39
Effective date September 4, 2005.

~ Revised Statutes Supplement 2005

Section 46-1640

Orders and approval; effect.

The findings and orders of the department, an application approval, and an approval to operate any dam issued by the department are final, conclusive, and binding upon all owners and state agencies, regulatory or otherwise, as to the safety of design, construction, reconstruction, enlargement, alteration, breach, removal, or abandonment of any dam.

The department may report all dam incidents as defined by the National Performance of Dams Program to the National Performance of Dams Program archive.

Section 46-1646

Dams; review and approval required; when.

(1) The department shall review and approve the design, construction, reconstruction, enlargement, alteration, breach, removal, or abandonment of all dams in the state for the protection of life and property as provided in the Safety of Dams and Reservoirs Act.

(2) No person shall construct, reconstruct, enlarge, alter, breach, remove, or abandon any dam without approval by the department.

(3) An owner of a dam who has entered into a cooperative agreement with the department pursuant to subdivision (2)(d) of section 46-1633 shall be deemed to be in compliance with the act.

Laws 2005, LB 335, § 46
Effective date September 4, 2005.

~ Revised Statutes Supplement 2005

Section 46-1647

Potentially hazardous dams; emergency action plans.

(1) In order to protect life and property, the owner of every high hazard potential dam shall develop and periodically test and update an emergency action plan to be implemented in the event of an emergency involving such dam. In order to protect life and property, the department may require the owners of any significant hazard potential dam to develop and periodically test and update an emergency action plan to be implemented in the event of an emergency involving such dams.

(2) Such emergency action plan shall include, but not be limited to, the following elements:

(a) Emergency notification plan with flowchart;

(b) A statement of purpose;

(c) A project description;

(d) Emergency detection, evaluation, and classification;

(e) General responsibilities;

(f) Preparedness;

(g) Inundation maps or other acceptable description of the inundated area; and

(h) Appendices.

(3) For purposes of evaluating the adequacy of an emergency action plan, the department shall review, evaluate for adequacy, and approve or disapprove each emergency action plan submitted under this section. The department shall accept emergency action plans developed for dams under a federal dam safety program.

(4) If the department determines that a dam constitutes an immediate risk to life or property, the department shall order the owner to take such action as is necessary to remove such risk.

Section 46-1649

Department; investigations and studies.

(1) The department may investigate and gather or cause the owner to gather such data, including advances made in safety practices elsewhere, as may be needed for a proper review and study of the various features of the design, construction, reconstruction, enlargement, alteration, breach, removal, or abandonment of dams.

(2) The department may make or cause the owner to make such watershed investigations and studies as are necessary to keep abreast of developments affecting runoff and peak storm discharges in the vicinity of a dam.

(3) The department may make or cause the owner to make such seismic investigations and studies as may be necessary to keep abreast of developments affecting seismic stability of a dam.

Laws 2005, LB 335, § 49
Effective date September 4, 2005.

~ Revised Statutes Supplement 2005

Section 46-1650

Department; enforcement; powers.

(1) The department may take any administrative or legal action necessary for the enforcement of the Safety of Dams and Reservoirs Act.

(2) An action or proceeding under this section may be initiated whenever any owner or any person acting as an agent of any owner:

(a) Fails to comply with the requirements imposed by the act or by any application approval, approval to operate, order, rule, regulation, or requirement of the department under the act; or

(b) Commits or allows the commission of violations of the act or of any application approval, approval to operate, order, rule, regulation, or requirement of the department under the act.

(3) Any action or proceeding under this section shall be initiated either administratively or in a court in a jurisdiction in which:

(a) The dam, area of hazard potential, or some part thereof exists;

(b) The person named in the complaint has its principal place of business; or

(c) The person named in the complaint resides.

Laws 2005, LB 335, § 50
Effective date September 4, 2005.

~ Revised Statutes Supplement 2005

Section 46-1651

Rules and regulations.

(1) The department may adopt and promulgate rules and regulations containing standards for the design, inspection, construction, reconstruction, enlargement, alteration, breach, removal, abandonment, and periodic testing of emergency action plans of dams to carry out the purposes of the Safety of Dams and Reservoirs Act. Such rules and regulations may also include, but are not limited to, establishing:

(a) Standards and criteria for the siting and design of dams, considering both existing and projected conditions which may affect the safety of a project during its construction and operational life;

(b) Requirements for operation of dams, including operational plans to be prepared and implemented by owners;

(c) Requirements for monitoring, inspection, and reporting of conditions affecting the safety of dams; and

(d) Requirements for emergency action plans to be prepared and implemented by owners in cooperation with emergency management authorities.

(2) In adopting rules and regulations applicable to dams which may have

a high hazard potential or a significant hazard potential, the department may consider:

(a) The state of scientific and technological knowledge and good engineering practices relating to various types of dams;

(b) The economic impact of a failure of a structure upon the state and its citizens; and

(c) The relationship of dams in hydrologic management in the watershed as a whole.

Laws 2005, LB 335, § 51
Effective date September 4, 2005.

~ Revised Statutes Supplement 2005

Section 46-1652

Construction or enlargement of dam; application for approval; contents.

(1) Construction of any new dam or the enlargement of any dam shall not commence until the owner has applied for and obtained from the department written application approval of plans and specifications.

(2) A separate application for each dam shall be filed with the department upon forms provided by the department. Plans and specifications signed and sealed by the design engineer shall accompany the application.

(3) The application shall provide the following information:

(a) The name and address of the owner;

(b) The name and address of the applicant, if different from the owner;

(c) The name and address of the operator or other person to be contacted regarding arrangements for inspections or other matters associated with the dam;

(d) The location, type, size, purpose, and height of the proposed dam;

(e) The reservoir surface areas and associated storage capacity at elevation intervals not exceeding two feet;

(f) Plans for proposed permanent instrument installations in the dam;

(g) The area of the drainage basin, rainfall records, streamflow records, and flood flow records and estimates, if available;

(h) Maps and design drawings showing plans, elevations, and sections of all principal structures and appurtenant works with other features of the project in sufficient detail, including design analyses, to determine safety, adequacy, and suitability of design;

(i) The estimated construction cost of the dam; and

(j) Such other pertinent information as the department requires.

(4) The department may, when in its judgment it is necessary, also require the following:

(a) Data concerning subsoil and rock foundation conditions and the materials involved in the construction of the dam;

(b) Investigations of, and reports on, subsurface conditions, exploratory pits, trenches and adits, drilling, coring, and geophysical tests to measure in place and in the laboratory the properties and behavior of foundation materials at the dam site;

(c) Investigations and reports on the geology of the dam site, possible geologic hazards, seismic activity, faults, weak seams and joints, availability and quality of construction materials, and other pertinent features; and

(d) Other appropriate information.

(5) If an application is incomplete or defective, it shall be returned to the applicant to complete or to correct the defects. The application shall be corrected and returned to the department within ninety days after it is returned to the applicant or within such additional time as may be allowed by the department. If the application is returned to the department after expiration of such time period, it shall be dismissed.

Laws 2005, LB 335, § 52
Effective date September 4, 2005.

~ Revised Statutes Supplement 2005

Section 46-1653

Modifications to existing dam; application for approval; contents; exemption.

(1) Before commencing the reconstruction or alteration of a dam or the abandonment, breach, or removal of a dam so that it no longer constitutes a dam, the owner shall file an application and secure the written application approval of the department.

(2) The application shall give such pertinent information or data concerning the dam as may be required by the department.

(3) The application shall give the name and address of the applicant and shall adequately detail, with appropriate references to the existing dam, the proposed reconstruction, alteration, abandonment, breach, or removal of the dam. The application shall be accompanied by plans and specifications signed and sealed by the design engineer. The department may waive any of the requirements of this section if the requirements are unnecessary for the application approval.

(4) If an application is incomplete or defective, it shall be returned to the applicant to complete or to correct the defects. The application shall be corrected and returned to the department within ninety days after it is returned to the applicant or within such additional time as may be allowed by the department. If the application is returned to the department after expiration of such time period, it shall be dismissed.

(5) In case of an emergency in which the department declares that repairs or breaching of the dam are necessary to safeguard life and property, repairs or breaching shall be started immediately by the owner or by the department at the owner's expense. The department shall be notified within twenty-four hours of emergency repairs or breaching when instituted by the owner.

(6) The proposed repairs or breaching shall conform to any orders issued by the department.

Laws 2005, LB 335, § 53
Effective date September 4, 2005.

~ Revised Statutes Supplement 2005

Section 46-1654

Application approval; issuance; public hearing.

(1) Approval of applications for which approval under sections 46-233 to 46-242 is not required shall be issued within ninety days after receipt of the completed application plus any extensions of time required to resolve matters diligently pursued by the applicant. At the discretion of the department, one or more public hearings may be held on an application.

(2) Approval of applications under the Safety of Dams and Reservoirs Act, for which approval under sections 46-233 to 46-242 is required, shall not be issued until all pending matters before the department under the Safety of Dams and Reservoirs Act or such sections have been resolved and approved. Approval under the act and approval under such sections shall be issued simultaneously.

(3) Application approval shall be granted with terms, conditions, and limitations necessary to safeguard life and property.

(4) If actual construction, reconstruction, enlargement, alteration, breach, removal, or abandonment of the dam is not commenced within the time established by the department, the application approval becomes void, except that the department may, upon written application and for good cause shown, extend the time for commencing construction, reconstruction, enlargement, alteration, breach, removal, or abandonment.

(5) Written notice shall be provided to the department at least ten days before construction, reconstruction, enlargement, alteration, breach, removal, or abandonment is to begin and such other notices shall be given to the department as it may require.

Laws 2005, LB 335, § 54
Effective date September 4, 2005.

~ Revised Statutes Supplement 2005

Section 46-1655

Fees.

(1) The application for approval of construction, reconstruction, enlargement, alteration, breach, removal, or abandonment of a dam shall be accompanied by a filing fee as established by rule and regulation of the department but not to exceed (a) two hundred dollars for a dam less than twenty-five feet in height, (b) three hundred dollars for a dam twenty-five feet in height to not more than fifty feet in height, and (c) four hundred dollars for a dam in excess of fifty feet in height.

(2) Only one filing fee shall be collected for an enlargement by flashboards, sandbags, earthen levees, gates, or other works, devices, or obstructions which are from time to time to be removed and replaced or opened and shut and thereby operated so as to vary the surface elevation of the reservoir.

(3) A dam subject to the Safety of Dams and Reservoirs Act and for which plans and specifications have been approved prior to September 4, 2005, shall not be required to pay any additional fee or submit an additional application for approval unless such dam requires reconstruction, enlargement, alteration, breach, removal, or abandonment.

(4) An application shall not be considered by the department until the filing fee is received.

(5) Fees collected by the department under this section shall be remitted to the State Treasurer for credit to the Dam Safety Cash Fund.

Effective date September 4, 2005.

~ Revised Statutes Supplement 2005

Section 46-1656

Dam Safety Cash Fund; created; use; investment.

The Dam Safety Cash Fund is created. The fund shall consist of fees credited pursuant to section 46-1655 and any money specifically appropriated to the fund by the Legislature. Money in the fund shall not be subject to any fiscal-year limitation or provision for lapse of unexpended balance at the end of any fiscal year or biennium. The fund shall be administered by the department. Money in the fund may be expended by the department for costs incurred by the department in the administration of the Safety of Dams and Reservoirs Act. Any money in the fund available for investment shall be invested by the state investment officer pursuant to the Nebraska Capital Expansion Act and the Nebraska State Funds Investment Act.

~ Revised Statutes Supplement 2005

Section 46-1657

New or modified dam; owner; filing requirements; approval to operate; issuance.

(1) Upon completion of a new or reconstructed dam and reservoir or of the enlargement of a dam and reservoir, the owner shall file with the department a completion certification accompanied by supplementary drawings or descriptive matter signed and sealed by the design engineer, showing or describing the work as actually completed. Such supplementary materials may include, but need not be limited to, the following as determined by the department:

(a) A record of all geological boreholes and grout holes and grouting;

(b) A record of permanent location points, benchmarks, and instruments embedded in the structure;

(c) A record of tests of concrete or other material used in the construction, reconstruction, or enlargement of the dam; and

(d) A record of initial seepage flows and embedded instrument readings.

(2) In connection with the enlargement of a dam, the supplementary drawings and descriptive matter need apply only to the new work.

(3) An approval to operate shall be issued by the department upon a finding by the department that the dam is safe to impound within the limitations prescribed in the application approval. No impoundment by the structure shall occur prior to issuance of the approval to operate.

Laws 2005, LB 335, § 57
Effective date September 4, 2005.

~ Revised Statutes Supplement 2005

Section 46-1658

Alteration of dam; owner; filing requirements; approval to operate; issuance.

(1) Upon completion of the alteration of any dam, the owner shall file with the department a completion certification accompanied by supplementary drawings or descriptive matter, as determined by the department, signed and sealed by the design engineer, showing or describing the work as actually completed.

(2) An approval to operate shall be issued upon a finding by the department that the dam is safe to impound within the limitations prescribed in the application approval. Pending issuance of a new or revised approval to operate, the owner of the dam shall not cause the dam to impound beyond the limitations prescribed in the existing application approval.

Effective date September 4, 2005.

~ Revised Statutes Supplement 2005

Section 46-1659

Removal, breach, or abandonment of dam; design engineer; duties; department; powers.

(1) Upon completion of the removal, breach, or abandonment of a dam, the design engineer shall file with the department a completion certification.

(2) Before final approval of the removal of a dam is issued, the department may inspect the site of the work and determine that all work was accomplished in substantial conformance with the application approval.

(3) Following the removal of a dam, the department may report such removal to the National Performance of Dams Program and to the National Inventory of Dams.

Source:
Laws 2005, LB 335, § 59
Effective date September 4, 2005.

~ Revised Statutes Supplement 2005

Section 46-1660

Approval to operate; department; powers; hearing; notice.

(1) Each approval to operate issued by the department under the Safety of Dams and Reservoirs Act shall contain such terms and conditions as the department may prescribe.

(2) The department shall revoke, suspend, or amend any approval to operate whenever it determines that the dam constitutes a danger to life and property.

(3) Before any approval to operate is revoked by the department, the department shall hold a public hearing. Written notice of the time and place of the hearing shall be mailed to the owner at least thirty days before the date set for the hearing. Any interested persons may appear at the hearing and present their views and objections to the proposed action.

Section 46-1661

Complaint; department; duties; unsafe condition; modification.

(1) Upon receipt of a written complaint alleging that the person or property of the complainant is endangered by the construction, reconstruction, enlargement, alteration, breach, removal, or abandonment of any dam, the department shall cause an inspection and investigation to be made unless the data, records, and inspection reports on file are found adequate to make a determination whether the complaint is valid. The complainant shall be provided with a copy of the official report of the inspection and investigation.

(2) If it is found that an unsafe condition exists, the department shall notify the owner of the dam to take such action as is necessary to correct the condition, including breaching or removal of any dam found to be beyond repair.

Source:
Laws 2005, LB 335, § 61
Effective date September 4, 2005.

~ Revised Statutes Supplement 2005

Section 46-1662

Periodic inspections; when; department; powers and duties.

(1) During the construction, reconstruction, enlargement, alteration, breach, removal, or abandonment of any dam, the department may make periodic inspections for the purpose of ascertaining compliance with the approved plans and specifications. The department shall require the owner to direct the design engineer to provide adequate supervision during construction, reconstruction, enlargement, alteration, breach, removal, or abandonment and to provide sufficient information to enable the department to determine that conformity with the approved plans and specifications is being attained.

(2) If, after any inspection or investigation, during the construction, reconstruction, enlargement, alteration, breach, removal, or abandonment of a dam or at any time prior to issuance of an approval to operate, it is found by the department that modifications or changes are necessary to ensure the safety of the dam, the department shall order the owner to revise his or her plans and specifications. The owner may, pursuant to section 46-1645, request an independent consulting board to review the order of the department.

(3) If at any time during construction, reconstruction, enlargement, alteration, breach, removal, or abandonment of any dam, the department finds that the work is not being done in accordance with the approved plans and specifications, the department shall deliver a written notice

of noncompliance to the owner. The notice shall be delivered by registered mail or by personal service to the owner, shall state the particulars in which the approved plans and specifications are not being or have not been complied with, and shall order immediate compliance with the approved plans and specifications. The department may order that no further work be done until such compliance has been effected and approved by the department.

(4) Failure to comply with the notice delivered under subsection (3) of this section may cause revocation of application approval by the department. If compliance with the notice has not occurred within sixty days after the date of the notice, the department shall order the incomplete structure removed sufficiently to eliminate any safety hazard to life.

Laws 2005, LB 335, § 62
Effective date September 4, 2005.

~ Revised Statutes Supplement 2005

Section 46-1663

Record-keeping requirements; maintenance, operation, and inspection; department; powers.

(1) The department shall require owners to keep original records and any modifications to construction available and in good order.

(2) The department may:

(a) Adopt such rules and regulations and issue such orders as necessary to secure adequate maintenance, operation, and inspection by owners;

(b) Require engineering and geologic investigations to safeguard life and property;

(c) Accept approvals and reports of equivalent inspections prepared for dams under a federal dam safety program; and

(d) Enter into cooperative agreements with the owners of dams which are required to comply with a federal dam safety program that has objectives, standards, and requirements that meet or exceed the purposes of the Safety of Dams and Reservoirs Act.

Laws 2005, LB 335, § 63
Effective date September 4, 2005.

~ Revised Statutes Supplement 2005

Section 46-1664

Safety inspections; when; department; powers and duties.

(1) The department shall inspect dams for the purpose of determining their safety. The normal inspection frequency shall be annually for high hazard potential dams, biennially for significant hazard potential dams, and every five years for low hazard potential dams and every five years or more for minimal hazard potential dams. The department may vary the inspection frequency of some sites based on an evaluation of the site performance history. The department may conduct additional inspections at any time. If serious safety concerns are found by the department during the inspections, the department shall require the owner to conduct tests and investigations sufficient for the department to determine the condition of the dam. After review of the tests or investigations, the department may require modification, removal, or breach of the dam or alteration of operating procedures to restore or improve the safety of the dam and may require installation of instrumentation to monitor the performance of the dam.

(2) The department may report the results of dam inspections that determine unsafe conditions or noncompliance to the National Performance of Dams Program.

Laws 2005, LB 335, § 64
Effective date September 4, 2005.

~ Revised Statutes Supplement 2005

Section 46-1665

Emergency actions involving a dam; owner; duties; department; duties.

(1) The owner of a dam has the primary responsibility for determining when an emergency exists. When the owner of a dam determines that an emergency exists involving a dam, the owner shall immediately implement the emergency action plan as required pursuant to section 46-1647. The owner shall immediately notify any persons who may be endangered if the dam should fail, notify emergency management organizations in the area, take necessary remedial action to prevent or mitigate the consequences of failure, and notify the department. The department shall take any remedial action necessary to protect life and property if, in its judgment, either:

(a) The condition of any dam is so dangerous to the safety of life or property as not to permit time for the issuance and enforcement of an order relative to maintenance or operation; or

(b) Passing or imminent floods or any other condition threatens the safety of any dam.

(2) In applying the remedial means provided for in this section, the department may in an emergency, with its own forces or by other means at its disposal, do any or all of the following:

(a) Take full charge and control of any dam;

(b) Lower the water level by releasing water from the reservoir;

(c) Completely drain the reservoir;

(d) Perform any necessary remedial or protective work at the site; or

(e) Take such other steps as may be essential to safeguard life and property.

(3) The department shall continue in full charge and control of such dam and its appurtenant works until they are rendered safe or the emergency occasioning the action has ceased and the owner is able to take back full charge and control. The department's taking full charge and control under this section does not relieve the owner of such dam of liability for any negligent acts of such owner.

(4) The department may report emergency actions involving the safety of a dam to the National Performance of Dams Program in a timely manner.

Section 46-1666

Violations; penalties.

(1) Violation of the Safety of Dams and Reservoirs Act or of any application approval, approval to operate, order, rule, regulation, or requirement of the department under the act is a Class V misdemeanor. Each day that the violation continues constitutes a separate and distinct offense.

(2) Any person who willfully obstructs, hinders, or prevents the department from performing the duties imposed by the act commits a Class IV misdemeanor.

(3) Any owner or any person who engages in the construction, reconstruction, enlargement, alteration, breach, removal, or abandonment of any dam or who knowingly does work on or permits work to be done on the dam without the approval of the department or in violation of the act and who fails to immediately notify the department thereof commits a Class V misdemeanor.

Laws 2005, LB 335, § 66
Effective date September 4, 2005.

~ Revised Statutes Supplement 2005

Section 46-1667

Notice of violation; orders; procedure.

(1) If the department has reason to believe that an owner or other person is violating or has violated the Safety of Dams and Reservoirs Act, an application approval, an approval to operate, a rule, a regulation, an order, or a requirement of the department issued or adopted pursuant to the act, the department shall give the owner or person written notice by certified mail that the owner or person appears to be in violation of the act. The owner or other person shall have thirty days from the mailing of such notice to respond or to request a hearing before the department as to why the owner or other person should not be ordered to cease and desist from the violation. The notice shall inform the owner or other person how to request the hearing and the consequences of failure to request a hearing.

(2) If the department finds that an owner or person is constructing, reconstructing, enlarging, altering, breaching, removing, or abandoning a dam without having first obtained the required application approval, the department shall issue a temporary order for the owner or person to cease and desist the construction, reconstruction, enlargement, alteration,

breach, removal, or abandonment pending final action by the department pursuant to subsection (3) of this section. The temporary order shall include written notice by certified mail to the owner or person of the time and date set by the department for a hearing to show cause why the temporary order should be vacated.

(3) After a response to a notice or a hearing pursuant to subsection (1) or (2) of this section or after the expiration of time to request a hearing, the department shall issue a decision and final order. The decision and final order may take such form as the department determines to be reasonable and appropriate and may include a determination of violation, a cease and desist order, the recommendation of a civil penalty, and an order directing that positive steps be taken to abate or ameliorate any harm or damage arising from the violation. The owner or person affected may appeal the hearing decision as provided in section 61-207.

(4) If the owner or person continues the violation after the department has issued a final decision and order pursuant to subsection (3) of this section or a temporary order pursuant to subsection (2) of this section, the department may apply for a temporary restraining order or preliminary or permanent injunction from a court of competent jurisdiction. A decision to seek injunctive relief does not preclude other forms of relief or enforcement against the violator.

Laws 2005, LB 335, § 67
Effective date September 4, 2005.

~ Revised Statutes Supplement 2005

Section 46-1668

Violations; civil penalty.

(1) Any person who violates the Safety of Dams and Reservoirs Act or an application approval, an approval to operate, a rule, a regulation, an order, or a requirement of the department under the act may be assessed a civil penalty in an amount not to exceed five hundred dollars per day for each day the violation continues.

(2) The department shall bring an action to recover a penalty imposed under this section in a court in the jurisdiction in which the violation occurred.

(3) In determining the amount of the penalty, the court shall consider the degree of harm to the public, whether the violation was knowing or willful, the past conduct of the defendant, whether the defendant has taken steps to cease, remove, or mitigate the violation, and any other relevant information.

Laws 2005, LB 335, § 68
Effective date September 4, 2005.

~ Revised Statutes Supplement 2005

Section 46-1669

Appeal.

Any affected person aggrieved by any final order or decision made by the director pursuant to the Safety of Dams and Reservoirs Act may appeal the order as provided in section 61-207. For purposes of this section, affected person means the applicant or holder of any approvals under the act and any owner of an estate or interest in or concerning land or water whose interest is or may be impacted in a direct and significant manner by such final order or decision.

Laws 2005, LB 335, § 69
Effective date September 4, 2005.

~ Revised Statutes Supplement 2005

Section 46-1670

Existing unapproved dams; requirements.

(1) Every owner of a dam subject to the Safety of Dams and Reservoirs Act that was completed prior to September 4, 2005, and not previously approved by the department when departmental approval was otherwise required shall file an application with the department for approval of such dam.

(2) A separate application for each dam shall be filed with the department upon forms supplied by the department and shall include such appropriate information concerning the dam as the department requires.

(3) The department may give notice, by certified mail to the owner's last address of record in the office of the county assessor of the county in which the dam is located, to the owner of dams required under this section to file an application who or which have failed to do so, and a failure to file within sixty days after receipt of such notice shall be punishable as provided in the act.

(4) The department may make inspections of such dams and may require owners of such dams and reservoirs to perform, at the owner's expense, such work or tests as may reasonably be required to disclose information sufficient to enable the department to determine whether to issue an approval to operate or to issue orders directing further work at the owner's expense necessary to safeguard life and property. For this purpose, the department may require an owner to lower the water level of or to drain the reservoir.

(5) If, upon inspection or upon completion to the satisfaction of the department of all work ordered, the department finds that the dam is safe to impound, an approval to operate shall be issued.

(6) If at any time the department finds that the dam is not safe to impound, the department shall notify the owner in writing and shall set a time and place for hearing on the matter. The owner of such dam shall ensure that such dam does not impound following receipt of such notice. Written notice of the time and place of the hearing shall be mailed, at least thirty days prior to the date set for the hearing, to the owner. Any interested person may appear at the hearing and present his or her views and objections to the proposed action.

NEBRASKA ADMINISTRATIVE CODE

Title 458 - NEBRASKA DEPARTMENT OF NATURAL RESOURCES
RULES FOR SAFETY OF DAMS AND RESERVOIRS

Chapter 1 – DEFINITIONS APPLICABLE TO TITLE 458

001 For purposes of Title 458 rules, the following definitions shall apply:

001.01 Abandonment means the process of rendering a dam incapable of impounding by (1) dewatering and filling the reservoir created by such dam with solid materials and (2) creating a stable watercourse around the site.

001.02 Adverse consequences means the negative impacts that may occur upstream, downstream, or at locations remote from the dam, including but not limited to, loss of human life, economic loss including property damage and lifeline disruption.

001.03 Alterations means alterations to an existing dam that directly affect the safety of the dam or reservoir, as determined by the Department, but do not include maintenance and repair of the dam to retain its initial structural integrity.

001.04 Application includes an application form, plans and specifications.

001.05 Application approval means authorization in writing issued by the Department to an owner who has applied to the Department for permission to construct, reconstruct, enlarge, alter, breach, remove, or abandon a dam and which specifies the conditions or limitations under which work is to be performed by the owner or under which approval is granted.

001.06 Appurtenant works include, but are not limited to: structures such as spillways, either in or separate from the dam; the reservoir and its rim; low-level outlet works; and water conduits including, but not limited to, tunnels, pipelines, or penstocks, either through the dam or its abutments.

001.07 Breach means partial removal of a dam creating a channel through the dam to the natural bed elevation of the stream.

001.08 Consulting Board means board appointed by the Department under the provisions of Neb. Rev. Stat. § 46-1645.

001.09 Dam means any artificial barrier, including appurtenant works, with the ability to impound water, wastewater, or liquid-borne materials and which (a) is twenty-five feet or more in height from the natural bed of the stream or watercourse measured at the downstream toe of the barrier, or from the lowest elevation of the outside limit of the barrier if it is not across a stream channel or watercourse, to the maximum storage elevation or (b) has an impounding capacity at maximum storage elevation of fifty acre-feet or more, except that any barrier described in this subsection which is not in excess of six feet in height or which has an impounding capacity at maximum storage elevation of not greater than fifteen acre-feet shall be exempt, unless such barrier, due to its location or other physical characteristics, is classified as a high hazard potential dam. Dam does not include: (1) an obstruction in a canal used to raise or lower water; (2) a fill or structure for highway or railroad use, but if such structure serves, either primarily or secondarily, additional purposes commonly associated with dams it shall be subject to review by the department; (3) canals, including the diversion structure, and levees; or (4) water storage or evaporation ponds regulated by the United States Nuclear Regulatory Commission.

001.10 Days, for purposes of establishing deadlines, means calendar days, including Sundays and holidays.

001.11 Department means the Department of Natural Resources.

001.12 Diversion dam means dam constructed solely for the purpose of raising water to divert it into a canal. The height of the dam must be limited such that it provides only this function and does not create unnecessary storage.

001.13 Engineer means a professional engineer licensed under the Engineers and Architects Regulation Act who (1) is competent in areas related to dam investigation, design, construction, and operation for the type of dam being investigated, designed, constructed, or operated, (2) has at least four years of relevant experience in investigation, design, construction, reconstruction, enlargement, alteration, breach, removal, or abandonment of dams, and (3) understands adverse consequences and dam failures.

001.14 Enlargement means any change in or addition to an existing dam which raises or may raise the normal storage elevation of the water impounded by the dam.

001.15 Hazard potential classification means classification of dams according to the degree of incremental adverse consequences of a failure or misoperation of a dam but does not reflect on the current condition of a dam, including but not limited to, safety, structural integrity, or flood routing capacity.

001.16 High hazard potential means a hazard potential classification such that failure or misoperation of the dam resulting in loss of human life is probable.

001.17 Incremental means the difference in impacts that would occur due to failure or misoperation of the dam over the impacts that would occur without failure or misoperation of the dam.

001.18 Landowner means person or persons with recorded title to land where dam and reservoir are or will be located.

001.19 Low hazard potential means a hazard potential classification such that failure or misoperation of the dam would result in no probable loss of human life and in low economic loss.

001.20 Maximum storage means the reservoir storage capacity between the top of dam elevation, or the maximum routed elevation of the probable maximum flood if lower than the top of dam elevation, and the lowest downstream toe or outside limit elevation of the dam.

001.21 Minimal hazard potential means a hazard potential classification such that failure or misoperation of the dam would likely result in no economic loss beyond the cost of the structure itself and losses principally limited to the owner’s property.

001.22 Normal storage means the reservoir storage capacity, excluding flood storage and freeboard allowances.

001.23 Owner includes any of the following who or which owns, controls, manages, or proposes to construct, reconstruct, enlarge, alter, breach, remove, or abandon a dam: (1) The United States Government and its departments, agencies, and bureaus; (2) the state and its departments, institutions, agencies, and political subdivisions; (3) a municipal or quasi-municipal corporation; (4) a public utility; (5) a district; (6) a person; (7) a duly authorized agent, lessee, or trustee of any person or entity listed in this section; and (8) a receiver or trustee appointed by a court for any person or entity listed in this section.

001.24 Person means any individual, partnership, limited liability company, association, public or private corporation, trustee, receiver, assignee, agent, municipality, other political subdivision, public agency, or other legal entity or any officer or governing or managing body of any public or private corporation, municipality, other political subdivision, public agency, or other legal entity.

001.25 Plan or plans mean engineering drawings, design reports, hazard classification studies, geotechnical reports, and other studies as required.

001.26 Probable means likely to occur and reasonably expected.

001.27 Probable maximum flood means the most severe flood that is considered probable at a site.

001.28 Reconstruction means partial or complete removal and replacement of an existing dam.

001.29 Removal means complete elimination of the dam embankment or structure to restore the approximate original topographic contours of the site.

001.30 Reservoir means any basin which contains or will contain impounded water, wastewater, or liquid-borne materials by virtue of such water, wastewater, or liquid-borne materials having been impounded by a dam.

001.31 Safety of Dams and Reservoirs Act means Neb. Rev. Stat. Sections 46-1601 to 46-1670.

001.32 Significant hazard potential means hazard potential classification such that failure or misoperation of the dam would result in no probable loss of human life but could result in major economic loss, environmental damage, or disruption of lifeline facilities.

001.33 Storage elevation means the elevation of the reservoir surface associated with a level of impoundment, such as maximum storage or normal storage.

001.34 Top of dam elevation means the maximum design elevation for the top of the dam, including design freeboard allowances but excluding any allowance for settlement due to consolidation of the foundation and embankment.

Chapter 2 – DOCUMENTATION OF SIGNATURES

001 The following documentation must be submitted when applicable with any document required to be filed and signed under the provisions of these rules.

001.01 Persons signing as landowner shall submit a copy of the deed or other document conveying ownership of all lands under the project.

001.02 Persons signing as owners shall submit the trust agreement, lease, memorandum of agreement, deed, or other document showing sufficient interest to operate and maintain the dam or reservoir.

001.03 If an owner or landowner is a trust, they shall submit a copy of the trust agreement and the name of the trust and the names of all the trustees.

001.04 Persons signing as attorney-in-fact (power of attorney) shall submit a copy of the document granting power of attorney.

001.05 Persons signing as the personal representative shall submit a copy of the document appointing the person personal representative.

001.06 Persons signing as an agent of the owner shall submit a copy of the document granting him or her authority to act as the owner's agent.

Title 458 - NEBRASKA DEPARTMENT OF NATURAL RESOURCES
RULES FOR SAFETY OF DAMS AND RESERVOIRS

Chapter 3 – FEES

001 The filing fee for an application for approval of the construction, enlargement, reconstruction, alteration, abandonment, breach, or removal of a dam shall be determined by measuring the height of the dam from the natural bed of the stream or watercourse at the downstream toe of the barrier, or from the lowest elevation of the outside limit of the barrier, if it is not across a stream channel or watercourse, to the maximum storage elevation.

001.01 The fee shall be one-hundred and fifty dollars ($150.00) for dams less than twenty-five feet in height.

001.02 The fee shall be two-hundred and fifty dollars ($250.00) for dams twenty-five feet in height to not more than fifty feet in height.

001.03 The fee shall be three-hundred and fifty dollars ($350.00) for dams in excess of fifty feet in height.

002 The amount of the filing fee for the approval of plans of a previously constructed dam is the same as the amount for construction of a new dam of the same size.

003 The filing fee for a request for consulting board review is $10.

004 The filing fee for a request for a waiver to install outlet works is $10.

STATUTORY AUTHORITY: Neb. Rev. Stat. § 46-1655
Neb. Rev. Stat. § 33-105(8)
Neb. Rev. Stat. § 61-206

EFFECTIVE DATE: July 2, 2008

NEBRASKA ADMINISTRATIVE CODE

Title 458 - NEBRASKA DEPARTMENT OF NATURAL RESOURCES
RULES FOR SAFETY OF DAMS AND RESERVOIRS

Chapter 4 – REQUIREMENTS FOR APPLICATION APPROVAL

001 Applications. Any person intending to construct, enlarge, reconstruct, alter, abandon, breach, or remove a dam must file an application and obtain application approval prior to construction, enlargement, reconstruction, alteration, abandonment, breach or removal of the dam. The application must be accompanied by the filing fee.

001.01 The applicant's engineer is required to meet with the Department in a pre-design conference prior to submission of an application for a significant or high hazard class dam.

001.02 Applications must be made on a form provided by the Department. Plans and specifications must be submitted with the application form.

001.03 If the proposed project will also require a surface water storage appropriation under Neb. Rev. Stat. § 46-241, the application may be submitted with the application for a surface water storage appropriation or anytime within six months of the filing of the application for the surface water appropriation. If the application is not filed within the six month period the application for a surface water storage appropriation shall be dismissed.

001.04 If the owner of the dam is not the landowner of the land where the dam and reservoir will be located, the application shall be accompanied by documentary evidence describing the relationship and responsibilities of the owner of the dam and the owner of the land as it relates to the dam and reservoir. Acceptable documentary evidence includes but is not limited to leases, contracts, memoranda of agreements, easements, options to buy or authority to condemn under existing laws for purposes of construction of a dam and reservoir. The application will not be approved if the owner of the dam does not have sufficient legal authority to construct, operate, and maintain the dam and reservoir for its anticipated design life or sufficient authority to comply with any order the Department issues regarding the safety of the dam or operation of the dam and reservoir.

001.05 The application must be signed by all the owners of the dam and reservoir.

001.06 The application shall include the name, mailing address, electronic address and telephone number of the person or persons responsible for maintaining and operating the dam and reservoir. Each person's responsibilities shall be described in sufficient detail to provide the Department with an understanding of who is responsible for each aspect of the dam's maintenance and operation along with accurate information about how each person can be contacted. The application must include copies of all contracts or other agreements between the applicant and the person responsible for operation and/or maintenance of the dam and reservoir.

001.07 Dams are required to have an outlet for releasing water in compliance with Neb. Rev. Stat. § 46-241(5). If the dam is designed without an outlet, a request for a waiver as described in Department rule Title 458, Chapter 6 must accompany the application for approval.

001.08 The Department will return applications that are incomplete or incorrectly filled out to the applicant. The corrected or completed application must be returned to the Department within ninety days or the application will be dismissed. Any associated application for a surface water appropriation will also be dismissed. Fees will not be refunded.

002 Plans and Specifications.

002.01 An engineer shall prepare all plans and specifications assisted by qualified engineering geologist, geotechnical engineers, geologists, and other specialists as necessary. Plans and specifications submitted to the Department shall be as detailed as they would be for submission to contractors bidding on the work.

002.02 Detailed specifications or references to standard specifications for both materials and construction aspects shall accompany the plans. The specifications shall be those currently acceptable and normally used by design and construction professionals. Material specifications are those specifications which will cover the materials proposed to be used. Construction specifications are those specifications describing how the work (construction, enlargement, reconstruction, alteration, abandonment, breach, or removal)

is to be accomplished, the sequence of procedures to be followed, the limitations, and the desired results.

002.03 Plans for construction, enlargement, reconstruction, alteration, abandonment, breach, or removal of a dam shall conform to the following:

002.03A Be made on sheets with minimum dimensions of 11 inches by 17 inches and maximum dimensions of 22 inches by 34 inches and shall have adequate margins on all sides.

002.03B Be of such clarity and with distinct characters of such size as to retain clarity and resolution when reduced to 11 inches by 17 inches. Characters shall not be smaller than one-tenth inch on the 11 inches by 17 inches drawings and two-tenths inch on the 22 inches by 34 inches drawings.

002.04 Plans shall include the following information:

002.04A A map showing the outside limits of the reservoir water line at maximum storage elevation and at normal storage elevation, the dam location, the government subdivisions in which the dam and reservoir are located including the quarter section, section, township, range, and county; the location and name of any and all streams which are the source of water or on which the dam is located and, if applicable, the location of any pump or diversion facility used to provide water to the reservoir.

002.04B The latitude and longitude of the intersection of the dam centerline with the natural stream channel. Latitude and longitude must be referenced to the North American Datum of 1983.

002.04C The course of the stream or watercourse and the drainage area boundary upstream from the proposed or existing dam.

002.04D The area, time of concentration and runoff curve number of the drainage basin.

002.04E The elevations, dimensions, materials, and maximum capacities of all spillways. Elevations shall be referenced to the North American Vertical Datum of 1988.

002.04F All pertinent hydrologic and hydraulic data. For each design storm analyzed, indicate the following:

002.04F1 The design rainfall and runoff amount,

002.04F2 The recurrence interval,

002.04F3 The peak inflow into the reservoir,

002.04F4 The maximum discharge from each spillway,

002.04F5 The peak reservoir elevation and flow velocity in the auxiliary spillway, and

002.04F6 The results of the auxiliary spillway stability analysis.

002.04G A topographic map of the dam site and the return area to the natural channel from all conduits and spillway(s). The map must be derived from on site or photogrammetric survey and show 2-foot contour intervals or less.

002.04H A topographic map of the reservoir within the reservoir area. The map must be derived from on site or photogrammetric survey and show 2-foot contour intervals or less.

002.04I A table showing the reservoir surface area and incremental and cumulative reservoir storage at 2-foot elevation intervals and at the crest elevation of the drawdown, principal and auxiliary spillways, other outlets and the top of dam elevation.

002.04J The cross sections listed below, with all elevations referred to in the cross sections referenced to the North American Vertical Datum of 1988 or an assumed benchmark.

002.04J1 The valley along the centerline of the dam showing the profile of the top of the dam and the original ground line;

002.04J2 A maximum cross section perpendicular to the dam centerline and other cross-sections or views to clarify construction details;

00204J3 Other cross-sections, profiles or plan views showing the location and elevations of the drawdown works, spillways and other components.

002.04K If there are multiple owners or there are easements appurtenant to the land where the dam and reservoir are located, a plan of survey showing the boundary line of each ownership and easement. The plan of survey shall include labels to indicate separate ownerships or easements. This drawing must agree with the information provided in the application described in Chapter 4.001.04 of these rules.

002.04L The certificate of the engineer responsible for design of the facility. Examples of engineer's certificates are available on the Department's web site. The engineer's certificate shall include a designation of the hazard classification for the dam. The certificate shall be on the first sheet of the drawings.

003 Emergency Action Plans.

003.01 An emergency action plan that meets the requirements of Neb. Rev. Stat. § 46-1647 must be submitted with an application if the dam is classified as a high hazard dam. If the dam is classified as a significant hazard dam, the Department will notify the applicant if an emergency action plan is required and when the plan must be filed.

003.02 An emergency action plan shall include:

003.02A an emergency notification plan with flowchart;

003.02B a statement of purpose;

003.02C a project description;

003.02D the plan for emergency detection, evaluation, and classification;

003.02E a chart identifying the general responsibilities of emergency personnel and their names and telephone numbers;

003.02F a preparedness plan;

003.02G inundation maps or other acceptable description of the inundated area;

003.02H appendices.

Title 458 - NEBRASKA DEPARTMENT OF NATURAL RESOURCES
RULES FOR SAFETY OF DAMS AND RESERVOIRS

Chapter 5 - REQUIREMENTS FOR DAMS CONSTRUCTED PRIOR TO SEPTEMBER 4, 2005, AND NOT PREVIOUSLY APPROVED BY THE DEPARTMENT.

001 This Chapter applies to all dams that were completed prior to September 4, 2005, but have not been approved by the Department.

002 Applications. Application must be made on a form provided by the Department. Plans and specifications for the dam must be submitted to the Department with the application form. The filing fee shall accompany the application.

002.01 If a surface water appropriation is required for the storage reservoir in accordance with Neb. Rev. Stat. § 46-241, the plans, specifications and application for approval shall be submitted at the same time as the application for a surface water appropriation.

002.02 If the owner of the dam is not the landowner of the land where the dam and reservoir are, the application shall be accompanied by documentary evidence describing the relationship and responsibilities of the owner of the dam and the landowner. Acceptable documentary evidence includes but is not limited to leases, contracts, memoranda of agreement, or easements. The application will not be approved if the owner of the dam does not have sufficient legal authority to operate and maintain the dam and reservoir for its anticipated design life or sufficient authority to comply with any order the Department issues regarding the safety of the dam or operation of the dam and reservoir.

002.03 The application form must be signed by all the owners of the dam and reservoir.

002.04 The application shall include the name, mailing address, electronic address and telephone number of the person or persons responsible for maintaining and operating the dam and reservoir. Each person's responsibility shall be described in sufficient detail to provide the Department a complete description of each person's duties and responsibilities and accurate information about how each person can be contacted. The application must include copies of all contracts or other agreements between the

applicant and the person responsible for operation and/or maintenance of the dam and reservoir.

002.05 If the dam does not have an outlet for releasing water in compliance with Neb. Rev. Stat. § 46-241(5), a request for a waiver as described in Department rule Title 458, Chapter 6 must accompany the application for approval.

002.06 The Department will return applications that are incomplete or incorrectly filled out to the applicant. The corrected or completed application must be returned to the Department within ninety days. Failure to refile within 90 days will result in the forfeiture of the fees, and dismissal of the application. If applicable, the application for an associated surface water storage appropriation will also be dismissed.

003 Plans. All plans and specifications shall be prepared by an engineer, assisted by qualified engineering geologists, geotechnical engineers, geologists and other specialists as necessary. Plans and specifications shall be as detailed as they would be for submission to contractors bidding on work. Plans shall include:

003.01 A topographic map of the reservoir area as determined by on-site or photogrammetric surveys with 2 foot contour intervals or less.

003.02 A table showing the incremental and cumulative reservoir surface area and reservoir storage at 2-foot elevation intervals and at the crest elevation of the drawdown, the principal and auxiliary spillways, other outlets and the top of dam elevation.

003.03 A map showing the outside limits of the reservoir water line at maximum storage elevation and at normal storage elevation, the dam location, the government subdivisions in which the dam and reservoir are located including the quarter section, section, township, range, and county; the location and name of any and all streams which are the source of water or on which the dam is located and, if applicable, the location of any pump or diversion facility used to provide water to the reservoir.

003.04 The height of the dam from the downstream toe of the dam to the maximum storage elevation.

003.05 The cross sections listed below. All elevations referred to in the cross sections must refer to the North American Vertical Datum of 1988 or an assumed benchmark.

003.05A The valley along the centerline of the dam showing the profile of the top of the dam and the original ground line;

003.05B A maximum cross section perpendicular to the dam centerline and other cross-sections or views to clarify construction details;

003.05C Other cross-sections, profiles or plan views showing the location and elevations of the drawdown works, spillways, and other components.

003.06 Elevations, dimensions, materials, and maximum capacities of all spillways.

003.07 If there are multiple owners or there are easements appurtenant to the land where the dam and reservoir are located, a plan of survey showing the boundary line of each ownership and easement. The plan of survey shall include labels to indicate separate ownerships or easements. This drawing must agree with the information provided in the application described in Chapter 5.002.02 of these rules.

003.08 A statement, certified by an engineer, as to the hazard classification of the dam and whether it is subject to the Safety of Dams and Reservoirs Act.

004 Emergency Action Plans.

004.01 An emergency action plan that meets the requirements of Neb. Rev. Stat. § 46-1647 must be submitted with an application if the dam is classified as a high hazard dam. If the dam is classified as a significant hazard dam, the Department will notify the applicant if an emergency action plan is required and when the plan must be filed.

004.02 An emergency action plan shall include:

004.02A an emergency notification plan with flowchart;

004.02B a statement of purpose;

004.02C a project description;

004.02D the plan for emergency detection, evaluation, and classification;

004.02E a chart identifying the general responsibilities of emergency personnel and their names and telephone numbers;

004.02F a preparedness plan;

004.02G inundation maps or other acceptable description of the inundated area;

004.02H appendices.

Title 458 - NEBRASKA DEPARTMENT OF NATURAL RESOURCES
RULES FOR SAFETY OF DAMS AND RESERVOIRS

Chapter 6 - OUTLET WORKS

001 REQUIREMENT. In order to protect the rights of persons downstream and to facilitate compliance with interstate compacts, decrees and agreements, all dams, including all structures subject to Chapter 4 and 5 of these rules, are required to have an outlet works. The Department may waive the requirement for an outlet works if the owner of the dam has an acceptable alternative method for passing water when ordered to do so. A request for a waiver must be filed on a form provided by the Department and must describe why an outlet works is not necessary, and how the owner of the dam will meet the requirements of Neb. Rev. Stat. § 46-241(5) and be accompanied by the filing fee. The Department will not allow waivers for dams associated with public roadways, or for dams required to have emergency action plans.

Chapter 7 - CHANGE OF OWNERSHIP

001 The owner of any dam shall notify the Department of any change in the ownership of the dam or reservoir or of the land where the dam and reservoir are located. The notification shall be made on a form provided by the Department. All forms shall include the following:

001.01 For those instances where the ownership of the land has changed, a copy of the deed or other document transferring ownership of the land occupied by the dam and reservoir shall be submitted with the form.

001.02 For those instances where the ownership of the dam has changed, and the owner of the dam is not the owner of the land where the dam and reservoir are located, a copy of the trust agreement, lease, memorandum of agreement, deed, or other document transferring ownership of the dam and describing the responsibilities and authorities of the new owner shall be submitted with the form.

001.03 If the dam and reservoir are located on a tract not under one contiguous ownership, or there are holders of easements on the land where the dam and reservoir are located, the owner of the dam shall submit with the change of ownership form, a copy of an agreement, signed by all owners and applicable holders of easements, describing: (1) who is responsible for the operation of the dam and reservoir, including any releases from the reservoir; (2) who is responsible for maintenance of the structure; and (3) for reservoirs that are permitted under the provisions of Neb. Rev. Stat. § 46-241, what amount of the appropriation to impound is to be appurtenant to each owner's property and what is the basis for the distribution. Such agreements are not required when the deed or document transferring ownership or an easement describes such information and such document is submitted with the form.

RULES FOR SAFETY OF DAMS AND RESERVOIRS

Chapter 9 - NOTICE OF CONSTRUCTION, RECONSTRUCTION, ENLARGEMENT, ALTERATION, BREACH, REMOVAL, OR ABANDONMENT

001 The owner of a dam shall provide written notice to the Department at least ten days before construction, reconstruction, enlargement, alteration, breach, removal, or abandonment of the dam is to begin. Notice shall be given immediately after foundation preparation and principal spillway construction and at least two days prior to backfilling the spillway. Notices must be in writing and addressed to the Chief Engineer or the Construction Inspector of the Department's Dam Safety Section. Notices may be delivered to the Department by mail, facsimile or electronic mail.

002. This rule does not apply to dams associated with livestock waste control facilities.

RULES FOR SAFETY OF DAMS AND RESERVOIRS

Chapter 10 - COMPLETION CERTIFICATION

001 The owner of a dam shall file with the Department a completion certification after completion of a new or reconstructed dam and reservoir or enlargement of a dam and reservoir, or the alteration of any dam. The completion certification shall be on a form provided by the Department accompanied by supplementary drawings or descriptive matter signed and sealed by the engineer, showing or describing the work as actually completed. The drawings and descriptive matter shall substantially conform to the requirements for plans and specifications in Chapter 4 of these regulations. If the construction, reconstruction, enlargement or alteration of the dam and reservoir meet the requirements of the Safety of Dams and Reservoirs Act and these regulations, the Department will issue an approval to operate to the owner.

002 The owner of a dam shall file with the Department a completion certification after completion of the removal, breach, or abandonment of the dam. The completion certification shall be made on a form provided by the Department accompanied by supplementary drawing or descriptive matter, signed and sealed by the engineer responsible for the work, showing or describing the work as actually completed. The drawings or descriptive matter shall substantially conform to the requirements for plans and specifications in Chapter 4 of these regulations.

003 For dams classified as high hazard, and for those significant hazard dams that are required to have an emergency action plan, the owner of the dam shall file a report of initial fill signed and sealed by the engineer. The report shall be filed by the first May 30 after the approval to operate was issued. The report shall include information on the initial seepage flows, information regarding the integrity of the dam, and the elevations and quantity of water impounded. The owner shall continue to file a report of initial fill by May 30 of each year until the reservoir has filled to the normal permitted storage capacity. After the reservoir has filled to

its normal permitted storage capacity, the owner shall submit the report of final fill. No further reports shall be required unless the Department orders the owner to submit a report to address a safety concern.

Title 458 - NEBRASKA DEPARTMENT OF NATURAL RESOURCES
RULES FOR SAFETY OF DAMS AND RESERVOIRS

Chapter 11 - CONSULTING BOARD

001 When the safety and technical considerations pertaining to an application approval, an approval to operate, or the plans and specifications of a dam require it, or when requested by the owner, the Department shall appoint a Consulting Board of three or more engineers to report to the Department on the safety features involved. The cost and expense of a Consulting Board, if appointed at the request of an owner, shall be paid by the owner.

002 Dam owners interested in having an independent third-party review performed shall submit their request to the Department in writing. The Department will not accept a request for review from anyone other than the owner of a dam. The request must be accompanied by the filing fee and include the following information:

002.01 The purpose of requesting a Consulting Board review.

002.02 The application number or plan number assigned to the project by the Department.

002.03 A statement acknowledging that the dam owner understands that the fees associated with the Consulting Board review are the responsibility of the dam owner and that the dam owner agrees to pay such fees.

002.04 A statement acknowledging that the conclusions and recommendations of the Consulting Board are not binding upon the Department and that the Department maintains the final authority for the approval of all designs, reports, studies, and other engineering documents.

003 Any engineer willing to serve on a Consulting Board may submit their qualifications to the Department.

004 The Department shall maintain a list of all engineers willing to serve on a Consulting Board on its website whom the Department has found to be qualified.

005 Upon receipt of a request for a Consulting Board review, the Department shall randomly appoint engineers on the list that are able to serve for the project described. Those appointed cannot have any conflict of interest concerning the project subject to review and shall not have been employed by the dam owner within the last five years.

006 Once the board is formed, the Department will schedule a meeting with the dam owner, Department and the Consulting Board. The purpose of the meeting is to discuss the purpose and extent of the review and the time frame for completing the review. The dam owner shall pay to the Board members one-half the probable costs of review prior to the start of the review.

007 The Consulting Board's role is to provide an independent review. Therefore, when reviewing plans and specifications of another engineer, the Consulting Board shall send to the Department in writing any questions it has for the design engineer, or shall request the Department to schedule a meeting with the design engineer.

008 The dam owner, the engineer or any agent of the owner are prohibited from contacting or lobbying the Consulting Board except for contact made during meetings scheduled and attended by the Department. Any contact by the dam owner, the engineer or any agent of the owner with a member of the Consulting Board shall be documented in writing by the board member and provided to the Department.

009 The Consulting Board shall compile a final report of its review and submit a copy to the Department and to the dam owner.

RULES FOR SAFETY OF DAMS AND RESERVOIRS

Chapter 12 - HAZARD POTENTIAL CLASSIFICATION

001 All dams shall be classified as high hazard potential, significant hazard potential, low hazard potential, or minimal hazard potential as defined in these rules. The Department will accept only those hazard potential classifications made by an engineer with experience in classifying dam hazard potential.

002 Any dam located within three miles of the jurisdictional limits of a city of the metropolitan class or primary class, or any dam within two miles of the jurisdictional limits of a city of the first class, or any dam within one mile of the jurisdictional limits of a city of the second class or a village, shall be classified as high hazard potential unless such dam and hazard classification were previously approved by the Department.

Classification can be mitigated or adjusted if development in the breach route area is sufficiently curtailed due to zoning restrictions, easements, deed restrictions, or other methods of restriction acceptable.

Chapter 13 - OPERATION AND MAINTENANCE OF A DAM AND RESERVOIR

001 Requirement**.** It is the responsibility of the owner(s) of the dam and reservoir to notify the Department of any changes in responsibility for the maintenance or operation of the dam or reservoir, including who is responsible for any releases from the reservoir. Notification shall be made on a form provided by the Department and include the name, mailing address, electronic address and telephone number of the person or persons responsible for maintaining and operating the dam and reservoir. The owner(s) shall provide a complete description of each person's duties and responsibilities and accurate information about how each person can be contacted. Copies of all contracts or other agreements between the dam owner and the person(s) responsible for operation and/or maintenance of the dam and reservoir shall be submitted with the notification form.

DAM SAFETY GUIDELINES

SPILLWAY DESIGN

The single most common cause of earthen dam failures is overtopping of the embankment. **An undersized spillway will lead to overtopping**, therefore spillway design is critical to reservoirs. Very often, the cost of a spillway of ample capacity will only be moderately higher than that of one that is woefully inadequate. The spillway must be located such that discharge will not erode or undermine the toe of the dam. If the banks of the spillway are made of erosive material, provision must be made for their protection. An emergency spillway must have sufficient capacity to allow for the conveyance of peak flows during floods. Consideration must be given to the hazard to human life and potential property damage that may result from the failure of the dam or excessive flow rates through the spillway. Further consideration must be given to the likelihood of downstream development that may result in an elevation of the hazard classification.

The following flood criteria should be used when designing a spillway given the different dam hazard designations (NAC 535.240):

High Hazard: Probable Maximum Flood (PMF) on all dams.

Significant Hazard: PMF if no provision for a spillway is incorporated into the design or it is classified as a "large" dam.

The greater of 1/2PMF or a "500-year" flood (0.2 percent chance of exceedence in any year) for "medium" and "small" dams. Low Hazard: "100-year" flood (1 percent chance of exceedence in any year) on all dams.	Most effluent, process fluid and tailing impoundments are exempt from having a spillway, however, there must be diversion channels to route flood flows around the structure and/or sufficient freeboard designed into the structure to accommodate the required precipitation event. A dam may also be designed to either impound the design flood or accommodate overtopping in which case no separate emergency spillway is necessary.

[Rev. 2/18/2010 11:16:04 AM]

CHAPTER 535 - DAMS AND OTHER OBSTRUCTIONS

NRS 535.005 Chapter does not authorize use of state land without authorization from State Land Registrar.
NRS 535.010 Construction, reconstruction or alteration of dam: Permit to appropriate water required; notice; approval of plans and specifications; inspection; exemptions; penalty.
NRS 535.020 State Engineer to file copy of application to construct dam with Board of Wildlife Commissioners; installation of fishways; protection and preservation of fish.
NRS 535.030 Inspection of dams by State Engineer; powers of State Engineer to protect life or property.
NRS 535.040 Statutes and performance of State Engineer's duties do not constitute warranty.
NRS 535.050 State Engineer may order removal of dam, diversion works or obstruction; limitation; procedure; payment of costs.
NRS 535.060 Obstruction of water by beaver's dam: Procedure for removal of beaver and dams.
NRS 535.070 Construction of weir in dam situated within 2 miles of incorporated city or town.
NRS 535.080 Attorney General and County Commissioners of Washoe County authorized to institute actions to maintain flow of Truckee River.
NRS 535.090 Unlawful obstruction of appropriator's water; penalty.
NRS 535.100 Injury or obstruction of flow of water by sawmill, slaughterhouse, brewery or tannery; civil action.
NRS 535.110 Unlawful removal, damage or destruction of piling, dike, dock or lock; unlawful structures.
NRS 535.200 Additional penalties.
NRS 535.210 Injunctive and other relief.

NRS 535.005 Chapter does not authorize use of state land without authorization from State Land Registrar. Nothing in this chapter authorizes a person to use any state land administered by the Division of State Lands of the State Department of Conservation and Natural Resources without the appropriate authorization for such a use from the State Land Registrar.

(Added to NRS by 1993, 1460)

NRS 535.010 Construction, reconstruction or alteration of dam: Permit to appropriate water required; notice; approval of plans and specifications; inspection; exemptions; penalty.

1. Any person proposing to construct a dam in this state shall, before beginning construction, obtain from the State Engineer a permit to appropriate, store and use the water to be impounded by or diverted by the dam.

2. Any such person obtaining or possessing such a permit shall:

(a) Before constructing, reconstructing or altering in any way any dam, notify the State Engineer thereof; and

(b) Where the dam is or will be 20 feet or more in height, measured from the downstream toe to the crest of the dam, or is less than 20 feet in height and will impound more than 20 acre-feet of water, submit to the State Engineer in triplicate plans and specifications thereof for approval 30 days before construction is to begin.

3. The State Engineer shall examine such plans and specifications and if the State Engineer approves them the State Engineer shall return one copy with such approval to the applicant. If the State Engineer disapproves any part of the plans and specifications the State Engineer shall return them to the applicant for correction or revision.

4. The construction and use of any dam is prohibited before approval of the plans and specifications by the State Engineer.

5. The State Engineer may at any time inspect or cause to be inspected the construction work while it is in progress to determine that it is being done in accordance with the approved plans and specifications.

6. This section applies to new construction, reconstruction and alteration of old structures.

7. The provisions of this section relating to approval of plans and specifications and inspection of dams do not apply to works constructed by the United States Bureau of Reclamation or the United States Army Corps of Engineers; but such federal agencies shall file duplicate plans and specifications with the State Engineer.

8. Any person beginning the construction of any dam before approval of the plans and specifications by the State Engineer, or without having given the State Engineer 30 days' advance notice of any proposed change, reconstruction or alteration thereof, is guilty of a misdemeanor. Each day of violation of this section constitutes a separate offense and is separately punishable.

[Part 77 1/2:140:1913; added 1951, 132]—(NRS A 1981, 1844; 1993, 206)

NRS 535.020 State Engineer to file copy of application to construct dam with Board of Wildlife Commissioners; installation of fishways; protection and preservation of fish.

1. Whenever an application for approval of plans and specifications for a new dam or for the alteration and enlargement of any dam in any stream in this state is filed with the State Engineer, the State Engineer shall file a copy of the application with the Board of Wildlife Commissioners.

2. In the construction of a dam, or the alteration or enlargement of a dam, the owner shall conform with the provisions of law for the installation of fishways over or around dams and for the protection and preservation of fish in streams obstructed by dams.

[Part 77 1/2:140:1913; added 1951, 132]—(NRS A 1979, 913)

NRS 535.030 Inspection of dams by State Engineer; powers of State Engineer to protect life or property.

1. The State Engineer from time to time shall:

(a) Make inspections of dams at state expense for the purpose of determining their safety; and

(b) Require owners to perform at their expense such work as may be necessary to supply the State Engineer with information as to the safety of such dams.

2. The owners shall perform at their expense any other work necessary to maintenance and operation which will safeguard life and property.

3. If at any time the condition of any dam becomes so dangerous to the safety of life or property as not to permit sufficient time for the issuance and enforcement of an order relative to the maintenance or operation thereof, the State Engineer may, if he or she deems it necessary, immediately employ the following remedial measures to protect either life or property:

(a) Lower the water level by releasing water from the reservoir.

(b) Completely empty the reservoir.

(c) Take such other steps as may be essential to safeguard life and property.

4. The provisions of this section shall not apply to works constructed by the United States Bureau of Reclamation or the United States Army Corps of Engineers.

[Part 77 1/2:140:1913; added 1951, 132]

NRS 535.040 Statutes and performance of State Engineer's duties do not constitute warranty. The provisions of NRS 535.010, 535.020 and 535.030 and the performance by the State Engineer of the duties of the State Engineer under them do not constitute a warranty in favor of anyone concerning the water to be impounded or diverted.

[Part 77 1/2:140:1913; added 1951, 132]—(NRS A 1973, 1170; 1981, 1844)

NRS 535.050 State Engineer may order removal of dam, diversion works or obstruction; limitation; procedure; payment of costs.

1. The State Engineer has the right, power and authority to order the removal of any dam, diversion works or obstruction that has been placed in any stream channel or watercourse when the dam, diversion works or obstruction has not been legally established and recognized through a valid claim of vested right, by decree of court or by a permit issued by the State of Nevada.

2. Nothing in this section is to be construed as giving the State Engineer any right or authority to remove any dam or diversion works that has been so legally recognized and established.

3. If the dam, diversion works or obstruction has not been removed after 30 days' notice in writing given by the State Engineer and served upon the owner or person controlling the dam, diversion works or obstruction, or if no appeal has been taken from the order of the State Engineer as is provided for in NRS 533.450, then the State Engineer may remove the dam, diversion works or obstruction.

4. The State Engineer shall charge the actual cost of that removal to the water distribution account and thereafter present an itemized statement of the charge to the board of county commissioners of the county wherein those expenses were incurred. The board of county commissioners shall thereupon present a bill for the expenses to the person liable therefor under this section, and if that person neglects for 30 days thereafter to pay it, the bill and costs become a lien upon the lands and property of the person so liable for the payment of the bill, and must be collected as delinquent taxes against the lands and property are collected.

[56 1/2:140:1913; added 1951, 132]—(NRS A 1979, 670)

NRS 535.060 Obstruction of water by beaver's dam: Procedure for removal of beaver and dams.

1. On any stream system and its tributaries in this state the distribution of the waters of which are vested in the State Engineer by law or the final decree of court, where beaver, by the construction of dams or otherwise, are found to be interfering with the lawful and necessary distribution of water to the proper users thereof, the State Engineer, upon complaint of any interested water user, shall investigate or cause the investigation of the matter.

2. The State Engineer and his or her assistants and water commissioners and the Department of Wildlife and its agents may enter upon privately owned lands for the purposes of investigating the conditions complained of and the removal and trapping of beaver.

3. If satisfied that such beaver are interfering with the flow of water to the detriment of water users, the State Engineer shall serve a written notice on the owner of the land, if it is privately owned, stating:

(a) That the beaver thereon are interfering with or stopping the flow of water necessary for the proper serving of water rights; and

(b) That unless, within 10 days from receipt of the notice, written objection to the removal of such beaver is filed with the State Engineer by the landowner, the Department of Wildlife will remove such beaver or as many thereof as will rectify the existing conditions.

4. Failure of the landowner to file such written objections shall be deemed a waiver thereof. Upon receipt of written objections, the State Engineer may make further investigation and may sustain or overrule the objections as the facts warrant. Upon the overruling of the objections, the landowner may have them reviewed by the district court having jurisdiction of the land by filing therein a petition for review within 10 days from the receipt of the order of the State Engineer overruling the objections. The proceedings on the petition must be informal and heard by the court at the earliest possible moment.

5. Upon the landowner's waiver of objections to the removal of beaver from his or her land, or upon final determination by the court that the beaver should be removed, the State Engineer shall immediately notify the Department of Wildlife of the waiver or determination and the Department or its agents shall enter upon the land from which the beaver are to be removed and remove them or as many as may be necessary to prevent the improper flow of water as directed by the State Engineer.

6. The State Engineer may remove or cause the removal of any beaver dam found to be obstructing the proper and necessary flow of water to the detriment of water users.

[Part 1:61:1949; 1943 NCL § 3148.01] + [2:61:1949; 1943 NCL § 3148.02]—(NRS A 1969, 1561; 1979, 914; 1993,

1702; 2003, 1581)

NRS 535.070 Construction of weir in dam situated within 2 miles of incorporated city or town.

1. The term "water of such river," as used in this section, means the normal and natural flow of water in the river unaffected by flood, storm or other abnormal natural causes.

2. Any person owning, leasing or constructing any dam in any river of this State within 2 miles of an incorporated city governed by a board of county commissioners shall make or construct a weir in the dam of such size as to admit of the free passage of the water of such river during such portions of the year as such water is not being used for irrigating purposes.

3. If any person fails, neglects or refuses to comply with the provisions of subsection 2, the district attorney of the county wherein the dam is situated or being constructed shall commence mandamus proceedings to compel the person to comply with the provisions of subsection 2, or the board of county commissioners of the county may order the weir to be constructed at the expense of the county, and the county has a right of action against the owner or lessee of the dam for all expenses incurred by the county in constructing the weir and may recover judgment on the right of action and satisfy the judgment in the manner provided by law.

4. The provisions of this section do not apply to dams constructed or being constructed or hereafter to be constructed for the purpose of permanently storing the waters of such river for beneficial purposes.

[1:182:1913; 1919 RL p. 2668; NCL § 8002] + [2:182:1913; 1919 RL p. 2669; NCL § 8003] + [3:182:1913; 1919 RL p. 2669; NCL § 8004] + [4:182:1913; 1919 RL p. 2669; NCL § 8005]—(NRS A 1987, 1725)

NRS 535.080 Attorney General and County Commissioners of Washoe County authorized to institute actions to maintain flow of Truckee River. The Attorney General and the Board of County Commissioners of Washoe County are authorized and empowered to commence suits or take such other action as may be necessary to maintain a regular or natural flow of water in the Truckee River, and in all suits so instituted, if necessary, to use the name of "The State of Nevada."

[1:120:1879; cited BH § 5013; RL § 4140; NCL § 7326]

NRS 535.090 Unlawful obstruction of appropriator's water; penalty.

1. Whenever any appropriator of water has the lawful right-of-way for the storage, diversion or carriage of water, it shall be unlawful to place or maintain any obstruction that shall interfere with the use of his or her works or prevent convenient access thereto.

2. Any person who violates any of the provisions of this section is guilty of a misdemeanor.

[82:140:1913; 1919 RL p. 3247; NCL § 7968] + [83:140:1913; 1919 RL p. 3247; NCL § 7969]—(NRS A 1967, 610)

NRS 535.100 Injury or obstruction of flow of water by sawmill, slaughterhouse, brewery or tannery; civil action.

1. Any person who is the owner of or in possession of any sawmill used for the making of lumber, or any slaughterhouse, brewery or tannery shall not injure or obstruct the natural flow of water in any river, creek or other stream.

2. Any city or county government, or any person, who is the owner of or in possession of any agricultural lands and who is injured by reason of the violation on the part of any person of the provisions contained in subsection 1 may commence and maintain an action against the person for any damage sustained, in such manner as may be provided by law.

[Part 1:98:1862; B § 3847; BH § 353; C § 432; RL § 4718; NCL § 8248] + [2:98:1862; B § 3848; BH § 354; C § 433; RL § 4719; NCL § 8249] + [3:98:1862; B § 3849; BH § 355; C § 434; RL § 4720; NCL § 8250]—(NRS A 1967, 610; 2007, 2022)

NRS 535.110 Unlawful removal, damage or destruction of piling, dike, dock or lock; unlawful structures.

1. Every person who willfully and maliciously removes, damages or destroys a pile or other material fixed in the ground and used for securing any bank or dam of any river or other water, or any dike, dock, quay, jetty or lock is guilty of a misdemeanor.

2. Every person who:

(a) Moors any vessel, scow, barge, raft or boom to any bridge; or

(b) Erects or maintains any unlawful structure in any stream or river,

➥ is guilty of a misdemeanor.

[Part 1911; C&P § 487; RL § 6752; NCL § 10434]—(NRS A 1993, 864)

NRS 535.200 Additional penalties.

1. In addition to any other penalty provided by law, the State Engineer may, after notice and opportunity for a hearing, require a person who violates any provision of this chapter, any permit, order or decision issued by the State Engineer pursuant to this chapter or any regulation adopted by the State Engineer pursuant to NRS 532.120 to pay an administrative fine not to exceed $10,000 per day for each violation as determined by the State Engineer.

2. If an administrative fine is imposed against a person pursuant to subsection 1, the State Engineer may require the person to pay the costs of the proceeding, including investigative costs and attorney's fees.

3. An order imposing an administrative fine or requiring the payment of costs or fees pursuant to this section may be reviewed by a district court pursuant to NRS 533.450.

(Added to NRS by 2007, 2021)

NRS 535.210 Injunctive and other relief.

1. The State Engineer may seek injunctive relief in the appropriate court to prevent the continuance or occurrence of any act or practice which violates any provision of this chapter, any permit, order or decision issued by the State Engineer pursuant to this chapter or any regulation adopted by the State Engineer pursuant to NRS 532.120.

2. On a showing by the State Engineer that a person is engaged, or is about to engage, in any act or practice which violates or will violate any provision of this chapter, any permit, order or decision issued by the State Engineer pursuant to this chapter or any regulation adopted by the State Engineer pursuant to NRS 532.120, the court may issue, without a bond,

any prohibitory or mandatory injunction that the facts may warrant, including a temporary restraining order issued ex parte or, after notice and hearing, a preliminary or permanent injunction.

3. Failure to establish lack of an adequate remedy at law or irreparable harm is not a ground for denying a request for a temporary restraining order or injunction.

4. The court may require the posting of a sufficient performance bond or other security to ensure compliance with the court order within the period prescribed.

5. Any proceeding conducted or injunction or order issued pursuant to this section is in addition to, and not in lieu of, any other penalty or remedy available for a violation of this chapter.

(Added to NRS by 2007, 2021)

E.28. New Hampshire

Section Env-Wr 704.02 Report of Findings; Decision

CHAPTER Env-Wr 800 ADMINISTRATIVE FINES - **EXPIRED**

Department of Environmental Services
Water Division
29 Hazen Drive
Concord, New Hampshire 03301
Tel. No. (603) 271-3406

CHAPTER Env-Wr 100 ORGANIZATIONAL RULES

PART Env-Wr 101 DEFINITIONS

Env-Wr 101.01 "100-year flood" means the flood that has a one chance in 100 of being equaled or exceeded in a period of one year.

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84, EXPIRED 11-7-90

New. #5080, eff 2-22-91; ss by #6462-A, eff 2-21-97; ss by #8288, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by *#8412, eff 8-20-05*

Env-Wr 101.02 "50-year flood" means the flood that has a one chance in 50 of being equaled or exceeded in a period of one year.

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84, EXPIRED 11-7-90

New. #5080, eff 2-22-91; ss by #6462-A, eff 2-21-97; ss by #8288, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by *#8412, eff 8-20-05*

Env-Wr 101.03 "Acre-foot" means the volume of water that would cover one acre to a depth of one foot.

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84, EXPIRED 11-7-90

New. #5080, eff 2-22-91; ss by #6462-A, eff 2-21-97; ss by #8288, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by *8412, eff 8-20-05*

Env-Wr 101.04 "Applicant" means the person or persons filing an application to construct or reconstruct a dam.

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84; rpld by #4491, eff 9-20-88

New. #5080, eff 2-22-91; ss by #6462-A, eff 2-21-97; ss by #8288, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by *#8412, eff 8-20-05*

Env-Wr 101.05 "Breached dam" means a dam which no longer impounds water at the level of the primary spillway or outlet structure because of a partial or full dam failure, or because a portion of the dam has been removed.

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84; ss by #4491, eff 9-20-88; ss by #5080, eff 2-22-91; ss by #6462-A, eff 2-21-97; ss by #8288, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by *#8412, eff 8-20-05*

Env-Wr 101.06 "Class AA structure" means a dam that is not a menace because it is in a location and of a size that failure or misoperation of the dam would not result in probable loss of life or loss to property, provided the dam is:

(a) Less than 6 feet in height if it has a storage capacity greater than 50 acre-feet; or

(b) Less than 25 feet in height if it has a storage capacity of 15 to 50 acre-feet.

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84, EXPIRED 11-7-90

New. #5080, eff 2-22-91; ss by #6462-A, eff 2-21-97; ss by #8288, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by *#8412, eff 8-20-05*

Env-Wr 101.07 "Class A structure" means a dam that has a low hazard potential because it is in a location and of a size that failure or misoperation of the dam would result in any of the following:

(a) No probable loss of life;

(b) Low economic loss to structures or property;

(c) Structural damage to a town or city road or private road accessing property other than the dam owner's which could render the road impassable or otherwise interrupt public safety services;

(d) The release of liquid industrial, agricultural, or commercial wastes, septage, or contaminated sediment if the storage capacity is less than 2 acre-feet and is located more than 250 feet from a water body or water course; or

(e) Reversible environmental losses to environmentally-sensitive sites.

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84, EXPIRED 11-7-90

New. #5080, eff 2-22-91; ss by #6462-A, eff 2-21-97; ss by #8288, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by *#8412, eff 8-20-05*

Env-Wr 101.08 "Class B structure" means a dam that has a significant hazard potential because it is in a location and of a size that failure or misoperation of the dam would result in any of the following:

(a) No probable loss of life;

(b) Major economic loss to structures or property;

(c) Structural damage to a Class I or II road which could render the road impassable or otherwise interrupt public safety services;

(d) Major environmental or public health losses, including:

(1) Damage to a public water system, as defined by RSA 485:1-a, XV, which will take longer than 48 hours to repair; or

(2) The release of liquid industrial, agricultural, or commercial wastes, septage, sewage, or contaminated sediments if the storage capacity is 2 acre-feet or more; or

(3) Damage to an environmentally-sensitive site that does not meet the definition of reversible environmental losses.

Source. #1702, eff 1-1-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84, EXPIRED 11-7-90

New. #5080, eff 2-22-91; ss by #6462-A, eff 2-21-97; ss by #8288, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by *#8412, eff 8-20-05*

Env-Wr 101.09 "Class C Structure" means a dam that has a high hazard potential because it is in a location and of a size that failure or misoperation of the dam would result in probable loss of human life as a result of:

(a) Water levels and velocities causing the structural failure of a foundation of a habitable residential structure or a commercial or industrial structure which is occupied under normal conditions;

(b) Water levels rising above the first floor elevation of a habitable residential structure or a commercial or industrial structure which is occupied under normal conditions when the rise due to dam failure is greater than one foot;

(c) Structural damage to an interstate highway which could render the roadway impassable or otherwise interrupt public safety services;

(d) The release of a quantity and concentration of materials which qualify as "hazardous waste" as defined by RSA 471-A:2 VI; or

(e) Any other circumstance which would more likely than not cause one or more deaths.

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84, EXPIRED 11-7-90

New. #5080, eff 2-22-91; ss by #6462-A, eff 2-21-97; ss by #8288, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by *#8412, eff 8-20-05*

Env-Wr 101.10 "Construction engineer" means a professional engineer, licensed in New Hampshire, who has been hired by the owner to oversee construction or reconstruction of a dam.

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84, EXPIRED 11-7-90

New. #5080, eff 2-22-91; ss by #6462-A, eff 2-21-97; ss by #8288, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by #*8412, eff 8-20-05*

Env-Wr 101.11 "Controlled breach" means an opening in a dam which extends from the top of the dam to the streambed made specifically for the purpose of lowering the level of impounded water to a safe level for the dam.

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84, EXPIRED 11-7-90

New. #5080, eff 2-22-91; ss by #6462-A, eff 2-21-97; ss by #8288, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by #*8412, eff 8-20-05*

Env-Wr 101.12 "Dam" means "dam" as defined by RSA 482:2, II, namely "any artificial barrier, including appurtenant works, which impounds or diverts water, and which has a height of 4 feet or more, or a storage capacity of 2 acre-feet or more, or is located at the outlet of a great pond. A roadway culvert shall not be considered a dam if its invert is at the natural bed of the water course, it has adequate discharge capacity, and it does not impound water under normal circumstances. Artificial barriers which create surface impoundments for industrial, or commercial wastes or municipal sewage, regardless of height or storage capacity, shall be considered dams".

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84, EXPIRED 11-7-90

New. #5080, eff 2-22-91; ss by #6462-A, eff 2-21-97; ss by #8288, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by #*8412, eff 8-20-05*

Env-Wr 101.13 "Dam in disrepair" means "dam in disrepair" as defined by RSA 482:2, V, namely "a dam which is a menace to public safety and is incapable of safely impounding flood waters to its crest, or incapable of maintaining a reasonably constant level of waters impounded, or is one which does not contain adequate gates and sluiceways to provide for the holding or controlled discharge of waters impounded."

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84, EXPIRED 11-7-90

New. #5080, eff 2-22-91; ss by #6462-A, eff 2-21-97; ss by #8288, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by #*8412, eff 8-20-05*

Env-Wr 101.14 "Days" means calendar days unless otherwise specified.

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84, EXPIRED 11-7-90

New. #5080, eff 2-22-91; ss by #6462-A, eff 2-21-97; ss by #8288, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by *#8412, eff 8-20-05*

Env-Wr 101.15 "Department" means the department of environmental services.

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84; ss by #4491, eff 9-20-88; ss by #5080, eff 2-22-91; ss by #6462-A, eff 2-21-97; ss by #8288, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by *#8412, eff 8-20-05*

Env-Wr 101.16 "Discharge capacity" means the amount of water which can safely pass the structure through its normal discharge channels.

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84, EXPIRED 11-7-90

New. #5080, eff 2-22-91; ss by #6462-A, eff 2-21-97; ss by #8288, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by *8412, eff 8-20-05*

Env-Wr 101.17 "Emergency condition" means:

(1) A situation has arisen at a dam which could jeopardize the integrity of the dam; or

(2) Failure of the dam is imminent or has occurred.

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84, EXPIRED 11-7-90

New. #5080, eff 2-22-91; ss by #6462-A, eff 2-21-97; ss by #8288, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by *#8412, eff 8-20-05*

Env-Wr 101.18 "Environmentally-sensitive site" means:

(a) A site listed and tracked by the natural heritage inventory, as maintained by the department of resource and economic development;

(b) A prime wetland designated per RSA 482-A:15;

(c) A river segment designated pursuant to RSA 483;

(d) A prime habitat for resident or migratory fishes, as determined by the fish and game department; or

(e) Surface waters immediately downstream of a dam that support coldwater fish communities, as determined by the fish and game department.

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84, EXPIRED 11-7-90

New. #5080, eff 2-22-91; ss by #6462-A, eff 2-21-97; ss by #8288, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by #*8412, eff 8-20-05*

Env-Wr 101.19 "Flashboards" means boards which temporarily raise the pond elevation above the permanent spillway crest and are designed to automatically fall over when the water level rises to a particular level.

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84, EXPIRED 11-7-90

New. #5080, eff 2-22-91; ss by #6462-A, eff 2-21-97; ss by #8288, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by #*8412, eff 8-20-05*

Env-Wr 101.20 "Freeboard" means the vertical distance from the water surface to the lowest elevation at which water would flow over the dam at a section not designed to be overflowed.

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84; amd by #4278, eff 6-30-87; ss by #4534, eff 11-30-88; ss by #5080, eff 2-22-91; ss by #6462-A, eff 2-21-97; ss by #8288, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by #*8412, eff 8-20-05*

Env-Wr 101.21 "Great Pond" means a water body of 10 acres or more in its natural condition.

Source. #4278, eff 6-30-87; ss by #5080, eff 2-22-91; ss by #6462-A, eff 2-21-97; ss by #8288, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by #*8412, eff 8-20-05*

Env-Wr 101.22 "Height" means the vertical distance from the lowest point of natural ground on the downstream side of the dam to the highest part of the dam which would impound water.

Source. #4278, eff 6-30-87; ss by #5080, eff 2-22-91; ss by #6462-A, eff 2-21-97; ss by #8288, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by #*8412, eff 8-20-05*

Env-Wr 101.23 "Inflow design flood" is the flood flow above which dam failure would not contribute to endangering public safety or property downstream of the dam.

Source. #4278, eff 6-30-87; ss by #5080, eff 2-22-91; ss by #6462-A, eff 2-21-97; ss by #8288, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by #*8412, eff 8-20-05*

Env-Wr 101.24 "Inland public water" as used in RSA 482:79 means any public water of 10 acres or more whose level is controlled by a dam.

Source. #4278, eff 6-30-87; ss by #5080, eff 2-22-91; ss by #6462-A, eff 2-21-97; ss by #8288, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by *#8412, eff 8-20-05*

Env-Wr 101.25 "Menace to public safety" as used in RSA 482:2, V and "menace to the public safety" as used in RSA 482:9, III, means that the failure or misoperation of the dam would threaten human life or public health or interrupt safety services. The term includes any class A, class B, or class C dam but does not include any class AA dam.

Source. #4278, eff 6-30-87; ss by #5080, eff 2-22-91; ss by #6462-A, eff 2-21-97; ss by #8288, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by *#8412, eff 8-20-05*

Env-Wr 101.26 "Mills" means "mills" as defined by RSA 482:2, VII, namely "manufacturing plants and plants at which electric power is generated for public distribution or for the operation of mills, railroads or public utilities."

Source. #4278, eff 6-30-87; ss by #5080, eff 2-22-91; ss by #6462-A, eff 2-21-97; ss by #8288, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by *#8412, eff 8-20-05*

Env-Wr 101.27 "Low economic loss" means economic loss to undeveloped agriculture, uninhabited structures such as storage sheds, or minor impact to sites listed or tracked by the natural heritage inventory, as maintained by the department of resource and economic development.

Source. #4278, eff 6-30-87; ss by #5080, eff 2-22-91; ss by #6462-A, eff 2-21-97; ss by #8288, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by *#8412, eff 8-20-05*

Env-Wr 101.28 "Non-permitted" means:

(a) For a dam constructed subsequent to 1917, that a permit, order, or authorization for construction or registration by the department or a predecessor state agency responsible for such at the time has never been issued; or

(b) For a dam constructed prior to 1917, that the location of the dam is not on file with the department.

Source. #4278, eff 6-30-87; ss by #5080, eff 2-22-91; ss by #6462-A, eff 2-21-97; ss by #8288, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by *#8412, eff 8-20-05*

Env-Wr 101.29 "Normal storage capacity" means the volume of water and material which could be impounded above the natural ground elevation, when the water level is at the elevation of the lowest free-flowing discharge structure.

Source. #4278, eff 6-30-87; ss by #5080, eff 2-22-91; ss by #6462-A, eff 2-21-97; ss by #8288, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by *#8412, eff 8-20-05*

Env-Wr 101.30 "Owner" means the person or persons who own a dam.

Source. #4278, eff 6-30-87; ss by #5080, eff 2-22-91; ss by #6462-A, eff 2-21-97; ss by #8288, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by *#8412, eff 8-20-05*

Env-Wr 101.31 "Person" means "person" as defined by RSA 482:2,VIII, namely "any individual, partnership, association, corporation, company, organization or legal entity of any kind."

Source. #4399, eff 4-19-88, EXPIRED 4-19-90

New. #5080, eff 2-22-91; ss by #6462-A, eff 2-21-97; ss by #8288, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by *#8412, eff 8-20-05*

Env-Wr 101.32 "Plans" means engineering drawings including plan views, elevations, sections, and details.

Source. #4491, eff 9-20-88; ss by #5080, eff 2-22-91; ss by #6462-A, eff 2-21-97; ss by #8288, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by *#8412, eff 8-20-05*

Env-Wr 101.33 "Reconstruction" means "reconstruction" as defined by RSA 482:2, X, namely:

"(a) A change in the height, length or discharge capacity the structure;

(b) Restoring a breached dam or one in ruins;

(c) Modification of flashboards which either increases their height or increases the headwater elevation at which the flashboards will fail; or

(d) A change in the structural configuration of a dam."

Source. #4491, eff 9-20-88; ss by #5080, eff 2-22-91; ss by #6462-A, eff 2-21-97; ss by #8288, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by *#8412, eff 8-20-05*

Env-Wr 101.34 "Removal" means the physical elimination of a dam as governed by Env-Wr 600.

Source. #4491, eff 9-20-88; ss by #5080, eff 2-22-91; ss by #6462-A, eff 2-21-97; ss by #8288, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by *#8412, eff 8-20-05*

Env-Wr 101.35 "Repair" means work on a dam that does not change the height, length or discharge capacity of the structure and that does not constitute reconstruction.

Source. #4491, eff 9-20-88; ss by #5080, eff 2-22-91; ss by #6462-A, eff 2-21-97; ss by #8288, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by *#8412, eff 8-20-05*

Env-Wr 101.36 "Reversible environmental losses" means damage to an ecosystem which is expected to self-remediate within 5 years.

Source. #5080, eff 2-22-91; ss by #6462-A, eff 2-21-97; ss by #8288, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by #*8412, eff 8-20-05*

Env-Wr 101.37 "Ruins" means the remains of a dam which no longer impounds water and whose deterioration is to the extent that the original configuration can no longer be determined.

Source. #5080, eff 2-22-91; ss by #6462-A, eff 2-21-97; ss by #8288, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by #*8412, eff 8-20-05*

Env-Wr 101.38 "Specifications" means the descriptions of materials and methods of work sufficient in quantity and detail to convey the intent of the designer.

Source. #5080, eff 2-22-91; ss by #6462-A, eff 2-21-97; ss by #8288, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by #*8412, eff 8-20-05*

Env-Wr 101.39 "Stage" means the depth of water or elevation of water surface.

Source. #5080, eff 2-22-91; ss by #6462-A, eff 2-21-97; ss by #8288, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by #*8412, eff 8-20-05*

Env-Wr 101.40 "Storage capacity" means the maximum volume of water and material which could be impounded by a dam above the natural ground elevation when the water level is at:

(a) The top of dam; or

(b) The highest elevation which could be hydrologically attained, if this elevation is below the top of dam.

Source. #5080, eff 2-22-91; ss by #6462-A, eff 2-21-97; ss by #8288, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by #*8412, eff 8-20-05*

Env-Wr 101.41 "Stream" means any watercourse delineated on a USGS topographic map as a dashed or solid line, or any watercourse not delineated on a USGS topographic map that flows continuously in a well-defined channel for at least 30% of the year.

Source. #5080, eff 2-22-91; ss by #6462-A, eff 2-21-97; ss by #8288, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by #*8412, eff 8-20-05*

Env-Wr 101.42 "Sunny day flow" means the flow occurring in a river or stream channel during normal hydrologic conditions.

Source. #5080, eff 2-22-91; ss by #6462-A, eff 2-21-97; ss by #8288, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by #*8412, eff 8-20-05*

Env-Wr 101.43 "Wave run-up" means the height of water above the still water level which would be expected to occur at a dam as a result of high winds.

Source. #5080, eff 2-22-91; ss by #6462-A, eff 2-21-97; ss by #8288, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by *#8412, eff 8-20-05*

PART Env-Wr 102 DUTIES OF THE DEPARTMENT

Env-Wr 102.01 Summary of Duties. Pursuant to its statutory authority under RSA 482, the department performs the following duties:

(a) Enters interstate compacts for conserving and regulating flow, lessening flood damages and removing or preventing sources of pollution, pursuant to RSA 482:91;

(b) Monitors flow by establishing and maintaining a network of stream flow gauging stations with cooperation from the United States Geological Survey, pursuant to RSA 482:85;

(c) Constructs, maintains and operates small watershed projects with cooperation from the U.S. Department of Agriculture Natural Resources Conservation Service (NRCS), pursuant to RSA 482:77;

(d) When duly-authorized by the legislature, accepts, repairs, maintains, and operates certain dams, pursuant to RSA 482:48;

(e) Makes determinations whether it will be in the public interest to grant the right to erect a dam, pursuant to RSA 482:9, V(a) and RSA 482:31;

(f) Maintains a current list of existing dams, including their size, location, classification and owner, pursuant to RSA 482:8;

(g) Regulates the construction and reconstruction of dams, pursuant to RSA 482:7-11;

(h) Makes determinations of whether dams are in disrepair and conduct follow-up proceedings, pursuant to RSA 482:11-a and RSA 482:61;

(i) Periodically inspects dams, pursuant to RSA 482:12;

(j) Makes determinations of public use and benefit, pursuant to RSA 482:17 and RSA 482:31;

(k) Grants owners of mill dams certain rights when in the public interest, pursuant to RSA 482:31;

(l) Makes channel improvements in the public interest, pursuant to RSA 482:1;

(m) Makes orders, conduct hearings, subpoena and examine under oath persons and their books, records, documents, correspondence, and accounts, as necessary to carry out its obligations, pursuant to RSA 482:87;

(n) Adopts and enforces rules, pursuant to RSA 482:87;

(o) Investigates the levels of inland public waters, pursuant to RSA 482:79;

(p) Contracts with village districts for the purpose of impounding water, pursuant to RSA 52:25;

(q) Monitors the ground water resources with the cooperation of the United States Geological Survey, pursuant to RSA 482:3, II;

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84, EXPIRED 11-7-90

New. #5080, eff 2-22-91; ss by #6462-A, eff 2-21-97; ss by #8288, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by #*8412, eff 8-20-05*

PART Env-Wr 103 ACCESS TO FILES

Env-Wr 103.01 Public Records; Access to Files.

(a) The files of the department relating to activities under RSA 482 shall be open to public inspection.

(b) Information which is available for public distribution may be copied. A fee of $0.15 per page shall be assessed for photocopies made at the department's public information center by the person requesting the copies, and a fee of $0.25 per page shall be assessed for photocopies prepared by department personnel.

New. #6462-A, eff 2-21-97 (formerly Env-Wr 105.01); ss by #8288, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by #*8412, eff 8-20-05*

CHAPTER Env-Wr 200 RULES OF PRACTICE AND PROCEDURE

PART Env-Wr 201 APPLICABILITY, PURPOSE AND DEFINITIONS

Env-Wr 201.01 Applicability. The rules within this chapter shall govern proceedings before the department. These rules shall be construed to secure a just and speedy determination of every proceeding.

(a) The rules in this chapter are intended to supplement Env-C 200 and RSA 541-A in governing proceedings before the department under RSA 482. These rules shall be construed to secure a just and speedy determination of every proceeding.

(b) The purpose of any proceeding governed by this chapter shall be to allow the department to acquire sufficient information to make a reasonable decision, and to afford persons who may be affected by decisions of the department the opportunity to present evidence and argument to the department prior to the making of that decision.

Source. #1644, eff 10-7-80; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84; ss by #5080, eff 2-22-91; ss by #6462-B, eff 2-21-97; ss by #8285, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by #8413, eff 8-20-05

Env-Wr 201.02 Applicability. These rules shall apply to all proceedings initiated under RSA 482 relative to dams and lake level determinations.

Source. #1644, eff 10-7-80; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84; ss by #5080, eff 2-22-91; ss by #6462-B, eff 2-21-97; ss by #8285, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by #8413, eff 8-20-05

PART Env-Wr 202 WAIVERS

Env-Wr 202.01 Applicability. The rules contained in subtitle Env-Wr are intended to apply to a variety of conditions and circumstances. It is recognized that strict compliance with all rules prescribed herein might not fit every conceivable situation. Thus, any person who is or would be directly and adversely affected by the strict application of these rules may request a waiver of the rule(s) or portion(s) thereof which so affect that person.

Source. #1644, eff 10-7-80; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84; ss by #5080, eff 2-22-91; ss by #6462-B, eff 2-21-97; ss by #8285, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by #8413, eff 8-20-05

Env-Wr 202.02 Waiver Request.

(a) The person requesting a waiver shall submit the request in writing unless the need for a waiver does not become apparent until a hearing is underway, in which case the request shall be presented orally and made part of the record.

(b) The request for a waiver shall contain the following information:

(1) A description of the dam to which the waiver request relates, including name, address, and dam number;

(2) A citation to the specific section(s) of the rules from which a waiver is sought;

(3) A full explanation of why a waiver is being requested, including an explanation of the hardship that would be caused by compliance with the rule;

(4) A full explanation of the alternative(s) to the rule(s) for which a waiver is sought, with backup data for support; and

(5) A full explanation of how the alternative(s) are consistent with the intent of RSA 482:11-a and RSA 482:12 and would adequately protect human life, public safety, and the environment.

Env-Wr 202.03 Action on Waiver Request.

(a) The department shall approve a request for a waiver upon determining that:

(1) The alternatives proposed are adequate to ensure that the intent of RSA 482 is met;

(2) The requirement is not one that is prescribed by statute; and

(3) Human life, public safety, and the environment will be protected.

(b) The department shall issue a written decision on a request for a waiver. If the request is denied, the decision shall specify the reason(s) for the denial.

PART Env-Wr 203 PROCEEDINGS

Env-Wr 203.01 Public Hearings. Any hearing held to receive public comment under the following statutory provisions shall be conducted in accordance with the provisions of Env-C 200 applicable to non-adjudicative hearings:

(a) RSA 482:6 relative to the management and control of the outlet of a great pond;

(b) RSA 482:9, V(a) relative to public benefit of a proposed class B or class C dam;

(c) RSA 482:30 relative to public benefit of a dam proposed under RSA 482:29; and

(d) RSA 482:79 relative to lake level determinations.

PART Env-Wr 204 DECISION AND APPEALS

Env-Wr 204.01 Department Decisions.

(a) All final department decisions under RSA 482 shall be issued in writing.

(b) A final decision to grant a permit application shall be distributed as follows:

(1) Subject to Env-Wr 404.02(b), the original shall be sent to the applicant; and

(2) Copies shall be sent to all municipalities which were notified of the application pursuant to Env-Wr 304.03 or Env-Wr 402.07.

(c) A final decision to deny a permit application shall be distributed as follows:

(1) The original shall be sent to the applicant; and

(2) Copies shall be sent to all municipalities which were notified of the application pursuant to Env-Wr 304.03 or Env-Wr 402.07.

(d) Copies of a final decision in a lake level investigation shall be sent to:

(1) The owner of the dam that is the subject of the order;

(2) The person(s) who requested the investigation, if any;

(3) Each municipality in which the impounded water is located; and

(4) Each person who participated in the investigation who specifically requested to be notified of the decision.

(e) Copies of an order issued pursuant to RSA 482:11 or RSA 482:12 shall be sent to:

(1) The owner of the dam that is the subject of the order; and

(2) Each municipality in which the impounded water is located.

Source. #1644, eff 10-7-80; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84; ss by #4336, eff 11-5-87; ss by #5080, eff 2-22-91; ss and moved by #6462-B, eff 2-21-97 (from Env-Wr 205.01); ss by #8285, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by #8413, eff 8-20-05

Env-Wr 204.02 Appeals. Appeals of department decisions under RSA 482 shall be directed to the water council in accordance with Env-WC 200.

CHAPTER Env-Wr 300 EXISTING DAMS

PART Env-Wr 301 PURPOSE AND APPLICABILITY

Env-Wr 301.01 Purpose. The purpose of this chapter is to ensure that existing dams are maintained in a manner so that public health, safety, and the environment are protected.

Source. #4399, eff 4-19-88; ss by #5080, eff 2-22-91; ss by #6462-B, eff 2-21-97; ss by #8285, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by #8414, eff 8-20-05

Env-Wr 301.02 Applicability.

(a) Subject to (b), below, the requirements in this chapter shall apply to:

(1) Any structure which qualifies as a dam in accordance with RSA 482:2, II; and

(2) Any roadway culvert meeting the requirements of Env-Wr 301.03.

(b) The requirements in this chapter shall apply to a dam regulated by the Federal Energy Regulatory Commission (FERC) pursuant to the Federal Power Act, 16 U.S.C. Chapter 12, Subchapter I, only when they do not conflict with rules, standards, protocols, licenses, certificates, or orders promulgated by the FERC pursuant to that authority.

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84; amd by #4399, eff 4-19-88; ss by #5080, eff 2-22-91; ss by #6462-B, eff 2-21-97; ss by #8285, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by #8414, eff 8-20-05

Env-Wr 301.03 Roadway Culverts.

(a) A roadway embankment whose culvert is set at the natural streambed shall be considered a dam if during the 25 year storm:

(1) The water surface elevation at the culvert inlet is 6 feet or more above the water surface elevation at the culvert outlet; and

(2) It impounds 2 acre-feet or more of water over the crown, or top, of the culvert.

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84; ss by #4399, eff 4-19-88; ss by #5080, eff 2-22-91; ss by #6462-B, eff 2-21-97; ss by #8285, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by #8414, eff 8-20-05

PART Env-Wr 302 DAM INSPECTIONS; REPAIRS; ALTERNATIVES TO REPAIR

Env-Wr 302.01 Dam Inventory. The department shall maintain an inventory of all dams in the state as to ownership, height, location, and hazard classification.

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84; amd by #4534, eff 11-30-88; ss by #5080, eff 2-22-91; ss by #6462-B, eff 2-21-97; ss by #8285, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by #8414, eff 8-20-05

Env-Wr 302.02 Dam Inspections.

(a) The department shall inspect dams in accordance with the following frequency:

(1) Class A structures shall be inspected at least once every 6 years;

(2) Class B structures shall be inspected at least once every 4 years;

(3) Class C structures shall be inspected at least once every 2 years; and

(4) Class AA structures having a height of 25' or more or having a storage capacity of 50 acre-feet or more shall be inspected at least once every 6 years.

(b) An individual may request the department to inspect any dam by putting such request in writing to the department.

(c) The written request for inspection shall include:

(1) The location of the dam or water body on which the dam is located;

(2) The name, mailing address, and daytime telephone number of the owner, if known; and

(3) A statement explaining why the requestor believes the dam should be inspected.

(d) The department shall review the request and any other available information on the dam. If the department determines that public safety requires the dam to be inspected, the department shall schedule an inspection of the dam.

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84; ss by #4534, eff 11-30-88; ss by #5080, eff 2-22-91; ss by #6462-B, eff 2-21-97; ss by #8285, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by #8414, eff 8-20-05

Env-Wr 302.03 Repairs Required.

(a) Subject to (c), below, if the department determines as a result of an inspection that repairs or reconstruction to a dam are needed to maintain the dam in a safe condition, it shall notify the owner in writing of such repairs or reconstruction as are necessary and request the owner to undertake such repairs within the time period specified in the notice.

(b) If the owner does not undertake the needed repairs or reconstruction within the time period indicated in a notice sent pursuant to (a), above, the department shall proceed under RSA 482:12 to order the owner to undertake the repairs or reconstruction.

(c) The department shall not issue a request but instead shall directly issue an order requiring repairs or reconstruction if:

(1) The condition of the dam poses an imminent threat to public safety; or

(2) The owner of the dam has been non-responsive to department requests relating to other compliance issues.

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84; amd by #4534, eff 11-30-88; ss by #5080, eff 2-22-91; ss by #6462-B, eff 2-21-97; ss by #8285, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by #8414, eff 8-20-05

Env-Wr 302.04 Alternatives to Repairing or Reconstructing a Dam.

(a) In lieu of repairing or reconstructing a dam as required pursuant to Env-Wr 302.03, the owner may:

(1) Remove the dam in accordance with Env-Wr 600; or

(2) Breach or modify the dam in accordance with Env-Wr 302.05.

(b) Such removal, breach, or modification shall be equivalent to complying with the repair or reconstruction order.

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84; amd by #4534, eff 11-30-88; ss by #5080, eff 2-22-91; ss by #6462-B, eff 2-21-97; ss by #8285, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by #8414, eff 8-20-05

Env-Wr 302.05 Controlled Breach; Modifications to Lower Impoundment.

(a) The owner may request approval from the department to perform a controlled breach or to modify the dam so that the impoundment is lowered to a level that is safe for the dam.

(b) To request approval for a controlled breach or modification, the owner shall submit the following information in writing to the department:

(1) The name, mailing address, and daytime telephone number of the owner;

(2) The date of the department's order to repair or reconstruct the dam, if any, and if none, the:

a. Tax map and lot number of the property on which the dam is located;

b. Location of the dam on the applicable USGS Quadrangle map;

c. Name of the stream, river, or other water body on which the dam is located, if applicable;

d. Reason(s) for the proposed breach or modification; and

e. Hazard classification of the dam;

(3) The amount of water currently impounded by the dam, in acre-feet;

(4) Whether the request is for a controlled breach or other modification;

(5) A detailed explanation of the specific work that will be performed, including anticipated flows during the work and the effect of such flows on upstream and downstream property and public safety;

(6) The name(s), mailing address(es), and daytime telephone number(s) of the person(s) proposed to perform the work; and

(7) A proposed schedule for the work, which shall include time for the notice and hearing required by RSA 482:13.

(c) The department shall approve the proposed breach or modification if the department determines that:

(1) The proposed breach or modification will cause the structure to no longer meet the definition of a dam; and

(2) The work will be performed in a manner that will not cause flows that would result in property damage or threaten public safety upstream or downstream of the dam.

(d) If the department determines that after the proposed breach or modification the structure will still meet the definition of a dam, the department shall approve the breach or modification of the dam provided that:

(1) The work will be performed in a manner that will not cause property damage or threaten public safety upstream or downstream of the dam;

(2) The threat posed to life or property after completion of the work is no more than it would have been if the work required by the department pursuant to Env-Wr 302.03 had been completed, if applicable; and

(3) The requirements of Env-Wr 303.11 relative to discharge capacity will be met as a result of the proposed work.

PART Env-Wr 303 REQUIREMENTS FOR EXISTING DAMS

Env-Wr 303.01 Annual Registration Fee.

(a) Pursuant to RSA 482:8-a, annual registration fees for dams in the amount specified in RSA 482:8-a shall be payable to the department on January 1 of each calendar year.

(b) The department shall send a written notice, by October 31 of each year, to each owner specifying the amount of the registration fee that shall be due.

(c) The department shall send a second notice to each owner who fails to submit the annual registration fee by January 1. Such notice shall inform the owner that the payment is overdue and that if the owner fails to submit the registration fee within 10 days, the owner shall be subject to the penalties authorized by RSA 482:15 and RSA 482:89.

(d) Notices sent pursuant to (b) and (c), above, shall include whatever information the department has relative to the tax map and lot number of the dam and the volume and page number of the deed to the dam and to the property on which the dam is located, if different. At the time of paying the annual registration fee, the owner shall confirm or, if necessary, provide or correct the information.

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84; amd by #4534, eff 11-10-88; ss by #5080, eff 2-22-91; ss by #6462-B, eff 2-21-97; ss by #8285, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by #8414, eff 8-20-05

Env-Wr 303.02 Review of Hazard Classification.

(a) The department shall review the classification of a dam in conjunction with any inspection conducted pursuant to Env-Wr 302.02.

(b) If the department determines that a dam no longer meets the criteria of the class to which it had been assigned, the department shall reassign the dam to the proper classification.

(c) Upon reassigning a dam to a different classification, the department shall notify the owner in writing of:

(1) The new classification; and

(2) Any new requirements that may apply as a result of the reclassification.

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84; ss by #4534, eff 11-30-88; ss by #5080, eff 2-22-91; ss by #6462-B, eff 2-21-97; ss by #8285, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by #8414, eff 8-20-05

Env-Wr 303.03 Appeal of Classification.

(a) If the owner disagrees with the department's decision to reclassify a dam's hazard classification, the owner may request that the department reconsider the decision.

(b) To request reconsideration, the owner shall submit a written request to the department that includes the following:

(1) The name, mailing address, and daytime telephone number of the owner;

(2) The dam number assigned by the department, if known, and if not known, the location of the dam by:

a. Tax map and lot number of the property on which the dam is located;

b. Location of the dam on the applicable USGS Quadrangle map; and

c. Name of the stream, river, or other water body on which the dam is located, if applicable;

(2) The results of a dam breach analysis, including routing of the flow downstream of the dam, completed in accordance with Env-Wr 502; and

(3) An assessment of all structures potentially impacted by a dam failure, including the depth of flooding at critical structures or groups of structures.

(c) If the department determines that the information requested in (b) is insufficient to grant the requested reconsideration, the department shall:

(1) Deny the request; or

(2) If the department believes that a favorable decision might be made if inundation mapping is provided, request the owner to provide inundation mapping completed in accordance with Env-Wr 503.01.

(d) The department shall notify the owner of its decision in writing within 60 days of receiving complete information.

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84; amd by #4534, eff 11-30-88; ss by #5080, eff 2-22-91; ss by #6462-B, eff 2-21-97; ss by #8285, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by #8414, eff 8-20-05

Env-Wr 303.04 Dam Monitoring.

(a) The owner of a class A, class B, or class C dam, or the owner's designee, shall monitor the dam in accordance with this section.

(b) The dam monitor shall:

(1) Be trained in the operation of the dam;

(2) Be trained to detect and assess conditions that could affect the safety of the dam;

(3) Have authority from the owner to operate the structure during emergency situations;

(4) For a class B or class C dam, be available at the dam within 2 hours at all times; and

(5) For a class A dam, be available at the dam within 2 hours during periods of heavy precipitation, high water levels, or receipt of notification of other events that could threaten the structural integrity of the dam.

(c) The owner of a class A, class B, or class C dam shall provide:

(1) A communication system between the monitor and the local communities; and

(2) The means, materials, and equipment needed to make emergency repairs to the structure.

(d) The owner of a class B or class C dam also shall provide the training and equipment, including alternative power sources, necessary to operate the structure.

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84; amd by #4534, eff 11-30-88; ss by #5080, eff 2-22-91; ss by #6462-B, eff 2-21-97; ss by #8285, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by #8414, eff 8-20-05

Env-Wr 303.05 Operation and Maintenance Plan.

(a) The owner of a class A, class B, or class C dam shall submit a written operation and maintenance plan for approval by the department.

(b) The operation and maintenance plan shall:

(1) Describe the seasonal control of impoundment levels;

(2) Describe regular maintenance activities; and

(3) Identify the name(s) and address(es) of the dam monitor(s) required by Env-Wr 303.04 and any other emergency contacts for operation of the dam that the owner wishes to designate.

(c) The department shall approve the plan if:

(1) The information submitted addresses the items specified in (b), above; and

(2) Compliance with the submitted plan will result in a dam that will be operated safely during all flow conditions and not become a dam in disrepair.

(d) The owner shall update the operation and maintenance plan as necessary and shall submit a written update to the department within 15 days of any changes.

(e) An owner that is required to complete an emergency action plan ("EAP") pursuant to Env-Wr 303.06 may incorporate the operation and maintenance plan as an appendix to the EAP.

(f) The owner shall operate and maintain the dam in accordance with the approved operation and maintenance plan.

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84; amd by #4354, eff 11-30-88; ss by #5080, eff 2-22-91; ss by #6462-B, eff 2-21-97; ss by #8285, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by #8414, eff 8-20-05

Env-Wr 303.06 Emergency Action Plan Required.

(a) As required by RSA 482:11-a, the owner shall develop an emergency action plan (EAP) for any dam, the failure of which may threaten life or property.

(b) The owner of a class B or class C dam shall develop an EAP in accordance with Env-Wr 500.

(c) The operation and maintenance plan prepared by the owner of a class A dam shall constitute the EAP for that dam.

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84; amd by #4534, eff 11-30-88; ss by #5080, eff 2-22-91; ss by #6462-B, eff 2-21-97; ss by #8285, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by #8414, eff 8-20-05

Env-Wr 303.07 Dam Repair and Reconstruction.

(a) Pursuant to RSA 482:9, the owner shall not initiate, or authorize anyone else to initiate, work on a dam which qualifies as reconstruction without first obtaining a permit from the department pursuant to Env-Wr 400.

(b) The owner may undertake repairs other than those qualifying as reconstruction without prior department approval.

(c) An owner wishing to perform a controlled breach or otherwise modify the dam to lower the impoundment to a safe level shall proceed in accordance with Env-Wr 302.05.

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84; amd by #4534, eff 11-30-88; rpld by #5080, eff 2-22-91

New. #8414, eff 8-20-05

Env-Wr 303.08 Transfer of Ownership.

(a) The owner shall provide the information specified in (b), below, to any prospective owner prior to transferring:

(1) Title to the dam; or

(2) If ownership of the dam is tied to ownership of the property, the property on which the dam is located.

(b) The owner shall provide the following information:

(1) The existence of the dam;

(2) The dam number assigned by the department; and

(3) Any letters or orders issued by the department relative to the condition of the dam.

(c) Within 30 days of the transfer of ownership of a dam or the property on which a dam is located, the new owner shall inform the department in writing of the transfer of ownership by providing the following information:

(1) The name of the former owner;

(2) The dam number assigned by the department;

(3) The name, mailing address, and daytime telephone number of the new owner;

(4) The tax map and lot number of the dam; and

(5) The volume and page number of the deed which transferred ownership of the dam or the property on which the dam is located.

Source. #8414, eff 8-20-05

Env-Wr 303.09 Emergency Breach.

(a) An owner may purposefully breach a dam without prior approval from the department only when a threat to public safety or public health exists or significant damage to public or private property is imminent.

(b) The owner shall notify the department and the local police and fire departments prior to performing an emergency breach, if possible.

(c) If it is not possible to notify the department and local police and fire departments prior to performing an emergency breach, the owner shall make such notification as soon as reasonably possible, but never more than one hour after the initiation of the emergency breach.

(d) Within 30 days of performing an emergency breach, the owner shall submit an application to the department:

(1) To reconstruct the dam in accordance with Env-Wr 400, indicating whether the owner plans to further modify or rebuild the dam; or

(2) To remove the dam in accordance with Env-Wr 600.

Source. #8414, eff 8-20-05

Env-Wr 303.10 Other Emergency Measures.

(a) An owner may take measures which otherwise would require a permit to reconstruct a dam, other than emergency breaches, when it is necessary to do so in order to eliminate or reduce the risk of full or partial dam failure. Emergency repairs shall be limited to temporary stabilization of the site or mitigation of the immediate threat.

(b) The owner shall notify the department prior to taking such measures if possible but never more than 24 hours after the initiation of necessary repairs.

(c) Within 48 hours of completing the emergency repairs, the owner shall submit a written statement to the department that explains the nature of the emergency and what corrective measures were taken.

(d) Within 30 days of performing the emergency repairs, the owner shall submit an application to the department to reconstruct a dam in accordance with Env-Wr 400.

Source. #8414, eff 8-20-05

Env-Wr 303.11 Discharge Capacity.

(a) All class A, class B, or class C dams constructed prior to February 19, 1981 shall pass the flows indicated below with one foot of freeboard and without manual operations:

(1) Class A dams shall pass a 50-year flood, or at the owner's option, the site specific inflow design flood;

(2) Class B dams shall pass the 100-year flood, or at the owner's option, the site specific inflow design flood; and

(3) Class C dam shall pass 250% of the 100-year flood, or at the owner's option, the site specific inflow design flood.

(b) Dams constructed after February 19, 1981 shall pass the flow required by the administrative rules in place at the time of the dam's construction, in accordance with the classification of the dam at the time of construction.

Env-Wr 303.12 Meeting Discharge Capacity Requirements.

(a) If a dam does not have adequate discharge capacity to pass the flood specified in Env-Wr 303.11 with one foot of freeboard, the owner shall submit a plan to the department to address the deficiency.

(b) The plan submitted pursuant to (a), above, shall:

(1) Specify the action to be taken, per (c), below;

(2) Specify the proposed timeframe for taking the action; and

(3) Include the results of hydrologic analyses completed pursuant to Env-Wr 403.05, assessing the floods and discharge capacity of the structure.

(c) The plan shall specify which of the following actions the owner intends to pursue:

(1) Increase the capacity of the dam to pass the flood with one foot of freeboard and without manual operations;

(2) Submit a stability analysis to the department showing that the dam is safe against sliding, overturning, or erosion by overtopping, as applicable, during the specified flood, using the methods outlined in "Engineering Guidelines for Evaluation of Hydropower Projects" published by the Federal Energy Regulatory Commission, October 2002;

(3) Stabilize the dam so that it is safe under the specified flood conditions; or

(4) Modify the dam so that the hazard classification is lowered and the dam passes the appropriate flow for the new classification.

(d) The department shall approve the plan if the department determines that:

(1) The proposed action will bring the dam into compliance with Env-Wr 303.11;

(2) The work can be done in a way that will not:

a. Endanger life or property downstream of the dam; or

b. Cause environmental losses that are not reversible environmental losses; and

(3) The time frame for the work is reasonable under the circumstances, including the risk posed by the deficiency, the owner's financial resources, and the timing of the work in relation to other uses of the impounded water.

(e) The department shall notify the owner in writing of its decision. If the plan is not approved, the notice shall specify the reason(s) for the non-approval.

(f) If work under the plan as approved constitutes reconstruction of the dam, the owner shall submit an application in accordance with Env-Wr 400.

Source. #8414, eff 8-20-05

Env-Wr 303.13 Request for Time Extension.

(a) An owner may request a time extension to comply with any directive of the department issued pursuant to RSA 482:12.

(b) The request shall be submitted in writing to the department with the following information:

(1) The reason(s) why an extension is needed;

(2) The current status of the repairs or investigations; and

(3) The length of time of extension requested.

(c) The department shall grant the request for time extension if it determines that:

(1) The owner has in good faith pursued the work required by the directive;

(2) The owner is unable to complete the work during the time period specified;

(3) The current condition of the dam is such that it is not expected to fail under flow conditions anticipated during the extension; and

(4) The condition of the dam will not deteriorate so as to pose a threat to public safety under flow conditions anticipated during the extension.

(d) The department shall notify the owner of the decision on the request in writing. If the department denies the request, the department shall state the reason(s) for the denial.

Source. #8414, eff 8-20-05

PART Env-Wr 304 NON-PERMITTED EXISTING DAMS

Env-Wr 304.01 Application to Permit Existing Dam.

(a) When the department gains knowledge of the existence of a non-permitted dam, either by its own reconnaissance or by reports of others, it shall send a letter by certified mail to the owner of the property on which the dam is located stating the non-permitted status of the dam and the requirements with which the owner shall comply.

(b) The department shall include with the letter an "application to permit an existing dam" and a copy of RSA 482:5.

(c) Upon written notice from the department that an existing dam is non-permitted, the owner shall file the following information on or with, as applicable, the permit application form:

(1) The height and length of the dam, in feet;

(2) The volume and page number at the county registry of deeds of the deed to the dam and of the property on which the dam is located, if different;

(3) The tax map and lot number of the property on which the dam is located;

(4) The location of the dam on the applicable USGS Quadrangle map;

(5) The name of the stream, river, or water body on which the dam is located, if applicable;

(6) The type and purpose of the dam;

(7) A description of the dam foundation material;

(8) The size of the drainage area, normal pond area, maximum pond area, normal storage capacity, and maximum storage capacity of the dam;

(9) An operation and maintenance plan prepared as specified in Env-Wr 303.05;

(10) Plans and specifications which shall, at a minimum, include the following:

a. A scaled plan view;

b. A scaled cross-section view of the dam through the outlet, showing elevations of pipe inlet and outlet, if applicable, watertight connections, and embankment material; and

c. Design and cover of embankment slopes; and

(11) The name, address, and daytime telephone number of the owner.

(d) The owner shall include the following with the application:

(1) The fee required by RSA 482:5, II; and

(2) A statement that the owner has legal flowage rights on all lands which will be permanently or temporarily flooded by the dam and an indication of whether those rights are fee simple ownership, a flowage easement, prescriptive rights, or mill privileges.

(e) The owner shall sign the application and the statement required by (d)(2), above, if such statement is separate from the application.

(f) The owner's signature shall constitute certification that the information provided is true and complete to the knowledge and belief of the owner.

(g) The owner shall return the completed permit application within 30 days of receiving the letter sent pursuant to (a), above.

Env-Wr 304.02 Inspection. Within 30 days of receipt of the permit application, the department shall inspect the dam and area affected by the dam for conditions and factors affecting the hazard potential classification, and determine whether repair or reconstruction of the dam is required for the public safety.

Env-Wr 304.03 Notice to Municipality.

(a) Pursuant to RSA 541-A:39, when the department receives an application to permit a non-permitted dam, the department shall issue a notice to the municipality in which the dam is located to invite the municipality to submit data or information pertaining to the department's assessment of the dam's potential hazard. If the department receives such correspondence within 20 days of the town's receipt of the notice, it shall consider the information in issuing a permit.

(b) For structures that are likely to be classified as class B or class C, the department shall notify the municipality in which the structure is located and any municipalities which could be affected by a failure of the structure of a public hearing to be held by the department in the municipality in which the dam is located or in a municipality which could be affected by a failure of the structure. At the public hearing, the owner shall present information about the dam and a draft emergency action plan, and the department shall receive comment from the public.

Env-Wr 304.04 Issuance of Permit. Subject to Env-Wr 304.05, the department shall issue a permit for the dam pursuant to RSA 482:5 if:

(a) The application is complete, including all information required by Env-Wr 304.01;

(b) The department has determined that the dam's condition is such that it does not pose an imminent threat to public safety; and

(c) Issuance of the permit is consistent with RSA 482:1.

Env-Wr 304.05 Limitations on Permit Issuance.

(a) A permit for a class B or class C non-permitted dam built on or after July 25, 2000 shall be issued only if the dam meets the criteria established in RSA 482:9, V.

(b) A permit for a dam on a great pond shall be issued only in accordance with RSA 482:6.

CHAPTER Env-Wr 400 CONSTRUCTION OR RECONSTRUCTING A DAM

PART Env-Wr 401 PURPOSE AND APPLICABILITY

Env-Wr 401.01 Purpose. The purpose of this chapter is to implement RSA 482:9 by specifying the procedures for applying for a permit to construct or reconstruct a dam.

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84, EXPIRED 11-7-90

New. #5080, eff 2-22-91; ss by #6462-B, eff 2-21-97; ss by #8285, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by #8414, eff 8-20-05

Env-Wr 401.02 Applicability.

(a) Subject to (b), below, the requirements in this chapter shall apply to any person who:

(1) Plans to construct or reconstruct a structure that qualifies as a dam pursuant to Env-Wr 301.02; or

(2) Has taken emergency measures as specified in Env-Wr 303.09 or Env-Wr 303.10.

(b) The requirements in this chapter shall apply to a dam regulated by the Federal Energy Regulatory Commission (FERC) pursuant to the Federal Power Act, 16 U.S.C. Chapter 12, Subchapter I, only when they do not conflict with rules, standards, protocols, licenses, certificates, or orders promulgated by the FERC pursuant to that authority.

PART Env-Wr 402 APPLICATION PROCEDURES

Env-Wr 402.01 Application Filing.

(a) An application to construct a dam shall be filed by the owner(s) of the property on which the dam is proposed to be located.

(b) An application to reconstruct a dam, including an application relative to emergency measures pursuant to Env-Wr 401.02(a)(2), shall be filed by the owner(s) of the dam.

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84, EXPIRED 11-7-90

Env-Wr 402.02 Content of Application.

(a) The applicant shall submit a completed "application to construct or reconstruct a dam" form to the department.

(b) The applicant shall provide the following information on or with the form:

(1) The name, mailing address, and daytime telephone number of each applicant;

(2) The volume and page number of the deed for the property on which the dam is or is proposed to be located and, for an existing dam that was conveyed separately from the property, the volume and page number of the deed for the dam;

(3) The location of the existing or proposed dam on the applicable USGS Quadrangle map;

(4) The city/town tax map number and lot number for the property on which the dam is or is proposed to be located;

(5) The name of the stream, river, or other water body on which the dam is or will be located, if applicable;

(6) The height and length of the existing or proposed dam;

(7) The type and purpose of the existing or proposed dam;

(8) A description of the type of existing or proposed foundation material;

(9) The size of the drainage area, normal pond area, maximum pond area, normal storage capacity, and maximum storage capacity of the existing or proposed dam; and

(10) A plan and cross-section sketch of proposed dam.

(c) The owner shall include the following with the application:

(1) The fee required by RSA 482:9, II; and

(2) A statement that the owner has legal flowage rights on all lands which will be permanently or temporarily flooded by the dam and an indication of whether those rights are fee simple ownership, a flowage easement, prescriptive rights, or mill privileges.

(d) All forms shall be printed in ink, or typed.

(e) The owner shall sign the application and the statement required by (c)(2), above, if such statement is separate from the application.

(f) The owner's signature shall constitute certification that the information provided is true and complete to the knowledge and belief of the owner.

(g) Incomplete or improperly completed forms shall be returned by the department to the applicant or applicants with a statement for the reason(s) for the return and the additional information required.

Env-Wr 402.03 Statutory Requirements for Certain Dams.

(a) Pursuant to RSA 482:7, a new dam on a great pond shall not be constructed without specific authorization from the legislature.

(b) The department shall hold a public hearing pursuant to RSA 482:30 and RSA 482:31 upon receipt of an application for construction or reconstruction of dams falling within the scope of RSA 482:17.

(c) The public hearing shall be conducted in accordance with the provisions of Env-C 200 relative to non-adjudicative proceedings.

(d) Pursuant to RSA 482:9, V, no permit to construct a class B or class C dam shall be issued unless the requirements of that section are met.

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84, EXPIRED 11-7-90

Env-Wr 402.04 Notice to Owner.

(a) Within 10 days of receipt of an application, the department shall provide the owner with the following:

(1) The dam number;

(2) The date of receipt of the application; and

(3) A statement that construction shall not commence until the department and all other appropriate state or federal agencies have granted final approval.

(b) Within 30 days of classification by the department, the department shall provide the owner with the following:

(1) Design and construction requirements for the particular structure depending upon classification;

(2) Specific information needed for design review per Env-Wr 403 if the submitted design is lacking in particular areas; and

(3) For class B and C structures, notification that a permit will not be issued until a draft EAP has been submitted to the department for review and a public hearing held by the department in the community in which the dam is located.

Source. #8414, eff 8-20-05

Env-Wr 402.05 Classification Procedure.

(a) The department shall review all new dam applications to classify the structure in accordance with Env-Wr 101.06 through Env-Wr 101.09.

(b) If the owner disagrees with the department's hazard classification, the owner shall submit, for review by the department, the following:

(1) The results of a dam breach analysis performed in accordance with Env-Wr 502.06;

(2) Breach routing in accordance with Env-Wr 502.07; and

(3) Inundation mapping in accordance with Env-Wr 503.01.

(c) The owner of a proposed dam shall meet specific requirements relative to design, construction, inspection and maintenance of the structure in accordance with the applicable provisions of Env-Wr 403.

Source. #8414, eff 8-20-05

Env-Wr 402.06 Additional Information Required. If the dam will be a class A, class B, or class C structure, the owner shall submit:

(a) Plans and specifications which shall, at a minimum, include the following:

(1) Scaled plan view;

(2) Scaled cross-sectional view of dam through the outlet, showing elevations of inlet and outlet, watertight connections, embankment material;

(3) Design of and cover treatment for embankment slopes;

(4) Gradation analysis for all soils to be used during construction;

(5) Compaction specifications in accordance with Env-Wr 403.02(d) and (e);

(6) Construction sequence; and

(7) For reconstruction, the plans shall be of sufficient detail to show the location of the proposed work in relation to the entire dam; and

(b) A written operation and maintenance plan, which:

(1) Describes the seasonal control of impoundment levels;

(2) Describes regular maintenance activities; and

(3) Includes the name(s) and address(es) of the dam monitor(s).

Source. #8414, eff 8-20-05

Env-Wr 402.07 Notice to Municipality.

(a) Subject to (b) and (c), below, when the department receives an application to construct or reconstruct a dam, it shall issue a notice to the municipality in which the proposed dam will be located pursuant to RSA 541-A:39, to inform the municipality of the location, height and size of the impoundment of the proposed dam. The municipality may submit data or information pertinent to the department's consideration of the application. If the department receives such correspondence within 20 days of the town's receipt of the notice, it shall consider the information in issuing a permit to construct or reconstruct the dam.

(b) When the department receives an application to construct a Class B or class C structure, the department shall send the notice to the municipality and any municipalities which could be affected by a failure of the dam, and shall include notice of a public hearing to be held by the department in the municipality in which the dam is located or in a municipality that may be affected by a failure of the dam. At the public hearing, the owner shall present information about the dam and a draft emergency action plan, and the department shall receive comment from the public.

(c) If the application is to construct a dam on a great pond, the department shall send the notice to all municipalities in which the great pond is located.

Source. #8414, eff 8-20-05

PART Env-Wr 403 SPECIFIC DESIGN REQUIREMENTS

Env-Wr 403.01 Purpose. The purpose of this part is to set forth the minimum design requirements for all new dams and the minimum design requirements for the specific work proposed for reconstruction of existing dams.

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84, EXPIRED 11-7-90

New. #5080, eff 2-22-91; rpld by #6462-B, eff 2-21-97

New. #8414, eff 8-20-05

Env-Wr 403.02 Minimum Design Requirements of All Dams. An application for construction of a new dam or reconstruction of an existing dam shall incorporate the following design requirements:

(a) The embankment slopes shall be no steeper than 2.5 horizontal to 1 vertical unless a specific design for a steeper slope shows that the embankment is stable and capable of being safely maintained;

(b) The embankment top width shall be 6 feet or greater;

(c) Any earthen spillway shall be constructed in natural ground;

(d) Soil compaction specifications shall be shown on the plans; and

(e) Pre-compacted lift thickness shall be compatible with the material and equipment to be used, but no greater than 12 inches in depth.

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84, EXPIRED 11-7-90

New. #8414, eff 8-20-05

Env-Wr 403.03 Additional Requirements Based on Hazard Classification.

(a) For the construction or reconstruction of a class A, class B, or class C dam:

(1) All final plans and design documents shall be stamped by a professional engineer, licensed in the State of New Hampshire, with a minimum of 5 years of engineering experience related to the design and construction of similar dam projects, as determined by the department after a review of the engineer's resume;

(2) The project shall be inspected in accordance with Env-Wr 405; and

(3) A construction inspection plan, prepared in accordance with Env-Wr 405.04, shall accompany the application for construction or reconstruction.

(b) A design for construction of a new class A, class B, or class C dam, with the exception of dams impounding liquid industrial, agricultural, or commercial wastes, or municipal sewage, shall be equipped with a pond drain.

(c) A design for construction of a class B or class C dam shall also include the following:

(1) The results of a stability analysis of the structure for overturning, sliding, and slope failure, as applicable, including factors of safety, using the methods outlined in the Federal Energy Regulatory Commission's publication, Engineering Guidelines for Evaluation of Hydropower Projects, October, 2002;

(2) The results of a seepage analysis;

(3) The results of subsurface explorations, including, but not limited to borings and test pits; and

(4) A draft emergency action plan (EAP), or if an EAP has already been approved, an updated EAP, in accordance with Env-Wr 500.

(d) A design for reconstruction of a class B or class C dam shall include the items identified in (c), above, if the department determines that the items are applicable based on the type of work to be done.

Env-Wr 403.04 Design Floods for New Dams.

(a) A new dam shall be designed to safely pass the flows indicated below without manual operation and with the freeboard requirements indicated:

(1) A class AA structure shall pass the 50-year flood or, at the owner's option, the site-specific inflow design flood, with one foot of freeboard or, at the owner's option, freeboard equal to the effects of maximum wave run-up;

(2) A class A structure shall pass the 100-year flood or, at the owner's option, the site-specific inflow design flood, with one foot of freeboard or, at the owner's option, freeboard equal to the effects of maximum wave run-up;

(3) A class B structure shall pass ½ of the probable maximum flood (PMF) as determined using Hydrometeorological Report No. 52 (HMR 52) from the National Oceanic and Atmospheric Administration (NOAA) or the site-specific inflow design flood, with freeboard equal to the effects of maximum wave run-up; and

(4) A class C structure shall pass the PMF as determined using HMR 52, or the site-specific inflow design flood, with freeboard equal to the effects of maximum wave run-up;

(b) Wave run-up calculations shall identify maximum wind speeds and fetch limitations.

(c) For a class B or class C dam, and when the option is applied for a class AA or class A dam, the owner shall submit wave run-up calculations with the application.

(d) The owner shall submit the results of calculations performed for hydrologic and hydraulic analyses pursuant to (a), above, and Env-Wr 403.05 with the application.

Env-Wr 403.05 Hydrologic Investigations.

(a) Hydrologic investigations shall be performed on the entire contributing drainage area.

(b) Precipitation estimates for the design flood shall be obtained from:

(1) NRCC Research Publication RR 93-5, Atlas of Precipitation Extremes for Northeastern United States and Southeastern Canada, 1995; or

(2) U.S. Dept. of Commerce, National Oceanic and Atmospheric Administration, Hydrometeorological Report No. 51, Probable Maximum Precipitation Estimates, United States East of the 105th Meridian, June 1978.

(c) Hydrologic modeling for 50-year or 100-year storms shall incorporate the following:

(1) The size of the drainage area;

(2) The shape of the drainage area;

(3) Antecedent moisture condition 2, as defined in the USDA NRCS National Engineering Handbook, 210-VI-NEH-630.10, August 1, 1969;

(4) Ground slopes;

(5) Soil types;

(6) Vegetation;

(7) Land use;

(8) Distribution of varying precipitation amounts throughout the watershed; and

(9) Ponds, swamps, and other factors affecting the amount and rate of runoff.

(d) The storm duration used in the modeling shall exceed the time for water to flow from the outermost point in the system to the subject location so as to ensure that the total runoff volume will be included in the routing of the storm through the dam structure.

Env-Wr 403.06 References for Hydraulic Determinations.

(a) Because the engineering science of hydraulics is documented in many competent texts, most of which rely on the same basic concepts, relationships and formulas, the designer may use any text, combination of texts, or related computer software applications for their design analysis.

(b) One or more of the following texts shall be used in evaluating the competence of the submitted design:

(1) "National Engineering Handbook, Section 5, Hydraulics" by USDA NRCS 1956; or

(2) "Handbook of Hydraulics", Sixth Edition, by Horace W. King and Earnest F. Brater, Mcgraw Hill Book Co., 1982.

Source. #8414, eff 8-20-05

Env-Wr 403.07 Concrete Design Criteria.

(a) Because the design of concrete structures is documented in many competent texts, the designer may use any text, combination of texts or related computer software application.

(b) One or more of the following texts shall be used in evaluating the competence of the submitted design:

(1) "Building Code Requirements for Structural Concrete & Commentary," ACI 318-05, American Concrete Institute, dated 2005;

(2) "Design of Small Dams" by US Department of Interior, Bureau of Reclamation, third Edition, 1987; or

(3) "National Engineering Handbook, Section 6, Structural Design", USDA NRCS, 1980.

PART Env-Wr 404 ISSUANCE AND CONDITIONS OF PERMITS

Env-Wr 404.01 Approval.

(a) Subject to (b) through (d), below, the department shall approve an application to construct or reconstruct a dam if:

(1) The requirements of Env-Wr 402 and Env-Wr 403 have been met; and

(2) Issuance of the permit is consistent with RSA 482:1 and any other applicable provisions of RSA 482.

(b) If the proposed dam is a class B or class C dam, the application shall not be approved until:

(1) A final emergency action plan has been completed and approved in accordance with Env-Wr 505; and

(2) The department has determined that the dam will serve a public benefit as required by RSA 482:9, V.

(c) If the proposed dam is a new dam on a great pond, the application shall not be approved until the owner has been granted authority by the legislature to construct or reconstruct the dam.

(d) If the dam is proposed under RSA 482:17, the application shall not be approved until the department has determined after holding a non-adjudicative hearing in accordance with the applicable provisions of Env-C 200 that it is in the public benefit to grant the permit pursuant to RSA 482:31.

Env-Wr 404.02 Issuance and Recordation of Permit/Registration.

(a) Upon review and approval of the application, the department shall issue a permit authorizing the construction or reconstruction. The permit shall include any restrictions, requirements or disclaimers as specified in Env-Wr 404.03.

(b) The department shall send the original permit to the registry of deeds for the county in which the dam is located to be recorded.

(c) The department shall send a copy of the permit to the owner at the time of approval. The department shall send the original permit to the owner upon receiving it back from the registry of deeds.

New. #8414, eff 8-20-05

Env-Wr 404.03 Conditions of Permit. The following conditions shall apply to all permits to construct or reconstruct a dam:

(a) The permit shall be valid for 2 years from the date of issuance;

(b) Work under the permit shall be completed within 2 years unless the owner has requested and received a time extension in accordance with Env-Wr 404.04;

(c) All work on the dam shall comply with the approved plans and specifications, subject to design changes approved and documented in accordance with Env-Wr 404.05;

(d) The construction engineer shall provide a final inspection report in accordance with Env-Wr 405.08;

(e) The construction engineer shall certify to the department that the work was completed in accordance with the approved plans and specification and design intent as required by Env-Wr 405.09;

(f) Inspections shall be performed in accordance with the plan submitted pursuant to Env-Wr 405.04;

(g) At least 10 days prior to commencing work, the owner shall notify the department by certified mail of the date that the work is expected to commence;

(h) The owner shall notify the department upon completion of the work in accordance with Env-Wr 405.10(a);

(i) If an emergency action plan is required, no liquid shall be impounded until the EAP is approved by the department.

(j) The owner shall maintain a current mailing address with the department;

(k) The owner shall operate and maintain the structure in accordance with the written operation and maintenance procedures submitted in accordance with Env-Wr 402.06(b); and

(l) The department shall include in the permit any other conditions necessary to ensure protection of public safety that are based on the specific design, site, and watershed.

New. #8414, eff 8-20-05

Env-Wr 404.04 Time Extension. The department shall grant a 2-year time extension to construct a dam if:

(a) The owner requests the extension in writing prior to the permit's expiration date;

(b) The hazard classification or the design requirements outlined in Env-Wr 403 have not changed since the issuance of the original permit; and

(c) The site is stabilized and the condition of the project is such that granting a time extension to complete the construction will not threaten human life, public safety, or the environment.

Env-Wr 404.05 Design Changes.

(a) No changes shall be made to the plans and specifications approved by the department, either before or during construction, unless:

(1) The changes are approved by the design engineer; and

(2) The changes are approved by the department in writing.

(b) To request a change, the owner or the owner's designee shall submit a request for the change in writing to the department, which shall include:

(1) The specific information regarding the requested change; and

(2) The reason the change is being requested.

(c) The department shall approve the change if the overall design as revised would have been approved if it had been submitted originally.

(d) The department shall notify the owner and the owner's designee, if applicable, of the decision on the request in writing. If the request is denied, the decision shall state the reason(s) for the denial.

(e) If time is of the essence, the department shall convey verbal approval prior to issuing written approval.

Env-Wr 405.03 Construction Engineer.

(a) Prior to any work on the dam starting, the owner shall engage a construction engineer to ensure compliance with approved plans and specifications.

(b) The construction engineer shall have a minimum of 5 years of engineering experience related to construction inspection or design of similar dam construction projects.

(c) The owner shall submit the construction inspector's resume of related construction inspection or design experience to the department for review and approval. Department approval shall be based upon satisfaction of the criterion of (b), above.

(d) The construction engineer shall have ultimate responsibility for:

(1) The accurate completion of all inspection tasks; and

(2) Compliance with approved plans and specifications.

(e) The construction engineer may assign some inspection tasks to a duly-authorized agent provided that the agent's inspection tasks are explicitly identified in the construction inspection plan described in submitted pursuant to Env-Wr 405.04.

(f) Prior to any work on the dam starting, the construction engineer shall sign, date, and submit to the department a completed acknowledgement form provided by the department, as specified in (g), below.

(g) The construction engineer shall provide the following on the acknowledgement form:

(1) The name and address of the owner of the dam;

(2) The name of the dam and the dam's location, by town;

(3) The dam number assigned by the department;

(4) The construction engineer's name and professional engineer's license number;

(5) The name and professional engineer's license number of the design engineer;

(6) The date of the plans, specifications, supporting assumptions, and calculations reviewed by the construction engineer; and

(7) A certification that he or she has reviewed the plans, specifications, supporting assumptions, and calculations, and understands the design and the intent of the design.

Env-Wr 405.04 Inspections During Construction or Reconstruction.

(a) Prior to any work on the dam starting, the owner shall submit a written inspection plan to the department.

(b) The plan required by (a) above shall contain detailed information relative, but not limited, to the following:

(1) Which activities shall be monitored and by whom;

(2) Field tests to be performed and the frequency of testing;

(3) Material testing requirements; and

(4) Documentation and reporting requirements, including inspection reports and construction progress photographs.

(c) The department shall approve the plan if it determines that the plan is adequate to ensure that the dam will be constructed or reconstructed in accordance with the approved plans and specifications.

(d) The department shall inform the owner of its decision on the plan in writing. If the plan is not approved, the decision shall state the reason(s) for the non-approval.

(e) Inspections during construction or reconstruction shall be performed in accordance with the approved plan.

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84, EXPIRED 11-7-90

New. #8414, eff 8-20-05

Env-Wr 405.05 Work Items to be Inspected. The construction engineer shall inspect, document, and photograph the following work items:

(a) Excavation and sub-grade preparation;

(b) Pipe placement;

(c) Placement of graded aggregate drain materials;

(d) Earthfill;

(e) Cut-off construction;

(f) Steel placement;

(g) Final grading; and

(h) Pouring of concrete.

New. #8414, eff 8-20-05

Env-Wr 405.06 Inspection Frequency. The frequency of inspections for construction and reconstruction projects shall be as follows:

(a) Class A dam inspections shall be as frequent as needed to ensure compliance with approved plans and specifications; and

(b) Class B and Class C dam inspections shall be conducted continuously by on-site inspectors unless specifically exempted by the approved inspection plan for particular items of work.

Source. #8414, eff 8-20-05

Env-Wr 405.07 No Design Changes Without Prior Approval. No changes from the approved plans and specifications shall be implemented unless the change is approved in accordance with Env-Wr 404.05.

Env-Wr 405.08 Final Inspection Report.

(a) The construction engineer shall submit an inspection report to the department within 30 days of the completion of the project.

(b) The report shall include:

(1) A copy of all test results;

(2) The construction engineer's observations of the work items specified in Env-Wr 405.05;

(3) Representative construction progress photographs;

(4) Documentation of department-approved changes in design;

(5) Documentation and results of all construction inspections, including photographs;

(6) Foundation conditions observed during excavation; and

(7) Any other data pertinent to determining the integrity of the structure.

Env-Wr 405.09 Affidavit of Compliance. Within 10 days of completing the project, the construction engineer shall provide the department with an affidavit of compliance indicating that the construction or reconstruction was completed in accordance with approved plans, specifications, and the intent of the design, including any design changes approved in accordance with Env-Wr 404.05.

Source. #8414, eff 8-20-05

Env-Wr 405.10 As-built Drawings. The construction engineer shall submit as-built drawings of the project to the department within 180 days of submitting the affidavit of compliance.

Source. #8414, eff 8-20-05

Env-Wr 405.11 Requirements Prior to Impounding.

(a) The owner shall notify the department in writing upon the completion of construction or reconstruction of any class A, class B, or class C dam and prior to filling the reservoir. The notice shall include the dam number and the location of the dam.

(b) Within 10 working days of receipt of notice from the owner, the department shall perform a final visual inspection with the reservoir drained.

(c) The department shall either authorize filling of the reservoir by issuance of a certificate of approval or order remedial action for noncompliance with the approved plans and specifications.

(d) No person shall close gates or take other actions that cause the dam to impound water until the owner is authorized by the department in writing to fill the reservoir.

(e) The department shall authorize the owner to fill the reservoir only after the department:

(1) Determines that the construction was completed in accordance with the approved plans and specifications;

(2) Performs a final visual inspection of the dam;

(3) Approves the emergency action plan; and

(4) Receives the construction engineer's final inspection report and affidavit of compliance.

Source. #8414, eff 8-20-05

CHAPTER Env-Wr 500 EMERGENCY ACTION PLANS

PART Env-Wr 501 PURPOSE AND APPLICABILITY

Env-Wr 501.01 Purpose and Applicability.

(a) The purpose of the rules in this chapter is to establish the requirements for an emergency action plan (EAP), whose purpose is to assist emergency responders in the event of a specific dam failure by:

(1) Delineating the area which could be affected;

(2) Providing notification procedures; and

(3) Identifying the responsibilities of individuals or agencies in a response.

(b) The owner shall prepare an EAP in accordance with these rules for:

(1) Any class C dam; and

(2) Any class B dam, unless:

a. The dam is classified as a class B structure only because it impounds a public water supply and the owner has submitted to the department an emergency plan for a community water system pursuant to Env-Ws 360.14; or

b. The dam is classified as a class B structure only because it impounds liquid industrial, agricultural, or commercial waste, septage, sewage, or contaminated sediments and the owner maintains a list of emergency contact numbers as a condition of the dam's permit under RSA 485-A or RSA 485-C.

(c) EAPs for dams subject to the jurisdiction of the Federal Energy Regulatory Commission (FERC) shall be prepared in accordance with Chapter 6 of FERC's Engineering Guidelines for the Evaluation of Hydropower Projects (November 1998) and filed with the department.

(d) EAPs for the following U.S. Army Corps of Engineers (USACE) dams shall be prepared in accordance with Chapter 6 of USACE "Dam Safety Preparedness", EP 1110-2-13 (June 1996) and filed with the department:

(1) Franklin Falls Dam;

(2) Blackwater Dam;

(3) Hopkinton-Everett Dams;

(4) Edward MacDowell Dam;

(5) Otter Brook Dam; and

(6) Surrey Mountain Dam.

PART Env-Wr 502 BREACH ANALYSIS

Env-Wr 502.01 When Required. Unless exempted pursuant to Env-Wr 502.02, prior to preparing an EAP the owner shall have a dam breach analysis performed in accordance with this part.

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84, EXPIRED 11-7-90

New. #5080, eff 2-22-91; ss by #6462-B, eff 2-21-97; ss by #8285, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by #8414, eff 8-20-05

Env-Wr 502.02 Exemption from Breach Analysis.

(a) Subject to Env-Wr 502.03, an owner shall be exempted from the development of a breach analysis if the department determines that the hazard classification is based solely on the potential damage to one or more isolated and easily identified bridges, roadways, or other structures located below the dam, and no other damages will result from a dam breach.

(b) If this exemption applies to a dam, department shall:

(1) Notify the owner in writing of the exemption; and

(2) Inform the owner of the exact structures to be delineated on a simplified inundation map, as required by Env-Wr 503.02.

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84; ss by #4534, eff 11-30-88; ss by #5080, eff 2-22-91; ss by #6462-B, eff 2-21-97; ss by #8285, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by #8414, eff 8-20-05

Env-Wr 502.03 Repeal of Breach Analysis Exemption.

(a) If downstream developments change such that additional bridges, roadways, or other structures would be affected by a dam failure and these structures are not isolated and easily identifiable, the department shall notify the owner in writing that a dam breach analysis, as described in Env-Wr 502.06, shall be required due to the new developments downstream of the dam.

(b) Within 90 days of notification pursuant to (a), above, the owner shall:

(1) Complete a breach analysis in accordance with this part; and

(2) Produce and distribute an inundation map in accordance with Env-Wr 503.

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84; ss by #4534, eff 11-30-88; ss by #5080, eff 2-22-91; ss by #6462-B, eff 2-21-97; ss by #8285, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by #8414, eff 8-20-05

Env-Wr 502.04 Expansion of Study Area.

(a) If after approving a breach analysis the department determines that downstream development has changed such that new structures would be affected by a dam failure and the threat to these structures is not

easily identifiable, the department shall notify the owner in writing that the scope of the dam breach analysis previously performed must be expanded

(b) Within 90 days of notification pursuant to (a), above, the owner shall:

(1) Expand the scope of the previously-approved breach analysis to include the newly developed area(s); and

(2) Produce an amended inundation map and distribute it to all EAP holders

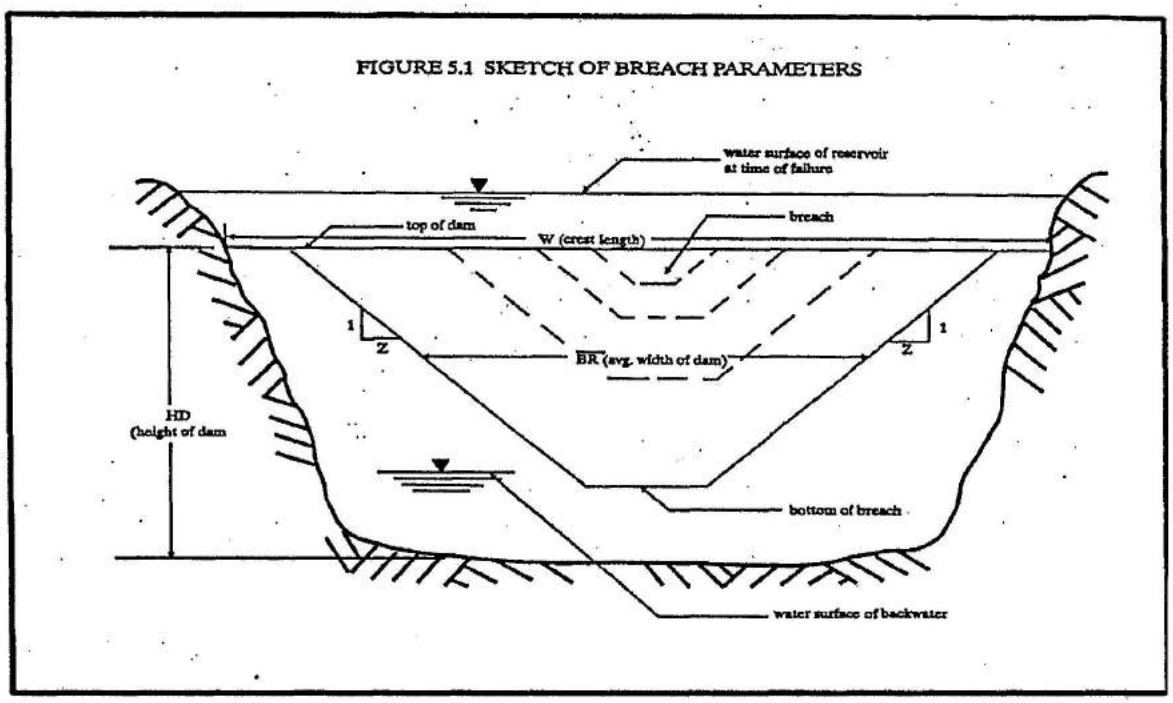
Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84; amd by #4580, eff 2-27-89; ss by #5080, eff 2-22-91; ss by #6462-B, eff 2-21-97; ss by #8285, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by #8414, eff 8-20-05

Env-Wr 502.05 Breach Analysis Required Due to Reconstruction. The owner shall complete a new or revised breach analysis, as applicable, to ascertain the impacts of a dam failure if:

(a) The dam is reconstructed, resulting in a larger or higher impoundment; or

(b) A change in the discharge capacity would result in reducing or increasing the effects of a dam failure.

Source. #8414, eff 8-20-05



Env-Wr 502.06 Specific Requirements and Breach Parameters.

(a) The dam breach analysis shall be performed under the direction of and stamped by a professional engineer licensed in New Hampshire and experienced in hydrology and hydraulics.

(b) The breach parameters shall be in accordance with Table 5.1 and Figure 5.1 below, unless the department approves the use of other parameters pursuant to (c), below:

Table 5.1 Dam Breach Parameters

PARAMETER	TYPE OF DAM	VALUE
Average Width of Breach (BR)	Arch	BR = Crest Length
	Masonry, Gravity	BR = Width of one or more monoliths, usually BR $\leq$0.5 W
	Earth, Rockfill, Timber Crib	HD $\leq$ BR $\leq$ 5HD (usually between 2HD and 4HD)
Horizontal Component of Side Slope of Breach (Z)	Arch	0 $\leq$ Z $\leq$ slope of valley walls
	Masonry, Gravity	Z = 0
	Earth, Rockfill, Timber Crib	1/4 $\leq$ Z $\leq$ 1
Time to Failure (TFH) in hours	Arch	TFH $\leq$ 0.1
	Masonry, Gravity	0.1 $\leq$ TFH $\leq$ 0.3
	Earthen (Engineered, Compacted) Timber Crib	0.1 $\leq$ TFH $\leq$ 1.0
	Earthen (Non-Engineered, Poor Construction)	0.1 $\leq$ TFH $\leq$ 0.5

(c) The department shall allow use of different parameters due to specific dam or site conditions, if the applicant requests to use different parameters and demonstrates by clear and convincing evidence that the use of the alternative parameters would result in an accurate model and would not underestimate the effects of a dam failure.

(d) A dam breach flow shall be routed together with each of the following base flows:

(1) The sunny day flow as defined in Env-Wr 101.42; and

(2) The 100-year flood flow.

(e) The breach flow together with the base flows in (d), above, shall:

(1) Be routed downstream of the dam; and

(2) Include provisions to identify the number of hours or minutes from the start of a failure to the time when the river initially starts to rise and the time to reach peak stage.

(f) Peak flow velocities also shall be determined and shown on the inundation map for critical stations such as road crossings and populated areas below the dam.

(g) The routing shall continue downstream until:

(1) The point at which the water surface elevation due to dam failure is no more than 2 feet above the non-failure conditions in areas of potential threat to life and major property damage; or

(2) A point upstream of the point determined pursuant to (1), above, if the owner shows that there is no longer a threat to public safety beyond that point.

Source. #8414, eff 8-20-05

Env-Wr 502.07 Breach Routing Methods.

(a) The owner shall use one of the following routing methods for dam breach analysis:

(1) Methods and procedures used by the United States Department of Agriculture, Natural Resources Conservation Service in:

a. Technical Release T.R. 66 "Simplified Dam Breach Routing Procedures", March 1979;

b. Computer Program for Project Formulation Hydrology, T.R. 20, March 1986; and

c. WSP 2 Computer Program, T.R. 61, May 1976, which shall be used in conjunction with each other; or

(2) Methods and procedures using the National Weather Service Dam-Break Flood Forecasting Model authored by Dr. Danny L. Fread, from the National Weather Service in Silver Springs, Maryland, dated July 18, 1984, reprinted February 1987; or

(3) Methods and procedures for dam breach simulation and routing developed by the U.S. Army Corps of Engineers' Hydrologic Engineering Center, and incorporated in HEC-RAS, version 3.1.

(b) An owner wishing to use other techniques for breach routing shall submit a written request for approval of the technique to the department for each particular site prior to using the technique. The request shall contain a description of the technique, including how the technique addresses the parameters addressed by the techniques identified in (a), above.

(c) If the department determines that the technique can be correctly applied to the hydrologic and topographic conditions of the dam and downstream area, within the limitations and capabilities of the modeling technique, and that it will provide the detailed information required by these rules, the department shall approve the technique for use on that site and shall so notify the owner in writing.

(d) The department shall not require previously-approved dam breach analyses that were completed using methods other than those specified in (a), above, to be reassessed using those methods, provided, however, that if an expansion of the breach analysis is required pursuant to Env-Wr 502.04, the owner shall use a technique specified in (a) or approved pursuant to (b) and (c), above.

Env-Wr 502.08 Downstream Dams.

(a) When there are dams downstream located within the study area as determined by Env-Wr 502.06(g), the owner shall evaluate the effect of the breach flow on these dams.

(b) If a downstream dam would not be overtopped, no stability analysis of this structure shall be required.

(c) If a downstream dam would be overtopped by failure of the subject dam, the owner shall:

(1) Include the downstream dam's failure in the breach model; or

(2) Submit to the department the results of a stability analysis for overturning and sliding or slope failure, as applicable, including factors of safety, on the downstream dam.

(d) If the stability analysis performed pursuant to (c)(2), above, indicates that a downstream dam is unstable during overtopping, the owner shall include the failure of the downstream dam in the breach model.

(e) If the stability analysis performed pursuant to (c)(2), above, indicates that a downstream dam is stable, its failure shall not be required to be modeled in the dam breach analysis.

Source. #8414, eff 8-20-05

Env-Wr 502.09 Review of Breach Analysis by Department.

(a) The owner shall submit the following to the department for review:

(1) Structural and hydraulic breach assumptions and base flow criteria;

(2) Methods for determining base flows;

(3) Structural stability analyses of downstream dams, if applicable; and

(4) Summary of the results of the breach analysis.

(b) The owner shall submit inundation maps prepared in accordance with Env-Wr 503 for review, by submitting draft inundation maps with the information listed in (a), above, or after receiving approval of the breach analysis.

(c) If the information submitted pursuant to (a), above, is incomplete or the dam failure is incorrectly modeled, the department shall, within 60 days of receipt of the information, notify the owner in writing of the items which need to be addressed and the deadline for submittal of the amended analysis, which shall be 60 days from the date of the notice.

(d) If the information submitted pursuant to (a), above, is complete and failure is correctly modeled, the department shall, within 60 days of receipt of the submitted information:

(1) Determine whether the sunny day failure or the 100-year flood failure represents the most critical threat to the downstream community; and

(2) Notify the owner in writing of which failure scenario to use in the mapping.

Source. #8414, eff 8-20-05

PART Env-Wr 503 INUNDATION MAPPING

Env-Wr 503.01 Inundation Map Requirements.

(a) The owner shall produce an inundation map to provide the local emergency responders with a tool for planning evacuation procedures.

(b) The inundation map shall delineate the area impacted by a potential dam failure, as determined by the breach analysis required by Env-Wr 502.

(c) The inundation map shall meet the following criteria:

(1) The map shall be at a scale of 1:2,000 or of greater detail;

(2) Residences, commercial, and industrial structures or clusters of structures, when located in close proximity to each other, within the inundation area shall be shown on the most recent USGS

topographic mapping, supplemented by locations derived from aerial photography available on the DES website, www.des.nh.gov;

(3) Roads within the inundation area and within at least 0.5 mile from the exterior boundary of the inundation area shall be shown;

(4) The time for the floodwave to reach critical areas, including those outlined in (2) and (3), above, including time to rise and time to peak shall be shown;

(5) Peak flood wave velocities at critical areas shall be shown;

(6) Peak flood wave depths shall be shown;

(7) Political boundaries shall be shown;

(8) The map shall indicate whether the inundation area represents a sunny day failure or a storm day failure scenario; and

(9) The date on which the map was prepared shall be included on the map.

(d) If the inundation map consists of 3 or more pages, the owner shall provide an index map which clearly directs the user to the appropriate map for a given area.

Env-Wr 503.02 Simplified Inundation Map.

(a) An owner who has been exempted from the requirement of a breach analysis pursuant to Env-Wr 502.02 shall submit a simplified inundation map.

(b) The simplified inundation map shall include the elements specified in Env-Wr 503.01(a), (c)(1) - (3), and (8).

Source. #8414, eff 8-20-05

Env-Wr 503.03 Department Review.

(a) The owner shall submit the inundation map to the department for review and approval prior to incorporating it into the emergency action plan.

(b) The department shall inform the owner in writing within 60 days of receipt whether the inundation map is approved or what changes are necessary.

Source. #8414, eff 8-20-05

PART Env-Wr 504 COORDINATION WITH LOCAL COMMUNITIES

Env-Wr 504.01 Communications with Community(ies).

(a) Prior to finalizing the EAP, the owner shall supply all local community(ies) located within the inundation area with an inundation map to assist them in determining their response to a potential dam failure.

(b) The owner shall discuss with the local emergency management director, or at the emergency management director's discretion, the local fire department or police department, to determine which individuals or agencies shall be notified during an actual or impending emergency condition at the dam. These discussions shall be held with the appropriate personnel in each of the towns which could be impacted, as shown on the inundation map. If a municipality has not designated an emergency management director, the owner shall meet with the local governing body.

Env-Wr 504.02 Acknowledgment of EAP by Local Community(ies).

(a) The owner shall request that each affected community in the inundation area sign a form acknowledging its role in the EAP.

(b) If a community refuses to provide such statement, the owner shall notify the department certifying that a copy of the draft EAP has been delivered to the community.

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84, EXPIRED 11-7-90

Part Env-Wr 505 PREPARATION AND FORMAT OF EAP DOCUMENT

Env-Wr 505.01 Submittal of Draft EAP.

(a) The owner shall submit a copy of the draft EAP prepared pursuant to Env-Wr 505.02 to the department for review. The draft may be submitted as unbound pages.

(b) The department shall review the document for compliance with this chapter. Within 60 days of submittal, the department shall notify the owner in writing of its approval of the EAP or of any inadequacies.

Env-Wr 505.02 Format of the EAP.

(a) The format of the EAP shall be 8½ x 11 loose-leaf paper in a 3-ring binder to allow for ease of supplementation and revision as required.

(b) The content of the EAP shall be standardized as follows:

(1) Table of Contents;

(2) Section 1, Notification flow-chart;

(3) Section 2, Responsibilities under the EAP;

(4) Section 3, Notification checklists;

(5) Section 4, Preventive action; and

(6) Appendices, including:

a. Appendix A, Dam and watershed description;

b. Appendix B, Summary of breach analysis;

c. Appendix C, Inundation map;

d. Appendix D, Monitor training and testing procedures;

e. Appendix E, Local evacuation procedure;

f. Appendix F, List of EAP holders; and

g. Appendix G, Documentation.

(c) The required contents of each section or appendix shall include the information identified in Env-Wr 505.03 through Env-Wr 505.12, as applicable.

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84; ss by #4452, eff 8-1-88; amd by #4580, eff 2-27-89; ss by #5080, eff 2-22-91; ss and moved by #6462-B, eff 2-21-97 (formerly Env-Wr 506.02); ss by #8285, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by #8414, eff 8-20-05

Env-Wr 505.03 Notification Flow-chart.

(a) Section 1 of the EAP shall be a chart identifying the individuals and local and state government agencies to be notified during a potential or actual emergency condition at the dam.

(b) The notification flow-chart shall be developed in accordance with local and state emergency responders and shall conform with the community's current notification protocol.

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84; ss by #4534, eff 11-30-88; ss by #5080, eff 2-22-91; ss and moved by #6462-B, eff 2-21-97 (formerly Env-Wr 506.03); ss by #8285, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by #8414, eff 8-20-05

Env-Wr 505.04 Responsibilities. Section 2 of the EAP shall describe the roles and responsibilities of each individual and local or state government agency in an emergency response.

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84; ss by #4534, eff 11-30-88; ss by #5080, eff 2-22-91; ss and moved by #6462-B, eff 2-21-97 (formerly Env-Wr 506.04); ss by #8285, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by #8414, eff 8-20-05

Env-Wr 505.05 Notification Checklists.

(a) Section 3 of the EAP shall include a notification checklist for each individual and local or state government agency responsible for making calls during an emergency situation or during a test of the EAP.

(b) The notification checklist shall include a table to be filled in by the participating individual or agency making notifications, including the name(s) of the agency(ies) or individual(s) to be contacted and the time at which the contact was made.

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84; ss by #4534, eff 11-30-88; ss by #5080, eff 2-22-91; ss and moved by #6462-B, eff 2-21-97 (formerly Env-Wr 506.05); ss by #8285, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by #8414, eff 8-20-05

Env-Wr 505.06 Preventive Action. Section 4 of the EAP shall:

(a) Indicate actions which the monitor shall take to correct a malfunction of the dam;

(b) Identify the means, materials, and equipment needed to make emergency repairs to the structure;

(c) Identify the necessary training and equipment including alternative power sources to operate the structure;

(d) Include a list of preventive and mitigative action measures to be undertaken during emergency situations.

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84; ss by #4534, eff 11-30-88; ss by #5080, eff 2-22-91; ss and moved by #6462-B, eff 2-21-97 (formerly Env-Wr 506.06); ss by #8285, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by #8414, eff 8-20-05

Env-Wr 505.07 Dam and Watershed Description. Appendix A of the EAP shall include the following information:

(a) The height and length of the dam, in feet;

(b) The normal and maximum surface area of the impoundment, in acres;

(c) The normal and maximum volume of the impoundment, in acre-feet;

(d) The size of the drainage area, in square miles; and

(e) A description of all outlet works, including the length of the spillway and a description of any gates.

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84; ss by #4534, eff 11-30-88; ss by #5080, eff 2-22-91; ss and moved by #6462-B, eff 2-21-97 (formerly Env-Wr 506.07); ss by #8285, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by #8414, eff 8-20-05

Env-Wr 505.08 Impact of Breach. Appendix B of the EAP shall be a summary of the breach analysis, written so as to be easily understood during an actual emergency, in order to provide local emergency responders with a brief description of the areas downstream of the dam which would be affected by a dam failure.

Source. #4534, eff 11-30-88; ss by #5080, eff 2-22-91; ss and moved by #6462-B, eff 2-21-97 (formerly Env-Wr 506.08); ss by #8285, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by #8414, eff 8-20-05

Env-Wr 505.09 Dam Monitor and Testing. Appendix D of the EAP shall include:

(a) The following information regarding the monitor(s) required by Env-Wr 303.04:

(1) Name, address and home and business telephone numbers;

(2) Type of training provided by owner; and

(3) Type of communication system between dam and local community; and

(b) The following information regarding EAP testing:

(1) A narrative describing the testing procedures, as outlined in Env-Wr 507.04;

(2) A summary of the responsibilities of the owner and the roles of any individuals or state or local agencies involved in the testing; and

(3) The name and mailing address of the person responsible for collecting the notification checklists after testing or after an actual emergency condition.

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84; ss by #4534, eff 11-30-88; ss by #5080, eff 2-22-91; ss and moved by #6462-B, eff 2-21-97 (formerly Env-Wr 506.09); ss by #8285, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by #8414, eff 8-20-05

Env-Wr 505.10 Local Evacuation Procedure and Recovery. Appendix E shall include any evacuation and recovery plans developed by the communities. If the communities have not developed such plans, the owner shall so indicate in this appendix.

Source. #4534, eff 11-30-88; ss by #5080, eff 2-22-91; ss and moved by #6462-B, eff 2-21-97 (from Env-Wr 506.10); ss by #8285, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by #8414, eff 8-20-05

Env-Wr 505.11 List of Official EAP Holders. Appendix F shall be a listing of all individuals and local and state agencies holding official copies of the EAP, as follows:

(a) The mailing addresses and telephone numbers of the local emergency responders, including police and fire departments in accordance with the town's procedures;

(b) The mailing addresses and telephone numbers of dispatchers for local emergency responders;

(c) The mailing addresses and telephone numbers of the local emergency management director(s);

(d) The telephone number of the contact person at the New Hampshire department of safety, bureau of emergency management;

(e) The telephone number of the contact person at the department's division of water;

(f) The telephone number of the contact person at the New Hampshire department of safety, state police;

(g) The names, mailing addresses, and telephone numbers of the owners of downstream dams that would be affected by a dam breach;

(h) The telephone number of the contact person at the New Hampshire department of transportation, highway district 5, dispatch section;

(i) If state roads would be impacted by a dam failure, the name and telephone number of the contact person at the appropriate New Hampshire department of transportation highway district office; and

(j) The telephone number of the contact person at the New Hampshire department of safety, emergency communications section (911).

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84; amd by #4534, eff 11-30-88; ss by #5080, eff 2-22-91; ss and moved by #6462-B, eff 2-21-97 (formerly Env-Wr 506.11); ss by #8285, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by #8414, eff 8-20-05

Env-Wr 505.12 Documentation. Appendix G shall include copies of signed acknowledgement forms, as described in Env-Wr 504.02, and any correspondence relative to the EAP's development.

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84; amd by #4534, eff 11-30-88; ss by #5080, eff 2-22-91; ss and moved by #6462-B, eff 2-21-97 (formerly Env-Wr 506.12); ss by #8285, INTERIM, eff 2-21-05, EXPIRES: 8-20-05; ss by #8414, eff 8-20-05

PART Env-Wr 506 FINAL DISTRIBUTION; PUBLIC NOTICE

Env-Wr 506.01 EAP Distribution. Upon receiving department approval of the draft EAP pursuant to Env-Wr 505.01, the owner shall distribute the EAP to local and state emergency response personnel who have responsibilities for implementing the EAP, as listed in Env-Wr 505.11.

Source. #8414, eff 8-20-05

Env-Wr 506.02 Public Notice. If the local community(ies) request information relative to the EAP to be given to the general public, the owner shall provide such information either by mail to all residential, industrial, and commercial buildings within the inundation area or by holding an informal meeting at a location near the dam or the inundation area.

Source. #8414, eff 8-20-05

PART Env-Wr 507 TESTING AND UPDATING PROCEDURES

Env-Wr 507.01 Notification Test.

(a) The owner shall conduct a test of the emergency communication network within one month of approval of the EAP and every 2 years thereafter for a class C dam and every 4 years thereafter for a class B dam.

(b) The test shall consist of the owner making the primary contact as shown on the flow-chart and indicating that a required test of the EAP is being conducted.

(c) The owner shall request each individual or agency contacted during the test to execute its duties relative to the notification flow-chart, complete the checklists, and return the checklists to the owner.

(d) Within 30 days of conducting the test, the owner shall inform the department of the results of the test, indicating the time it took each individual and agency to make their notifications and whether miscommunications occurred.

(e) The owner shall provide records of communication for each individual and agency, including time of contact and person contacted, if the notifications were not made within a 15-minute time period.

Source. #8414, eff 8-20-05

Env-Wr 507.02 EAP Review and Changes.

(a) If the owner becomes aware of any changes necessary to the notification flow-chart, either as a result of the notification test or by other means, the owner shall:

(1) Make the changes to the notification flow-chart and in other portions of the EAP as necessary; and

(2) Distribute update pages to all holders of the EAP.

(b) The owner shall review the entire EAP annually to ensure the accuracy of the communication flow-chart and inundation areas.

(c) If development has occurred within the inundation area, the owner shall:

(1) Revise the inundation map to show the new development; and

(2) Distribute the updated map to all holders of the EAP.

(d) The owner shall submit written documentation to the department that the annual review of the EAP was performed, by providing one of the following:

(1) A statement that the EAP was reviewed and that no changes to the EAP were necessary; or

(2) Any applicable sections of the EAP which required revision.

Source. #8414, eff 8-20-05

Env-Wr 507.03 Reprinting of EAP.

(a) The owner shall reprint the entire EAP document and distribute the pages to all holders of the EAP every 8 years, to ensure that all holders have complete and orderly copies, unless:

(1) No changes have been required; or

(2) Changes have been made only to the notification flow-chart, and copies of the updated flow-chart have been distributed to all EAP holders.

(b) When a reprint of the EAP is required, the owner shall:

(1) Send the reprint return receipt requested; or

(2) Include forms with the mailing to be signed by the EAP holders and returned to the owner, indicating that a copy of the reprinted EAP was received.

(c) If there have been no changes to the inundation map since the last reprint of the EAP and the owner does not include an inundation map in the mailing, the owner shall:

(1) Specify the date of the current inundation map; and

(2) Include a check-off item on the form required by (b), above, indicating the EAP holder has a copy of the current inundation map.

(d) If an EAP holder does not have the current inundation map, the owner shall provide a copy of the map to the EAP holder upon being so notified by the EAP holder.

CHAPTER Env-Wr 600 REMOVAL OF DAMS

PART Env-Wr 601 PURPOSE AND APPLICABILITY

Env-Wr 601.01 Purpose. The purpose of the rules in this chapter is to specify the procedures to be followed when proposing to remove a dam under the auspices of the department's river restoration program and the criteria that will be applied in reviewing such proposals.

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84, EXPIRED 11-7-90

New. #8414, eff 8-20-05

Env-Wr 601.02 Applicability. The requirements of this part shall apply to any person who seeks to remove a dam under the auspices of the department's river restoration program.

Source. #8414, eff 8-20-05

PART Env-Wr 602 DAM REMOVAL PROPOSALS

Env-Wr 602.01 Qualifying Removals.

(a) In order to qualify as a dam removal under this chapter, the structure shall be removed:

(1) To at least the depth of the natural streambed elevation; and

(2) Subject to (b) and (c), below, to the width of the free-flowing ordinary high water mark of the river or stream in the area of the footprint of the dam from bank to bank.

(b) The person seeking to remove a dam pursuant to this chapter may request the department to approve a narrower opening by submitting the request in writing with the following:

(1) The width of the free-flowing ordinary high water mark of the river or stream in the area of the footprint of the dam from bank to bank, in feet;

(2) The width of the proposed opening, in feet, at:

a. The natural streambed elevation;

b. The ordinary high water mark; and

c. The widest point of the opening, if other than the natural streambed elevation or ordinary high water mark;

(3) The shape of the proposed opening; and

(4) An explanation of how the narrower opening will meet the criteria specified in (c), below.

(c) The department shall approve the request for a narrower opening if the department determines that:

(1) The structure will no longer be considered a dam as defined in RSA 482:2, II;

(2) The remains of the dam between the ordinary high water marks on both sides of the river will not create a safety hazard to the public when using the river;

(3) The natural flow of sediment and nutrients will not be impeded; and

(4) The passage of fish and other aquatic species will not be impeded.

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84, EXPIRED 11-7-90

New. #8414, eff 8-20-05

Env-Wr 602.02 Dam Removal Proposal. The person seeking to remove a dam shall submit:

(a) A "standard dredge and fill application" as required under RSA 482-A and Wt 500, including the plans and specifications required for that application; and

(b) An "attachment to the standard dredge and fill application for dam removal projects" as specified in Env-Wr 602.03.

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84, EXPIRED 11-7-90

New. #8414, eff 8-20-05

Env-Wr 602.03 Attachment for Dam Removal Projects. The information provided on the "attachment to the standard dredge and fill application for dam removal projects" shall include the following:

(a) The name, mailing address, and daytime telephone number of the applicant and, if the applicant is not the owner, the name and mailing address of the owner;

(b) The state dam identification number;

(c) The hazard classification of the dam;

(d) The current use of the dam;

(e) The height and length of the dam, in feet;

(f) The type of construction of the dam;

(g) The approximate surface area of the impoundment, in acres;

(h) The name(s), mailing address(es), and daytime telephone number(s) of the person(s) proposed to remove the dam;

(i) A description of the proposed methods to remove the dam, including construction sequence, so as to meet the criteria of Env-Wr 602.01 and Env-Wr 604.01(a)

(j) An explanation of the purpose for removing the dam.

Source. #1716, eff 2-20-81; ss by #2207, eff 12-13-82; ss by #2900, eff 11-7-84, EXPIRED 11-7-90

New. #8414, eff 8-20-05

PART Env-Wr 603 REVIEW PROCEDURES

Env-Wr 603.01 Notification.

(a) The person proposing to remove a dam shall notify the local governing body of the municipality or municipalities in which the dam or the water body formed by the dam is located in accordance with RSA 482:13, I.

(b) The person proposing to remove the dam shall provide a copy of the notice sent pursuant to (a), above, to the department.

New. #8414, eff 8-20-05

Env-Wr 603.02 Review.

(a) Upon receiving an application to remove a dam, the department shall review the application to determine whether it is complete.

(b) If the department determines that all of the information required by Env-Wr 602.02 or the notice required by Env-Wr 603.01(b) has not been submitted, the department shall notify the person proposing to remove the dam of what is needed to complete the application.

(c) After receiving a complete application and after the meeting required by RSA 482:13, II has been held, the department shall review the application.

PART Env-Wr 604 APPROVAL; REPORT

Env-Wr 604.01 Dam Removal Approval.

(a) The department shall approve the removal of the dam if the applicant:

(1) Proposes a dam removal project that meets the criteria of Env-Wr 602.01; and

(2) Demonstrates that the dam removal will be performed in a manner that:

a. Will not cause damage to structures downstream of the dam; and

b. Will not cause environmental damage that cannot self-restore within one year.

(b) The department shall notify the applicant and the owner, if the applicant is not the owner, in writing of its decision.

CHAPTER Env-Wr 700 LAKE LEVEL DETERMINATIONS

PART Env-Wr 701 PURPOSE AND APPLICABILITY

Env-Wr 701.01 Purpose. The purpose of the rules in this chapter is to specify the procedures to be followed when a lake level investigation is conducted pursuant to RSA 482:79.

Source. #4278, eff 6-30-87; ss by #5662, eff 7-1-93, EXPIRED: 7-1-99

New. #8414, eff 8-20-05

Env-Wr 701.02 Applicability. The requirements of this chapter shall apply to any lake level investigation initiated pursuant to RSA 482:79.

Source. #4278, eff 6-30-87; ss by #5662, eff 7-1-93, EXPIRED: 7-1-99

New. #8414, eff 8-20-05

PART Env-Wr 702 REQUEST; PRELIMINARY INVESTIGATION

Env-Wr 702.01 Formal Request.

(a) A request for a lake level investigation pursuant to RSA 482:79 shall be:

(1) In writing; and

(2) Mailed or delivered to the department at the following address:

Department of Environmental Services
Water Division
29 Hazen Drive
P.O. Box 95
Concord, NH 03302-0095

(b) The request shall state clearly the reason(s) for the request.

(c) The request shall be signed by at least 10 property owners whose land abuts the water body whose water level is the subject of the request.

New. #8414, eff 8-20-05 (formerly Env-Wr 401.01)

Env-Wr 702.02 Preliminary Investigation.

(a) As required by RSA 482:79, the department shall commence a preliminary investigation of conditions affecting the use and enjoyment of a water body under any of the following circumstances:

(1) Upon receipt of a request per Env-Wr 702.01;

(2) Upon request of the New Hampshire attorney general; or

(3) On its own motion, when information received by the department warrants further investigation.

(b) The department shall investigate:

(1) The current and past management and control of the outlet; and

(2) The effects, if any, of such management and control on:

a. The use and enjoyment of shore property above the outlet;

b. Any riparian rights below the outlet; and

c. The use and enjoyment of the waters above and below the outlet by the public and by owners of littoral or riparian property.

(c) Based upon the preliminary investigation, the department shall determine whether the management and control of the outlet is having a serious and adverse effect on any of the factors identified in (b)(2), above.

(d) For purposes of the determination in (c), above, a "serious and adverse effect" means an impact that has a reasonable likelihood of interfering with the use and enjoyment of littoral or riparian property or public waters by:

(1) Eroding shorelines above or below the outlet;

(2) Flowing property that is not covered by a flowage easement;

(3) Interfering with access to the waters above or below the outlet;

(4) Causing the waters above or below the outlet to be unsuitable for navigation or recreation;

(5) Causing harm to aquatic or land-based habitat; or

(6) Any combination of (1) through (5), above.

New. #8414, eff 8-20-05 (formerly Env-Wr 401.02)

PART Env-Wr 703 FURTHER INVESTIGATIONS; PUBLIC HEARING

Env-Wr 703.01 Further Investigation and Public Hearing.

(a) If the department finds a serious and adverse effect under Env-Wr 702.02(c), the department shall conduct a further investigation.

(b) If the department determines that a public hearing to receive information would be helpful to its further investigation, the department shall schedule and conduct the public hearing in accordance with Env-C 200 relative to non-adjudicative procedures.

New. #8414, eff 8-20-05 (formerly Env-Wr 401.03)

Env-Ws 703.02 Determinations. Based on the further investigation, the department shall:

(a) Ascertain the rights of the owner of the outlet by considering whether:

(1) The dam is registered with the department;

(2) Flowage is within any clear deeded flowage limits;

(3) Base flows are sufficient to accommodate downstream riparian rights;

(4) The operation is in accordance with any deeded rights associated with the former mill dam act, RSA 482:17 through RSA 482:41, if applicable; and

(5) Any other factors identified by the owner within the jurisdiction of the department under RSA 482.

(b) Ascertain the rights of the public and owners of property above and below the outlet, by considering the following:

(1) Whether there is public access to the impoundment or the stream below the outlet via a government-owned access point;

(2) The extent to which the impoundment or the stream below the outlet is used for fishing, including whether the impoundment is stocked by the New Hampshire fish and game department;

(3) What range of water levels is optimum for the ecological health of the impoundment and the stream below the outlet;

(4) The extent to which the impoundment or the stream below the outlet is used for navigation and what range of water levels is optimum for such navigation;

(5) The extent to which the impoundment or the stream below the outlet is used for swimming and what range of water levels is optimum for swimming; and

(6) The extent to which the impoundment or the stream below the outlet is used for other recreation and range of what water levels is optimum for such other recreation.

(c) In making its determination, the department shall consider all information and testimony presented as part of the proceeding.

New. #8414, eff 8-20-05 (formerly Env-Wr 401.03)

PART Env-Wr 704 FINDINGS; DECISION

Env-Wr 704.01 Findings. After completing its further investigation in accordance with Env-Wr 703, the department shall prepare written findings regarding whether:

(a) The management and control of the outlet is adversely affecting the rights of owners of property above the outlet by eroding shorelines, flowing property not covered by a flowage easement, preventing access to property that is accessible only by boat, or interfering with the use and enjoyment of the water for recreational purposes, including boating, swimming, and fishing;

(b) The management and control of the outlet is adversely affecting the rights of owners of property below the outlet by eroding shorelines, releasing insufficient water for reasonable riparian uses, or interfering with the use and enjoyment of the water for recreational purposes, including boating, swimming, and fishing;

(c) The management and control of the outlet is adversely affecting the rights of the public to use public waters for navigation or recreational purposes, including boating, swimming and fishing;

(d) The management and control of the outlet is lawful;

(e) The benefits of the current management and control of the outlet outweigh any adverse effects that may be occurring;

(f) Changes to the management and control of the outlet would be of benefit to the public and private interests concerned; and

(g) Changes in the management and control of the outlet to benefit the use and enjoyment of the waters above or below the outlet by the public or by owners of property above or below the outlet would deprive the owner of the outlet or others of rights to which they are lawfully entitled.

New. #8414, eff 8-20-05 (formerly Env-Wr 401.04)

Env-Wr 704.02 Report of Findings; Decision. Based upon its findings, the department shall:

(a) Order no change in the management and control of the outlet if it finds that:

(1) The benefits of the present management and control of the outlet outweigh any adverse effects on the public and on owners of property above or below the outlet; and

(2) Changes in the management and control of the outlet would not be expected to produce benefits that:

a. Are greater than those resulting from the present management; and

b. Would outweigh any adverse effects of the changes;

(b) Order changes in the management and control of the outlet if the benefits expected from the change are:

(1) Greater than the benefits from the present management and control of the outlet; and

(2) Expected to outweigh any adverse effects of the changed management and control of the outlet;

(c) Report to the governor and council its findings, including an estimate of damages, if it finds that changes in the management and control would be of benefit to the public and private interests concerned but would deprive the owner of the outlet or others of rights to which they are lawfully entitled; or

(d) Report to the attorney general if the management and control of the outlet is unlawful.

FEMA

Hydrologic Research Needs for Dam Safety Analyses

by
Joseph J. Skupien, PE, PP[1]

Somerset County Dam Safety Program

The following describes both the current scope and research needs of the dam safety program of Somerset County, New Jersey. The County encompasses 305 square miles in the central portion of the state and has a population of approximately 300,000, yielding a population density of approximately 1000 people per square mile. The County has experienced significant land development pressure since the 1970's with no significant abatement expected in the foreseeable future.

Somerset County's dam safety program includes the analysis, operation, inspection, and maintenance of nine Significant Hazard dams ranging in height from 13 to 40 feet with drainage areas ranging from approximately 50 acres to 10 square miles. Eight of these dams serve as regional stormwater detention facilities that help offset the adverse hydrologic impacts of land developments within their watersheds. The remaining dam is a former water intake dam located on property acquired from a private water purveyor and converted into a County park. Since their original design, engineering activities at the dams include the determination and periodic reassessment of their hazard classifications and Spillway Design Floods (SDFs) as well as any subsequent revisions to their Emergency Action Plans (EAPs). These activities are performed in accordance with the Dam Safety Standards (N.J.A.C. 7:20) of the Dam Safety Section of the N.J. Department of Environmental Protection (NJDEP).

In addition to the dam safety activities described above, the County Planning Board also regulates that stormwater management aspects of all new land developments in the County that front on a County road and/or drain to a County bridge or culvert. These regulations typically result in the design and construction of one or more onsite stormwater detention basins that can range up to approximately 15 feet in height and up to 100 acres in drainage area. While the design of such basins do not normally require a dam break and downstream inundation analysis, the design does include the determination of emergency spillway size and top of dam elevation. This is done using County-based emergency spillway criteria at all dams not subject to the NJDEP Dam Safety Standards noted above. An unofficial survey indicates that there are presently more than 500 such basins in County, most close to residential, commercial, and/or industrial structures.

[1] Principal Hydraulic Engineer, Division of Engineering, Somerset County, New Jersey

Current State and County Practices

As noted above, all County-owned dams are regulated by the Dam Safety Standards of the NJDEP's Dam Safety Section. Similar to the FERC's Engineering Guidelines for the Evaluation of Hydropower Projects, these state standards classify dams by Hazard Class based upon the threat posed by a dam failure to downstream structures and roadways. A summary of the various NJDEP Hazard Classes is presented in Table 1 below.

Table 1

Summary of Dam Hazard Classes and Spillway Requirements
NJDEP Dam Safety Standards

Hazard Class	Downstream Failure Threat	Spillway Design Storm
I – High	Loss of Life or Extensive Property Damage	PMP
II- Significant	Significant Property Damage	One-Half PMP
III – Low	Minor Property Damage	100-Year NRCS Type III
IV – Small Dams	Height < 15 Feet, Storage < 15 Acre-Feet, Drainage Area < 150 Acres*	100-Year + 50 Percent NRCS Type III

* Class IV Dam criteria only applicable if Class I or II threats do not exist.

According to discussions with NJDEP Dam Safety personnel, PMP rainfall amounts are typically obtained from HMR No. 51. For the majority of projects, spatial distribution of the rainfall is not necessary and the rainfalls are temporally distributed in accordance with a variety of storm distributions, including the NRCS Type III distribution and the U.S. Army Corps of Engineers PMP distribution as contained in HEC-1 Flood Hydrograph Package. One foot of freeboard is required above the routed SDS water surface. The NRCS Runoff Equation and Dimensionless Unit Hydrograph are typically used to compute losses and convert the rainfall to runoff. Antecedent Moisture Conditions are typically assumed to be either average (AMC II) or high (AMC III). Sources of dam failure parameters vary, with those published in the FERC Engineering Guidelines or derived from the Froelich equations utilized most frequently.

Downstream discharges and water surface profiles are typically computed using steady flow assumptions with HEC-1 used for discharge and failure computations and either HEC-2 Water Surface Profiles or HEC-RAS River Analysis System used for profile computations. Unsteady flow computations using either DAMBRK or FLDWAV are used on approximately 10 percent of the projects, which typically involve large dams and drainage areas. Downstream failure impacts are typically assessed based upon the difference in water surface with and without a dam failure, with a difference greater than two feet considered excessive. A minority of projects utilizes the Downstream Hazard Classification Guidelines published by the Bureau of Reclamation.

As noted above, the Somerset County dam safety criteria, which were originally established in 1975, apply to all structures subject to County Planning Board approval unless superceded by the NJDEP regulations described above. Hazard classification for

all dams is assumed to be Class B as defined by the NRCS unless a reconnaissance of downstream conditions warrants a higher classification. Safe spillway capacity and freeboard requirements are based upon routing Emergency Spillway (ESH) and Freeboard (FBH) Hydrographs through the facility based upon 24-hour rainfalls of 10 and 17 inches, respectively. These rainfalls were derived from the same equations used by the NRCS to develop the Service's 6-hour ESH and FBH rainfalls. It should also be noted that the County's 17 inch FBH rainfall is equivalent to one-half of the 24-hour PMP for the County.

Problems and Research Needs

A summary of technical and operational problems and related hydrologic research needs of both the NJDEP and Somerset County dam safety programs is presented below. The NJDEP problems and needs were identified during interviews with representatives of the NJDEP's Dam Safety Section. Resolution of these problems and needs, either through research and/or policy decisions, will help improve the effectiveness and efficiency of both programs.

1. Perhaps the most significant operational problem facing the State and County dam safety programs is the lack of hydrologic and hydraulic expertise in many of the engineers performing dam failure, inundation, and hazard classification studies and/or preparing emergency spillway designs. In the last 20 years, both the sophistication and availability of computer-based models to perform such studies and designs has increased significantly, along with the data to base them on. Unfortunately, these models and databases have exceeded, in many instances, the knowledge and expertise of the modelers and designers of small dams. This "ability gap" leads to inaccurate studies and designs and prevents many dam safety programs from realizing their full potential, thereby negating the efforts of researchers and regulators to create advanced, effective dam safety programs. Under such conditions, further technical advances can be expected to only widen this gap.

Research Request: Investigate the feasibility of establishing minimum education and/or experience requirements for engineers performing dam safety studies and designs for small dams. Alternately, develop a basic set of small dam hydrology and hydraulic courses that can be presented by state and/or local dam safety officials to engineers within their jurisdictions.

2. A technical problem that has grown more acute in recent years involves the presence of concrete corewalls within older earthen dams that have come under closer scrutiny by dam safety personnel. Similar problems also arise with older dams that have been constructed with masonry or concrete walls along their upstream face. These walls were commonly utilized to prevent seepage from the upstream impoundment and, while they theoretically have little structural strength, experience has shown that some have been able to remain intact even after the loss of large portions of the downstream fill material. Such dams, due to their age, typically have principal spillways that are inadequate under

present standards and, as such, are prone to failure due to overtopping. However, modeling this failure can be difficult, particularly in the selection of failure width and time due to the presence of the concrete wall within or upstream of the earthen fill. While conservatively large width and short time parameters can be selected, their use may result in overestimates of hazard class and Spillway Design Storm. This, in turn, may require the construction of excessive remedial measures that the owners, who are predominantly private individuals or organizations, may find cost-prohibitive.

Research Request: Develop typical failure parameters and/or policies for dams with corewalls and upstream face walls that can be utilized or adopted by local and state dam safety programs.

3. Standard computation methods for drainage area Time of Concentration (TC) are typically intended for use in estimating flood peaks and hydrographs for frequencies up to the 100-Year storm. However, both theory and experience suggest that shorter TCs should be used when computing peaks and hydrographs from larger, less frequent events such as the PMF, due primarily to the greater flow depths and velocities. As such, the standard computation methods may be yielding lower peak flow estimates for such events, which can lead to inaccurate hazard classification and underdesigned remedial measures.

Research Request: Investigate accuracy of standard TC computation methods under extreme storm conditions. If necessary, develop alternative methods or policies for estimating drainage area TCs for such extreme events.

4. Since the majority of dams subject to local or state dam safety regulations have drainage areas less than 10 square miles, questions arise over the most appropriate temporal rainfall distribution to utilize in a hazard classification and/or Spillway Design Storm analysis. These questions include concerns whether the NRCS design storm distributions are appropriate for extreme rainfall amounts and whether other popular storm distributions such as the Corps of Engineers' Standard Project Storm is appropriate for small drainage areas.

Research Request: Investigate suitability of popular design storm distributions for extreme rainfall amounts falling over small drainage areas. Develop appropriate distribution for such rainfalls and areas through research and/or policy.

5. As noted above, the majority of water surface profile computations downstream of a dam failure are based upon steady rather than unsteady flow assumptions. In most instances, however, the selection of steady over unsteady flow is not based upon theoretical grounds but rather on the difficulty in performing the unsteady flow computations with the DAMBRK and FLDWAV computer programs (see 1 above). The recent inclusion of unsteady flow in HEC-RAS offers an opportunity to address this problem. However, limited training has been available to date to small dam designers and analysts and local and state dam safety personnel.

Research Request: Develop guidelines and limitations for use of steady flow models in dam safety studies. Also develop effective HEC-RAS unsteady flow and FLDWAV training courses for small dam analysts and designers and local and state dam safety personnel.

6. The most significant and, at times, prohibitive cost of an accurate hazard classification or Spillway Design Storm study for a small dam is incurred during the development of the hydraulic model of the downstream waterway. Costs associated with field surveys, topographic mapping, and model data development often exceed the remaining study costs.

Research Request: Develop inexpensive techniques to develop waterway and floodplain topography and cross sections in a digital format that can readily be input into available hydraulic computer models.

7. According to the FERC's Engineering Guidelines, dam failures should not be assumed to begin on the rising limb of the inflow hydrograph. Instead, the presumably more conservative assumption of failure starting at the maximum water surface should be made. However, instances have arisen where greater discharges are computed when the failure is assumed to occur somewhat before the maximum water surface is achieved. This is particularly true at certain small dams with very short (10 to 15 minute) failure times. In these instances, the rapid enlargement of the dam breach begins while the water surface is still rising, leading to ultimately greater heads and resultant peak outflows due to the failure. While these greater peak outflows can be identified through sensitivity analyses of failure starting times, such analyses can increase costs for small dam projects.

Research Request: Determine the sensitivity of starting water surface elevation to peak outflows from small dam failures and establish parameters to identify the most conservative starting water surface assumptions.

SAFE DAM ACT

58:4-1 Reservoir, dam restrictions.

58:4-1. a. No municipality, corporation or person shall, without the consent of the Commissioner of Environmental Protection, hereafter in this chapter designated as the commissioner, build any reservoir or construct any dam, or repair, alter or improve existing dams on any river or stream in this State or between this State and any other state which will raise the waters of the river or stream more than five feet above its usual mean low-water height.

No municipality, corporation or person shall, without the consent of the commissioner, build any reservoir or construct any dam, or repair, alter or improve existing dams in the pinelands area, as designated by subsection a. of section 10 of P.L.1979, c.111 (C.13:18A-11), which will raise the waters of any river or stream more than eight feet above the surface of the ground where the drainage area above the dam or reservoir is more than one square mile in extent and where the water surface created by the dam or reservoir is more than 100 acres in extent.

The commissioner may investigate and take appropriate action regarding any dam or reservoir about which the commissioner has a security or safety concern.

With respect to dams and reservoirs located on lands utilized for agricultural or horticultural purposes within the pinelands area, the commissioner's actions shall be undertaken after consultation with the Secretary of Agriculture.

b. The commissioner shall not require a permit for the repair of any dam used for agricultural purposes within a special agricultural production area designated pursuant to N.J.A.C.7:50-5.14 in the pinelands area.

Amended 1981, c.249, s.3; 1985, c.33; 1995, c.402, s.1; 2001, c.82, s.1.

58:4-2. Approval of plans of reservoirs and dams

Every municipality, corporation or person, before constructing any reservoir or dam subject to the provisions of this chapter shall apply to the commissioner for the approval of the plans of such reservoir or dam, which approval the commissioner may grant with such modifications, limitations or changes as in his judgment may be necessary for the protection of life and property.

Amended by L.1981, c. 249, s. 4, eff. Aug. 6, 1981.

58:4-3. Descriptions, surveys and plans of existing reservoirs and dams

Every municipality, corporation or person owning and maintaining or having control of any reservoir or dam shall, upon written request therefor, furnish to the commissioner as full, true and particular description of the reservoir or dam as may be practicable, and shall, when so requested by the commissioner cause to be made such surveys, plans and drawings of the reservoir or dam as may be necessary to give sufficient information for the determination of its safety as may be required by the commissioner.

Amended by L.1981, c. 249, s. 5, eff. Aug. 6, 1981.

58:4-4. Inspection of reservoirs and dams

Upon written application by any person owning or representing property liable to be injured or destroyed by the breaking of any reservoir or dam, or upon application by the mayor or governing body of any municipality on account of possible danger of loss of life or of injury to any property within the municipality from the breaking of any reservoir or dam, or without such complaint whenever the commissioner shall choose, he shall forthwith thoroughly inspect such reservoir or dam.

Amended by L.1981, c. 249, s. 6, eff. Aug. 6, 1981.

58:4-5 Alterations, additions and repairs of unsafe reservoirs or dams; duties of owner.

58:4-5. a. An owner or person having control of a reservoir or dam shall:

(1)Implement all measures required pursuant to this chapter or the provisions of P.L.1981, c.249 (C.58:4-8.1 et seq.), or any rule, regulation, code, permit or order issued pursuant thereto, including but not limited to, performance of periodic inspections required pursuant to section 2 of P.L.1981, c.249 (C.58:4-8.2) or development, updating and implementation of emergency action plans;

(2)Provide to the Department of Environmental Protection, upon request, any reports or information required pursuant to this chapter or the provisions of P.L.1981, c.249, or any rule or regulation adopted, or permit or order issued pursuant thereto; and

(3)Implement any action ordered by the Commissioner of Environmental Protection to correct conditions that render the reservoir or dam to be considered, as determined by the commissioner, unsafe or improperly maintained or to bring the reservoir or dam into compliance with standards established pursuant to this chapter, or any rule or regulation adopted, or permit or order issued pursuant thereto.

b. If, in the judgment of the commissioner, any reservoir or dam is not sufficiently strong to resist the pressure of water that is or may be upon it or there is reasonable cause to believe that danger to life or property may be anticipated from the reservoir or dam, or if for any other cause the commissioner shall determine the reservoir or dam to be unsafe or improperly maintained, the commissioner shall take any action authorized pursuant to this section to compel compliance with the provisions of this chapter, or any rule or regulation adopted, or permit or order issued pursuant thereto, and shall determine whether the water in the reservoir or above the dam shall be drawn off in whole or in part, and what alterations, additions and repairs are necessary to be made to the reservoir or dam to make it safe and properly maintained or whether the dam or appurtenant structures located therein should be removed. The commissioner also may take action as authorized pursuant to R.S.58:4-6 against the owner or person having control of the reservoir or dam for such relief as the commissioner may determine. The commissioner shall forthwith in writing order the owner or person having control of the reservoir or dam to cause the alterations, additions and repairs to be made within the time to be limited in the order. A copy of any order issued by the commissioner pursuant to this section shall be sent to the clerk of the municipality and the clerk of the county in which the reservoir or dam is located. The commissioner also may order the water in the reservoir or above the dam to be drawn off in whole or in part as the commissioner may determine. The commissioner shall not approve the decommissioning of a reservoir or dam until the commissioner has provided 30 days' prior notice

and the commissioner has complied with the provisions of R.S.58:4-10 as applicable. The notice of the proposed decommissioning shall be published at least 30 days prior to the decommissioning of the reservoir or dam in at least one newspaper of general circulation in the municipality in which the reservoir or dam is located. The commissioner shall have the right to enter upon any and all properties for the purpose of obtaining information about the safety and proper maintenance of any reservoir, dam or appurtenant structures located therein.

c. Any owner or person having control of a reservoir or dam who fails to comply with an order issued pursuant to this section or R.S.58:4-6 may be liable to the department in an amount equal to the cost of removal of the dam or appurtenant structures located therein undertaken by the department, including attorney's fees and court costs, pursuant to subsection d. of this section.

Whenever two or more owners or persons having control of a reservoir or dam are liable for the cost of removal, including attorney's fees and court costs, the department may allocate the cost of removal among the liable parties using such factors as the department determines are appropriate. Nothing in this subsection shall affect the right of any party to seek contribution from any other person responsible for the cost of removal of the dam pursuant to any other statute or under common law.

d. (1) Whenever the commissioner determines that a dam is in imminent danger of failure and has reasonable cause to believe that danger to life or property may be anticipated from the reservoir, dam or appurtenant structures located therein, and the owner of the dam or person having control of the reservoir or dam has failed to comply with an order to repair the dam issued pursuant to subsection a. of this section or R.S.58:4-6, or to take such interim measures as the department determines are appropriate, including reducing the amount of water impounded by the dam or breaching the dam, the department may, in addition to actions authorized pursuant to R.S.58:4-6, enter upon any and all properties wherein the reservoir, dam or appurtenant structures are located and, using resources and personnel available to the department, remove or cause to be removed the dam or appurtenant structures located therein, allowing the water to flow freely.

Prior to any action by the department pursuant to this subsection, the owner or person having control of the reservoir or dam, shall, no later than 60 days after receipt of a notice from the department of a pending removal action, submit to the department, in writing, an acceptable implementation plan addressing the proposed actions to be taken regarding the failed or failing reservoir or dam.

(2)Any expenditures made by the department pursuant to this section shall constitute, in each instance, a debt to the State. The debt shall constitute a lien on all property owned by the owner or person having control of the reservoir or dam when a certificate of debt, incorporating a description of the property of the owner or person having control of the reservoir or dam subject to the repair, and related costs, is duly filed with the clerk of the Superior Court. The clerk shall promptly enter upon the civil judgment and order docket the name and address of the owner or person having control of the reservoir or dam and the amount of the lien as set forth in the certificate of debt. Upon entry by the clerk, the lien, to the amount committed by the department for dam repair, shall attach to the revenues and all real and personal property of the owner or person having control of the reservoir or dam, whether or not the owner or person having control of the reservoir or dam is insolvent.

The certificate of debt filed pursuant to this paragraph which affects the property of an owner or person having control of a reservoir or dam subject to the dam repairs shall create a lien with priority over all other claims or liens which are or have been filed against the property, except if the property comprises six dwelling units or less and is used exclusively for residential purposes, this certificate of debt shall not affect any valid lien, right or interest in the property filed in accordance with established procedure prior to the filing of this certificate of debt.

The certificate of debt filed pursuant to this subsection which affects any property of an owner or person having control of a reservoir or dam, other than the property subject to the repairs, shall have priority from the day of the filing of the certificate of debt over all other claims and liens filed against the property, but shall not affect any valid lien, right, or interest in the property filed in accordance with established procedure prior to the filing of a certificate of debt pursuant to this subsection.

Whenever the owner or person having control of the reservoir or dam is a private lake association or other body representing owners of property adjacent to the reservoir or lake created by the dam or impoundment, liens may be imposed upon the individual owners of the property represented by the association. An owner whose property has such a lien imposed may release the property from a lien claimed under this subsection by filing with the clerk of the Superior Court a cash or surety bond, payable to the department in the amount of the sums expended by the department pursuant to this section, including attorney's fees and court costs, or the value of the property after the abatement action is complete, whichever is less.

e. The provisions of this section shall not limit the use of other remedies available to the department pursuant to law.

f. The commissioner may adopt, pursuant to the "Administrative Procedure Act," P.L.1968, c.410 (C.52:14B-1 et seq.), any rules or regulations necessary to implement the provisions of this section.

Amended 1981, c.249, s.7; 1994, c.84, s.1; 2005, c.228, s.1.

58:4-6 Enforcement powers of department, civil, criminal; violations; penalties.

58:4-6. a. Whenever the Commissioner of Environmental Protection finds that a person has violated any provision of the "Safe Dam Act," P.L.1981, c.249 (C.58:4-8.1 et seq.), or any rule, regulation or order issued pursuant thereto, the commissioner may:

(1)Issue an order requiring any such person to comply in accordance with subsection b. of this section; or

(2)Bring a civil action in accordance with subsection c. of this section; or

(3)Levy a civil administrative penalty in accordance with subsection d. of this section; or

(4)Bring an action for a civil penalty in accordance with subsection e. of this section; or

(5)Petition the Attorney General to bring a criminal action in accordance with subsection f. of this section.

Recourse to any of the remedies available under this section shall not preclude recourse to any of the other remedies prescribed in this section or by any other applicable law.

b. Whenever, on the basis of available information, the commissioner finds a person in violation of any provision of P.L.1981, c.249, or any rule, regulation or order issued pursuant thereto, the commissioner may issue an administrative order: (1) specifying the provision or provisions of the law, rule, regulation, or order, of which the person is in violation; (2) citing the action which constituted the violation; (3) requiring compliance with the provision or provisions violated; (4) requiring the restoration of the area which is the site of the violation; and (5) providing notice to the person of the right to a hearing on the matters contained in the order.

c. The commissioner is authorized to institute a civil action in Superior Court for appropriate relief from any violation of P.L.1981, c.249, or any rule, regulation or order issued pursuant thereto. Such relief may include, singly or in combination:

(1)A temporary or permanent injunction, including an order or judgment as will effectually secure the persons interested from danger of loss from the breaking of a dam. The court may proceed in the action in a summary manner or otherwise;

(2)Assessment of the violator for the costs of any investigation, inspection, or monitoring survey which led to the establishment of the violation, and for the reasonable costs of preparing and bringing legal action under this subsection;

(3)Assessment of the violator for any costs incurred by the State in removing, correcting, or terminating the adverse effects resulting from any violation for which legal action under this subsection may have been brought;

(4)Assessment against the violator for compensatory damages for any loss or destruction of wildlife, fish or aquatic life, and for any other actual damages caused by a violation;

(5)A requirement that the violator restore the site of the violation to the maximum extent practicable and feasible.

d. The commissioner is authorized to assess a civil administrative penalty of up to $25,000 for each violation of any provision of P.L.1981, c.249, or any rule, regulation or order issued pursuant thereto, and each day during which each violation continues shall constitute an additional, separate, and distinct offense. Any amount assessed under this subsection shall fall within a range established by regulation by the commissioner for violations of similar type, seriousness, and duration. In adopting rules and regulations establishing the amount of any penalty to be assessed, the commissioner may take into account the economic benefits from the violation gained by the violator. No assessment shall be levied pursuant to this section until after the party has been notified by certified mail or personal service. The notice shall: (1) identify the section of the law, rule, regulation or order violated; (2) recite the facts alleged to constitute a violation; (3) state the amount of the civil penalties to be imposed; and (4) affirm the rights of the alleged violator to a hearing. The ordered party shall have 20 days from receipt of the notice within which to deliver to the commissioner a written request for a hearing. After the hearing and upon finding that a violation has occurred, the commissioner may issue a final order specifying the amount of the fine imposed. If no hearing is requested, the notice shall become final after the expiration of the 20-day period. Payment of the assessment is due when a final order is issued or

the notice becomes a final order. The authority to levy an administrative penalty is in addition to all other enforcement provisions in this act and in any other applicable law, rule, or regulation, and the payment of any assessment shall not be deemed to affect the availability of any other enforcement provisions in connection with the violation for which the assessment is levied. Any civil administrative penalty assessed under this section may be compromised by the commissioner upon the posting of a performance bond by the violator, or upon such terms and conditions as the commissioner may establish by regulation.

e. A person who violates any provision of P.L.1981, c.249 or any rule, regulation or order issued pursuant thereto, an administrative order issued pursuant to subsection b. of this section, or a court order issued pursuant to subsection c. of this section, or who fails to pay a civil administrative penalty in full pursuant to subsection d. of this section, shall be subject, upon order of a court, to a civil penalty not to exceed $10,000 per day of such violation, and each day during which the violation continues shall constitute an additional, separate, and distinct offense. Any civil penalty imposed pursuant to this subsection may be collected with costs in a summary proceeding pursuant to the "Penalty Enforcement Law of 1999," P.L.1999, c.274 (C.2A:58-10 et seq.). In addition to any penalties, costs or interest charges, the court may assess against the violator the amount of actual economic benefit accruing to the violator from the violation. The Superior Court and the municipal court shall have jurisdiction to enforce the provisions of the "Penalty Enforcement Law of 1999" in connection with this section.

f. A person who purposely, knowingly or recklessly violates any provision of P.L.1981, c.249, or any rule, regulation or order issued pursuant thereto, shall be guilty, upon conviction, of a crime of the fourth degree and, notwithstanding any provision of N.J.S.2C:43-3 to the contrary, shall be subject to a fine of not less than $2,500 nor more than $25,000 per day of violation, in addition to any other applicable penalties and provisions under Title 2C of the New Jersey Statutes. A second or subsequent offense under this subsection shall subject the violator to a fine, notwithstanding any provision of N.J.S.2C:43-3 to the contrary, of not less than $5,000 nor more than $50,000 per day of violation, in addition to any other applicable penalties and provisions under Title 2C of the New Jersey Statutes. A person who knowingly makes a false statement, representation, or certification in any application, record, or other document filed or required to be maintained under the provisions of P.L.1981, c.249 shall be guilty, upon conviction, of a crime of the fourth degree and, notwithstanding any provision of N.J.S.2C:43-3 to the contrary, shall be subject to a fine of not more than $10,000, in addition to any other applicable penalties and provisions under Title 2C of the New Jersey Statutes.

g. In addition to the penalties prescribed in this section, a notice of violation of any provision of P.L.1981, c.249, or any rule, regulation or order issued pursuant thereto, shall be recorded on the deed of the property wherein the violation occurred, on order of the commissioner, by the clerk or register of deeds and mortgages of the county wherein the affected property is located and with the clerk of the Superior Court and shall remain attached thereto until such time as the violation has been remedied and the commissioner orders the notice of violation removed.

h. The department may require an owner or person having control of a reservoir or dam to provide any information the department requires to determine compliance with any provision of P.L.1981, c.249, or any rule, regulation or order issued pursuant thereto.

i. Any person who knowingly, recklessly, or negligently makes a false statement, representation or certification in any application, record, or other document filed or required to be maintained

under the provisions of P.L.1981, c.249, shall be in violation of the act and shall be subject to the penalties assessed pursuant to subsections d. and e. of this section.

j. All penalties collected pursuant to this section or sums collected pursuant to R.S.58:4-5 shall be deposited in the "Environmental Services Fund," established pursuant to section 5 of P.L.1975, c.232 (C.13:1D-33), and kept separate from other receipts deposited therein, and appropriated to the department for the removal of dams in the State.

k. The department shall have the authority to enter any property, facility, premises, or site for the purpose of conducting inspections to determine the condition of any dam, or to conduct inspections of ordered repairs or to otherwise determine compliance with the provisions of P.L.1981, c.249.

Amended 1953, c.54, s.5; 1981, c.249, s.8; 2005, c.228, s.2.

58:4-8. Personnel to conduct inspections

The commissioner may, when provided with sufficient funds, employ personnel for the inspection of existing reservoirs and dams and the supervision of the erection of new reservoirs and dams in this State or between this and any other state so that said structures may be built with due regard for the safety of property and life which might be endangered by improper construction thereof.

Amended by L.1981, c. 249, s. 9, eff. Aug. 6, 1981.

58:4-8.1. Short title

This act shall be known and may be cited as the "Safe Dam Act."

L.1981, c. 249, s. 1, eff. Aug. 6, 1981.

58:4-8.2. Periodic dam safety inspection and reporting procedure

The Commissioner of Environmental Protection shall, by rule, establish a periodic dam safety inspection and reporting procedure, on an annual or longer term basis, for the owner of any dam meeting the criteria contained in R.S. 58:4-1. The owner shall have a professional engineer inspect the dam and prepare and submit a report containing such information as the commissioner may require, concerning the safety of said dam and appurtenant structures. Every dam which raises the waters of any stream more than 70 feet above its usual mean low-water height or which impounds more than 10,000 acre-feet of water shall be inspected on an annual basis by a professional engineer retained by the owner, in the company of a professional engineer assigned from the Department of Environmental Protection.

L.1981, c. 249, s. 2, eff. Aug. 6, 1981.

58:4-9. Maintenance of existing reservoirs and dams; petition against abandonment

58:4-9. Where a reservoir or dam has been in existence 20 years and the owners of land along the shores above the dam or on the reservoir have made or shall have made permanent improvements on the land or where the shores have become a populated community, depending upon the permanency of the condition created, or where the reservoir or dam has become a valuable resource for the quality of life in the municipality in which the reservoir or dam is located, and a petition signed by a majority of the landowners along the shore of any pond formed by the reservoir or dam, or by any number of residents of the municipality in which the

reservoir or dam is located, or by the governing body of the municipality, protesting against the removal of the reservoir, water or dam or the decommissioning of the reservoir or dam has been filed with the commissioner, the owner or owners of the reservoir or dam shall not, without the consent of the commissioner, tear down, destroy or abandon the reservoir or dam, or, except for the purpose of making necessary repairs, withdraw the water below the usual low-water mark, or maintain the water at the reduced level.

Amended 1981,c.249,s.10; 1994,c.84,s.2.

58:4-10. Hearing on petition; fixing low-water mark; maintenance expenses

58:4-10. When a petition has been filed protesting against the removal of any reservoir, water or dam or against the decommissioning of any reservoir or dam as provided in R.S.58:4-9, the commissioner shall hold a public hearing, upon 30 days' notice to all parties interested, and following prior notice published 30 days before the hearing in at least one newspaper of general circulation in the municipality in which the reservoir or dam is located. Following this public hearing, the commissioner may make a determination concerning the removal of the reservoir, water or dam or decommissioning of the reservoir or dam and may then establish and fix a permanent low-water mark. Should it appear that the maintenance of the reservoir or dam would be an undue burden upon the owner thereof, the commissioner shall enter into negotiations with the landowners interested around the reservoir or above the dam, the governing body of the municipality in which the reservoir or dam is located, and any other parties to the petition filed with the commissioner protesting against the removal of the reservoir, water or dam or the decommissioning of the reservoir or dam, for the purpose of determining how and by whom the expenses of maintenance shall be paid.

Amended 1981,c.249,s.11; 1994,c.84,s.3.

THIS IS A COURTESY COPY OF THIS RULE. ALL OF THE DEPARTMENT'S RULES ARE COMPILED IN TITLE 7 OF THE NEW JERSEY ADMINISTRATIVE CODE.

N.J.A.C. 7:20

Dam Safety Standards

Statutory authority: Safe Dam Act, N.J.S.A. 58:4-1

Date last amended: June 16, 2008

THIS IS A COURTESY COPY OF THIS RULE. ALL OF THE DEPARTMENT'S RULES ARE COMPILED IN TITLE 7 OF THE NEW JERSEY ADMINISTRATIVE CODE.

DAM SAFETY STANDARDS
N.J.A.C. 7:20
EFFECTIVE DATE: SEPTEMBER 8, 2005,
AMENDMENT JUNE 16, 2008
EXPIRATION DATE: SEPTEMBER 8, 2010

SUBCHAPTER 1. APPLICATION PROCEDURE; DESIGN CRITERIA FOR DAM CONSTRUCTION; DAM INSPECTION PROCEDURE

N.J.A.C. 7:20-1.1 Scope and applicability

The rules in this subchapter were adopted pursuant to the authority of N.J.S.A. 58:4-1 et seq., as amended by the Safe Dam Act of 1981, and N.J.S.A. 13:1D-l et seq.

1. These rules set forth procedures for application to construct, repair or modify a dam, as defined in N.J.A.C. 7:20-1.2 and set standards for design and maintenance of dams. These rules also establish a dam inspection procedure.

2. Any dam which raises the waters of a stream five feet or less above its usual, mean, low water height falls under the jurisdiction of the Flood Hazard Area Control Act, N.J.S.A. 58:16A-50 et seq.

3. The requirements in this subchapter shall not affect or relate to a dam or reservoir in the pinelands area, as designated by subsection a. of section 10 of P.L. 1979, c.111 (C. 13:18A-ll), which will raise the waters of any river or stream less than eight feet above the surface of the ground where the drainage area above the same is less than one square mile in extent and where the water surface created by the dam or reservoir is less than 100 acres in extent except that the commissioner may investigate and take appropriate action regarding any dam or reservoir about which he has a security or safety concern. With respect to dams and reservoirs located on lands utilized for agricultural or horticultural purposes within the pinelands area, the commissioner's actions shall be undertaken after consultation with the Secretary of Agriculture. See N.J.S.A. 58:4-1, P.L. 1985, c.33, Sl and 2.

N.J.A.C. 7:20-1.2 Definitions

The following words and terms, as used in this chapter, shall have the following meanings, unless the context clearly indicates otherwise.

"Applicant" means any person making application for a dam permit.

"Auxiliary spillway" means the second used spillway during flood flows which is not the emergency spillway.

THIS IS A COURTESY COPY OF THIS RULE. ALL OF THE DEPARTMENT'S RULES ARE COMPILED IN TITLE 7 OF THE NEW JERSEY ADMINISTRATIVE CODE.

"Dam" means any artificial dike, levee or other barrier, together with appurtenant works, which is constructed for the purpose of impounding water on a permanent or temporary basis, that raises the water level five feet or more above the usual, mean, low water height when measured from the downstream toe-of-dam to the emergency spillway crest or, in the absence of an emergency spillway, the top-of dam.

"Department" means the New Jersey Department of Environmental Protection.

"Design freeboard" means the minimum freeboard which would exist during passage of the design flood.

"Division" means the Division of Engineering and Construction in the Department of Environmental Protection.

"Emergency spillway" means the spillway capable of passing the spillway design storm with the principal and/or auxiliary spillway blocked.

"Environmental impact statement" means a report which describes the real and potential impacts which will or may result from the construction and operation of a proposed dam project, the adverse environmental impacts which cannot be avoided, the steps to be taken to minimize adverse impacts and the alternatives to the project with reasons for the acceptability or unacceptability; and

1. The report shall address real or potential impacts upon ecology, natural resources, historical and archeological resource, recreational resources, aesthetic resources, endangered and non-game species, fisheries and any other identifiable impacts;

2. The report shall include a listing of qualifications of those preparing the report and a reference list of pertinent published information relating to the project, the project site and the surrounding region.

"Formal inspection" means the inspection by a New Jersey licensed professional engineer to reevaluate the safety and integrity of the dam and appurtenant structures to determine if the structure meets current design criteria, including a field inspection and a review of the records on project design, construction and performance.

"Freeboard" means the vertical dimension between the crest of the embankment of a dam (without camber) and the reservoir water surface at the spillway design flood stage.

"Height-of-dam" means the vertical dimension from the lowest point in the stream bed or ground surface at the downstream toe of the dam to the elevation of the top of dam (without camber).

"Independent Review Board" means one or more independent professional engineers who are qualified in the design, construction and rehabilitation of dams to perform a review of

THIS IS A COURTESY COPY OF THIS RULE. ALL OF THE DEPARTMENT'S RULES ARE COMPILED IN TITLE 7 OF THE NEW JERSEY ADMINISTRATIVE CODE.

the project design and construction.

"Informal inspection" means the visual inspection of the dam by the dam owner or operator to detect apparent signs of deterioration or other deficiencies of the dam structure or function.

"Levee" or "dike" means any artificial barrier together with appurtenant works that will divert or restrain the flow of a stream or river.

"One-hundred-year storm" means the storm which is estimated to have a one percent chance, or one chance in 100, of being equaled or exceeded in one year.

"Outlet" means an opening through which water can be freely discharged from a reservoir for a particular purpose.

"Owner and/or operator" means any person who owns, controls, operates, maintains, manages or proposes to construct a dam.

"Permit" or "dam permit" means all approvals required under N.J.S.A. 58:4-1 et seq. for the construction and operation of a dam.

"Person" means any individual, proprietorship, partnership, association, corporation, municipality, county or public agency.

"Pipe conduit" means any hollow tube which conveys water through a dam from a reservoir, either as a spillway or as a drain.

"Principal spillway" means the primary or first used spillway during normal inflow and flood flows.

"Probable maximum precipitation" or "(PMP)" means the theoretically greatest depth of precipitation for a given duration that is physically possible, over a given size storm area, at a particular geographic location, at a certain time of year.

"Regular inspection" means the visual inspection of a dam by a New Jersey licensed professional engineer to detect any signs of deterioration in material, developing weaknesses or unsafe hydraulic or structural behavior.

"Reservoir" means any impoundment or any potential impoundment that will be created by a dam, dike or levee.

"Spillway" means a structure other than low flow outlets, over or through which flood flows are discharged.

"Spillway design storm" means the storm upon which the hydraulic capacity of the spillway structure is designed.

THIS IS A COURTESY COPY OF THIS RULE. ALL OF THE DEPARTMENT'S RULES ARE COMPILED IN TITLE 7 OF THE NEW JERSEY ADMINISTRATIVE CODE.

"Toe-of-dam" means the junction of the downstream face of a dam with the ground surface or the invert of the outlet pipe whichever is the lowest point.

N.J.A.C. 7:20-1.3 Permit-by-rule

(a) All dams must be designed, constructed, operated, maintained or removed in compliance with the rules in this subchapter except as set forth below:

1. Owners and operators of Class IV dams (see N.J.A.C. 7:20-1.8, Dam classification) are not required to file documents with nor obtain a permit from the Department, but must meet the following requirements, in addition to those set forth elsewhere in this subchapter:

i. Design must be based upon a spillway design storm that results in rainfall of 50 percent greater than a 24- hour, 100-year, Type III storm (Later technology adopted by the United States Department of Agriculture, Natural Resources Conservation Service may be substituted for the use of the Type III storm.); and

ii. All necessary local approvals must be obtained;

iii. A New Jersey licensed professional engineer must design the Class IV Dam to meet all technical requirements of this subchapter; and

iv. If the Class IV dam is designed or constructed for stormwater management purposes, the dam shall comply with the Stormwater Management Rules at N.J.A.C. 7:8.

2. Owners and operators of Class III agricultural impoundments, meaning any impoundment used for fish and wildlife, fire control or livestock or crop production and maintenance, where the drainage area is less than one-half square mile in extent, must meet only the following requirements.

i. All necessary local approvals must be obtained;

ii. Design and construction must be supervised by the United States Department of Agriculture, Natural Resources Conservation Service.

(b) The Department may, in its discretion, require the owner or operator of any dam subject to (a) above to obtain a permit and/or to submit any information relating to dam design, construction, operation or maintenance.

THIS IS A COURTESY COPY OF THIS RULE. ALL OF THE DEPARTMENT'S RULES ARE COMPILED IN TITLE 7 OF THE NEW JERSEY ADMINISTRATIVE CODE.

(c) The Department may, in its discretion, require the owner or operator of any dam to make modification of the design, construction or operation of the dam in order to comply with the intent of this chapter and the Safe Dam Act, N.J.S.A. 58:4-1 et seq.

N.J.A.C. 7:20-1.4 General requirements and prohibitions

(a) No person may construct or operate a new dam or modify or repair an existing dam without first having obtained a permit from the Department, unless subject to the permit-by-rule provision in N.J.A.C. 7:20-1.3. Where emergency circumstances justify, repairs of a dam may be undertaken prior to obtaining a permit, in accordance with (i) below.

(b) No dam may be approved by the Department where, in the opinion of the Department, there is an unacceptable potential for harm to human health or to human safety.

(c) Backwater created by a dam during a 100-year storm shall be the minimum which is contained within the applicant's property unless written consent is obtained from all potentially affected property owners. Effects on both surface and ground water shall be considered, during normal pool conditions.

(d) No person may construct a dam in any waterway of this state which is a runway for migratory fish, without installing a fish ladder or other approved structure to permit the fish to pass the dam in either direction (see N.J.S.A. 23:5-29.1).

1. This provision is applicable to dams of any size.

2. The Department will determine whether a stream is currently a runway for migratory fish, during the review of the dam permit application. Applicants should consult the Division of Fish and Wildlife in this matter prior to finalizing the application.

(e) Unless otherwise approved by the Department, dam construction shall commence within one year from the date of the permit and be completed within two years from the said date or the permit will become null and void. For good cause shown, the Department may extend the two year construction deadline for a total of no more than five years, one year at a time. Applicants must make written request for an extension, prior to the expiration date of the permit or prior extension.

(f) No action shall be brought against the State or the Department or its agents or employees for the recovery of damages caused by the partial or total failure of any dam or reservoir or through the operation of any dam or reservoir upon the ground that the Department is liable by virtue of any of the following:

THIS IS A COURTESY COPY OF THIS RULE. ALL OF THE DEPARTMENT'S RULES ARE COMPILED IN TITLE 7 OF THE NEW JERSEY ADMINISTRATIVE CODE.

1. The approval of the dam or reservoir, or approval of flood handling plans during construction.

2. The issuance or enforcement of orders relative to maintenance or operation of the dam or reservoir.

3. Control, regulation and inspection of the dam or reservoir.

4. Measures taken to protect against failure during an emergency.

(g) The Department may deny any application for a dam permit, based upon its conclusion that the construction or operation of dam will cause an unacceptable threat to or impact on natural or cultural resources or the environment.

(h) The Department shall be notified immediately by the owner or operator upon the detection of any condition which may jeopardize the safety of the structure.

(i) Situations which threaten the public health, safety, and welfare and require emergency dam repair will be considered by the Department under the following procedure:

1. The owner or operator shall inform the Department by telephone as to the extent of work to be performed, the reason for the emergency and the location of the project.

2. The owner or operator shall perform the emergency work upon verbal approval of the Department, which approval shall be verified by the Department in writing within three working days. The Department shall offer guidance and instructions in performing the work.

3. After the work has been completed in accordance with the Department's instructions, the owner or operator shall submit a dam Permit Application and "as built" drawings to the Department for review. A letter shall be issued by Department in lieu of a dam permit.

(j) The Department shall be notified in writing on or before the transfer of dam ownership.

(k) Unless otherwise approved by the Department in writing, no person shall dredge within 200 feet of a dam.

(l) Utilities crossing within dam embankments are prohibited unless demonstrated to the satisfaction of the Department that such utilities will not jeopardize the safety of the dam.

THIS IS A COURTESY COPY OF THIS RULE. ALL OF THE DEPARTMENT'S RULES ARE COMPILED IN TITLE 7 OF THE NEW JERSEY ADMINISTRATIVE CODE.

(m) No person shall remove or breach an existing dam without first having obtained a permit from the Department unless subject to the permit-by-rule provisions in N.J.A.C. 7:20-1.3.

(n) Unless otherwise approved by the Department, no trees shall be permitted to grow on the dam embankment.

N.J.A.C. 7:20-1.5 General application procedures

(a) The procedures for applying for a dam construction, modification or repair permit and for submitting the supporting engineering documents include the preapplication stage and the application stage, as described below. For Class III dams (see N.J.A.C. 7:20-1.8) all required information may be submitted at one time, with such detail as is appropriate to the safe design of the type of structure proposed.

(b) The applicant for a dam permit must use a New Jersey licensed professional engineer to prepare the plans and specifications and to supervise the inspection of the construction.

(c) The Department may require any owner or operator of an existing dam to obtain a permit for repair or modification of the dam and appurtenances where:

1. Repair or modification is necessary to insure protection of human health or safety; or

2. Modification is required to comply with the provisions of this chapter, unless the following circumstances exist:

i. Compliance is impracticable; and,

ii. Noncompliance poses no unacceptable threat to human health or safety.

(d) Appeal procedures; permit denials

1. 1. An applicant for a dam permit may request in writing an administrative hearing from the Department within 15 days of receipt of the decision by the Department to deny the application. The request for a hearing shall be sent to the Office of Legal Affairs, ATTENTION: Adjudicatory Hearing Requests, Department of Environmental Protection, CN 402, Trenton, New Jersey 08625-0402.

THIS IS A COURTESY COPY OF THIS RULE. ALL OF THE DEPARTMENT'S RULES ARE COMPILED IN TITLE 7 OF THE NEW JERSEY ADMINISTRATIVE CODE.

2. The request for a hearing shall specify in detail the basis for the request, including all issues of fact or law. The Department may attempt to settle the dispute by conducting such proceedings, meetings and conferences as deemed appropriate. Should the efforts to settle the dispute fail and if the Department determines that the matter is a contested case, the Department shall forward the request for a hearing to the Office of Administrative Law, pursuant to the provisions of the Administrative Procedure Act (N.J.S.A. 52:14B-l et seq.)

(e) Applicants for a dam permit for a Class III dam, as defined pursuant to N.J.A.C. 7:20-1.8, may submit a preliminary application, which should include that information needed to establish a Class III hazard classification. Thereafter, in its discretion, the Department may waive certain documentation and inspection requirements set forth in these rules.

N.J.A.C. 7:20-1.6 Preapplication Stage

(a) The applicant must submit a written Preliminary Report which must include the following:

1. A general description of the dam and all appurtenances thereto, and the proposed dam classification, pursuant to N.J.A.C. 7:20-1.8. The description shall include the following:

i. A statement of the purpose for which the dam and appurtenances are to be used; and

ii. A description of the potential effects of project construction and operation upon the environment.

2. Maps of the area within one-half mile of the dam and impoundment boundary, showing the following:

i. The location of the proposed dam and all appurtenances, thereto;

ii. The location of all structures;

iii. The county and township;

iv. The boundary of the reservoir;

THIS IS A COURTESY COPY OF THIS RULE. ALL OF THE DEPARTMENT'S RULES ARE COMPILED IN TITLE 7 OF THE NEW JERSEY ADMINISTRATIVE CODE.

v. The location of all streets and roads;

vi. The location of all major utilities, i.e. pipe lines and transmission, telegraph, and telephone lines; all minor utilities shall be identified in the immediate vicinity of the dam and impoundment area.

vii. The topography and scale; and

viii. All other structures or facilities affected by the proposed dam, including the area downstream from the dam (State, county, and U.S.G.S. maps and aerial photographs may be used for this purpose).

3. A written report of the surficial conditions (i.e. geology, topography, and culture), based upon a field reconnaissance by the applicant's engineer;

4. Typical cross-sections of the dam, and any dike(s) and levee(s), showing proposed elevations, pool levels and top and bottom widths;

5. Preliminary design data, tentative conclusions and references. The design data shall address hydrologic features such as drainage area and rainfall data, the basis for proposed dam location, the basis for the type of structure and spillway proposed, the soils and geologic engineering criteria and the basis for design and construction;

6. The hydrologic design procedure and the storm durations which are used in the design;

7. All documentation and information related to determining hazard classification; and

8. Other information required by the Department.

(b) Upon review of the pre-application, the Department will notify the applicant of what design criteria will apply.

(c) Applicants for a permit to repair an existing dam are not required to submit a preliminary report unless the Department determines it to be necessary.

N.J.A.C. 7:20-1.7 Application Stage

(a) The application shall be on forms specified and supplied by the Department and

THIS IS A COURTESY COPY OF THIS RULE. ALL OF THE DEPARTMENT'S RULES ARE COMPILED IN TITLE 7 OF THE NEW JERSEY ADMINISTRATIVE CODE.

must be accompanied by two copies of the final design report, construction specifications and all plans, drawings, and designs. Upon the written request of the applicant, the Department may waive certain requirements for documentation in the application stage set forth at (b) to (g) below for a permit to modify, repair or remove an existing dam.

(b) The application shall include a Final Design Report, which must contain the following:

1. A report of the field and laboratory investigation(s) of the foundation soils and/or bedrock, a location map to identify borings and the materials that will comprise the dam and any dikes or levees. Stability and settlement analyses and seepage and underseepage studies are required, unless the applicant can demonstrate to the satisfaction of the Department that these analyses are not necessary.

2. The bases, references, calculations and conclusions relative to hydrologic studies and design of spillway.

3. Structural and hydraulic design studies and calculations. Structural, hydraulic and hydrologic design procedures should be used, as established by one of the following: the U.S. Army Corps of Engineers, the U.S. Bureau of Reclamation, the U.S. Natural Resources Conservation Service and other procedures universally accepted as sound engineering practice.

(c) The application must include all drawings necessary to fully describe the proposal. Drawings must be prepared in accordance with the following:

1. All drawings must be prepared by a New Jersey licensed professional engineer or land surveyor, as appropriate. Each drawing shall have a title block which meets the requirements of the State Board of Professional Engineers and Land Surveyors.

2. Drawings must clearly show the datum to which elevations shown are referred. The National Geodetic Vertical Datum of 1929 (N.G.V.D.), formerly known as the U.S. Coast & Geodetic Survey datum, should be used wherever possible. If the N.G.V.D. datum is not used, an appropriate conversion equation must be indicated on the drawings.

3. The applicant must submit drawings showing the following information:

i. A general plan of the dam, drawn to an appropriate scale, which must show accurately the position of all essential details, such as the spillway and its point of discharge into the stream, pipes through the dam, inlets, outlets, screen chambers, gate or valve houses, head-races, the canal mill or power plant, tailraces and downstream

THIS IS A COURTESY COPY OF THIS RULE. ALL OF THE DEPARTMENT'S RULES ARE COMPILED IN TITLE 7 OF THE NEW JERSEY ADMINISTRATIVE CODE.

bridges which might cause backwater on the dam;

ii. A longitudinal section of the dam and cross-section of the valley at the site of the dam, showing the elevation of the crest of the dam, the elevation of the normal and design storm flow line of the lake or reservoir, the original surface of the ground, the nature and depth of the underlying strata, the probable depth of the excavation for the foundation of the dam and for the cutoff, foundation treatment, elevation of the restored surface of the ground, the location and elevation of all pipes or conduits passing through the dam, the core wall, if any, and the spillway structure;

iii. Typical cross sections, including a maximum section of the dam and of a spillway section which shall meet the following requirements;

(1) Cross sections must show the original surface of the ground, subsurface conditions as disclosed by test pits or borings, the probable depth of excavations for the foundation and for cutoff, the elevations of the top of the dam, the crest of the spillway and the normal flow line or water surface in the reservoir;

(2) For earth dams, the depth of stripping must be shown, as well as the position, material and dimensions of the cutoff or core wall, the width of the crest, the slopes and the nature and dimensions of the slope protection, the position and dimensions of the outlet pipes or conduits and the cutoff to prevent seepage along such structures, the disposition of different classes of embankment material if of varying composition, toe drains and clay blankets;

(3) For concrete or other composite dams, the cross sections shall show all dimensions and shall indicate the position and kinds of material to be included in the structure.

iv. If not clearly indicated on one or more of the drawings listed above, the following details shall be shown on additional detail sheets:

(1) Detail of spillway or overflow, showing the length and depth of opening, together with the width and shape of the crest, grade and shape of the approach and discharge channels, if any, methods of protecting the toe of the dam or end of the discharge channel from erosion and the dimensions of all

THIS IS A COURTESY COPY OF THIS RULE. ALL OF THE DEPARTMENT'S RULES ARE COMPILED IN TITLE 7 OF THE NEW JERSEY ADMINISTRATIVE CODE.

walls, floors and paving;

(2) Details of the intake and outlet works, showing the location and dimensions of all valves or sluice gates, intakes, screen chambers, racks, outlet towers and gate houses and appurtenances;

(3) For reinforced concrete dams, detailed drawings must also be submitted, showing the size, spacing and arrangement of all reinforcing steel and expansion joints; and

(4) Special drawings shall be submitted showing any special construction features not otherwise shown, such as piling, fishways, aprons, materials used in the core wall, movable dams, tainter gates and mechanical devices, drains and instrumentation.

(d) The application must include specifications, containing the following:

1. General provisions, specifying the rights, duties and responsibilities of the owner, applicant, applicant's engineer and the builder;

2. The estimated project schedule and sequence of work; and

3. Technical provisions, describing carefully and in detail the approved work methods and procedures, standards for equipment and testing, materials to be used and the results to be obtained.

(e) The applicant shall complete all investigations, including the following, prior to submission of the final design report which shall meet the following requirements:

1. The scope and the degree of precision of investigations required for a specific project shall be based on the complexities of the site, the importance of the proposed structure and the hazard created by the proposed structure.

2. The foundation investigation shall consist of borings, test pits, seismic investigations or other subsurface explorations and must be performed so as to accurately define the soil and rock stratigraphy and the ground water conditions to the satisfaction of the Department.

3. Laboratory testing of undisturbed and remolded soil specimens and rock samples may be required by the Department.

THIS IS A COURTESY COPY OF THIS RULE. ALL OF THE DEPARTMENT'S RULES ARE COMPILED IN TITLE 7 OF THE NEW JERSEY ADMINISTRATIVE CODE.

4. The applicant must determine the nature and extent of materials which are proposed for use in the structure, (e.g., borrow material, concrete aggregate, riprap stone, filter materials) and their structural properties when incorporated into the proposed structure.

5. Stability analysis and calculations for the proposed structure to ensure safety against failure due to overturning, sliding or overstressing must be submitted and approved by the Department.

6. Topographic surveys must be performed with sufficient accuracy to locate the proposed construction and to define the volume of the storage in the reservoir and the flowage limits. The upstream and downstream area must be investigated in order to delineate the area of potential damage in case of failure or flooding. Locations of baselines, centerlines and other horizontal and vertical control points must be shown on the topographic map of the site.

7. The drainage area must be accurately determined. Both present and projected future land use must be considered in determining the runoff characteristics of the drainage area. The most severe of these two conditions must be used in the design. The hydrologic assumptions and design calculations used in spillway designs shall be specified and shall include:

   i. Drainage area size;

   ii. Rainfall and runoff data;

   iii. Reservoir inflow hydrographs;

   iv. Reservoir area-capacity-elevation data;

   v. Spillway elevation-discharge data; and

   vi. Reservoir flood routings, except as otherwise provided in this subchapter.

(f) All applicants must submit an Operation and Maintenance Manual in accordance with N.J.A.C. 7:20-1.1 and applicants for Class I and II dams (see N.J.A.C. 7:20-1.8) shall prepare and submit an Emergency Action Plan which shall at least include a Dam Breach Analysis, Inundation Maps and Emergency Notification and Evacuation Plans.

(g) The Department may require the submission of an Environmental Impact

THIS IS A COURTESY COPY OF THIS RULE. ALL OF THE DEPARTMENT'S RULES ARE COMPILED IN TITLE 7 OF THE NEW JERSEY ADMINISTRATIVE CODE.

Statement, as defined in N.J.A.C. 7:20- 1.2, by any applicant for a dam permit.

(h) The application to remove or breach a dam shall include the following:

1. Design report, and plans and computations to effect the breach including size of breach, shape of breach, disposal of spoil material;

2. Plans and computations for stabilization of the lake bed including the channel upstream of the breach, and for the control of sediment within the lake and downstream of the breach during and after the breach has been effected;

3. Computations for design of the method and timing for dewatering the lake;

4. Computations detailing the effects of the breach on the downstream channel and demonstrating that the project will not adversely affect flooding conditions downstream during the 10, 50 and 100 year storms;

5. Specifications containing the technical provision which describe in detail the proposed work methods and equipment and, in addition, a work schedule for the entire project;

6. A plan of the existing dam and lake along with surrounding property lines;

7. Evidence that all adjoining property owners of the impoundment and the municipality where the reservoir or dam is located have received notification that an application has been submitted to the Department to remove or breach a dam and proof of publication of notice of the proposed removal application in at least one newspaper of general circulation in the municipality where the reservoir or dam is located;

8. A description of the potential effects of the dam removal or breach upon the environment; and

9. A description of the potential effects of the dam removal or breach upon life and property downstream of the dam.

(i) When a petition has been filed in accordance with the Safe Dam Act, N.J.S.A. 58:4-9, protesting against the removal of any reservoir, water or dam or against the decommissioning of any reservoir or dam, the Commissioner shall, pursuant to the requirements of N.J.S.A. 58:4-10, hold a public hearing, upon 30 days notice to all parties interested, and following prior notice published 30 days before the hearing in at least one newspaper of general circulation in the municipality in which the reservoir or dam is located.

THIS IS A COURTESY COPY OF THIS RULE. ALL OF THE DEPARTMENT'S RULES ARE COMPILED IN TITLE 7 OF THE NEW JERSEY ADMINISTRATIVE CODE.

N.J.A.C. 7:20-1.8 Dam Classification

(a) The Department will use the following guidelines to classify dams according to hazard. Probable future development of the area downstream from the dam which might be affected by its failure will be considered in determining the hazard classification. The Department may, in its discretion, change the hazard class of any proposed or existing dam.

1. Class I - High Hazard Potential: This classification includes those dams, the failure of which may cause the probable loss of life or extensive property damage.

   i. The existence of normally occupied homes in the area that are susceptible to significant damage in the event of a dam failure will be assumed to mean "probable loss of life".

   ii. Extensive property damage means the destructive loss of industrial or commercial facilities, essential public utilities, main highways, railroads or bridges. A dam may be classified as having a high hazard potential based solely on high projected economic loss.

   iii. Recreational facilities below a dam, such as a campground or recreation area, may be sufficient reason to classify a dam as having a high hazard potential.

2. Class II - Significant Hazard Potential: This classification includes those dams, the failure of which may cause significant damage to property and project operation, but loss of human life is not envisioned. This classification applies to predominantly rural, agricultural areas, where dam failure may damage isolated homes, major highways or railroads or cause interruption of service of relatively important public utilities.

3. Class III - Low Hazard Potential: This classification includes those dams, the failure of which would cause loss of the dam itself but little or no additional damage to other property. This classification applies to rural or agricultural areas where failure may damage farm buildings other than residences, agricultural lands or non-major roads.

4. Class IV - Small Dams: This classification includes any project which impounds less than 15 acre-feet of water to the top of dam, has less than 15 feet height-of-dam and which has a drainage area above the dam of 150 acres or less in extent. No dam may be included in Class IV if it meets the criteria for Class I or II. Any applicant may request consideration as a Class III dam upon submission of a positive report and demonstration proving low hazard.

THIS IS A COURTESY COPY OF THIS RULE. ALL OF THE DEPARTMENT'S RULES ARE COMPILED IN TITLE 7 OF THE NEW JERSEY ADMINISTRATIVE CODE.

N.J.A.C. 7:20-1.9 Design criteria

(a) The minimum design storm used to calculate required spillway capacity must be determined according to the following table:

Hazard	Spillway Design Storm (SDS)
Class I	PMP
Class II	One-half PMP
Class III	24 hour 100 year frequency, Type III storm*
Class IV	24 hour 100 year frequency, Type III storm plus 50%*

*Any later technology adopted by the U.S. Department of Agriculture, Natural Resources Conservation Service may be substituted for the use of the Type III storm.

(b) For existing dams, it is recognized that the relationships between valley slope and width, total reservoir storage, drainage area, and other hydrologic factors have a critical bearing on determining the safe spillway design flood. When appropriate, based on the design of a dam, rational selection of a reduced spillway design for specific site conditions based on quantitative and relative impact analysis is acceptable. The spillway should be sized so that the increased downstream damage resulting from overtopping failure of the dam would not be significant as compared with the damage caused by the flood in the absence of a dam overtopping failure. The minimum design storm for the dam shall be the 100 year storm.

(c) All Class II and III dams shall, where practicable incorporate in the proposed design, the ability to make modifications necessary to increase the spillway capacity of the facility or other alternative measures if the downstream hazard potential increases.

(d) All dams shall have an adequate storage for the design storm or have a spillway system which will safely pass the design storm without endangering the safety of the dam.

(e) Each spillway shall include a satisfactory means of dissipating the energy of flow at its outlet without endangering the safety of the dam.

(f) The capacity of the spillway system shall be equal to the peak inflow of the design flood unless the applicant demonstrates by flood routing procedures that the spillway system has the capacity to safely pass the resulting water flow.

THIS IS A COURTESY COPY OF THIS RULE. ALL OF THE DEPARTMENT'S RULES ARE COMPILED IN TITLE 7 OF THE NEW JERSEY ADMINISTRATIVE CODE.

(g) Pipe conduits may be used for the primary (principal) spillway. When so used, the following requirements shall be met:

1. Pipe conduits shall be of such design as to safely support the total external loads in addition to the total internal hydraulic pressure without leakage. The type of construction material used shall be consistent with the anticipated life of the structure. Corrugated metal pipe shall not be used in the construction of new dams.

   i. For Class I and II dams, the minimum allowable inside dimension of the pipe conduit is 30 inches.

   ii. For Class III dams, the minimum allowable inside diameter of the pipe conduit is 18 inches.

   iii. For Class IV dams, the minimum allowable inside diameter of the pipe conduit is 12 inches.

2. All pipe conduits shall convey water at the maximum design velocity without damage to the interior surface;

3. The pipe conduit must be designed so that negative pressures will not occur at any point along the primary (principal) spillway system;

4. Drainage filters or other methods approved by the Department must be installed to control seepage along the conduit;

5. Adequate allowances shall be incorporated in the design to compensate for differential settlement and possible elongation of the pipe conduit;

6. An anti-vortex device must be included in the design, unless the applicant can demonstrate that one is not necessary.

7. A trash rack, approved by the Department, shall be installed at the intake to prevent clogging of the pipe conduit; and

8. An emergency spillway shall be provided; and

9. Cathodic protection is required for all metal pipes .

(h) Should a vegetated or unlined auxiliary spillway, approved by the Department, be installed, it must be able to pass the design storm without jeopardizing the safety of

THIS IS A COURTESY COPY OF THIS RULE. ALL OF THE DEPARTMENT'S RULES ARE COMPILED IN TITLE 7 OF THE NEW JERSEY ADMINISTRATIVE CODE.

the structure and that has a predicted average frequency of use less than:

1. Once in 100 years for Class I dams:

2. Once in 50 years for Class II dams; or

3. Once in 25 years for Class III and IV dams.

(i) Drawdown requirements are as follows:

1. Except for excavated impoundments, all dams shall include a device to permit draining the reservoir, as approved in writing by the Department. Computations for the minimum time required to drain the reservoir shall be required for new and existing dams.

2. Unless the applicant demonstrates to the satisfaction of the Department that there is a need to locate a valve downstream from the dam and that the areas downstream of the dam will remain protected, all valves or sluice gates in pipe conduit drains must be installed upstream of the dam.

3. All pipe conduits used as drawdown drains for all dam classifications shall meet requirements of (g) above, except that the minimum allowable inside dimension may be less than 30 inches.

4. Dams which impound water on a permanent basis shall include a means to allow the reduction of the reservoir water surface elevation five feet in 10 days at a rate not to exceed one foot per day. This requirement shall not apply to dams whose intended purpose requires and whose design allows faster drawdown times. For existing dams which satisfactorily meet Department safety and operating criteria, the applicant may, with prior approval of the Department, present alternative reservoir drawdown plans.

(j) Design references used shall be cited in the information submitted to the Department.

(k) Monitoring devices to permit inspection and assessment of the dam's condition may be required by the Department for use in the inspections during and after completion of construction.

(1) The applicant shall demonstrate to the Department that the riparian rights of downstream property owners will be protected during construction, during the period when the reservoir is being filled and during the life of the dam and reservoir.

(m) Unless the applicant can demonstrate that an alternative slope is acceptable, upstream slopes of an earth dam may be no steeper than three horizontal to one

THIS IS A COURTESY COPY OF THIS RULE. ALL OF THE DEPARTMENT'S RULES ARE COMPILED IN TITLE 7 OF THE NEW JERSEY ADMINISTRATIVE CODE.

vertical ratio, and downstream slopes may be no steeper than two horizontal to one vertical ratio. Measures are required for protection of upstream slopes against wave action or rapid draw-down and for protection of the downstream slope against scour or erosion due to high tailwater.

(n) Freeboard requirements are as follows:

1. Sufficient freeboard shall be provided to prevent overtopping of the dam or any dike or levee due to passage of the design flood or due to frost damage, ice damage or wave action.

2. For all dams the minimum elevation of the top of the dam must be that necessary to pass the design storm with at least one foot of freeboard to the top of dam.

3. Where special conditions of severe frost damage, ice damage or wave action may occur, higher elevations than required in (n)2 above may be required and should be considered by the applicant.

(o) The Department may require the design and installation of any additional or modified measures by any applicant for a dam permit where appropriate to insure the protection of human health or safety.

N.J.A.C. 7:20-1.10 Construction

(a) Requirements relating to supervision of dam construction are as follows:

1. All applicants shall submit a written description and schedule of the proposed construction, including:

i. The estimated time to complete the construction activities, see N.J.A.C. 7:20-1.4(e);

ii. Where applicable, a description of the means by which stream flow will be diverted around or through the dam site, or otherwise kept from interfering with the work;

iii. The number of inspectors designated for inspection for construction quality control; and

iv. Steps to be taken to minimize erosion and sediment production during construction.

2. The extent and method of inspection for construction quality control must be described and approved by the Department, including an inspection schedule.

THIS IS A COURTESY COPY OF THIS RULE. ALL OF THE DEPARTMENT'S RULES ARE COMPILED IN TITLE 7 OF THE NEW JERSEY ADMINISTRATIVE CODE.

3. The diversion facility, as outlined in l.i above, must remain open and no water may be permanently stored in the reservoir until the permittee demonstrates to the Department that storage of water will neither interfere with construction activities nor create a hazard to life, health or property.

4. The professional engineer responsible for inspecting the construction must submit progress reports to the Department at least once each month, during the construction period.

5. The permittee shall promptly advise the Department of all proposed changes in the approved design, plans or specifications. There may be no change in the approved design, plans or specifications without prior approval of the Department. All approved changes must be recorded on the complete set of as-built plans, required in (a) 6, below. The Department may require the submission of revised designs at any time. Written prior approval from the Department is required for major modifications, which shall include significant changes in scale, use, design, impact, etc. of the project, as initially approved. The Department may require written, prior approval of any proposed modification.

6. A complete set of as-built designs, plans and specifications must be submitted to the Department upon completion of the project.

7. The professional engineer who has inspected the construction shall submit written certification that the structure has been built in conformance with the designs, plans and specifications, and with any changes approved by the Department.

(b) The Department may, in its discretion, require the owner to obtain the services of an Independent Review Board to oversee the design and construction of any proposed or existing dam.

(c) Construction inspection program requirements are as follows:

1. The Department may inspect the dam during construction to insure that it is being built in compliance with the designs, plans and specifications submitted to the Department. Departmental inspections in no way relieve either the permittee or the professional engineer in charge from the responsibility of providing adequate inspection of the work.

2. If, at any time during the progress of the work, the Department finds that the work is not being performed in accordance with the approved designs, plans and specifications and any approved changes, the Department will serve a written notice to that effect on the permittee or his representative. Such notice will state the particulars with which the work has not complied.

THIS IS A COURTESY COPY OF THIS RULE. ALL OF THE DEPARTMENT'S RULES ARE COMPILED IN TITLE 7 OF THE NEW JERSEY ADMINISTRATIVE CODE.

Additionally, the Department may order the immediate compliance with such designs, plans, specifications, and changes and suspension of all other work until compliance has been effected. If the owner or his representative fails to comply with this order, the permit under which construction is authorized may be revoked or suspended by the Department.

3. Upon receipt of the as-built plans required in subsection (a) 6 above and the engineer's certification required in subsection (a) 7 above the Department will inspect the completed construction within 45 days. If the Department finds that construction was completed in accordance with the approved designs, plans, specifications and approved changes, the construction will be approved in writing within 30 days. The approval date shall be the date such approval is sent by the Department.

4. In the 12th month following approval of construction by the Department pursuant to (b) 3 above, the Department will make a final inspection of the construction. If the Department makes a final inspection of the construction, a final approval may be given by the Department, if the final inspection shows that the terms of the permit, designs, plans, specifications and approved changes thereof have been met.

N.J.A.C. 7:20-1.11 Dam operating requirements and inspections: new and existing dams

(a) The owners and operators of all dams shall develop and use an Operation and Maintenance Manual which provides guidance and instruction to project personnel for the proper operation and maintenance of the reservoir and dam, and meets the following requirements:

1. The manual shall be composed of two parts:

i. Part One shall include an introduction, project description, project authorizations, project history and list of project contracts.

ii. Part Two shall contain the operation and maintenance instructions for major project facilities and equipment and a schedule for maintenance.

(b) The owners or operators of all dams which raise the waters of any stream more than 70 feet above its usual mean low-water height or which impound more than 10,000 acre-feet of water shall have a regular inspection performed annually and formal inspections performed every three years by a New Jersey licensed professional engineer. These inspections must be attended by a professional engineer assigned from the Department. In the year of the formal inspection, regular or informal

THIS IS A COURTESY COPY OF THIS RULE. ALL OF THE DEPARTMENT'S RULES ARE COMPILED IN TITLE 7 OF THE NEW JERSEY ADMINISTRATIVE CODE.

inspections need not be performed.

(c) Owners or operators of Class I dams not meeting the size characteristics described in (b) above shall have a regular inspection performed once every two years and a formal inspection performed every six years.

(d) Owners or operators of Class II dams shall have a regular inspection performed once every two years and a formal inspection performed every 10 years.

(e) Owners or operators of Class III and IV dams shall have a regular inspection performed every four years. The Department may at its discretion require the owner or operators to perform a formal inspection of a Class III or IV dam.

(f) All dam inspections shall be performed from March through December.

(g) All inspections shall be performed in compliance with the following requirements:

1. A written guide provided by the Department for the preparation of a Report on Condition of the dam shall be used for all inspections.

2. Formal and regular dam inspections shall be performed by a licensed New Jersey professional engineer. Except for Class IV dams, the required report shall be submitted to the Department by the engineer within 30 days of completion of the inspection. The report shall indicate the results of the inspection, documenting the conclusions and recommendations. Reports for Class IV dams shall be submitted to the county and/or municipal engineer having jurisdiction over the dam structure.

3. Informal inspections may be performed by the dam owner or operator and the Report on Condition shall be part of the owner's or operator's permanent file and, unless requested by the Department, Reports shall not be submitted to the Department.

4. The Department may extend the time for submission of the required material for up to 30 days, if the owner or operator justifies the need for such extension.

5. Failure by the permittee to inspect within the required time periods or failure to submit the Report on Condition may result in an order to drain the impoundment under the provisions of the Safe Dam Act (N.J.S.A. 58:4-1 et seq.), and/or any other remedy allowed by law.

(h) For good cause, the Department may require the owner or operator of any dam to perform an inspection of any type at any time.

THIS IS A COURTESY COPY OF THIS RULE. ALL OF THE DEPARTMENT'S RULES ARE COMPILED IN TITLE 7 OF THE NEW JERSEY ADMINISTRATIVE CODE.

(i) The owner or operator of all Class I and II dams shall prepare and use an Emergency Action Plan, as described in N.J.A.C. 7:20-1.7(f).

N.J.A.C. 7:20-1.12 Duty to Provide Information

The Department may require an owner or person having control of a reservoir or dam to provide any information the Department requires to determine compliance with any provision of the Safe Dam Act, or any rule, regulation or order issued pursuant to the Safe Dam Act.

N.J.A.C. 7:20-1.13 Inspection Authority

The Department shall have the authority to enter any property, facility, premises, or site for the purpose of conducting inspections to determine the condition of any dam, or to conduct inspections of ordered repairs or to otherwise determine compliance with the provisions of the Safe Dam Act.

Subchapter 2. CIVIL ADMINISTRATIVE PENALTIES; REQUESTS FOR ADJUDICATORY HEARINGS; ACTIONS BY THE DEPARTMENT TO REPAIR OR MITIGATE

N.J.A.C. 7:20-2.1 Authority and purpose

(a) This subchapter governs the assessment of uniform civil administrative penalties pursuant to the Safe Dam Act, N.J.S.A. 58:4-1 et seq. and the issuance of orders for the violation of any provision of the Safe Dam Act or any regulation, rule, permit or order adopted or issued by the Department pursuant thereto. This subchapter also establishes the procedure for requesting an adjudicatory hearing or appeal from a notice of civil administrative penalty assessment or administrative order.

(b) Neither the issuance of an administrative order nor the assessment of a civil administrative penalty shall affect the availability to the Department of any other enforcement provision in N.J.S.A. 58:4-5 and 4-6 or any other action or remedy available by law.

N.J.A.C. 7:20-2.2 Procedures for Issuing an Administrative Order Pursuant to the Safe Dam Act

(a) Whenever the Department finds that a person has violated any provision of the Safe Dam Act, or any regulation, rule or order adopted or issued by the Department pursuant thereto, the Department may issue an administrative order specifying the provision or provisions of the law, rule, regulation, or order, of which the person is in

THIS IS A COURTESY COPY OF THIS RULE. ALL OF THE DEPARTMENT'S RULES ARE COMPILED IN TITLE 7 OF THE NEW JERSEY ADMINISTRATIVE CODE.

violation citing the action which constituted the violation requiring compliance with the provision or provisions violated; requiring specific actions by the violator to achieve compliance with provisions violated; and providing notice to the person of the right to an adjudicatory hearing on the matters contained in the order. The ordered party shall have 20 days from receipt of the order within which to deliver to the Department a written request for a hearing in accordance with N.J.A.C. 7:20-2.4.

N.J.A.C. 7:20-2.3 Procedures for assessment, settlement and payment of civil administrative penalties for violations

(a) To assess a civil administrative penalty, the Department shall notify the violator by certified mail (return receipt requested) or personal service. This notice of civil administrative penalty assessment shall:

1. Identify the section of the Safe Dam Act, or the rule, regulation and/or administrative order violated;

2. State the facts which constitute the violation;

3. State the amount of the civil administrative penalty to be imposed and the amount of any other costs and economic benefit to be imposed; and

4. Advise the violator of the right to request an adjudicatory hearing under N.J.A.C. 7:20-2.4.

(b) The violator shall pay a civil administrative penalty immediately upon receipt of the Department's final order in a contested case, or as soon as a notice of civil administrative penalty assessment becomes a final order as follows:

1. If no hearing is requested pursuant to N.J.A.C. 7:20-2.4, a notice of civil administrative penalty assessment becomes a final order on the 21st day after the violator receives the notice;

2. If the Department denies a hearing request under N.J.A.C. 7:20-2.4, a notice of civil administrative penalty assessment becomes a final order upon the violator's receipt of the denial; or

3. If the Department grants the hearing request, a notice of civil administrative penalty assessment becomes a final order upon issuance of a final order by the Department.

N.J.A.C. 7:20-2.4 Procedures to Request an Adjudicatory Hearing to Contest an Administrative Order and/or a Notice of Civil Administrative Penalty Assessment; Procedures for Conducting Adjudicatory Hearings

THIS IS A COURTESY COPY OF THIS RULE. ALL OF THE DEPARTMENT'S RULES ARE COMPILED IN TITLE 7 OF THE NEW JERSEY ADMINISTRATIVE CODE.

(a) To request an adjudicatory hearing to contest an administrative order and/or a notice of civil administrative penalty assessment issued pursuant to the Safe Dam Act, the person to whom the administrative order and/or notice of civil administrative penalty assessment was issued, shall within 20 days of receipt of the order and/or notice submit an original written request for an adjudicatory hearing to:

New Jersey Department of Environmental Protection
Office of Legal Affairs
Attention: Adjudicatory Hearing Requests
401 East State Street
P.O. Box 402
Trenton, New Jersey 08625-0402

(b) A complete copy of the request shall be submitted to the Bureau of Dam Safety and Flood Control at :

New Jersey Department of Environmental Protection
Bureau of Dam Safety and Flood Control
501 E. State Street
P.O. Box 419
Trenton, New Jersey 08625-0419

(c) The written request shall include all information required by the "Adjudicatory Hearing Request Checklist and Tracking Form" available from the Bureau of Dam Safety and Flood Control, 501 E. State Street, P.O. Box 419, Trenton, NJ 08625-0419 and on the Department's website at www.state.nj.us/dep/damsafety, including the following:

1. The name, address, and telephone number of the violator and its authorized representative;

2. The date the violator received the enforcement document being contested;

3. A copy of the administrative order and/or notice of civil administrative penalty assessment and a list of all issues being appealed;

4. The violator's defenses to each of the findings of fact stated in short and plain terms;

5. An admission or denial of each of the findings of fact. If the violator is without knowledge or information sufficient to form a belief as to the truth of a finding, the violator shall so state and this shall have the effect of a denial. A denial shall fairly meet the substance of the findings denied. When the violator intends in good faith to deny only a part or a qualification of a finding, the violator shall specify so much as is true

THIS IS A COURTESY COPY OF THIS RULE. ALL OF THE DEPARTMENT'S RULES ARE COMPILED IN TITLE 7 OF THE NEW JERSEY ADMINISTRATIVE CODE.

and material and deny only the remainder. The violator may not generally deny all of the findings but shall make all denials as specific denials of designated findings. For each finding the violator denies, the violator shall allege the fact or facts as the violator believes it or them to be;

6. Information supporting the request and specific reference to or copies of other written documents relied upon to support the request;

7. An estimate of the time required for the hearing (in days/and or hours); and

8. A request, if necessary, for a barrier-free hearing location for physically disabled persons.

(d) If the Department does not receive the written request for a hearing within 20 days after receipt by the person of the administrative order and/or notice of civil administrative penalty assessment being contested, the Department shall deny the hearing request.

(e) The Department shall notify the requester if the request for a hearing is granted and, if denied, the reason why. If a hearing request is granted, the Department shall refer the matter to the Office of Administrative Law for an adjudicatory hearing in accordance with the Administrative Procedure Act, N.J.S.A. 52:14B-1 et seq., and the Uniform Administrative Procedure Rules, N.J.A.C. 1:1.

(f) If the person fails to include all the information required by (a) above, the Department may deny the hearing request.

N.J.A.C.7:20-2.5 Civil Administrative Penalty Assessment for Violation of the Safe Dam Act

(a) The Department may assess a civil administrative penalty of up to $25,000 for each violation of any provision of the Safe Dam Act, N.J.S.A. 58:4-1 et seq., or for any failure to comply with any rule or regulation adopted pursuant to the Act, or for any failure to comply with any permit, order or directive issued pursuant to the Act, or for failure to comply with a request for information or request to enter upon the property.

(b) Each violation of any provision of the Safe Dam Act, or any rule or regulation adopted pursuant to the Act, or for any failure to comply with any permit, order or directive issued pursuant to the Act, or for failure to comply with a request for information or request to enter upon the property shall constitute a separate and distinct offense.

(c) and Each day during which a violation continues shall constitute an additional, separate distinct offense.

THIS IS A COURTESY COPY OF THIS RULE. ALL OF THE DEPARTMENT'S RULES ARE COMPILED IN TITLE 7 OF THE NEW JERSEY ADMINISTRATIVE CODE.

(d) When the Department determines that the violator has gained economic benefit from a violation, the Department may, in addition to any other civil administrative penalty assessed, include as a part of a civil administrative penalty the economic benefit that the violator has realized as a result of not complying or delaying compliance. Economic benefit shall include the amount of savings realized from avoided costs; the return earned or that may be earned on the amount of the avoided costs; and any other benefits resulting from the violation.

N.J.A.C.7:20-2.6 Civil Administrative Penalty Amount for Violation of the Safe Dam Act

(a) The Department may assess the following civil administrative penalty for each day that the respective identified violations continue:

1. Failure to draw off (drain or lower) an impoundment:

   i. Class I Dams $10,000-$25,000;

   ii. Class II Dams $5,000-$10,000;

   iii. Class III and IV Dams $1,000-$5,000;

2. Failure to submit a permit application, compliance schedule, inspection report, Emergency Action Plan or Operation and Maintenance plan or other document required by the Safe Dam Act or these rules, or failure to respond to a request for information:

   i. Class I Dams $5,000;

   ii. Class II Dams $2,500;

   iii. Class III and IV Dams $1,000;

3. Failure to conduct or complete dam repairs, maintenance, modification or removal:

   i. Class I Dams $10,000-$25,000;

   ii. Class II Dams $5,000-$10,000;

   iii. Class III and IV Dams $1,000-$5,000;

4. Failure to obtain Department approval prior to the construction or modification of a dam or appurtenant structure:

   i. Class I Dams $10,000-$25,000;

THIS IS A COURTESY COPY OF THIS RULE. ALL OF THE DEPARTMENT'S RULES ARE COMPILED IN TITLE 7 OF THE NEW JERSEY ADMINISTRATIVE CODE.

ii. Class II Dams $5,000-$10,000;

iii. Class III and IV Dams $1,000-$5,000;

5. Failure to allow access to a dam site, including appurtenant structures, to representatives of the Department presenting proper credentials:

i. All dams $1,000-$5,000;

6. Failure to implement a security plan:

i. Class I Dams $10,000-$25,000;

ii. Class II Dams $5,000-$10,000;

iii. Class III and IV Dams $1,000-$5,000;

7. Failure to comply with any permit requirement:

i. Class I Dams $10,000-25,000;

ii. Class II Dams $5,000-$10,000;

iii. Class III and IV Dams $1,000-$5,000;

8. Knowingly, recklessly, or negligently making a false statement, representation, or certification in any application, record or other document filed or required to be maintained by the Safe Dam Act:

i. All Dams $1,000-$5,000.

(b) The civil administrative penalty shall be established at the mid-point of the ranges set forth at (a) above unless adjusted by the Department in its discretion within the range on the basis of the following factors:

1. The compliance history of the violator;

2. The number, frequency and severity of the violations;

3. The measures taken by the violator to mitigate the effect of the current violation or to prevent future violations;

4. The cooperation of the violator in correcting the violation, remedying the damage caused by the violation and ensuring the violation does not reoccur;

5. The deterrent effect of the penalty;

THIS IS A COURTESY COPY OF THIS RULE. ALL OF THE DEPARTMENT'S RULES ARE COMPILED IN TITLE 7 OF THE NEW JERSEY ADMINISTRATIVE CODE.

6. Any costs or impacts directly or indirectly imposed on the public or the environment as a result of the violation; and

7. Other specific circumstances of the violator or violation.

(c) In settling a civil administrative penalty, the Department may in its discretion consider the following:

1. Mitigating and extenuating circumstances;

2. Measures taken to mitigate impact of the violation; and

3. Other terms and conditions acceptable to the Department.

N.J.A.C. 7:20-2.7 Notice of Violation Recorded on Property Deed

In addition to penalties prescribed in this subchapter, a notice of violation issued pursuant to the Safe Dam Act, or any rule, regulation or order issued pursuant thereto, shall, on order of the Commissioner, be recorded on the deed of the property wherein the violation occurred, by the clerk or register of deeds and mortgages of the county wherein the affected property is located and with the clerk of the Superior Court and shall remain attached thereto until such time as the violation is remedied and the Commissioner orders the notice of violation removed.

N.J.A.C. 7:20-2.8 Penalty Collection

All penalties collected pursuant to this subchapter or sums collected pursuant to N.J.S.A. 58:4-5 shall be deposited in the "Environmental Services Fund," established pursuant to N.J.S.A. 13:1D-33, and kept separate from other receipts deposited therein, and appropriated to the Department for the removal of dams in the State.

N.J.A.C. 7:20-2.9 Action by the Department to Repair and Mitigate

(a) Whenever the Commissioner determines that a dam is in imminent danger of failure and has reasonable cause to believe that danger to life or property may be anticipated from the reservoir, dam or appurtenant structures located therein, and the owner of the dam or person having control of the reservoir or dam has failed to comply with an order to repair the dam or to take such interim measures as the Department determines are appropriate, including reducing the amount of water impounded by the dam or breaching the dam, the Department may, in addition to other actions authorized by the Safe Dam Act, these regulations and other law, enter upon any and all properties wherein the reservoir, dam or appurtenant structures are located, and using resources and personnel available to the Department, remove or cause to be removed the dam and/or appurtenant structures located therein, allowing the water to flow freely.

THIS IS A COURTESY COPY OF THIS RULE. ALL OF THE DEPARTMENT'S RULES ARE COMPILED IN TITLE 7 OF THE NEW JERSEY ADMINISTRATIVE CODE.

(b) The Department shall provide notice to the owner or person having control of the reservoir or dam prior to the removal action provided for in (a) above. The owner shall, no later than 60 days after receipt of notice, submit to the Department in writing, an implementation plan addressing the proposed actions the owner or person having control of the reservoir or dam intends to take to repair or remove the failed or failing reservoir or dam, along with a schedule for implementation of the proposed actions. Any permits required for the proposed actions shall be applied for within the 60-day time period.

(c) If the proposed actions, schedule and permit applications are timely submitted and the Department in its discretion determines that the proposed actions and schedule will satisfactorily address the danger specified in (a) above, and that the permits applied for can properly be issued, the Department shall allow the owner or person having control of the reservoir or dam to take the actions identified. If the owner or person having control of the reservoir or dam fails to comply with the proposed schedule, the Department may take removal action in (a) above.

(d) Any expenditures made by the Department pursuant to (a) shall constitute a debt to the State and a lien on all property owned by the owner or person having control of the reservoir or dam. When a certificate of debt incorporating a description of the property subject to the removal action and the costs is filed with the clerk of the Superior Court, the lien shall attach to all revenues and all real and personal property of the owner or person having control of the reservoir or dam.

(e) The lien described in (d) above shall have priority over all other liens, interests or claims on the dam or reservoir property subject to the Department's removal action. However, if that property is six dwelling units or less and used exclusively for residential purposes, the certificate of debt shall not affect any valid lien, claim or interest which was filed prior to the certificate of debt. When the lien described in (d) above affects property other than the property subject to the removal action, it shall have priority from the date of filing but shall not affect any valid lien, interest or claim filed prior to filing of the certificate of debt.

(f) Whenever the owner or person having control of the reservoir or dam is a private lake association or other body representing owners or property adjacent to the reservoir or lake created by the dam or impoundment, liens may be imposed upon the individual owners of the property represented by the association. An owner whose property has such a lien imposed may release the property from a lien claimed under this subsection by filing with the clerk of the Superior Court a cash or surety bond, payable to the Department in the amount of the sums expended by the Department pursuant to this section, including attorney's fees and court costs, or the value of the property after the abatement action is complete, whichever is less.

(g) The provisions of this section shall not limit the use of other remedies available to the Department pursuant to law.

THIS IS A COURTESY COPY OF THIS RULE. ALL OF THE DEPARTMENT'S RULES ARE COMPILED IN TITLE 7 OF THE NEW JERSEY ADMINISTRATIVE CODE.

E.30. New Mexico

RULES AND REGULATIONS

GOVERNING DAM DESIGN, CONSTRUCTION

AND DAM SAFETY

JOHN R. D'ANTONIO, JR., P.E.

STATE ENGINEER

March 31, 2005

The New Mexico Office of the State Engineer Dam Safety Bureau is located in Santa Fe. Copies of forms referred to herein and a copy of these rules and regulations can be obtained from the Dam Safety Bureau or from the Office of the State Engineer website. All documents filed for dams shall be delivered to the Dam Safety Bureau.

TITLE 19 NATURAL RESOURCES AND WILDLIFE
CHAPTER 25 ADMINISTRATION AND USE OF WATER – GENERAL PROVISIONS
PART 12 DAM DESIGN, CONSTRUCTION AND DAM SAFETY

19.25.12.1 ISSUING AGENCY: New Mexico Office of the State Engineer
[19.25.12.1 NMAC - N, 3/31/2005]

19.25.12.2 SCOPE: These regulations apply to the design and construction of all jurisdictional dams in New Mexico and are intended to facilitate the continued safe operation and maintenance of all non-federal jurisdictional dams. These regulations govern the review and acceptance of plans for construction, alteration, modification, repair, enlargement and removal of a jurisdictional dam. These regulations ensure the continued safe operation, maintenance, site security and emergency preparedness for existing non-federal jurisdictional dams. These regulations do not authorize the appropriation or use of water pursuant to 19.26 NMAC and 19.27 NMAC.
[19.25.12.2 NMAC - N, 3/31/2005]

19.25.12.3 STATUTORY AUTHORITY: Section 72-5-32 NMSA requires any person, association or corporation, public or private, the state or the United States that is intending to construct a jurisdictional dam to submit detailed plans to the state engineer. Sections 72-5-9 and 72-5-10 NMSA establish the state engineer's authority over the construction of works and issuing certificates of construction. Sections 72-5-8 and 72-5-14 NMSA require construction to be completed in a time limit set by the state engineer and procedures for requesting an extension of time. Sections 72-5-11, 72-5-12 and 72-5-13 NMSA gives the state engineer jurisdiction over unsafe works, penalties for failure to comply with state engineer orders and priority of liens. Section 72-2-6 NMSA gives the state engineer the authority to assess fees. Section 72-2-8 NMSA gives the state engineer authority to adopt regulations and codes to implement and enforce any provision of any law administered by him. Section 72-8-1 NMSA gives the state engineer the authority to enter upon private property for the performance of his duties. Nothing in these rules shall be construed so as to limit the state engineer's authority to take lawful alternative or additional actions relating to the design, construction and safety of dams.
[19.25.12.3 NMAC - N, 3/31/2005]

19.25.12.4 DURATION: Permanent.
[19.25.12.4 NMAC - N, 3/31/2005]

19.25.12.5 EFFECTIVE DATE: March 31, 2005 unless a later date is cited at the end of a section.
[19.25.12.5 NMAC - N, 3/31/2005]

19.25.12.6 OBJECTIVE: To establish minimum design requirements, minimum submittal requirements and dam site owner responsibilities that shall be addressed to the state engineer's satisfaction in order to ensure a dam is designed, constructed, operated, maintained and secured in a safe manner.
[19.25.12.6 NMAC - N, 3/31/2005]

19.25.12.7 DEFINITIONS: Unless defined below or in a specific section of these regulations, all other words used herein shall be given their customary and accepted meaning.

A. Abutment: That part of the valley side against which the dam is constructed. The left and right abutments of dams are defined with the observer viewing the dam looking in the downstream direction.

B. Alteration, modification, repair, rehabilitation or enlargement of an existing dam: To change from the state engineer accepted construction drawings and specifications or current condition.

C. Appurtenant structure: Auxiliary features of a dam such as outlets, spillways, access structures, tunnels and related housing at a dam.

D. American society for testing and materials (ASTM): An accepted standard for testing the properties of materials. Methods cited in these regulations include laboratory compaction characteristics of soils.

E. Breach: An opening through a dam or spillway that is capable of draining a portion of the reservoir or the entire reservoir. A controlled breach is a constructed opening. An uncontrolled breach is an unintentional discharge from the reservoir.

F. Consequences of failure: Potential loss of life or property damage downstream of a dam caused by waters released at the dam or by waters released by partial or complete failure of dam; includes effects of landslides upstream of the dam on property located around the reservoir.

G. Crest width: The thickness or width of a dam at the crest level (excluding corbels or parapets). In general, the term thickness is used for gravity and arch dams and width is used for other dams.

H. Dam: A man-made barrier constructed across a watercourse or off-channel for the purpose of storage, control or diversion of water.

(1) Jurisdictional dam: A dam that is more than 10 feet in height measured from the lowest point on the downstream toe to the dam crest or impounds more than 10 acre-feet of water as measured from the lowest point on the downstream toe to the spillway crest. Dams constructed under the supervision of the U.S. army corps of engineers before May 19, 2004, become jurisdictional when such supervision by the U.S. army corps of engineers is terminated. For purposes of these regulations, reference to a dam means a jurisdictional dam unless otherwise noted.

(2) Non-jurisdictional dam: Any dam less than or equal to 10 feet in height and having storage less than or equal to 10 acre-feet of water. The state engineer does not regulate the design, construction and operation of a non-jurisdictional dam unless the dam is unsafe and there is a threat to life or property, as determined by the state engineer. Waters impounded by a non-jurisdictional dam may not be exempt from water right permit requirements; therefore a separate state engineer water right permit for the water impounded in the reservoir created by a non-jurisdictional dam may be required. Non-jurisdictional dams shall meet the requirements of 19.26.2.15 NMAC unless otherwise exempt. The structures listed below are considered non-jurisdictional dams:

(a) Stock dam: A stock dam constructed prior to May 19, 2004 with a storage capacity of 10 acre-feet or less regardless of the height of the dam.

(b) Erosion control dam: A dam for the sole purpose of erosion control constructed on a naturally dry watercourse as determined by the state engineer, with a storage capacity of 10 acre-feet or less as measured from the lowest point on the downstream toe to the spillway crest and the reservoir drains in 96 hours unless a quicker drain time is required by court decree.

(c) Levee or diversion dike: A structure where water flows parallel to the length of the levee or diversion dike as determined by the state engineer.

(d) Roadway embankment: A structure across a watercourse designed for the sole purpose of supporting a roadbed or other means of conveyance for transportation as determined by the state engineer; where the area upstream has not been enlarged to increase flood storage; and where the embankment is provided with an uncontrolled conduit of sufficient capacity to satisfy requirements of the appropriate state or local transportation authority. If no transportation authority has jurisdiction over the structure, the current drainage design criteria of the New Mexico department of transportation shall apply.

I. Dam crest: The lowest elevation of the uppermost surface of a dam, usually a road or walkway excluding any parapet wall, railing, etc.

J. Dam failure: The breakdown of a dam, characterized by the uncontrolled release of impounded water. There are varying degrees of failure.

K. Dam height: The vertical distance from the lowest point on the downstream toe to the dam crest.

L. Dam incident: An event at a dam that interrupts normal procedures and performance, affects the safety of the dam or results in a potential loss of life or damage to property.

M. Fetch: The straight-line distance across a body of water subject to wind forces. The fetch is one of the factors used to calculate wave heights in a reservoir.

N. Freeboard: The vertical distance between the spillway crest and the lowest point of the dam crest not including camber.

O. Functional exercise: A meeting in a conference room environment involving the dam owner and state and local emergency personnel with responsibilities in the emergency action plan. The exercise takes place in a stress-induced environment with time constraints and involves simulation of a dam failure and other specific events. The exercise is designed to evaluate both the internal capabilities and responses of the dam owner and the workability of the information in the emergency action plan used by emergency management officials.

P. High water line: The highest water level elevation in the reservoir as determined from routing the spillway design flood or inflow design flood.

Q. Inflow design flood: The flood flow above which the incremental increase in downstream water surface elevation due to failure of a dam is no longer considered to present an unacceptable additional downstream threat. The upper limit of the inflow design flood is the flood resulting from the probable maximum precipitation and the lower limit is the flood resulting from the 100-year precipitation.

R. Inundation map: A map delineating the area that would be flooded by a particular flood event.

S. Length of dam: The length measured along the dam axis at the dam crest. This also includes the spillway, powerplant, navigation lock, fish pass, etc., where these form part of the length of the dam. If detached from the dam these structures should not be included.

T. Loss of life: The likely number of human fatalities that would result from a dam failure flood event. No allowances for evacuation or other emergency actions by the population should be considered.

U. Naturally dry watercourse: A watercourse or portion thereof, which under normal conditions is dry, which flows only in direct response to precipitation and whose channel is at all times above the groundwater table.

V. Normal operating level: The water level elevation corresponding to the maximum storage level that excludes any flood control or surcharge storage.

W. North American vertical datum 1988 (NAVD88): The current vertical control datum in use in North America established from nine space geodetic stations. This basis of establishing elevation provides a precise surface, whereas the North American vertical datum 1927 (NAVD27) is elevation established from mean sea level.

X. One-hundred year flood: A flood that has 1 chance in 100 of being equaled or exceeded during any year.

Y. Owner: The individual, association or corporation, public or private, the state or the United States, owning the land upon which a dam is constructed; having a contractual right to construct, operate or maintain a dam; or the beneficiary of an easement to construct, operate or maintain a dam.

Z. Probable maximum precipitation: Theoretically, the greatest depth of precipitation for a given duration that is physically possible over a given size storm area at a particular location during a certain time of year.

AA. Spillway: A structure over or through which excess flow is discharged from a reservoir. If the rate of flow is controlled by mechanical means such as gates, it is considered a controlled spillway. If the geometry of the spillway is the only control, it is considered an uncontrolled spillway. For purposes of these regulations, an uncontrolled outlet conduit that is used to drain the reservoir is not considered a spillway.

BB. Spillway crest: The lowest level at which water can flow over or through the spillway.

CC. Spillway design flood: The required flood that a spillway must pass without failure of the dam.

DD. Storage: For purposes of determining whether a dam is jurisdictional, the storage is the volume of water impounded by the dam above the lowest elevation of the downstream toe to the elevation of the spillway crest. For dams with no spillway, storage is measured to the dam crest. Definitions of specific types of storage in reservoirs are:

(1) Dead storage is the storage volume of a reservoir that lies below the invert of the lowest outlet and therefore, cannot readily be withdrawn from the reservoir.

(2) Flood surcharge storage is the storage volume between the maximum operating level and the maximum water level during the spillway design flood.

(3) Live storage is the storage volume of a reservoir that is available for use and lies above the invert of the lowest outlet.

(4) Reservoir storage capacity is the sum of the dead and live storage of the reservoir.

(5) Maximum storage is the sum of the reservoir storage capacity and flood surcharge storage.

EE. Tabletop exercise: A meeting in a conference room environment involving the dam owner and state and local emergency personnel with responsibilities in the emergency action plan. The format is a discussion of an emergency event, response procedures to resolve concerns regarding coordination and responsibilities.

FF. Toe: The contact line between the outer shell of the dam and the natural ground surface.

GG. Wave runup: Vertical height above the water level to which water from a specific wave will run up the face of a structure or embankment.

[19.25.12.7 NMAC - N, 3/31/2005]

19.25.12.8 FEE SCHEDULE: The state engineer assesses fees for filing forms, reviewing plans and specifications for dams and appurtenant structures and construction inspections.

A. For filing an application for permit to construct and operate a dam the fees shall be $25.

B. For each review of design plans, construction drawings and specifications for a dam the fee shall be $2 per $1000 or fraction thereof of the estimated construction cost. For determination of fees, inclusion of contingencies, taxes and other permit fees is not required. Assessment of multiple review fees for the same application is at the sole discretion of the state engineer.

C. For issuing an extension of time for construction of a dam the fee shall be $50.

D. For inspecting construction of a dam the fee shall be $100/8-hour day and actual and necessary traveling expenses.

E. For filing a proof of completion of works for a dam the fee shall be $25.

F. For filing a change of ownership for a dam the fee shall be $5.

G. For copies of dam safety records up to 11 inches by 17 inches the fee shall be $0.20 per copy.

H. For copies of dam safety records greater than 11 inches by 17 inches the fee shall be $3.00 per copy.

[19.25.12.8 NMAC - N, 3/31/2005]

19.25.12.9 SIZE CLASSIFICATION: A dam shall be less than or equal to the maximum height and storage to qualify for the size classification.

A. Small: A small dam is greater than 10 feet but less than or equal to 40 feet in height, or greater than 10 acre-feet but less than or equal to 1000 acre-feet of storage.

B. Intermediate: An intermediate dam is greater than 40 feet but less than or equal to 100 feet in height, or greater than 1000 acre-feet but less than or equal to 50,000 acre-feet of storage.

C. Large: A large dam is greater than 100 feet in height, or greater than 50,000 acre-feet of storage.

[19.25.12.9 NMAC - N, 3/31/2005]

19.25.12.10 HAZARD POTENTIAL CLASSIFICATION: The hazard potential classification is a rating for a dam based on the potential consequences of failure. The rating is based on loss of life, damage to property and environmental damage that is likely to occur in the event of dam failure. No allowances for evacuation or other emergency actions by the population should be considered. The hazard potential classification is not a reflection of the condition of the dam.

A. Low hazard potential: Dams assigned the low hazard potential classification are those dams where failure or misoperation results in no probable loss of life and low economic and/or environmental losses. Losses are principally limited to the dam owner's property.

B. Significant hazard potential: Dams assigned the significant hazard potential classification are those dams where failure or misoperation results in no probable loss of human life but can cause economic loss, environmental damage, disruption of lifeline facilities, or can impact other concerns. Significant hazard potential classification dams are often located in predominantly rural or agricultural areas but could be located in populated areas with significant infrastructure.

C. High hazard potential: Dams assigned the high hazard potential classification are those dams where failure or misoperation will probably cause loss of human life.

[19.25.12.10 NMAC - N, 3/31/2005]

19.25.12.11 DESIGN OF A DAM: Any person, association or corporation, public or private, the state, or the United States that is intending to construct a dam shall submit an application to construct and operate a dam and supporting documentation acceptable to the state engineer. This section primarily addresses the design and construction of embankment dams. Other types of dams shall conform to sound engineering principles and current state of the practice. Because each site, design and operating practice is unique, waivers of specific requirements in this section will be considered on a case-by-case basis. Request for waiver shall be in writing accompanied with documentation justifying the request. If the request is not justified to the satisfaction of the state engineer the request will be denied. Construction shall not begin until the state engineer has accepted the supporting documentation and approved the application with construction and operation conditions. The application and supporting documentation shall include:

A. Application: An application form shall be completed with original signature of the dam owner and accompanied with a filing fee in accordance with Subsection A of 19.25.12.8 NMAC. The form will be the only information available to the public before the project is approved for construction. All other supporting documentation is considered draft until accepted by the state engineer. A plan review fee in accordance with Subsection B of 19.25.12.8 NMAC shall accompany the submittal of the design report, construction drawings and specifications. A detailed estimate of the construction cost for the proposed dam and appurtenant structures shall be submitted in support of the plan review fee.

B. Water right: A water right is required for water impounded by the dam. If the dam owner has a permit for the diversion of water, documentation addressing the necessity for storage, diversion periods and release conditions for the reservoir may be required. This requirement is waived for flood control dams that do not detain

water longer than 96 hours in accordance with Subparagraph (b) of Paragraph (7) of Subsection C of 19.25.12.11 NMAC or provide documentation that a waiver by the state engineer has been granted. Flood control dams that do not drain within 96 hours require a water right for water permanently stored beyond the 96-hour drain time requirement and for associated losses due to evaporation and other potential depletions to the system unless a waiver in accordance with 19.25.12.11 NMAC is obtained.

C. Design report: A design report, which includes information to evaluate the safe design of the dam and appurtenant structures, shall be submitted in a form acceptable to the state engineer. The design report shall contain the information described below and any other additional information determined necessary by the state engineer. A professional engineer licensed in the state of New Mexico qualified in the design and construction of dams shall prepare or supervise the preparation of the design report. The front cover shall show the name of the dam (identical to the application), the county in which the dam is located and type of report. The first page behind the front cover shall show the name of the dam (identical to the dam name on the application), the county in which the dam is located and the signed certifications for the engineer and state engineer in accordance with Subsections B and E of 19.25.12.12 NMAC. The design report shall include:

(1) Hazard potential classification. A hazard potential classification shall be based on the dam failure condition that results in the greatest potential for loss of life and property damage. If the state engineer concurs, the classification may be based on the judgment and recommendation of the professional engineer. For all other cases, a low or significant hazard potential classification shall be supported by a dam breach analysis, which includes calculations and data that supports the predicted dam failure flood. This analysis shall also address the potential for foreseeable future development. Evaluation of the effects of flooding from dam failure shall extend at least to the location downstream where the classification can be properly identified. The dam breach analysis shall include, but not be limited to:

(a) dam failure inundation maps;

(b) map of the water surface profiles;

(c) cross-sections drawn to scale showing water surface elevation at critical sections where structures are impacted and showing discharge in cubic feet per second, average velocity in feet per second, flood wave travel times, rate of rise and structures located in the flooded sections;

(d) a tabulation and justification of assumed parameters used in the analysis;

(e) a sensitivity analysis of the assumed parameters used in the analysis;

(f) references to all computer models, data and supporting justification used in the analysis; and

(g) appropriate data sheets and computer program output computations from computerized analysis shall be provided.

(2) Hydrologic analysis. The hydrologic analysis shall include a discussion of methodology used to calculate the spillway design flood for determining the available flood storage and spillway capacity. Consideration of how the dam will perform under these hypothetical flood conditions shall be evaluated. The hydrologic analysis shall include, but not be limited to:

(a) a topographic map of the drainage area above the dam with the drainage area and sub-basins delineated and presented on a map of appropriate scale and size;

(b) a description of the topography, soils and vegetative cover of the drainage area;

(c) a discussion of the depth, duration and distribution of the spillway design storm;

(d) a tabulation, discussion and justification of all hydrologic parameters and methodology used to calculate runoff from rainfall;

(e) a discussion of the peak inflow, volume of runoff and maximum reservoir water level elevation for the inflow hydrograph;

(f) a plot of the reservoir inflow and outflow hydrographs extended until flow is negligible and plotted on the same figure of appropriate size and scale;

(g) a table showing the reservoir area (in acres) and storage capacity (in acre-feet) for each foot of elevation above the bottom of the reservoir to the dam crest; the table shall be determined from the reservoir topography map; indicate the amount of dead storage, elevation of the invert of the outlet and elevation of the crest of each spillway; all elevations shall be based on North American vertical datum 1988 or more recent adjustment; and

(h) appropriate data sheets and computer program output computations from computerized analysis shall be provided.

(3) Spillway design flood. The spillway design flood is the flood that a spillway must be capable of conveying without dam failure. For perimeter embankment dams with no spillway and no external drainage area, the dam must be capable of impounding the spillway design flood without dam failure. A spillway design flood less than these requirements is acceptable to the state engineer if an incremental damage analysis is presented to justify the inflow design flood in accordance with Paragraph (4) of Subsection C of 19.25.12.11 NMAC. The spillway design flood is based on size classification and hazard potential classification of the dam as follows:

(a) Dams classified as low hazard potential, regardless of size, shall have spillways designed to pass a flood resulting from a 100-year precipitation event expressed as a percentage of the probable maximum precipitation.

(b) Dams classified as small and intermediate, with a significant hazard potential rating shall have spillways designed to pass a flood resulting from 50 percent of the probable maximum precipitation.

(c) Dams classified as large, with a significant hazard potential rating shall have spillways designed to pass a flood resulting from 75 percent of the probable maximum precipitation.

(d) Dams classified as high hazard potential, regardless of size, shall have spillways designed to pass a flood resulting from the probable maximum precipitation.

(4) Incremental damage assessment. Where spillways are not in compliance with Paragraph (3) of Subsection C of 19.25.12.11 NMAC an incremental damage assessment shall justify the inflow design flood used to size the spillway. The assessment shall evaluate the consequences of dam failure. The assessment shall compare the impact of with-failure and without-failure conditions on downstream water levels and existing and known future development. The assessment shall include a dam breach analysis in accordance with Subparagraphs (a) through (g) of Paragraph (1) of Subsection C of 19.25.12.11 NMAC for the failure and non-failure conditions. Methods for assessing the damage between failure and non-failure conditions shall be fully documented.

(5) Spillway capacity. The spillway capacity shall be adequate to pass the spillway design flood in accordance with Paragraph (3) of Subsection C of 19.25.12.11 NMAC or accepted inflow design flood in accordance with Paragraph (4) of Subsection C of 19.25.12.11 NMAC without failure of the dam. If design calculations show that overtopping will occur, an erosion study of the embankment documenting that the dam will not breach is required. If the outlet works are gated, the design discharge of the outlet works shall not be considered when routing the spillway design flood through the reservoir and spillway. The water level shall be at the normal operating level at the beginning of the spillway design storm. A spillway rating curve and table showing elevation in one-foot increments versus maximum discharge capacity shall be prepared. The rating curve and table shall include data from the crest of the spillway to the dam crest. The parameters used to calculate the spillway capacity shall be justified and appropriate data sheets and computer program output computations from computerized analysis shall be provided. Elevations shall be based on North American vertical datum 1988 or more recent adjustment.

(6) Spillway design. Spillways shall be evaluated for erosion potential during normal operation and the design flood event. Damage to a spillway during the design flood event is acceptable; however, a breach of the spillway is unacceptable. The spillway design shall address the following minimum requirements:

(a) The material required for spillway lining depends on the spillway location, frequency of discharge and velocity of discharge to adequately address erosion and breach potential. The design shall provide adequate justification for the material selected.

(b) The design shall provide aeration of the nappe for cavitation control where control weirs are used at the spillway crest.

(c) The spillway must discharge away from the toe of the dam and abutment slopes.

(d) The potential for the accumulation of debris that may block the spillway shall be addressed.

(e) Energy dissipation to control erosion of the natural channel due to spillway discharge shall be addressed.

(f) Channel lining shall be placed on a suitably prepared, stable subgrade. All edges and joints in channel lining material must be designed to prevent undermining and erosion. Concrete channel lining must be provided with adequate jointing to permit thermal expansion and contraction and adequate reinforcing to control thermal cracking. Adequate water stops are required at joints in the spillway lining. Concrete lining shall be adequately anchored against displacement and uplift and shall be provided with adequate subdrainage to relieve hydrostatic pressure and prevent frost heave.

(g) Where training dikes are used to divert the water away from the dam, the dike shall be designed with a compaction to at least 95% of the maximum standard Proctor density, ASTM D 698, or at least 90% of the maximum modified Proctor density, ASTM D 1557, or at least 70% relative density if Proctor testing is not

appropriate. Erosion protection for the dike shall be addressed in accordance with Paragraph (16) of Subsection C of 19.25.12.11 NMAC.

(7) Outlet works capacity. Dams shall be designed with a low level outlet to drain the entire contents above the elevation of the downstream toe of the dam. If environmental consequences prevent draining of the reservoir, the state engineer will grant a waiver if written justification is provided to the satisfaction of the state engineer. The outlet shall be sized to provide adequate capacity to satisfy water rights of downstream priority users. A stage discharge curve and table showing elevation in one-foot increments versus discharge capacity shall be prepared. The rating curve and table shall be from the invert of the outlet to the dam crest. The parameters used to calculate the outlet works capacity shall be justified and appropriate data sheets and computer program output computations from computerized analysis shall be provided. Elevations shall be based on North American vertical datum 1988 or more recent adjustment. The outlet works capacity shall meet the following minimum requirements:

(a) Outlets for water storage reservoirs shall drain in 45 days with supporting calculations provided.

(b) Outlets for flood control dams shall drain the reservoir in 96 hours unless a waiver is granted by the state engineer. The 96-hour time frame begins once the reservoir storage drops to the emergency spillway crest or reaches its peak during the 100-year, 24-hour event. Documentation supporting the waiver shall include the time to drain more frequent events.

(8) Outlet works design. The outlet works design includes the intake structure, conduit and terminal structure. The outlet works design shall meet the following minimum requirements:

(a) Minimum conduit diameter is 18 inches unless a waiver is granted by the state engineer. Documentation supporting a waiver shall include identification of methods to inspect the interior of the conduit.

(b) Metal conduits used in dams that are classified as significant hazard potential where the sole purpose of the dam is flood control, or in dams classified as low hazard potential, shall have adequate strength after corrosion for a minimum of 200 years, based on corrosivity testing of onsite soils. Cathodic or other protection of metal conduits is permissible and may be considered in this analysis. Metal conduits are not acceptable for dams classified as high hazard potential or dams classified as significant hazard potential with permanent water storage except as interior forms for cast-in-place concrete conduits.

(c) Outlet conduits for storage reservoirs shall be gated at the upstream end unless a waiver is granted by the state engineer. Where gates are located other than at the upstream end of the conduit, a guard gate or bulkhead shall be provided at the upstream end to allow draining of the conduit for inspection, maintenance and repair.

(d) Outlet conduits shall be adequately vented. Where the outlet conduit ties directly to a downstream pipe, a by-pass valve shall be provided.

(e) Outlet controls and equipment shall be properly designed to be secure from damage due to vandalism, weather, ice, floating debris, wave action, embankment settlement and other reasonably foreseeable causes. The outlet control operators shall remain accessible during outlet works and spillway releases.

(f) Outlets for flood control structures shall be ungated. Where a gate is required to satisfy downstream release restrictions, a waiver from the state engineer is required. The written request for waiver shall include a plan for timely release of the floodwater.

(g) Outlet works intake structures shall be provided with trash racks or grates to prevent clogging with debris. Grate opening size or bar spacing shall be adequate to satisfy applicable public safety requirements, if appropriate. Total size of grate openings must be at least three times the cross-sectional area of the outlet conduit.

(h) The design of the outlet works terminal structure shall address energy dissipation to prevent erosion and shall include supporting calculations.

(i) Outlet conduits shall be designed for full embankment loading and for hydrostatic pressure equal to the maximum reservoir head, acting separately and in combination, with an adequate factor of safety for the conduit material. If future increases in embankment height and/or reservoir head are foreseeable, allowance shall be made in the design.

(j) The conduit together with all joints and fittings shall be watertight at the design pressure and shall be pressure tested prior to backfilling. Conduits shall be designed for all reasonably foreseeable adverse conditions including corrosion, abrasion, cavitation, embankment settlement and spreading, thermal effects and seismic loading. The ability of the conduit to withstand deflection and separation at the joints shall be addressed in the design of the outlet conduit.

(k) Outlet works shall be supported by stable, well-consolidated foundation materials. Where the conduit is placed in embankment fill or native overburden materials, settlement analysis shall be performed.

(l) Minimizing seepage along conduits shall be addressed including the methods for ensuring compaction of backfill around and beneath the conduit.

(m) All supporting documentation and calculations for the outlet works design shall be provided. The outlet works design shall include all foreseeable loading conditions, including but not limited to ice loading, debris buildup, wave action and embankment settlement. Structural design calculations for the intake structure, conduit and outlet structure shall be submitted.

(9) Geological assessment. A geological assessment of the dam and reservoir site is required for all dams classified as high or significant hazard potential. The geological assessment may be included in the geotechnical investigation or seismic study, or may be submitted as a separate document. The geological assessment shall address regional geologic setting; local and site geology; geologic suitability of the dam foundation; slide potential of the reservoir rim and abutment areas; and seismic history and potential.

(10) Geotechnical investigation. A geotechnical investigation shall assess site conditions and support the design. A professional engineer licensed in the state of New Mexico qualified to provide geotechnical expertise in the design and construction of dams shall prepare, stamp and sign the geotechnical investigation, which may be submitted as a separate report. The scope of the geotechnical investigation is dependent on the size classification, hazard potential classification, anticipated materials and construction methods, site geology and seismicity, anticipated soil strata and other site-specific conditions. The geotechnical investigation shall include a field investigation and laboratory testing. Results of field and laboratory testing shall be presented in a report, including recommended parameters to be used in design and construction of the dam and appurtenant structures. The field investigation and laboratory testing shall include but not be limited to the following:

(a) test borings in the footprint of the embankment, spillway excavations and appurtenant structures extending to bedrock or to a depth equal to at least the height of the dam; where appropriate, borings may include coring of bedrock materials to determine the quality and character of the rock;

(b) standard penetration tests or other field-testing to assess soil character and consistency;

(c) "undisturbed" sampling for further tests such as insitu density, shear strength and compressibility;

(d) supplemental test pits, if deemed necessary, to obtain bulk and undisturbed samples, assess soil layering and measure bedrock orientation;

(e) measurement of water level in drill holes;

(f) field permeability testing, if feasible;

(g) logs of test borings and test pits, location map and profile along dam axis with soil information shown;

(h) testing to determine the relevant properties of the material to be used in construction, including but not limited to shear strength, permeability, compressibility and filter characteristics; the testing method shall conform to accepted industry standards and be appropriate for the material being tested;

(i) evaluation of liquefaction potential and dynamic shear strength testing if deformation analysis is required; and

(j) identification of the location of the borrow material to be used during construction.

(11) Seepage and internal drainage. The effects of seepage and potential for internal erosion shall be evaluated. A seepage analysis shall be performed to address the performance of the embankment under steady-state conditions for dams classified as high or significant hazard potential. All parameters and assumptions used in the analysis shall be summarized in a table and justified in the seepage analysis. A waiver may be requested in writing for flood control dams or reservoirs with synthetic liners. The seepage analysis and internal drainage design shall include but not be limited to the following:

(a) Flow nets of appropriate size and scale shall be prepared. The effects of anisotropy with respect to permeability shall be addressed. Ratios of horizontal to vertical permeability of less than 4 for constructed embankments and less than 9 for native deposits shall be supported by field and laboratory permeability tests. Appropriate data sheets and computer program output computations from computerized analysis shall be provided.

(b) The design shall address the effects of anticipated seepage beneath, around and through the dam. Seepage shall not exit on the dam face and excessive exit seepage gradients are unacceptable. All filter, transition and drainage zones within earth dams shall have a thickness adequate to address constructability and enhance seismic stability with a minimum thickness of 3 feet for each zone.

(c) Collector pipes and conduits for internal drains shall be made of non-corrodible material capable of withstanding the anticipated loads. If possible, pipes shall be located where they can be exposed for repair or replacement without threatening the stability of the dam. Collector pipes for drains shall be enveloped in a free-draining medium meeting filter criteria for adjacent embankment or foundation zones. Where surging or hydraulic gradient reversal is likely, perforation size must be less than the diameter at which 15 percent of the surrounding medium is finer. Where surging or hydraulic gradient reversal are unlikely, the perforation size must be less than the diameter at which 85 percent of the surrounding medium is finer.

(d) Drain pipes shall be sized to provide a flow depth no more than ¼ of the pipe diameter when carrying the anticipated discharge. Drain pipes shall be at least 6 inches in diameter unless the availability of technology for inspection and maintenance can be demonstrated. Individual pipes shall discharge to a gallery, well, manhole, or to daylight such that the flow of each pipe can be monitored and measured. Manifold connections, tees and wyes are not permitted. If the anticipated flow from a drain line exceeds 10 gpm, a measuring flume or weir shall be provided for that line. If the anticipated flow from a drain line is less than 10 gpm, the outfall shall be designed to allow a 5 gallon bucket to be used to collect and measure discharge. Where pipes from internal drains are discharged to daylight, a rodent screen shall be provided.

(12) Stability analysis. Cross-sectional design for dams shall be supported by slope stability analysis. Dams classified as low hazard potential with upstream slopes no steeper than 3 horizontal to 1 vertical, downstream slopes no steeper than 2 horizontal to 1 vertical and which are 25 feet or less in height will not require slope stability analysis. The analysis model shall adequately represent the geometry and zoning, shear strength parameters, material unit weights, pore pressure and seepage conditions, external loading and other relevant factors of the critical cross section or sections. Manual computations in the analysis will be accepted if judged to be sufficiently rigorous. Where appropriate, the analysis shall consider noncircular or block and wedge type failure surfaces as well as circular failures. All parameters and assumptions used in the analysis shall be summarized in a table and justified in the geotechnical investigation. A scale drawing, utilizing the same scale for vertical and horizontal dimensions, shall be provided for each cross-sectional model used in the analysis, with the critical failure surface(s) identified. Appropriate data sheets and computer program output computations from computerized analysis shall be provided. Dams shall be designed to provide the following minimum factors of safety from the stability analysis:

(a) 1.5 for steady state long-term stability;

(b) 1.5 for operational drawdown conditions;

(c) 1.2 for rapid drawdown conditions; and

(d) 1.2 for end of construction.

(13) Seismic design and analysis. Dams classified as high or significant hazard potential shall be analyzed for seismic stability. Seismic analysis for water storage dams shall be based on full reservoir under steady state seepage conditions. Flood control dams with ungated outlets that satisfy Subparagraph (b) of Paragraph (7) of Subsection C of 19.25.12.11 NMAC without waiver shall be designed for earthquake loads under empty reservoir conditions and need not consider steady-state seepage. Dams sited on active faults shall obtain a waiver from the state engineer. To obtain a waiver the analysis shall show that the location of the dam is unavoidable and the dam must be designed to withstand anticipated fault movement without compromising its integrity. Appropriate data sheets and computer program output computations from computerized analysis shall be provided. The seismic analysis shall meet the following minimum requirements:

(a) A seismological investigation for the dam area and reservoir area. This study may be part of the geological or geotechnical report for the structure, or may be a separate effort. The study shall determine and justify the appropriate seismic parameters to be used for design. The seismic parameters shall be based on the following design earthquake:

(i) Dams classified as high hazard potential other than flood control structures shall be designed for the maximum credible earthquake or for an earthquake with a 5000-year return frequency.

(ii) Dams classified as significant hazard potential or high hazard potential dams whose sole purpose is for flood control shall be designed for a 2% chance of occurrence in 50 years (approximately 2500-year return frequency).

(b) An analysis of materials in the foundation, reservoir area and proposed embankment shall be completed to determine the potential for liquefaction, earthquake-induced sliding, or other seismic sensitivity, which may be accomplished as part of the geotechnical investigation.

(c) Pseudostatic analysis will be acceptable for the following cases:

(i) the embankment is to be mechanically compacted to at least 95% of the maximum standard Proctor density, ASTM D 698, or at least 90% of the maximum modified Proctor density, ASTM D 1557 or

at least 70% relative density if Proctor testing is not appropriate; no materials prone to liquefaction are present in the foundation and peak bedrock acceleration is 0.20g or less; or

(ii) the embankment is to be mechanically compacted to at least 95% of the maximum standard Proctor density, ASTM D 698, or at least 90% of the maximum modified Proctor density, ASTM D 1557; potentially submerged portions of the embankment except for internal drain elements are constructed of clayey material; the dam is constructed on clayey soil or bedrock foundation and peak bedrock acceleration is 0.35g or less; and

(iii) all safety factor requirements in accordance with Subparagraphs (a) through (d) of Paragraph (12) of Subsection C of 19.25.12.11 NMAC are met;

(iv) minimum freeboard requirements in accordance with Subparagraphs (a) through (e) of Paragraph (15) of Subsection C of 19.25.12.11 NMAC are met; and

(v) the pseudostatic coefficient selected for analysis must be at least 50% of the predicted peak bedrock acceleration, but not less than 0.05g and the factor of safety under pseudostatic analysis shall be 1.1 or greater. In determining the factor of safety for pseudostatic analysis, a search for the critical failure surface shall be made.

(d) For dams not satisfying the requirements for pseudostatic analysis, a deformation analysis is required. The resulting embankment must be capable of withstanding the design earthquake without breaching and with at least 3 feet of freeboard remaining after deformation. The analysis shall also assess the potential for internal erosion as a result of cracking during deformation.

(e) The seismic assessment shall also address the stability of appurtenant structures to the dam during the design earthquake as appropriate, unless failure of an appurtenance due to earthquake does not represent an immediate threat to the dam, in which case the operating basis earthquake may be used.

(14) Dam geometry. The dam geometry shall be supported by the stability and seismic analysis and meeting the following minimum requirements:

(a) The crest width shall be at least equal to the dam height in feet divided by 5 plus 8 feet, with the minimum permissible crest width being 10 feet and the maximum required crest width being 24 feet.

(b) Roads located on the crest shall have appropriate surfacing to provide a stable base that resists rutting and provides adequate friction for safety in wet conditions.

(c) The crest design shall provide a minimum of 2 feet of cover or the depth of frost penetration; whichever is greater, above clay cores to prevent cracking of the core due to desiccation or frost penetration.

(d) Turnarounds should be provided on dead-end service roads on dam crests, located in such a manner that backing maneuvers longer than 300 feet are eliminated.

(e) The crest shall be provided with adequate cross slope to prevent ponding.

(f) The slope or slopes to which crest drainage is directed must be provided with adequate erosion protection to accept the crest drainage.

(g) The crest longitudinal profile shall be provided with adequate camber to maintain the profile after embankment settlement. Camber should be based on settlement analysis and shall be at least 2 percent of the total embankment height, with a minimum of 1 foot at the highest point of the dam. The tops of internal core zones shall also be provided with camber in a similar manner to the crest of the dam.

(h) In the event that safety berms, street curbs, or other longitudinal features which block, control, or concentrate drainage are required on the dam crest, the design shall provide for collection and conveyance of accumulated water to discharge away from the embankment without erosion.

(15) Freeboard. Dams shall be provided with adequate freeboard. Wave runup shall be determined taking into consideration wind speed, reservoir fetch, embankment slope and roughness of the slope surface. Freeboard shall satisfy the following conditions:

(a) Anticipated wave runup resulting from a 100 mph wind with reservoir level at the spillway crest will not overtop the dam.

(b) Anticipated wave runup resulting from a 50 mph wind with maximum reservoir level from routed spillway design flood will not overtop the dam.

(c) Clay core cover and capillary rise requirements in accordance with Subparagraph (c) of Paragraph (14) of Subsection C of 19.25.12.11 NMAC are satisfied.

(d) A minimum of 3 feet of freeboard remains after seismic deformation.

(e) In any case, at least 4 feet of freeboard shall be provided. The minimum of 4 feet of freeboard may be waived for perimeter embankments with no spillway, provided a written request is made to the state engineer accompanied with supporting justification.

(16) Erosion protection. Erosion protection shall be addressed to protect the dam and appurtenant structures from erosion that can threaten the safety of the structure. At a minimum, the following areas of erosion shall be addressed:

(a) Wave erosion. The upstream slope shall be protected from wave erosion. The material selected and area of coverage shall be appropriate for the protection required with justification provided. Flood control dams in compliance with Subparagraph (b) of Paragraph (7) of Subsection C of 19.25.12.11 NMAC without waiver are exempt from wave protection.

(b) Surface erosion. The slope, crest, abutment and groins, toe areas and any other constructed areas associated with the dam and appurtenant structures shall be protected from surface erosion and concentrated flows. The material selected and area of coverage shall be appropriate for the protection required with justification provided.

(17) Geotextile design. Geotextiles are an acceptable material for use in dam design if the geotextile is placed so that it does not jeopardize the dam or appurtenant structures during repair or failure of the geotextile. The geotextile material shall be used in accordance with the manufacturer's recommendations and intended use for the product. Installation shall be by certified personnel and the completed installation certified by installer or manufacturer, if required by the manufacturer.

(18) Structural design. The structural design information for all appurtenant structures, addressing water, earth, ice and any other applicable load shall be provided. Reinforced concrete design including assumptions for loads and limiting stresses and sample calculations shall be provided. Appropriate data sheets and computer program output computations from computerized analysis shall be provided.

(19) Utilities design. Utility placement or relocation shall be addressed as applicable. Utilities located in the vicinity of the proposed embankment footprint should be relocated and trenches backfilled and compacted with suitable material to the satisfaction of the state engineer. If utilities are allowed to remain, they will be required to satisfy applicable provisions for outlet conduits in accordance with Paragraph (8) of Subsection C of 19.25.12.11 NMAC.

(20) Miscellaneous design. Because each design is unique, all design elements not specifically addressed in these regulations shall be documented and justified with sample calculations and appropriate data sheets and computer program output computations from computerized analysis shall be included in the design report.

D. Construction drawings: A professional engineer licensed in the state of New Mexico qualified in dam design and construction shall prepare the construction drawings. Illegible, mutilated, careless or otherwise poorly prepared drawings are not acceptable for filing with the state engineer. Plan drawings and maps prepared with the aid of a computer require the submittal of the digital data files in tagged image file format or other format acceptable to the state engineer. The preparation of construction drawings is described below and shall include the following items:

(1) Quality. Construction drawings and maps shall be made from actual field or photogrammetric surveys of an accuracy acceptable to the state engineer. Construction drawings and maps shall be prepared with permanent black ink on mylar. All original signatures, dates and acknowledgments appearing on the sheet(s) shall be in permanent ink. Plan drawings and maps shall always be rolled, never folded, for transmittal.

(2) Scale and size. Sheets shall be twenty-four (24) inches by thirty-six (36) inches with one (1) inch margins on all sides. The scale(s) used on the drawings may vary according to requirements and space available to show all necessary data in detail clearly in feet and decimals and to be clearly legible when the drawings are reduced to eleven (11) inches by seventeen (17) inches. Detailed dimensions of appurtenant structures shall be given in feet and inches. All sheets shall have bar scales in order to allow scaling of reduced drawings.

(3) Sheet numbers. Each sheet shall be numbered sequentially with the first sheet being sheet number one in conjunction with the total numbered sheets (example Sheet 1 of 5). The sheet number on the last sheet shall equal the total number of sheets.

(4) Engineer's seal and signature. Each sheet shall have the responsible engineer's seal and signature.

(5) Orientation and date. The direction of north and the basis of bearings shall be shown on all maps. The date that field surveys are made or the date of the aerial photography used shall be shown on the maps.

(6) Title sheet. The first sheet of a set of plans is the title sheet. The title sheet shall only contain sufficient information to summarize the scope of the project, the title of the project and signed certifications for the

dam owner, engineer and state engineer in accordance with Subsections A, B and E of 19.25.12.12 NMAC. The title sheet shall summarize the properties of the dam and shall include the following information, as appropriate:

(a) name of the dam (same as shown on the application);
(b) type of dam (material);
(c) hazard potential classification;
(d) maximum height above the downstream toe in feet;
(e) maximum length in feet;
(f) crest width in feet;
(g) slope of the upstream face (horizontal to 1 vertical);
(h) slope of the downstream face (horizontal to 1 vertical);
(i) elevation of the dam crest;
(j) elevation of spillway crest;
(k) elevation of outlet conduit flow line;
(l) freeboard in feet;
(m) maximum spillway discharge capacity in cubic feet per second;
(n) type of outlet conduit (give size and material);
(o) maximum outlet conduit discharge capacity in cubic feet per second; and
(p) location of the outlet works intake structure (using latitude and longitude or to the New Mexico state plane coordinate system).

(7) Vicinity map. A vicinity map of sufficient scale and size to locate the pertinent area shall be shown on the title sheet or second sheet of the drawings.

(8) Site topography. A detailed topography of the dam site including sufficient area upstream and downstream and at the abutments shall be provided. Elevations shall be based on North American vertical datum 1988 or more recent adjustment.

(9) Design details. Detailed information of the various construction features including plan view, elevations, cross-sections at the maximum section and along the outlet works, profile along and section through the centerline of the dam showing construction features and cross-sections and a profile of the emergency spillway with dimensions and construction details shall be provided. Any other information necessary for the state engineer to determine the feasibility and safety of the dam shall be required.

(10) Reservoir area, capacity and high water line traverse. The topography of any proposed reservoir site shall be determined to industry standards and a contour map with a contour interval of 1 foot shall be prepared. Elevations of the contours shall be tied to the North American vertical datum of 1988 or more recent adjustment. The high water line at the elevation of the dam crest will be highlighted on the contour map. A curve or table of elevation versus area and storage capacity for the reservoir shall be prepared from the contour map. The curve or table shall be from the bottom of the reservoir to the dam crest. Area shall be provided in acres and storage capacity in acre-feet.

(11) Point of outlet. A location of the outlet works shall be referenced using latitude and longitude or to the New Mexico state plane coordinate system.

(12) Permanent bench mark. A permanent bench mark shall be established above the high water line at a location unlikely to settle or be disturbed. The North American vertical datum of 1988 or more recent adjustment and latitude and longitude or the New Mexico state plane coordinate system for the bench mark elevation and location shall be provided. A detail of construction of the permanent bench mark shall be provided.

E. Specifications: Specifications shall be prepared for each project describing work to be done and materials to be used to supplement construction drawings. Specifications must be clear and concise and include detailed methods of construction, qualities and sizes of materials, unit amounts to be used and methods of testing and quality control, construction supervision and inspection. Specifications shall be prepared by a professional engineer licensed in the state of New Mexico qualified in the design and construction of dams. The specifications shall meet the following requirements:

(1) The front cover of the specifications shall show the name of the dam (identical to the application) and the county in which the dam is located. The first page behind the front cover shall show the name of the dam (identical to the dam name on the application), the county in which the dam is located, signed certifications for the engineer and state engineer in accordance with Subsections B and E of 19.25.12.12 NMAC and a statement recognizing the authority of the state engineer. An approved model statement recognizing the authority of the state engineer is provided below. Changes to the model statement require prior approval of the state engineer.

"All construction shall be performed in strict accordance with the accepted plans and specifications. Representatives of the state engineer shall have full authority to perform inspections during construction and shall have full power to act pursuant to the law and in accordance with Title 19, Chapter 25, Part 12, Dam Design, Construction and Dam Safety of the New Mexico Administrative Code if plans and specifications are not followed."

(2) The specifications shall be indexed.

(3) The specifications shall be bound and submitted on a good grade of white 8 1/2-inch by 11-inch paper.

(4) The general conditions shall include statements that the construction drawings and specifications cannot be significantly changed without the prior written approval of the state engineer.

F. Boundary, easement or right of way plat of survey: A professional surveyor licensed in the state of New Mexico shall prepare a plat of survey showing the dam owner's property boundaries or easement and/or right of way granted by the land owner. The plat of survey shall be prepared in conformance with the requirements as set forth in the Minimum Standards for Surveying in New Mexico, 12.8.2 NMAC. The plat of survey shall clearly state to whom an easement is granted and what rights are conveyed with the easement. The plat of survey shall show the footprint of the dam and appurtenant structures and the high water line in the reservoir. The plat of survey shall be submitted with the construction drawings and recorded with the county clerk of the county or counties in which the survey is located. A certificate signed by the surveyor in accordance with Subsection C of 19.25.12.12 NMAC shall appear on the plat of survey. A certified copy of the recorded plat of survey bearing the recorded page and endorsement of the county clerk shall be submitted to the state engineer for filing upon completion of construction. Adequate property ownership, easement or right of way shall be required for the following conditions:

(1) to access the dam and outlet controls during normal and flood events;

(2) to prevent development encroachment into the reservoir area defined by normal operation and the spillway design flood;

(3) to prevent development in the approach, control and discharge section of the spillway that may restrict flow through the spillway;

(4) to return outlet works and spillway discharge to the natural drainage and allow the outlet works to discharge freely; and

(5) to perform maintenance on the dam, appurtenant structures and surrounding areas to ensure the safe performance of the dam.

G. Dam site security: Dams classified as high or significant hazard potential shall address security at dams to prevent unauthorized operation or access. If in the opinion of the state engineer, the failure of the dam will result in catastrophic consequences, a security and risk management program for the dam will be required. Elements of a security and risk management program are:

(1) threat, vulnerability and risk assessments;

(2) physical security plans; and

(3) integration of security operational procedures.

H. Instrumentation plan: An instrumentation plan providing the ability to monitor and evaluate the performance of a dam is required for dams classified as high or significant hazard potential. The instrumentation plan may be submitted as a separate report or part of the operation and maintenance manual. Minimum requirements of the instrumentation plan shall include:

(1) general description of instrumentation;

(2) reading schedule;

(3) identification of critical readings;

(4) specifics for each installation including:

(a) detailed description of installations;

(b) purpose of the instrumentation;

(c) reading and maintenance schedule instructions; and

(5) special instrumentation or monitoring requirements.

I. Operation and maintenance manual: An operation and maintenance manual is required for dams classified as high or significant hazard potential. The operation and maintenance manual identifies activity necessary to address the continued safe operation, maintenance and overall performance of the dam. Any restrictions imposed by the design shall be addressed in the operation and maintenance manual. The operation and maintenance manual shall conform to the requirements set forth in 19.25.12.17 NMAC.

J. Emergency action plan: An emergency action plan is required for dams classified as high or significant hazard potential. The emergency action plan identifies potential emergency conditions at a dam and specifies preplanned actions to be followed to minimize property damage and loss of life. The emergency action plan shall conform to the requirements set forth in 19.25.12.18 NMAC.
[19.25.12.11 NMAC - N, 3/31/2005]

19.25.12.12 CERTIFICATIONS: Signed certifications by the dam owner, engineer, surveyor, state office of emergency management and the state engineer are required by these regulations on specific documents. Approved model certifications for the dam owner, engineer, surveyor, state office of emergency management and state engineer are provided below. Changes to the model certifications require prior approval of the state engineer.

A. DAM OWNER'S CERTIFICATE: A certificate followed by the dated signature of the dam owner and notary public acknowledgment is required on the title sheet of the construction drawings and first page behind the front cover of the operation and maintenance manual and emergency action plan. The following model certification is considered to be an example of the minimum that the dam owner shall certify. If the dam owner is a corporation, political subdivision or other governmental entity a model certificate is also provided.

state of _____)
) ss.
county of _____)

I, (dam owner's name) , being first duly sworn, upon my oath, state that I have read and examined the accompanying _____ (construction drawings consisting of ____ sheets, operation and maintenance manual, or emergency action plan) and know the contents and representations therein for _____ dam and all that is shown herein is done with my free consent and in accordance with my wishes and state that the same are true and correct to the best of my knowledge and belief.

_____
Dam owner signature Date

Subscribed and sworn to before me this _____ day of _____ , 20__.

_____
Notary public

My commission expires _____ (SEAL)

If a claimant is a corporation, political subdivision or other governmental entity the following shall be used:

state of _____)
) ss.
county of _____)

I, (representative's name), being first duly sworn, upon my oath, state than I am the _____ (officer) of the _____, a corporation duly organized under the laws of the state of _____, that the accompanying _____ (construction drawings consisting of ____ sheets, operation and maintenance manual, or emergency action plan) for _____ dam were made under authority of the board of directors of said corporation and that, in their behalf, I have read and examined the statements and representations and all that is shown herein is done with their free consent and in accordance with their wishes and state that the same are true and correct to the best of my knowledge and belief.

_____
Representative signature, title Date

Subscribed and sworn to before me this _____ day of _____ , 20__.

_____
Notary public

My commission expires _____ (SEAL)

B. ENGINEER'S CERTIFICATE: A certificate followed by the dated signature, license number and seal of the engineer responsible for preparing the design report, construction drawings, specifications, operation and maintenance manual and engineering elements of the emergency action plan is required. The certificate shall be placed on the title sheet of the construction drawings and first page behind the front cover of the design report, specifications, operation and maintenance manual and emergency action plan. The following model certification is considered to be an example of the minimum that the engineer should certify to:

state of _____)
) ss.
county of _____)

I, (engineer's name) , hereby certify that I am a professional engineer licensed in the state of New Mexico, qualified in _____ (civil, geotechnical, etc.) engineering; that the accompanying _____ (design report, construction drawings consisting of ____ sheets, specifications, operation and maintenance manual, or _____ elements of the emergency action plan) was prepared by me or under my supervision; that the accompanying _____ (design report, construction drawings consisting of ____ sheets, specifications, operation and maintenance manual, or _____ elements of the emergency action plan) is in compliance with the Dam Design, Construction and Dam Safety Regulations (19.25.12 NMAC) and that the same are true and correct to the best of my knowledge and belief.

(Engineer's signature), License number _____, (SEAL)
Engineer's name

Date submitted _____

C. SURVEYOR'S CERTIFICATE: The professional surveyor licensed in the state of New Mexico preparing the plat of survey showing property boundaries, acquired easements or rights-of-way shall include a certificate on the plat of survey as modeled in Paragraph (2) of Subsection J of 12.8.2.9 NMAC, the Minimum Standards for Surveying in New Mexico. The following model certificate is considered to be an example of the minimum that the surveyor should certify to:

I, (surveyor's name) , New Mexico professional surveyor no. (surveyor's license number), do hereby certify that this (boundary, easement, or right of way) plat of survey and the actual survey on the ground upon which it is based were performed by me or under my direct supervision; that I am responsible for this survey; that this survey meets the Minimum Standards for Surveying in New Mexico; and that it is true and correct to the best of my knowledge and belief. I further certify that this survey is not a land division or subdivision as defined in the New Mexico Subdivision Act and that this instrument is a (boundary, easement, or right of way) plat of survey of _____ dam.

(Surveyor's signature), License number _____, (SEAL)
Surveyor's name

Date submitted _____

D. STATE OFFICE OF EMERGENCY MANAGEMENT: A certificate form for the state office of emergency management acceptance shall be placed on the first page behind the front cover of the emergency action plan. This certificate is to be signed by state office of emergency management after all necessary corrections or additions, if any, have been made.

state of _____)
) ss.
county of _____)

I hereby certify that the accompanying emergency action plan for _____ dam has been duly examined by me and accepted for filing on the _____ day of _____, 20__.

_____
State office of emergency management

E. STATE ENGINEER'S CERTIFICATE: A certificate form for the state engineer acceptance shall be placed on the title sheet of the construction drawings and first page behind the front cover of the design report, specifications, operation and maintenance manual and emergency action plan. This certificate is to be signed by the state engineer or his representative after all necessary corrections or additions, if any, have been made.

state of _____)
) ss.
county of _____)

I hereby certify that the accompanying _____ (design report, construction drawings, specifications, operation and maintenance manual or emergency action plan) for _____ dam and appurtenant structures has been duly examined by me and accepted for filing on the _____ day of _____, 20__.

_____
State engineer

[19.25.12.12 NMAC - N, 3/31/2005]

19.25.12.13 CONSTRUCTION AND OPERATION CONDITIONS: After reviewing the required documentation, the state engineer will notify the dam owner if any deficiencies are found with the submittal to construct and operate a dam. The dam owner will be given an opportunity to correct any deficiencies noted in the review process. Once all deficiencies have been addressed the state engineer will approve the application for permit to construct and operate a dam with conditions under which construction and operation shall occur. Failure to comply with conditions of the approved permit may result in the state engineer issuing an order to redesign, reconstruct or restrict operation of the dam and reservoir until conditions are met. Construction must be completed within two years of approving the application unless an extension of time for the construction is requested and approved by the state engineer. The conditions of construction and operation shall include, but not be limited to the following:

A. Engineer supervising construction: Prior to initiation of construction, the dam owner shall designate a professional engineer licensed in the state of New Mexico qualified in the design and construction of dams to supervise construction. If the state engineer finds the engineer acceptable, an order is issued approving the engineer and setting forth conditions under which the engineer will supervise construction. Conditions shall include, but shall not be limited to:

(1) The engineer supervising construction shall submit monthly progress reports including summary of test results, problems encountered and their solutions.

(2) Construction shall be in accordance with accepted drawings and specifications. State engineer approval of any modifications to the accepted drawings or specifications is required prior to undertaking the modifications. Requests for changes or modifications by the engineer supervising construction shall be submitted in writing, supported with appropriate documentation.

(3) The engineer supervising construction shall provide the state engineer a minimum of 72 hours notice to perform inspections as specified in the conditions of construction.

(4) Upon completion of construction, the engineer supervising construction shall submit to the state engineer the following items:

(a) a completion report, which shall include descriptions of problems and their solutions;

(b) a summary of materials test data and labeled and dated construction photographs;

(c) record mylar construction drawings including signed certifications on the title sheet; and

(d) a certificate that the dam was constructed in accordance with the accepted drawings and specifications and is in satisfactory condition. An approved model certificate for the engineer supervising construction is shown below. Changes to the language in the certification require prior approval by the state engineer.

state of _____)
) ss.
county of _____)

I, _____, (engineer's name) state that I am a qualified professional engineer licensed in the state of New Mexico, that I have inspected the _____ dam and appurtenant structures and find them to be completed in accordance with the record construction drawings and specifications and are now in a satisfactory condition for acceptance.

(Engineer's signature)____ License number _____, (SEAL)
Engineer's name

Date submitted _____

B. State engineer's authority during construction: The state engineer may perform inspections at any time during construction of the dam and appurtenant structures. Inspections will vary with each project, based on the complexity of the design. Inspection of specific construction items are standard construction conditions in the permit and require the engineer supervising construction to provide the state engineer with a minimum of 72 hours advanced notice. If the state engineer receives a minimum of 72 hours advanced notice, a delay of construction to schedule a state engineer inspection is not required. State engineer inspection fees are charged in accordance with Subsection D of 19.25.12.8 NMAC. Fees for inspection of construction by the state engineer not paid on demand shall become a lien on any land or other property of the dam owner and may be recovered by the state engineer.

C. Completion of construction: Upon completion of construction, a proof of completion of works form for the dam shall be submitted in accordance with 19.25.12.14 NMAC. Owners of dams classified as high or significant hazard potential shall submit to the state engineer an updated operation and maintenance manual in accordance with 19.25.12.17 NMAC and an updated emergency action plan in accordance with 19.25.12.18 NMAC incorporating any modifications made during construction. Upon the satisfactory completion of all conditions in the permit, pending the issuance of a certificate of construction and license to operate a dam, use of the reservoir shall require written permission from the state engineer. Use of the dam and reservoir are restricted until the state engineer accepts the updated operation and maintenance manual and emergency action plan, if required.

D. Extension of time for construction: The state engineer will grant an extension of time for completing construction upon proper showing by the dam owner of due diligence or reasonable cause for delay and accompanied with a fee in accordance with Subsection C of 19.25.12.8 NMAC. An affidavit by a professional engineer licensed in the state of New Mexico qualified in the design and construction of dams shall be filed with the state engineer providing evidence that the design of the dam meets or exceeds the design requirements in accordance with 19.25.12.11 NMAC. An extension of time may be granted for a period not to exceed five (5) years. No extension of time shall be granted which in combination extend the time allowed by the permit beyond ten (10) years from the initial date of approval of the application, unless the state engineer in his discretion expressly waives this limitation pursuant to NMSA 1978, Section 72-5-14. Failure to request an extension of time shall result in cancellation of the permit by the state engineer.
[19.25.12.13 NMAC - N, 3/31/2005]

19.25.12.14 PROOF OF COMPLETION OF WORKS: Upon completion of all construction conditions a proof of completion of works for the dam shall be filed on a form provided by the state engineer with appropriate fees in accordance with Subsection E of 19.25.12.8 NMAC. The proof of completion of works for the dam shall be filed with original signature of the dam owner and engineer supervising construction.
[19.25.12.14 NMAC - N, 3/31/2005]

19.25.12.15 CERTIFICATE OF CONSTRUCTION OF A DAM: Upon receipt of the proof of completion of works form, the state engineer will determine if all construction conditions of the permit were met. Upon a

determination by the state engineer that all construction conditions have been complied with, the state engineer shall issue a certificate of construction. The certificate of construction shall address the general properties of the dam and appurtenant structures. The dam owner shall record the certificate of construction with the county clerk of the county within which the works are located.
[19.25.12.15 NMAC - N, 3/31/2005]

19.25.12.16 LICENSE TO OPERATE A DAM: Upon issuance of a certificate of construction the state engineer shall issue a license to operate a dam. The license to operate a dam shall address operation conditions and dams shall be operated in accordance with the operation conditions. In addition, dams classified as high and significant hazard potential shall operate in accordance with the operation and maintenance manual and emergency action plan prepared in accordance with Sections 17 and 18 of 19.25.12 NMAC. Failure to comply with the conditions of the license to operate a dam may result in a state engineer order that limits operation, requires specific action by the owner and if necessary the license to operate a dam may be revoked by the state engineer. If a license to operate a dam is revoked the state engineer may order the dam breached in accordance with Subsections B or C of 19.25.12.19 NMAC.
[19.25.12.16 NMAC - N, 3/31/2005]

19.25.12.17 OPERATION AND MAINTENANCE MANUAL: Owners of dams classified as high or significant hazard potential shall prepare, maintain and adhere to an operation and maintenance manual that addresses the continued safe operation, maintenance and performance of the dam. Because each site, design and operating practice is unique, waivers of specific requirements in this section will be considered on a case-by-case basis. Request for waiver shall be in writing accompanied with documentation justifying the request. If the request is not justified to the satisfaction of the state engineer the request will be denied. A professional engineer licensed in the state of New Mexico qualified in the design and construction of dams shall prepare the operation and maintenance manual. The front cover shall show the name of the dam (identical to the application), the county in which the dam is located and type of report. The first page behind the front cover shall show the name of the dam (identical to the dam name on the application), the county in which the dam is located and signed certifications for the dam owner, engineer and state engineer in accordance with Subsections A, B and E of 19.25.12.12 NMAC. Operation or maintenance of the dam in violation of the procedures presented in the accepted operation and maintenance manual that affect the safety of the dam will result in an order being issued requiring the dam owner to address the problem. Failure to comply with orders issued by the state engineer may result in the license to operate the dam being revoked and the dam being ordered breached in accordance with Subsection B or C of 19.25.12.19 NMAC. Generally, the operation and maintenance manual shall address the following, with modification depending on the specific dam application:

A. Project information: General information on the project including the purpose, location, history, responsibilities and description and properties of the dam and appurtenant structures shall be required.

B. Operation: Operation instructions for the project shall include but not be limited to the following:

(1) Reservoir:

(a) storage allocations;

(b) spillway design flood water level;

(c) emergency reservoir evacuation procedures and maximum discharge rate; and

(d) first filling criteria and monitoring requirements.

(2) Outlet works:

(a) first operation;

(b) seasonal startup;

(c) seasonal shutdown;

(d) installation and removal of bulkhead;

(e) operation procedures for specific equipment; and

(f) electrical systems and controls.

C. Instrumentation: The following elements for monitoring instrumentation shall be addressed

(1) general description;

(2) purpose;

(3) critical readings;

(4) reading and maintenance procedures; and

(5) reading schedule.

D. Maintenance: Maintenance requirements and schedule shall be included.

E. Inspection: Inspection requirements, schedule and recommended checklist shall be included.

F. Updates and revisions: An update and revision procedure shall be included.

G. Appendices: Appendices to include any design consideration and the instrumentation plan to ensure any restrictions imposed by the design are incorporated into the operation and maintenance manual shall be included. Copies of inspections forms and any other information that supports and supplements the material used in the development and maintenance of the operation and maintenance manual.

[19.25.12.17 NMAC - N, 3/31/2005]

19.25.12.18 EMERGENCY ACTION PLAN: Owners of dams classified as high or significant hazard potential shall prepare, maintain and exercise an emergency action plan for immediate action in the event of a potential dam failure. The emergency action plan shall follow the format provided by the state engineer or a format that has prior approval of the state engineer. Because each site and operating practice is unique, waivers of specific requirements in this section will be considered on a case-by-case basis. Request for waiver shall be in writing accompanied with documentation justifying the request. If the request is not justified to the satisfaction of the state engineer the request will be denied. The front cover shall show the name of the dam (identical to the application), the county in which the dam is located and type of report. The pages immediately behind the front cover shall show the name of the dam (identical to the dam name on the application), the county in which the dam is located and signed certifications for the dam owner, engineer, state office of emergency management and state engineer in accordance with Subsections A, B, D and E of 19.25.12.12 NMAC. The dam owner shall coordinate with the local emergency management office in preparing the emergency action plan. The coordination is required to ensure that there is an agreement on responsibilities. The dam owner shall submit a copy to the state office of emergency management for acceptance prior to submittal to the state engineer. The dam owner shall review the emergency action plan annually, update as necessary and furnish a copy of updates to the state engineer, state office of emergency management and all copyholders. The dam owner shall exercise the emergency action plan to verify those involved in its implementation know their roles and responsibilities. It is recommended the dam owner conduct a functional exercise of the emergency action plan every 5 years with a table top exercise conducted 2 to 3 years before the functional exercise. The exercise may result in updates to ensure the emergency action plan maintains operational readiness, timeliness and responsiveness. Failure to act in accordance with the accepted emergency action plan that affects the safety of the dam will result in an order being issued requiring the dam owner to address the problem. Failure to comply with orders issued by the state engineer may result in the license to operate the dam being revoked and the dam being ordered breached in accordance with Subsection B or C of 19.25.12.19 NMAC. A professional engineer licensed in the state of New Mexico qualified in the design and construction of dams shall prepare engineering elements of the emergency action plan as specified below. An emergency action plan shall contain the following minimum elements:

A. Notification flowchart: A notification flowchart showing who is to be notified, by whom and in what priority.

B. Emergency detection, evaluation and classification: Procedures for reliably and timely identifying an emergency situation to ensure that an appropriate course of action is implemented. A professional engineer licensed in the state of New Mexico qualified in the design and construction of dams shall prepare this element.

C. Responsibilities: A list designating responsibilities for the emergency action plan related tasks including, but not limited to developing, maintaining, exercising, implementing, warning, evacuation and termination of the emergency.

D. Preparedness: A list of materials, equipment and manpower available to moderate or alleviate the effects of a dam failure or spillway release. A professional engineer licensed in the state of New Mexico qualified in the design and construction of dams shall prepare this element.

E. Inundation map: An inundation map delineating the areas that will be flooded as a result of dam failure. The dam breach analysis shall be prepared in accordance with Subparagraphs (a) through (g) of Paragraph (1) of Subsection C of 19.25.12.11 NMAC for the failure with the water level at the reservoir storage capacity and at the maximum water level during the spillway design flood event. If a dam is located upstream, failure scenarios with the upstream dam shall also be evaluated. Flood control dams that have not experienced a fill to the spillway crest shall prepare a failure scenario with the water level at the spillway crest. Flood inundation maps shall also be prepared for the maximum release without failure of the dam. Evaluation of the effects of flooding from dam failure shall extend at least to the location downstream where the flood no longer poses a threat to life or property. A

professional engineer licensed in the state of New Mexico qualified in the design and construction of dams shall prepare this element.

F. Appendices: All information that supports and supplements the material used in the development and maintenance of the emergency action plan.

[19.25.12.18 NMAC - N, 3/31/2005]

19.25.12.19 CHANGES TO AN EXISTING DAM: A dam owner proposing to reconstruct, enlarge, modify, restore reservoir capacity, repair, remove or breach an existing dam must make application to and receive approval from the state engineer prior to undertaking any such action. The current condition of the dam, the type of repair or modification and the proposed means to achieve the repair or modification shall dictate the detail of the information provided to the state engineer in order to obtain approval. Because each site, design change and operating practice is unique, waivers of specific requirements in this section will be considered on a case-by-case basis. Request for waiver shall be in writing accompanied with documentation justifying the request. If the request is not justified to the satisfaction of the state engineer the request will be denied. Existing dams present the same hazards to life and property downstream as new dams. Therefore, owners of dams classified as high or significant hazard potential shall evaluate the current condition of the dam and address in the submittal to the state engineer whether the dam is in compliance with the design requirements in Subsection C of 19.25.12.11 NMAC. If the state engineer determines compliance with requirements in Subsection C of 19.25.12.11 NMAC are critical to the safety of the dam, the state engineer shall issue an order requiring the deficiency be addressed as part of the proposed change. Owners of dams classified as low hazard potential shall comply with the design requirements in Subsection C of 19.25.12.11 NMAC for the proposed change only. Maintenance activity performed in accordance with 19.25.12.17 NMAC does not require prior state engineer approval. Dam owners shall not abandon a dam without breaching or removing the dam to ensure the dam no longer poses a risk to life, property, the environment surrounding the dam or downstream of the dam. In the event of any changes of ownership affecting the title to a dam, the new owner shall file a change of ownership form for a dam with the state engineer. Recognition of the responsibility and liability associated with dam ownership is required along with fees for filing the change in ownership form for a dam in accordance with Subsection F of 19.25.12.8 NMAC. This section exempts federal dams if no change to the water storage permit is required. In general, the following minimum submittal is required to make changes to an existing dam:

A. Proposed changes to an existing dam: For dam owners proposing to reconstruct, enlarge, modify, restore reservoir capacity, or repair an existing dam, the following supporting documentation is required prior to undertaking any such action:

(1) An amended application if properties of the dam and appurtenant structures change. Fees for filing the amended application and for reviewing drawings and specifications shall be in accordance with Subsections A and B of 19.25.12.8 NMAC. Fees are waived if the state engineer requires the change to address a dam safety deficiency.

(2) Documentation of sufficient water rights if changes in storage or release requirements are proposed in accordance with the requirements of Subsection B of 19.25.12.11 NMAC.

(3) A design report addressing the proposed change in accordance with the requirements of Subsection C of 19.25.12.11 NMAC. Owners of dams classified as high or significant hazard potential shall submit a design report addressing whether the existing condition of the dam is in compliance with the design requirements listed in Subsection C of 19.25.12.11 NMAC. Where the existing condition of the dam is not in compliance with the design requirements of Subsection C of 19.25.12.11 NMAC, the design report shall propose changes to address compliance with the design requirements of Subsection C of 19.25.12.11 NMAC or request a waiver that the deficiency is not critical to the safety of the dam and provide adequate justification for the waiver.

(4) Construction drawings and specifications addressing the proposed change in accordance with the requirements of Subsections D and E of 19.25.12.11 NMAC.

(5) A plat of survey showing the dam owner's property boundaries, easement, or right of way. The plat of survey shall be in accordance with the requirements of Subsection F of 19.25.12.11 NMAC.

(6) For dams classified as high or significant hazard potential, a dam site security assessment in accordance with the requirements of Subsection G of 19.25.12.11 NMAC.

(7) For dams classified as high or significant hazard potential, an instrumentation plan in accordance with the requirements of Subsection H of 19.25.12.11 NMAC.

(8) For dams classified as high or significant hazard potential, an updated operation and maintenance manual and emergency action plan in accordance with the requirements of Sections 17 and 18 of 19.25.12 NMAC.

B. Removal or breach of dams classified as high or significant hazard potential: Dam owners intending to breach or remove a dam classified as high or significant hazard potential shall submit a plan to the state engineer for approval prior to breaching or removing the dam. The plan shall evaluate the potential effects of the dam removal or breach on life, property and the environment downstream. A professional engineer licensed in the state of New Mexico qualified in the design and construction of dams shall prepare the plan. The state engineer will revoke the license to operate a dam upon completion of all construction conditions. The plan shall meet the following conditions:

(1) The reservoir shall be emptied in a controlled manner, which will not endanger lives or damage property downstream.

(2) The dam or breach area shall be excavated down to the level of natural ground and the breach shall be of sufficient width to safely pass the 100-year, 24-hour flood.

(3) The side slopes of the breach shall be excavated to a stable angle.

(4) The breach shall be armored as necessary to prevent erosion of the breach area.

(5) The plan shall control sediment previously deposited in the reservoir.

(6) Drawings and specifications shall be prepared in accordance with the appropriate requirements listed in Subsections D and E of 19.25.12.11 NMAC and shall include a title sheet with required certifications and signatures, the location, dimensions and lowest elevation of the breach and any other detail to sufficiently describe the proposal.

(7) Designation of the professional engineer licensed in the state of New Mexico qualified in the design and construction of dams that will supervise construction of the breach or dam removal. Submittal of the professional engineer's qualifications for state engineer approval is required.

C. Removal or breach of dams classified as low hazard potential: Owners of dams classified as low hazard potential shall submit a written notice to the state engineer of intent to breach the dam. The state engineer will revoke the license to operate a dam upon completion of all construction conditions. The breach notice shall meet the following minimum requirements:

(1) The bottom width elevation of the breach shall be to original ground.

(2) The bottom width of the breach shall be a minimum of one-half the height of the dam but not less than 10 feet.

(3) The side slopes not steeper than one horizontal to one vertical.

(4) The excavated material shall not be placed in the streambed.

D. Closure of a tailings facility. A closure plan is prepared to address the closure of a tailings facility. State engineer approval is required before any modification occurs to a jurisdictional tailings dam. A professional engineer licensed in the state of New Mexico qualified in the design and construction of tailings dams shall prepare the closure plan, which shall include a design report, drawings and specifications prepared in accordance with the appropriate requirements listed in Subsections C, D and E of 19.25.12.11 NMAC. The state engineer will revoke the license to operate a dam upon completion of all construction conditions. The plan shall address the following issues:

(1) long-term stability under static and dynamic conditions;

(2) control of surface runoff to avoid erosion;

(3) plan for long term monitoring, if appropriate; and

(4) identification of an engineer licensed in the state of New Mexico qualified in tailings dam design and construction to supervise implementation of the closure plan. Submittal of the engineer's qualifications for state engineer approval is required.

E. Construction and operating conditions: After reviewing the required documentation, the state engineer will notify the dam owner if any deficiencies are found with the submittal. The dam owner will be given an opportunity to correct any deficiencies noted in the review process. Once all deficiencies have been addressed the state engineer will approve the amended application or proposed change with conditions under which construction and operation shall occur. Action by the state engineer will be in accordance with 19.25.12.13 NMAC, appropriately modified to address the proposed changes.

F. Proof of completion of works, certificate of construction and license to operate: Requirement for a proof of completion of works form for the dam, certificate of construction and license to operate a dam for changes to a dam shall be in accordance with the Sections 14, 15 and 16 of 19.25.12 NMAC, appropriately modified to address the proposed changes. If the dam is breached, the state engineer will cancel the permit and revoke the license to operate a dam.

[19.25.12.19 NMAC - N, 3/31/2005]

19.25.12.20 CHANGES TO AN EXISTING NON-JURISDICTIONAL DAM: A dam owner proposing to reconstruct, enlarge, or modify a non-jurisdictional dam, resulting in a jurisdictional dam after construction is completed, shall comply with 19.25.12.11 NMAC before construction begins. If the purpose of a non-jurisdictional dam changes, resulting in a jurisdictional dam, or if ownership changes, resulting in a jurisdictional dam, the owner shall comply with 19.25.12.11 NMAC. The state engineer will give the owner a reasonable amount of time to comply with 19.25.12.11 NMAC. If the owner fails to comply with 19.25.12.11 NMAC, the dam will be ordered breached in accordance with Subsection B or C of 19.25.12.19 NMAC.
[19.25.12.20 NMAC - N, 3/31/2005]

19.25.12.21 EXISTING DAMS: The state engineer inspects existing dams to verify dams are operated and maintained in a safe manner. Access to the dam site shall be made available to the state engineer upon request. If a critical dam safety problem is observed by the state engineer or reported to the state engineer, an order will be issued requiring the dam owner to address the problem. If a dam incident occurs at a dam, the dam owners shall report the incident to the state engineer within 72 hours. If a major repair is required at an existing dam, the plan to repair the dam shall be in accordance with 19.25.12.19 NMAC. Minor repairs not identified as maintenance activity in accordance with 19.25.12.17 NMAC require state engineer approval. Failure to comply with orders issued by the state engineer may result in the license to operate a dam being revoked and the dam ordered breached in accordance with Subsection B or C of 19.25.12.19 NMAC. Owners of existing dams shall comply with the following:

A. Owners acquiring property with a dam shall promptly notify the state engineer on a form provided by the state engineer of the change in ownership. Recognition of the responsibility and liability associated with dam ownership is required along with fees for filing the change in ownership form for a dam in accordance with Subsection F of 19.25.12.8 NMAC.

B. Owners of dams classified as low or significant hazard potential shall evaluate the hazard classification if downstream development occurs. The dam owner shall submit the results of the hazard potential evaluation prepared in accordance with Paragraph (1) of Subsection C of 19.25.12.11 NMAC to the state engineer for approval and a plan for addressing design deficiencies. If the hazard potential classification changes due to downstream development, the state engineer shall give the dam owner a time limit to address deficiencies. Deficiencies shall be addressed in accordance with Paragraphs (3), (12) and (13) of Subsection C of 19.25.12.11 NMAC and Sections 17 and 18 of 19.25.12 NMAC. If the dam owner fails to address a deficiency, the state engineer may revoke the license to operate the dam and order the dam breached in accordance with Subsection B or C of 19.25.12.19 NMAC.

C. Dams classified as high or significant hazard potential shall be inspected on an interval no greater than 5 years by a professional engineer licensed in the state of New Mexico qualified in the design and construction of dams. The owner is responsible for securing the services of the professional engineer. The professional engineer shall provide a signed and sealed report to the state engineer describing the findings of the inspection and recommendations for corrective action or changes to the operating procedures. Routine inspection by the state engineer as described in 19.25.12.21 NMAC satisfies this requirement.

D. Owners of dams classified as high or significant hazard potential in an unsafe condition may receive an order from the state engineer to address the deficiency pursuant to NMSA 1978, Section 72-5-11 (1979). The state engineer may also issue an order to an owner of a non-jurisdictional dam if the dam is unsafe and a threat to life or property, as determined by the state engineer. Owners shall comply with orders issued by the state engineer pursuant to NMSA 1978, Section 72-5-12 (1979).

E. Owners of dams classified as high or significant hazard potential shall comply with 19.25.12.17 NMAC requiring an operation and maintenance manual. Upon compliance with 19.25.12.17 NMAC the state engineer will issue a license to operate the dam. Dams classified as high hazard potential shall comply by December 31, 2008. Dams classified as significant hazard potential shall comply by December 31, 2010.

F. Owners of dams classified as high or significant hazard potential shall comply with 19.25.12.18 NMAC requiring an emergency action plan. Dams classified as high hazard potential shall comply by December 31, 2008 unless the dam is for flood control purposes with no permanent storage, then compliance by December 31, 2010 is required. Dams classified as significant hazard potential shall comply by December 31, 2010 unless the dam is for flood control purposes with no permanent storage, then compliance by December 31, 2012 is required. Owners of 5 or more dams classified as high or significant hazard potential may propose a schedule for compliance with the emergency action plan requirement. The schedule must be submitted by the owner to the state engineer by December 31, 2005 and is subject to review and approval or modification by the state engineer. The schedule must

propose compliance dates for each dam. The first dam must be in compliance by December 31, 2008 and at least an additional dam must be in compliance each year thereafter. All dams must be in compliance by December 31, 2015. Upon failure to meet an approved compliance schedule all dams will revert to compliance dates shown above.

G. Dam owners that transfer the entire water right out of the reservoir shall have their license to operate a dam revoked and may receive from the state engineer an order to breach the dam in accordance with Subsection B or C of 19.25.12.19 NMAC.

H. Dam owners that fail to obtain state engineer approval prior to construction of a dam shall comply with all conditions imposed by the state engineer within a time limit established by the state engineer or the state engineer may order the dam breached in accordance with Subsection B or C of 19.25.12.19 NMAC.

[19.25.12.21 NMAC - N, 3/31/2005]

19.25.12.22 SEVERABILITY: If any portion of this part is found to be invalid, the remaining portion of this part shall remain in force and not be affected.

1. INTRODUCTION

The Dam Safety Design and Operation Criteria (Criteria) describes the State Engineer's authority over dams in the State of New Mexico. It addresses design criteria and filing requirements in order to obtain a permit for the construction of a dam. The Criteria also addresses the State Engineer's authority over the continued safe operation and maintenance of the dam, modification to the dam, abandonment of a dam or removal of a dam.

Dam owners and potential dam owners must recognize that impoundment of water entails risk, and the responsibility of constructing, operating and maintaining a safe dam rests with the owner. Because dam failures present the same consequence to life and property downstream, the standards for existing dams should be the same for new dams. Therefore, the Criteria are applicable to both new and existing dams.

The Criteria are intended to provide a minimum standard for dam design, operation and maintenance, with consideration given to current engineering practice and accumulated experience. The Criteria are not intended to be a textbook of dam design and construction, and are not a substitute for experience and sound judgment on the part of the design engineer. Compliance with the Criteria will not guarantee a safe structure or prevent failure. However, competent design by engineers experienced in dams and in compliance with the Criteria and current engineering practices, followed by careful construction, safe operation and diligent maintenance, can substantially reduce the risk of failure.

The State Engineer recognizes that certain requirements contained in the Criteria may be mitigated by site conditions, operating practices, design details, and other factors specific to the dam in question. In these cases, requirements can often be modified or waived. However, modification or waiver of requirements will only be considered when requested in writing by the responsible engineer and supported with adequate

documentation justifying the waiver. The request and justification will be evaluated by the State Engineer and accepted or rejected on its merits. Deviations from the Criteria that are not accompanied by a written request and justification will not be accepted. The State Engineer will be the ultimate authority for acceptance or rejection of the design, requests for waiver or modification of requirements.

The Criteria primarily address design and construction of earth embankment dams, as this is the predominant type of dam currently submitted for State Engineer review. Other types of jurisdictional dams, such as concrete arch, gravity, and buttress dams, roller compacted concrete dams, soil-cement dams, rockfill dams, etc. are occasionally constructed. While many elements of the Criteria will apply to these structures, dams constructed using these methods would also be expected to conform to sound engineering principles and current state of the practice for the proposed type of dam. It is recommended that owners and engineers considering dam types other than earth embankment dams confer with State Engineer dam safety personnel regarding appropriate design standards before executing the design.

Appendices in this publication provide additional information related to the Criteria. A Glossary of Terms used in the Criteria is listed in Appendix A and was derived from the Federal Emergency Management Agency's (FEMA) Glossary of Terms for Dam Safety[1].

2. STATE ENGINEER'S JURISDICTION OVER DAMS

The State Engineer is charged with approving permits for all dams in the state with a few exceptions. Dams that store less than or equal to 10 acre-feet of water and are less than or equal to 10 feet in height from the lowest point on the downstream toe to the top of the dam do not require a permit for the dam; however, a permit to store water is required regardless of storage or height if the dam was constructed after June 20, 1997. Flood control and sediment control dams supervised by the U.S. Army Corps of Engineers (COE) do not require a permit before construction; however, if the dam is transferred to an owner other than the COE, the new owner must obtain a permit. Stock dams and erosion control dams storing less than or equal to 10 acre-feet are also

exempt from obtaining a permit for the dam, however, a Water Right permit may still be required. If the purposes of the stock or erosion control dam changes, then a dam permit shall be required. If the owner is unable to comply with the conditions to obtain a permit, an order to breach the dam will be issued by the State Engineer. The State Engineer's permitting authority over dams is contained in Section 72-5-32, NMSA 1978 and the Manual of Rules and Regulations Governing the Appropriation and Use of the Surface Waters of the State of New Mexico (Rules and Regulations). The State Engineer's authority over construction is contained in Section 72-5-9, NMSA 1978. The dam safety statutes, rules and regulations related to dams and application for permit is contained in Appendix B.

A dam is a potential hazard to life and property downstream if the dam were to fail or operate while storing water. Because of this hazard, dam safety is regulated by almost all states in the country. The Office of the State Engineer Dam Safety Bureau administers the New Mexico Dam Safety Program. The State Engineer's authority over unsafe non-federal dams is defined in Section 72-5-11 through and 72-5-12, NMSA 1978. Bureau staff inspects existing non-federal dams to verify the dams are operated and maintained in a safe manner. Operation and Maintenance (O&M) Manuals are required for High and Significant Hazard potential dams to ensure the continued safe performance of the dam. Emergency Action Plans (EAP) are required for High and Significant Hazard potential dams to ensure a plan of action is available in the event of an emergency. Dam owners are responsible for the preparation of the O&M Manual and EAP.

3. PERMITTING / ACCEPTANCE OF PLANS

Any activity related to the safety of dams that are within the jurisdiction of the State Engineer require a permit or approval from the State Engineer before any construction begins. Activities that commonly fall within this category include the following:

- Construction of a new dam;
- Reconstruction of an existing dam;
- Enlargement of an existing dam;

- Modification or alteration of an existing dam;
- Repair of an existing dam;
- Removal of an existing dam;
- Abandonment of an existing dam;
- Operation and maintenance of an existing non-federal dam;
- Impoundment of water; and
- Change of ownership.

3.1. Application for Permit

Prior to initiation of construction for a new dam, reconstruction of an existing dam, enlargement of an existing dam or modification of an existing dam a permit or amended permit from the State Engineer is required. In order for the State Engineer to act on an application for permit, the following minimum items are required.

1. Application for Permit to Construct and Operate a Dam shall be submitted to the State Engineer in triplicate with original signatures by the Dam Owner on each copy. Fees for filing the application and reviewing the plans and specifications are $10 application fee and $2 per $1000 or fraction thereof of the estimated construction cost. Fees for reviewing plans are waived when the State Engineer requires plans to address a dam safety deficiency.

2. Water Right Permit shall be submitted for water impounded by the dam. The permit shall address the recommended fill rate that will satisfy downstream release requirements. A pending Application for a Water Right Permit does not meet this requirement. If the applicant has a permit for the diversion of water, a letter from the Water Rights Division is needed addressing storage and release conditions for the reservoir. This requirement is waived for flood control dams that adhere to the Flood Control Dam Detention Time policy or provide documentation that an exception by the State Engineer has been granted.

3. The Design Report shall be prepared by a Professional Engineer registered in New Mexico and experienced in the design and construction of dams. The Design Report shall address:

    a) Hazard Potential Classification;
    b) Hydrologic Analysis;
    c) Outlet Works Design;
    d) Spillway Design; and
    e) Geotechnical Design;

4. Construction drawings and specifications shall be prepared in accordance with the filing requirements in the Rules and Regulations. A professional engineer registered in New Mexico and experienced in the design and construction of dams shall prepare the construction drawings and specifications.

5. Flood and Maintenance Right-of-Way certification from the owner is required. Supporting documentation that a permanent easement has been obtained for the reservoir inundation zone, reservoir and spillway releases and adequate easement for operation and maintenance of the dam and appurtenances shall accompany the certification. A map with certification showing the Right-of-Way boundaries shall be provided with the construction drawings.

6. Designer's Operating Criteria (DOC), if required, for inclusion in the Operation and Maintenance (O&M) Manual shall accompany the application. The O&M Manual shall be required on or before completion of construction.

7. Instrumentation Plan, if required, for inclusion in the O&M Manual shall accompany the application.

8. Draft copy of Emergency Action Plan and Final Dambreak Analysis and Flood Inundation Maps, if required, shall accompany the application. The Final EAP shall be required on or before completion of construction. The State Office of Emergency Management shall approve the EAP before being submitted to the State Engineer for approval.

Checklist addressing submittal requirements is provided in Appendix C.

3.2. Design Report

A Design Report shall be submitted with construction drawings and specifications. The Design Report shall include a description of the project, purpose of the dam, ownership of the dam and address the hazard potential classification, hydrologic design, spillway and outlet conduit design, structural design, geotechnical design and any other information needed to support the design of the dam. A professional engineer registered in New Mexico with experience in dam design and construction shall prepare and stamp the Design Report. The Design Report shall address compliance with all applicable State and Federal rules and regulations.

3.2.1. Hazard Potential Classification

The Hazard Potential Classification shall be indicated on the application form and on the first sheet of the construction drawings. The State Engineer has adopted the Hazard Potential Classification[2] published by FEMA. These classifications take environmental consequences into account and restrict dams having a low hazard potential classification to primarily harming the dam owner's property. The hazard potential is not a reflection of the condition of the dam itself, but rather an indication of the damage if a dam failure should occur. The Hazard Potential Classifications are shown in Table 1.

The hazard potential classification assigned to a dam shall be based on the worst-case failure conditions. In other words, the classification is based on failure consequences resulting from the failure condition that will result in the greatest potential for loss of life and property damage. In most cases, the worst-case condition occurs if the dam were to fail during an extreme flood event.

Table 1

Hazard Potential Classifications

Low	Dams assigned the low hazard potential classification are those dams where failure or misoperation results in no probable loss of life and low economic and/or environmental losses. Losses are principally limited to the owner's property.
Significant	Dams assigned the significant hazard potential classification are those dams where failure or misoperation results in no probable loss of human life but can cause economic loss, environmental damage, disruption of lifelines facilities, or can impact other concerns. Significant hazard potential classification dams are often located in predominantly rural or agricultural areas but could be located in areas with population and significant infrastructure.
High	Dams assigned the high hazard potential classification are those dams where failure or misoperation will probably cause loss of human life.

In situations where the hazard potential is obvious, the classification may be based on engineering judgment provided the State Engineer concurs with the selected classification. For the remaining situations the hazard potential classification shall be based on dambreak/inundation studies. Dambreak studies shall assume a “sunny day” as the initial failure scenario. If other than a high hazard potential is valid for the “sunny day” assumption then the loading condition is increased to a probable maximum flood (PMF) with failure. If the dam break plus the PMF results in a higher hazard potential classification, determining the incremental effects of a dambreak flood and inflow flood becomes necessary. The Bureau of Reclamation (USBR)[3] provides guidelines and criteria for identifying downstream hazards and evaluating the incremental effects of dam failure.

When evaluating the potential for loss of life from a dam failure, the presence of facilities that would attract people on a temporary basis (e.g., public facilities, improved campgrounds, recreation areas, State or National Parks) requires special consideration. The type of flow conditions from the flood wave such as flow velocity, flow depth, debris flow and terrain conditions may increase the potential for loss of life and need to be considered in temporary occupied areas.

The hazard potential classification determines the level of engineering analysis, the criteria that are applicable and the inspection frequency by the State Engineer. The hazard potential of a dam can change due to downstream development. Therefore, the likelihood of future downstream development must be considered when determining the hazard potential classification of a dam, and the hazard potential for low and significant hazard potential dams must periodically be reevaluated to ensure public safety if downstream conditions change.

3.2.2. Hydrologic Analysis

When designing a dam, consideration of how the dam will perform under flood conditions must be evaluated. The hydrologic analysis will produce a design storm volume and peak runoff that the dam must safely pass or impound without failure of the

structure. The hydrologic analysis shall include a detailed study of the watershed draining into the dam and design storm characteristics. All parameters and assumptions used in the analysis shall be summarized in a table and justified in the hydrologic report. Appropriate data sheets and computer program output computations from the computerized analysis shall be provided. A plot of the inflow and outflow hydrographs shall be shown on the same figure in the hydrologic report. The outflow hydrograph shall be extended until discharge is negligible. The time of peak reservoir storage shall be shown on the outflow hydrograph for flood control dams in order to determine the time to drain the reservoir.

3.2.2.1. Spillway Design Flood

The State Engineer has adopted spillway design standards that focus on ensuring public safety; therefore, the capacity of a spillway shall be based on the hazard potential and size of a dam, or based on an incremental damage assessment. A summary of the Size Classifications and Spillway Design Flood (SDF) criteria are shown in Table 2 and 3, respectively. A dam must be less than or equal to both the height and storage criteria to qualify for the size classification. A spillway stage/discharge curve or table to the top of dam shall be provided. The SDF shall also be used for determining the maximum height of the dam, freeboard and flood storage requirements.

Table 2

Size Classifications

Size	Height (Feet)	Storage (Acre-feet)
Small	> 10 and ≤ 40	> 10 and ≤ 1000
Intermediate	> 40 and ≤ 100	> 1000 and ≤ 50,000
Large	> 100	> 50,000

Table 3

Spillway Design Flood

Hazard	Size	Spillway Design Flood
High	All Sizes	PMF
Significant	Small	0.5 PMF
	Intermediate	0.5 PMF
	Large	0.75 PMF
Low	All Sizes	100-Year (Expressed as a percentage of the PMF)

At the discretion of the State Engineer, a SDF less than the standard shown in Table 3 may be acceptable if the SDF is based on an incremental damage assessment. FEMA has published guidelines for selecting an Inflow Design Flood (IDF)[4], which provides procedures to determine the appropriate design flood based on incremental damage assessment. Additional discussion is also contained in Subsections 3.2.2.4 and 3.2.2.5

3.2.2.2. 100-Year Frequency Storm

Low hazard potential dams by definition have minimal impact on property or no probable loss of life downstream; therefore the spillway shall have the minimum capacity to safely pass the 100-year flood event. The 100-year flood event shall be estimated from the 100-year precipitation[5] and the peak discharge from the 100-year event shall be expressed as a percentage of the peak discharge from the PMF hydrograph. Where adequate flood records are available for the drainage area above the dam, a flood flow frequency analysis should be performed to evaluate the model results.

3.2.2.3. Probable Maximum Flood and Probable Maximum Precipitation

The Probable Maximum Flood (PMF) is the flood that may be expected from the most severe combination of critical meteorologic and hydrologic conditions that are

reasonably possible in the drainage basin under study. The Probable Maximum Precipitation (PMP) shall be used to determine the PMF and average conditions for the watershed may be assumed for the PMF analysis. Hydrometeorological Reports (HMR)[6, 7] provide regionalized estimates for the PMP. The HMRs provide step-by-step procedures for computing the local and general storm PMP. These procedures should be addressed in the design report. The PMP derived from both local and general storm will have to be individually evaluated in the PMF analysis and the more critical flood used in the design. The spatial and temporal distribution for the design storm shall be documented. When the volume of the runoff hydrograph is an important consideration (i.e. retention and detention ponds), the duration of the rainfall must extend for a period long enough to include all rainfall excess. The State Engineer may accept a detailed site-specific hydrometeorologic analysis if adequate justification is provided.

3.2.2.4. Inflow Design Flood (IDF)

The IDF is the flood flow above which the incremental increase in water surface elevation downstream due to failure of a dam is no longer considered to present an "unacceptable additional downstream threat". The upper limit of the IDF is the PMF. The lower limit of the IDF is the 100-year frequency event. The peak discharge from the IDF shall be expressed as a percentage of the peak discharge from the PMF hydrograph.

The degree of study required to sufficiently define the impacts of dam failure for selecting an appropriate IDF will vary with the extent of existing and potential downstream development, the size of the reservoir (depth and storage volume), and type of dam. Evaluation of the river reach and areas impacted by a dam failure should proceed until sufficient information is generated to reach a sound decision or until there is a good understanding of the consequences of failure. Evaluation of the consequences of dam failure must be based on the dam being in place, and must compare the impacts of with-failure and without-failure conditions on existing development and known and prospective future development. The consequences of dam failure must be defined in order to evaluate whether a dam failure causes an

"unacceptable additional downstream threat". In most cases, detailed studies, including dambreak analyses, will be required to fully evaluate the consequences of dam failure.

When preparing dambreak studies, the water surface profiles with and without dam failure, the flood wave travel times, and rates of rise should be determined for each flood flow condition. Dambreak studies require selection of the size, shape and time of formation of the breach as input parameters for the computations; therefore, sensitivity analyses are considered necessary as well as documentation of the methodology for selecting breach parameters.

3.2.2.5. Incremental Increase in Damage

Methods of assessing the incremental increase in damage vary from examining individual structures to applying general criteria. The Federal Energy and Regulatory Commission (FERC)[8] have criteria where an incremental increase in flood level of 2 feet or less is not judged to pose a significant increase in the hazard. The USBR[3] has guidelines for assessing the hazards posed by floods. The application of general criteria for evaluating incremental damage will be reviewed on a case-by-case basis.

3.2.3. Outlet Works Design

Outlet conduits shall be sized to provide the capacity to satisfy water rights of downstream priority users and meet owner's release requirements and shall be a minimum of 18-inches in diameter. The 18-inch minimum diameter may be waived if documentation is provided supporting that the inspection of the interior of the conduit can be performed in accordance with Section 7. The conduit design shall address the required operation and maintenance items in Section 7.

Metal conduits may be used in low hazard dams and in significant hazard flood control dams with no permanent storage, provided they are designed to possess adequate strength after corrosion for a minimum period of 200 years, based on corrosivity testing (e.g. resistivity and pH) of onsite soils. Cathodic or other protection of metal conduits is permissible to obtain this value. Metal conduits will not be accepted for other dams

except as an interior form for cast-in-place reinforced concrete conduits, in which case no structural contribution for the metal conduit shall be considered in the design.

All dams shall be provided with a low–level outlet positioned in such a manner that the entire contents of the reservoir above the lowest point of the embankment can be efficiently drained. If environmental consequences prevent draining, a waiver shall be submitted fully justifying the waiver. Outlets for water storage reservoirs shall be capable of evacuating the reservoir contents in less than 45 days, unless a waiver supported by justification acceptable to the State Engineer is granted. The design report shall justify the size selected and shall provide an inspection, maintenance and emergency evacuation plan including documentation of technology to be used.

Outlet conduits for storage reservoirs shall be gated at the upstream end unless exception is granted by the State Engineer. At a minimum, outlet gate valves in earth dams should be located upstream of low permeability core materials and within the upstream third of the dam. Where gates are located other than at the upstream end of the conduit, a guard gate or bulkhead shall be provided at the upstream end to allow draining of the conduit for inspection, maintenance and repair. Pressurized conduits through the dam are discouraged. The conduit downstream of the gate or valve shall be adequately vented. Where the outlet conduit discharges directly to a downstream pipe, a bypass valve shall be provided.

Outlet gate operators and equipment shall be properly designed to be secure from damage due to vandalism, weather, ice, floating debris, wave action, embankment settlement, and other reasonably foreseeable causes. Outlets shall be secure from unauthorized operation. Direction of operation for outlet controls must be clearly marked to minimize the possibility of overstressing and damage to the mechanism by operating in other than the intended direction. Outlet controls must remain accessible during outlet works and spillway releases.

Outlets for flood control structures shall be ungated. Where a gate is required to satisfy downstream release restrictions, a waiver from the Water Rights Division is required. The waiver shall include justification for the request and an operating plan for eventual release of floodwater and exercise and maintenance of the gate. Gated flood control dams must meet design requirements for water storage dams. No dead storage shall be allowed unless a separate permit to store water is provided. The outlet conduit for Flood Control Dams shall be sized to adhere to the Detention Time Policy. The 96-hour time frame begins once the reservoir storage reaches its peak during any inflow event including the Spillway Design Flood (SDF). If the design does not meet the 96-hour requirement, an exception from the Water Rights Division is required. If an exception to the Flood Control Dam Detention Time regulation is requested, documentation estimating the time to drain less frequent events, such as the 2-year, 5-year, 10-year and 100-year, should be submitted to the Water Rights Division in support of the request.

Outlet works intake must be provided with trash racks or grates to prevent clogging with debris. Openings in trash racks or grates shall be sized to pass small debris without clogging the grate, but collect large debris that would potentially clog the outlet conduit. Grate opening size or bar spacing shall be adequate to satisfy applicable public safety requirements, if appropriate. Total size of grate openings must be at least three times the cross-sectional area of the outlet conduit. Where the intake requires discharge over a weir, the need for aeration of the nappe shall be evaluated. The design of the outlet structure shall address energy dissipation to prevent erosion with supporting calculations provided.

Outlet conduits shall be designed for full embankment loading and for hydrostatic pressure equal to the maximum reservoir head, acting separately and in combination, with an adequate factor of safety. If future increases in embankment height and/or reservoir head are foreseeable, allowance shall be made in the design. The conduit together with all joints and fittings shall be watertight at the design pressure, and shall be pressure tested prior to backfilling. Conduits shall be designed for all reasonably

foreseeable adverse conditions including corrosion, abrasion, cavitation, embankment settlement and spreading, thermal effects, and seismic loading. The required joint extensibility shall be addressed in the design of outlet conduits.

Outlet works must be supported by stable, well-consolidated foundation materials. Where the conduit is placed in embankment fill or native overburden materials, settlement analysis should be performed and consideration given to articulated design. The outlet works design shall address prevention of seepage along conduits. Typical methods for seepage control include concrete or grout encasement and filter diaphragms with drains. Past practices have allowed cutoff collars; however, cutoff collars are seldom effective in controlling seepage and may apply unwanted stresses to the conduit. For these reasons, use of cutoff collars is discouraged. Regardless of the method used for seepage control, methods for compaction of backfill around and beneath the conduit must be addressed.

The design report shall include all supporting documentation and calculations for the outlet works design. The outlet works design shall include all foreseeable loading conditions, including but not limited to ice loading, debris buildup, wave action and embankment settlement. Structural design calculations for the intake structure, conduit and outlet structure shall be submitted in the design report. A stage/discharge curve or table to the top of dam for the outlet works shall be provided in the Design Report.

3.2.3. Spillway Design

Spillways should be located in natural ground and not on the embankment if possible. Unprotected earth or vegetated earth spillways will be accepted for low hazard structures only. Spillways excavated in rock or weathered rock will be evaluated on an individual basis. Unprotected spillways should be provided with a check structure at the crest to minimize the possibility for headcutting. Where control weirs are used at the spillway crest, aeration of the nappe for cavitation control must be addressed. Where a potential exists for accumulation of large floating debris that could block the spillway, the use of log booms or other debris control features should be a design element.

The spillway must discharge away from the toe of the dam and abutment slopes. Where training dikes are used to divert the water away from the dam, the dike shall be designed with adequate compaction and erosion protection. Energy dissipation shall be addressed to allow spillway discharge to be released to the natural channel without destructive erosion.

The material required for spillway lining will depend on the spillway location and frequency of discharge. Design analysis shall address these factors and provide adequate justification for the material selected. Table 4 may be used as a general guideline for selecting spillway lining materials.

Table 4

Guidelines for Spillway Lining

Spillway Lining	**Allowable Frequency of Discharge, Open Channel Spillways**	
	Spillway in Native Ground	**Spillway on Embankment**
Concrete	Continuous	2 years
Soil Cement	1 year	5 years
Grouted Riprap	2 years	10 years
Wire-enclosed Riprap	2 years	10 years
Riprap	5 years	25 years
Unweathered Bedrock	5 years	N/A
Weathered Bedrock	10 years[1]	N/A
Vegetated Earth	25 years[1, 2]	Not Permitted
Bare Earth	50 years[1, 2]	Not Permitted

1. Concrete check structure required at spillway crest.
2. For low-hazard structures only.

Channel lining must be placed on a suitably prepared, stable subgrade. All edges and joints in channel lining material must be designed to prevent undermining and erosion. Concrete channel lining must be provided with adequate jointing to permit thermal expansion and contraction, and adequate reinforcing to control thermal cracking. Adequate water stops are required at joints in the spillway lining. Concrete lining shall be adequately anchored against displacement and uplift, and shall be provided with adequate subdrainage to relieve hydrostatic pressures and prevent frost heave.

3.2.4. Miscellaneous Design Issues

Retaining walls associated with dams and appurtenances shall be designed for full at-rest earth pressure rather than active earth pressure. Where earth fill will be placed against vertical concrete surfaces, the surfaces shall be battered from vertical at least 1 horizontal to 10 vertical to facilitate compaction of fill. Hydrostatic pressure at retaining walls shall be addressed in the design. To the extent practical, the design should be such that self-propelled mechanical compaction equipment can be used effectively, and areas requiring hand-operated compacting equipment should be minimized or if possible eliminated.

The structural design information for all appurtenances, addressing water, earth, ice and any other applicable load shall be included in the Design Report. Reinforced concrete design including assumptions for loads and limiting stresses and sample calculations shall be provided.

Underground utilities located in the vicinity of the proposed embankment footprint shall be relocated and trenches backfilled and compacted with suitable material to the satisfaction of the State Engineer. If utilities are allowed to remain, they will be required to satisfy standards for outlet conduits. Since typical utility bedding, backfill, etc., does not meet these standards, these utilities will require reconstruction in most cases.

3.2.5. Geotechnical Design

When locating and designing a dam, a detailed geotechnical design must be submitted with the design report. The geotechnical design shall include a geological assessment, geotechnical investigation including a field investigation and laboratory testing of soil samples, seepage analysis, seismic analysis and design addressing potential for liquefaction, and recommended geometry of the dam.

3.2.5.1. Geological Assessment

A geological assessment of the dam and reservoir site is required for all high and significant hazard dams. The geological assessment may be included in the geotechnical investigation report or seismic study, or may be submitted as a separate document. The geological assessment shall be based on available literature and mapping, aerial photography interpretation, unpublished reports and data, site reconnaissance, and other sources as available and appropriate. At a minimum, the geological assessment shall address regional geologic setting, local and site geology, geologic suitability of the dam foundation, slide potential of reservoir rim and abutment areas, and seismic history and potential unless covered in a separate seismicity study.

3.2.5.2. Geotechnical Investigation

A geotechnical investigation is required for all dams meeting jurisdictional requirements regardless of hazard classification. Scope of the study will depend on a variety of factors including size, hazard classification, anticipated materials and construction methods of the dam, site geology and seismicity, anticipated soil strata, etc., and may be modified during the course of the investigation due to materials and conditions encountered. The investigation must adequately assess site conditions and support the design. The exact scope of the investigation should be determined by the geotechnical engineer. If in the judgment of the State Engineer the geotechnical investigation is not adequate for the structure in question, additional work will be required.

Typically, the geotechnical investigation shall include, but not be limited to, the following elements:

Field Investigation:

1. Test borings in the footprint of the proposed embankment, spillway excavations and appurtenances to the dam, extending to bedrock or to a depth equal to at least the height of the dam. Where appropriate, borings may include coring of bedrock materials to determine the quality and character of the rock.
2. Supplemental test borings to determine soil characteristics in borrow and cut areas, spillway excavations and beneath appurtenances to the dam, etc.
3. Standard penetration tests or other field testing to assess soil character and consistency.
4. “Undisturbed” sampling for further tests such as insitu density, shear strength, and compressibility.
5. Supplemental test pits to obtain bulk and undisturbed samples, assess soil layering, measure bedrock orientation, etc. as required.
6. Measurement of water level in drill holes.
7. Field permeability testing, if feasible.
8. Logs of test borings and test pits, location map, and profile along dam axis with soil information shown.

Laboratory Testing:

1. Classification testing (gradation and plasticity characteristics) and classification according to the Unified Soil Classification System.
2. Laboratory determination of insitu density and moisture content.
3. Shear strength testing of embankment and foundation materials.
4. Laboratory permeability testing.
5. Volume change testing (consolidation, expansion, collapse, etc.).
6. Proctor tests for potential embankment materials.
7. Test for dispersive clays.
8. Gradations for potential filter and drain materials if appropriate.
9. Evaluation of liquefaction potential, and dynamic shear strength testing if deformation analysis is required.

The investigation should identify the location of sufficient borrow material to construct the dam as designed. Sufficient testing should be done to determine or estimate relevant properties of each zone or layer of the embankment and foundation, including but not limited to shear strength, permeability, compressibility, and filter characteristics.

Shear strength testing shall be selected to be appropriate for the material being tested and to provide appropriate parameters for the intended analysis. Most commonly, triaxial testing is performed on clays, and direct shear testing is performed on nonplastic materials. Effective stress parameters for clayey soils, when required, can be

determined from consolidated-undrained triaxial testing with pore pressure measurements to permit calculation of drained parameters. In the event that the direct shear test is used to determine effective stress parameters of clayey soils, supporting documentation must be provided to assure that specimens are saturated during testing, that strain rates are adequate to allow drainage to occur, and that excessive consolidation is not induced during shearing.

Results of field investigations and laboratory testing shall be presented in a formal report, including recommended parameters to be used in design and other pertinent information or recommendations for design and construction of the dam and appurtenances. The geotechnical investigation report may be included as part of the design report or as a separate document.

3.2.5.3. Seepage Analysis and Internal Drainage

The effects of seepage and internal drainage and the potential for internal erosion shall be evaluated for all structures. For significant and high hazard structures, a seepage analysis shall be performed to address the performance of the embankment under steady-state conditions.

The seepage analysis requirement may be waived for flood control dams with ungated outlets that satisfy the 96-hour drainage requirement, provided a written request for the waiver is made, accompanied by supporting justification. However, the geotechnical investigation, engineering analysis, design details, and construction techniques must be adequate to ensure that these dams will not have high-permeability layers that serve as a conduit for seepage water. In some cases, low-permeability cutoff trenches or upstream blankets may be required. The seepage analysis requirement may also be waived for reservoirs having synthetic impermeable liners constructed on well-drained sites, provided a written request is made with supporting justification.

Seepage analysis may be performed with hand-drawn flow nets or with computer techniques. Permeabilities for this analysis should be determined by field and

laboratory tests where feasible; values derived from published sources or obtained from similar soils in the region may be accepted with adequate justification. The effects of anisotropy with respect to permeability must be addressed, particularly the ratio of vertical to horizontal permeability of a given soil material. Ratios of horizontal to vertical permeability of less than four for constructed embankments and less than nine for native deposits will not be accepted unless supported by permeability test data acceptable to the State Engineer.

The design shall address the effects of anticipated seepage beneath and around the dam. Where practical, a cutoff trench integral with the core zone extending through permeable deposits and into low permeability bedrock should be provided. Where permeable foundation deposits are too deep for a cutoff trench to be practical, other cutoff options such as slurry walls and grout curtains may be considered. Partial cutoffs are often ineffective and generally should be avoided. Where complete cutoff is not practical or economically feasible, possible solutions include upstream impermeable blankets, extended downstream embankment zones, downstream horizontal drainage blankets, toe drains, drainage curtains, and re-siting the dam.

The dam shall be designed so that seepage does not exit on the face of the dam and excessive exit gradients are avoided. Embankment zoning and/or internal drainage may be necessary in order to control seepage. All adjacent material zones in the dam and foundation shall satisfy filter criteria acceptable to the State Engineer. The State Engineer has previously accepted filter criteria used by the Natural Resource Conservation Service (NRCS)[9], the U.S. Army Corps of Engineers (COE)[10, 11], and the USBR[12]. Other criteria will be reviewed for acceptability on a case-by-case basis. Where materials do not meet filter criteria with respect to one another, transition zones meeting the filter criteria will be necessary. All filter, transition, and drainage zones within earth dams shall have a thickness adequate to address constructability and enhance seismic stability, with a minimum thickness of 3 feet for each zone. Clay core zones shall extend above the anticipated phreatic surface a sufficient distance that water will not be lifted above the core by capillary rise in the adjacent material zones.

Collector pipes and conduits for internal drains shall be made of non-corrodible material capable of withstanding the anticipated loads. Insofar as possible, pipes should be located where they can be exposed for repair or replacement without threatening the stability of the dam. Collector pipes for drains shall be enveloped in a free-draining medium meeting filter criteria for adjacent embankment or foundation zones. Pipe perforation size (e.g. hole diameter or slot width) depends on the surrounding medium and condition of use. Where surging or gradient reversal is likely, perforation size must be less than the D_{15} of the surrounding medium. Where surging and gradient reversal are unlikely, the perforation size must be less than D_{85} of the surrounding medium.

Drain pipes should be sized to provide a flow depth no more than ¼ of the pipe diameter when carrying the anticipated discharge. Drain pipes must be at least 6 inches in diameter unless the availability of technology for inspection and maintenance can be demonstrated. Individual pipes must discharge to a gallery, well, manhole, or to daylight such that the flow of each pipe can be monitored. Manifold connections, tees, and wyes will not be permitted. If the anticipated flow from a drain line exceeds 10 gpm, a measuring flume or weir shall be provided for that line. If the anticipated flow from a drain line is less than 10 gpm, the outfall shall be designed to allow a 5-gallon bucket to be used to collect and measure discharge. Where pipes from internal drains are discharged to daylight, a rodent screen shall be provided.

3.2.5.4. Stability Analysis

Cross-sectional design for dams shall be supported by adequate slope stability analysis. The analysis model shall adequately represent the geometry and zoning, shear strength parameters, material unit weights, pore pressure and seepage conditions, external loading, and other relevant factors of the critical cross section or sections. Computer-assisted limit-equilibrium analyses with automated search routines are typical and preferred. Manual computations will be accepted if judged to be sufficiently rigorous. Chart solutions and infinite slope analysis may be accepted in certain cases, with justification and supporting documentation that the solution is applicable to the problem

and the results are conservative. Where appropriate, the analysis shall consider noncircular or block and wedge type failure surfaces as well as circular failures.

All parameters and assumptions used in the analysis shall be summarized in a table and justified in the geotechnical investigation. A scale drawing, utilizing the same scale for vertical and horizontal dimensions, shall be provided for each cross-sectional model used in the analysis, with the critical failure surface(s) identified. Appropriate data sheets and computer program output computations from computerized analysis shall be provided.

Dams shall be designed to provide the following minimum factors of safety from the stability analysis:

- Steady state long-term stability 1.5
- Operational drawdown conditions 1.5
- Rapid Drawdown conditions 1.2
- End-of-construction 1.2

Low hazard dams with upstream slopes no steeper than 3 horizontal to 1 vertical and downstream slopes no steeper than 2 horizontal to 1 vertical and which are 25 feet or less in height will not require slope stability analysis.

3.2.5.5. Seismic Analysis and Design

All High and Significant hazard dams shall be analyzed for seismic stability. Seismic analysis may also be warranted for low hazard structures if a future change in hazard classification can be reasonably foreseen or if otherwise deemed necessary by the State Engineer. The level of effort required for seismic analysis will be unique for each dam depending on the type of dam, site geology and seismicity, embankment and foundation materials, dam and foundation geometry, construction methods used, consequences of failure, and other factors.

Seismic analysis for water storage dams should be based on full reservoir under steady state seepage conditions. Flood control dams with ungated outlets that satisfy the 96-hour release requirement should be designed for earthquake loads under full reservoir conditions, but need not consider steady-state seepage since it is unlikely to develop.

At a minimum, seismic analysis shall include the following steps:

1. A seismological investigation shall be made for the dam area and reservoir area, considering local and regional earthquake history, available technical literature, unpublished reports or data if available, geologic mapping, and field mapping and measuring of faults if appropriate, and other information deemed relevant by the investigator. This study may be part of the geological or geotechnical report for the structure, or may be a separate effort. The study shall determine and justify the appropriate seismic parameters to be used for design. High hazard dams other than flood control structures shall be designed for the Maximum Credible Earthquake (MCE) or for an earthquake with a 5000-year return frequency. For significant hazard dams and high hazard flood control dams, a 2% chance of occurrence in 50 years (approx. 2500 year return frequency) used in determining the design earthquake will be accepted.

2. An analysis of materials in the foundation, reservoir area, and proposed embankment shall be completed, to determine the potential for liquefaction, earthquake-induced sliding, or other seismic sensitivity. This is generally accomplished as part of the geotechnical investigation for the structure. However, if potentially liquefiable materials are encountered or anticipated, additional field and laboratory testing and engineering analysis may be warranted.

3. Pseudostatic analysis will be acceptable for the following cases:

    a. The embankment is to be mechanically compacted to at least 95% of the maximum standard Proctor density, ASTM D 698, or at least 90% of the maximum modified Proctor density, ASTM D 1557 (or at least 70% relative density if Proctor testing is not appropriate), no materials prone to liquefaction are present in the foundation, and peak bedrock acceleration is 0.20g or less; or

    b. The embankment is to be mechanically compacted to at least 95% of the maximum standard Proctor density, ASTM D 698, or at least 90% of the maximum modified Proctor density, ASTM D 1557, potentially submerged portions of the embankment except for internal drain elements are constructed of clayey material (classified as CL, CH, CL-ML, SC, or GC under

the Unified Soil Classification System), the dam is constructed on clayey soil or bedrock foundation, and peak bedrock acceleration is 0.35g or less; and

c. All safety factor requirements for static stability given in the Criteria are met; and

d. Minimum freeboard requirements of the Criteria are met.

The pseudostatic coefficient selected for analysis must be at least 50% of the predicted peak bedrock acceleration, but not less than 0.05g. Factor of safety under pseudostatic analysis shall be 1.1 or greater. In determining the factor of safety for pseudostatic analysis, a search for the critical failure surface shall be made, rather than simply applying pseudostatic coefficients to the failure surface from static analysis.

4. For dams not satisfying the requirements for pseudostatic analysis, a deformation analysis acceptable to the State Engineer will be required. The resulting embankment must be capable of withstanding the design earthquake without breaching and with at least 3 feet of freeboard remaining after deformation. The analysis shall also assess the potential for internal erosion as a result of cracking during deformation. Defensive design measures, such as treating or removing sensitive materials, flaring or widening cores and drainage zones, adjusting location of internal zones to minimize embankment saturation, providing additional freeboard, or adding outlet capacity to shorten reservoir drainage times should be considered for embankments in this category.

5. The seismic assessment shall also address the stability of appurtenances to the dam during the design earthquake as appropriate. However, if failure of an appurtenance due to earthquake does not represent an immediate threat to the dam, the Operating Basis Earthquake (OBE) may be used for this assessment.

Where possible, dams must not be sited on active faults. If this is unavoidable, the dam must be designed to withstand anticipated fault movement without compromise to its integrity.

3.2.5.6. Dam Geometry and Freeboard

Dam Crest - Crest width shall be at least h/5 + 8 feet, with the minimum permissible crest width being 10 feet and the maximum required crest width being 24 feet. Where access and maintenance roads are located on the crest, appropriate surfacing shall be placed to provide a stable base that resists rutting and provides adequate friction for safety in wet conditions. Crest design shall include adequate cover above clay cores to prevent cracking of the core due to desiccation or frost penetration. A minimum of 2 feet of cover is required above the core, with additional cover being required if

warranted by local conditions. Turnarounds should be provided on dead-end service roads on dam crests, located in such a manner that backing maneuvers longer than 300 feet are eliminated. The crest shall be provided with adequate cross slope to prevent ponding. The slope or slopes to which crest drainage is directed must be provided with adequate erosion protection to accept the crest drainage. The crest longitudinal profile shall be provided with adequate camber to maintain the profile after embankment settlement. Camber should be based on settlement analysis and shall be at least 2 percent of the total embankment height, with a minimum of 1 foot at the highest point of the dam. The tops of internal core zones shall also be provided with camber in a similar manner to the crest of the dam.

In the event that safety berms, street curbs, or other longitudinal features which block, control, or concentrate drainage are required on the dam crest, the design shall provide for collection and conveyance of accumulated water to discharge away from the embankment without erosion.

Freeboard Requirements - Dams shall be provided with adequate freeboard. Freeboard is defined as the vertical distance between the spillway crest and the lowest point of the top of the dam, without camber. Freeboard shall satisfy the following conditions:

- Anticipated wave runup resulting from a 100 mph wind with reservoir level at the spillway crest will not overtop the dam.
- Anticipated wave runup resulting from a 50 mph wind with maximum reservoir level from routed SDF will not overtop the dam.
- Clay core cover and capillary rise requirements are satisfied.
- A minimum of 3 feet of freeboard remains after seismic deformation.
- In any case, at least 4 feet of freeboard shall be provided.

Wave runup shall be determined taking into consideration wind speed, reservoir fetch, embankment slope, and roughness of the slope surface. Crest camber shall not be considered as part of available freeboard. The minimum of 4 feet of freeboard may be

waived for parameter embankments with no spillway, provided a written request is made with supporting justification.

3.2.5.7. Erosion Protection

The dam shall be protected against erosion. Erosion protection shall be extended onto abutments and toes of slopes a sufficient distance that erosion in these areas does not threaten the dam. Additionally, the dam owner is responsible for compliance with any applicable environmental laws and regulations concerning erosion and sediment control.

Wave Erosion Protection – The upstream slope of the dam shall be provided with armoring sufficient to protect against anticipated wave erosion. At a minimum, the armoring shall extend from the lowest operational water surface elevation to the highest anticipated wave runup elevation. Wave erosion protection materials typically include dumped riprap, soil-cement, hand-placed riprap, and concrete slope paving, in general order of preference. Selection of wave protection material is primarily based on economics. If riprap is used for armoring, it shall be placed on a properly designed filter bedding layer. Flood control structures that have ungated outlets and are designed to release their contents within 96 hours are exempted from the wave erosion protection requirement.

Surface Erosion Protection – Slopes and crest of earth dams, abutment and toe areas adjacent to dams, and any other constructed or graded slopes associated with the dam or appurtenances shall be protected from surface erosion. This may be accomplished with vegetative cover, gravel surfacing, slope paving, or other approved means. Where vegetative cover is used, a site-specific seed mixture shall be provided, with supporting documentation that the proposed vegetative cover will become established and survive under anticipated climate conditions. The seed mixture shall be free of woody vegetation types and potentially large brushy vegetation types. The dam design shall address methods of establishing and maintaining vegetation, including seeding season,

supplemental watering during establishment if necessary, future removal of undesirable vegetation, and management of burrowing rodents attracted to vegetation.

Dam safety inspections seem to indicate that a surface gravel or stone layer is much more effective than seed and mulch in preventing surface erosion in the arid portions of New Mexico. Angular crushed or quarried products, if available, stay in position and are more effective than rounded gravel, particularly where the material will be subject to foot or vehicle traffic. A heavy gravel layer also appears to be effective in discouraging small burrowing rodents, and may be adequate for relatively low volume concentrated flows, such as at abutment groins.

Erosion From Concentrated Flows – The design shall address erosion at locations where flows become concentrated, such as abutment groins, intersecting dikes, points of inflection of the embankment, areas behind spillway retaining walls, low points of crest roads, low ends of diversion berms, and bare slopes beneath paved areas. Possible solutions at these locations may include riprap, paved swales, heavy angular gravel, half-pipe sections, small check dams or grade stabilization structures, slope drains, etc.

3.2.5.8. Geotextiles

The acceptance of geotextiles by the State Engineer for dam design will be application-specific and will be determined for each design on a case-by-case basis. Geotextiles must be used in a manner consistent with the manufacturer's recommendations and intended use for the product. Geotextiles generally should only be used where failure of the geotextile would not cause a catastrophic release of the contents of the reservoir. Geotextiles should not be used at a location where their exposure for repair or replacement may jeopardize the stability of the dam or appurtenances.

Geotextiles and geosynthetic membranes used for impermeable liners of reservoirs, lagoons, and retention ponds shall be placed in accordance with the manufacturer's requirements, including certification of installation personnel if required. Liners either

must be certified by the manufacturer for long-term exposure to sunlight or must be covered with a suitable protective layer. Where the reservoir will be periodically or normally empty, the liner shall be adequately ballasted or anchored for stability in the wind. Ballast and anchoring material must be capable of withstanding sunlight and weather conditions; for example, where sandbags are used for ballast, the bag material must be resistant to degradation from sunlight exposure. Joints or seams between liner panels and anchorage details at edges must be in compliance with manufacturer recommendations. Penetrations in the liner such as at inlets and outlets must be designed and constructed to minimize leakage. Drainage zones or filter diaphragms may be an appropriate defense against damage caused by leakage at penetrations.

3.3. Construction Drawings and Specifications

Construction drawings and specifications shall be prepared in accordance with the requirements of the Rules and Regulations. Drawings shall be submitted with all appropriate review and application fees. A Professional Engineer licensed in New Mexico, with experience in the design and construction of dams, shall prepare the construction drawings and specifications. An as-built mylar drawing submittal is required at completion of construction. The State Engineer may waive mylar drawings during the review process and require mylar as-built drawings if a request is submitted in writing. In the event the requirement for mylar drawings is waived until submittal of as-built drawings, a mylar filing sheet will still be required as part of the permit application submittal.

3.4. Easement and Access

The owner shall obtain permanent right of way or easements to access the dam during normal operation and flood events; to impound water and safely discharge water; and to maintain the dam and appurtenances in a safe manner. Easements for returning spillway flows to the natural drainage are required. Urban dams have unique flood easement issues that will be evaluated on a case-by-case basis. A detailed map, with certifications, showing all right of way easements shall be provided with the construction drawings.

3.5. Designer's Operating Criteria and Instrumentation Plan

The Designer's Operating Criteria (DOC) is prepared by the design engineer to ensure the dam and appurtenances are operated within any restrictions imposed by the design. The Instrumentation Plan provides a means to monitor and evaluate the performance of a dam. The DOC and Instrumentation Plan are critical elements of the Operation and Maintenance (O&M) Manual, which shall be addressed in the design phase of the project for significant and high hazard potential dams. An O&M Manual is also required for all significant and high hazard potential dams. The O&M Manual shall conform to the requirements set forth in Section 7 and is required at completion of construction. The DOC and Instrumentation Plan shall be submitted during the review process for new dams or modification to an existing dam.

3.6. Emergency Action Plan

An Emergency Action Plan (EAP) is required for all significant and high hazard potential dams. The EAP shall conform to the requirements set forth in Section 8. The EAP shall be prepared under the direction of a Professional Engineer licensed in New Mexico, with experience in the design and operation of dams. A draft copy of the EAP shall be submitted during the review process for new dams or modification to an existing dam. The draft copy shall include final submittal of the dambreak analysis and flood inundation maps, including all supporting documentation and calculations. A final EAP is required at completion of construction.

4. CONSTRUCTION AND OPERATION APPROVAL

Final action by the State Engineer on the application to Construct and Operate a Dam will address construction and operation conditions. Following the State Engineer's approval of the application and prior to commencement of construction, the owner nominates an engineer, registered in New Mexico, with experience in dam construction to supervise construction of the dam. If the State Engineer finds the engineer acceptable an order is issued approving the engineer and setting forth conditions under which the engineer will supervise construction. Construction shall be in accordance

with approved plans and specifications. The State Engineer must approve any modifications to the approved plans and specifications or design changes in writing prior to undertaking the modifications.

The engineer supervising construction shall submit monthly progress reports to the State Engineer, which shall include a summary of test results. The State Engineer has full authority to perform inspections at any time during construction of the dam and appurtenances. Inspections will vary with each project, based on the complexity of the design. Generally, representatives of the State Engineer inspect construction when

- The foundation is exposed;
- The embankment is one-half complete;
- Construction of any major structural feature is in progress; and
- Final completion of the dam or modification.

Inspection fees are charged at the rate of $100/day. Inspection fees may be waived when construction is required by the State Engineer to address dam safety deficiencies.

Upon completion of construction, the engineer supervising construction shall submit to the State Engineer:

- A completion report, which shall include descriptions of problems and their solutions.
- A summary of materials test data and construction photographs.
- As-built mylar drawings including all signatures on the title sheet.
- A certificate that the dam as constructed is safe for the intended use.

Once all construction conditions in the approved permit are met, pending the issuance of a Certificate of Construction, use of the reservoir shall require written permission from the State Engineer. Use of the reservoir is restricted until the State Engineer approves the final O&M Manual and EAP.

5. CERTIFICATE OF CONSTRUCTION

Upon completion of construction, the owner shall submit an O&M Manual and EAP for approval by the State Engineer and Proof of Completion of Works form, with appropriate fees. Upon receiving this form, the State Engineer will determine if all conditions of the approved application were met. If there are no outstanding conditions, the State Engineer will issue a Certificate of Construction. The dam owner shall record the Certificate of Construction with the county clerk of the county where the dam is located.

6. CHANGES TO THE APPROVED PERMIT

State Engineer approval of reconstruction, enlargement, modification, reservoir capacity restoration, repair, removal, abandonment or ownership change of an existing dam is required prior to any construction taking place. The current condition of the dam, the type of repair or modification, and the proposed means to achieve the repair or modification all dictate the detail of the information that shall be provided to the State Engineer in order to obtain approval. Construction drawings shall adhere to the requirements in the Rules and Regulations and shall include a design report to support the proposed plan. Changes to the permit will require that all deficiencies with the Criteria be addressed. Routine maintenance work defined in the O&M Manual does not require prior approval. All other repair or modification activities not covered by the O&M Manual require State Engineer approval. Preliminary submittal of the drawings, specifications and design report is recommended to determine what criteria are appropriate.

6.1. Removal or Breach of an Existing Dam

The removal, breach or abandonment of an existing dam under the jurisdiction of the State Engineer requires the State Engineer's advanced approval. An existing dam may not be abandoned without breaching, removing or reclaiming the dam to ensure the dam no longer poses a risk to life, property, the environment surrounding the dam or

downstream of the dam. The dam owner shall notify the State Engineer that the owner wishes to remove, breach or reclaim the dam and cancel the permit.

Owners of significant and high hazard potential dams shall submit to the State Engineer a plan evaluating the potential effects of the dam removal or breach on the environment and life and property downstream. A Professional Engineer licensed in New Mexico, with experience in the operation of dams, shall prepare the plan. The plan shall meet the following conditions:

- The dam shall be excavated down to the level of natural ground and the breach shall be of sufficient width to safely pass the 100-year, 24-hour flood;
- The side slopes of the breach shall be excavated to a stable angle;
- The breach shall be armored as necessary to prevent erosion of the breach area;
- The breach shall be designed to control sediment previously deposited on the reservoir bottom;
- The reservoir shall be emptied in a controlled manner, which will not endanger lives or damage property downstream; and
- Drawings shall include a filing sheet, the location, dimensions and lowest elevation of the breach, and any other detail to sufficiently describe the proposal.
- Identification of an engineer registered in New Mexico, with experience in dam construction, to supervise construction of the breach or dam removal. Submittal of engineer's qualifications is required.

If the State Engineer finds the plan and construction engineer acceptable, an order is issued approving the engineer and setting forth conditions under which the engineer will supervise construction of the breach or dam removal. Upon completion of the breach or dam removal, the supervising engineer shall certify that the dam no longer posses a hazard to life and property.

Owners of low hazard potential dams shall submit a written notice to the State Engineer of intent to breach the dam. The breach shall meet the following minimum requirements:

- The bottom width of the breach shall be to original ground;
- The bottom width of the breach shall be a minimum of one-half the height of the dam but not less than 10 feet;
- The side slopes not steeper than one horizontal to one vertical; and
- The excavated material shall not be placed in the streambed.

6.2. Permanent Closure of a Tailings Facility

The permanent closure of a Tailings Facility typically involves numerous regulatory agencies including the State Engineer. Typically a Closure Plan is prepared to address the permanent closure. State Engineer approval is required before any modification occurs to a jurisdictional tailings dam. A Professional Engineer licensed in New Mexico, with experience in the design and construction of tailings dams, shall prepare the closure plan. The plan shall address the following issues:

- Long-term stability under static and dynamic conditions;
- Control of surface runoff to avoid erosion;
- Plan for long term monitoring, if appropriate; and
- Identification of an engineer, registered in New Mexico, with experience in tailings dam construction to supervise construction of the closure plan. Submittal of engineer's qualifications is required.

If the State Engineer finds the plan and construction engineer acceptable, an order is issued approving the engineer and setting forth conditions under which the engineer will supervise construction of the closure plan. Upon completion of construction, the supervising engineer shall certify that the tailings dam no longer posses a hazard to life, property and the environment.

7. OPERATION AND MAINTENANCE MANUAL

An Operation and Maintenance (O&M) Manual shall be prepared for the purpose of documenting accurate, current and comprehensive information for operation, maintenance and monitoring a dam. Because failure of a dam has a potential catastrophic impact on dam owners, water users and downstream public and private

property, an O&M Manual is required for all new and existing high and significant hazard potential dams. The O&M Manual shall contain, at a minimum, all information and instructions necessary for dam owners and operating personnel to operate and maintain a safe dam. A Professional Engineer licensed in New Mexico, with experience in the design and operation of dams, shall prepare the O&M Manual.

An O&M Manual shall be reviewed and updated at least annually or (1) whenever modifications or replacement of the facilities or equipment are completed, or (2) if a need is recognized by the dam owner or operator. Updates shall be submitted to the State Engineer with documentation to support the results of the review.

The O&M Manual shall be bound with a fastening system to facilitate revisions, and each page shall bear the date of the original page or revision. Additional information and discussion is provided in Appendix D. The O&M Manual shall contain the following elements:

- Certification statements by the owner and engineer with approval by the State Engineer.
- General information on the project including the purpose, location, history, responsibilities and description of project and properties.
- Operation instructions for the reservoir, control mechanisms and any other feature of the project.
- Instrumentation details and monitoring requirements.
- Maintenance requirements and schedule.
- Inspection requirements and schedule.
- An update and revision procedure.
- Appendices to include the Designer's Operating Criteria and Instrumentation Plan to ensure any restrictions imposed by the design are included in the O&M Manual.

8. EMERGENCY ACTION PLAN

The Emergency Action Plan (EAP) identifies potential emergency conditions at a dam and specifies preplanned actions to be followed to minimize property damage and loss of life. The EAP assists in pre-planning with the responsible local, state and federal emergency organizations to provide timely notification of a warning of a dam emergency and evacuation in the event of potential dam failure.

An EAP is required for all new and existing significant and high hazard potential dams. The EAP shall conform to the standardized format included in Appendix E and be bound with a fastening system to facilitate revisions. The EAP shall also be submitted to the State Office of Emergency Management (SOEM) for review and approval, prior to submittal to the State Engineer. Annual review and updates (as necessary) to the EAP shall be provided to the State Engineer and SOEM for review and approval. The EAP shall be prepared by a Professional Engineer licensed in New Mexico, with experience in the design and operation of dams.

The EAP should be user friendly and reflect the capabilities and responsibilities of the dam owner and each organization. The EAP must be tailored to each dam's specific conditions, to the capabilities of the owner and operator, and to the emergency response organizations that will implement the EAP. Preparation of an EAP requires coordinated planning with all the principal parties responsible for emergency response and public safety.

The State Engineer requires that owners of high and significant hazard potential classified dams address the following:

- Prepare, maintain and exercise an EAP for immediate action in the event of an emergency at a dam.
- Have the Local Emergency Manager or government official responsible for public safety review their plan, and make appropriate modifications.

- Provide the primary persons and agencies responsible for executing the plan with copies of the EAP and distribute the EAP to all affected entities.
- Review, update and exercise the plan on an annual basis.

The State Engineer has adopted EAP guidelines and standardized format developed by FEMA[13]. A summary of FEMA's guidelines is discussed below.

The following six basic elements shall be included in an EAP:

1. **Notification Flowchart**. The notification flow chart shows who is to be notified, by whom and in what priority. The information on the notification flowchart is necessary for the timely notification of persons responsible for taking emergency action.
2. **Emergency Detection, Evaluation and Classification**. This element includes early detection and evaluation of the situation or event that would trigger the initiation of the EAP or require an emergency action. This element also includes the procedures for reliably and timely identifying an emergency situation to ensure that an appropriate course of action is implemented. Defining various types of emergency situations would be included in this element in order to determine the level of action required for each type of emergency.
3. **Responsibilities.** A determination of responsibility for EAP related tasks must be made during the development of the plan. Since the dam owner is responsible for the development, maintenance and implementation of the EAP, the dam owner will need to work with the emergency preparedness agency in the county in order to define the responsibilities. State and local emergency management officials have statutory obligations and are responsible for warning and evacuation within the affected areas. The dam owner's responsibilities must also be clearly specified to ensure effective and timely action is taken in the event of an emergency at the dam. The EAP must be site-specific since the conditions at a dam and downstream of a dam are different for each dam.
4. **Preparedness.** This section of the EAP will include preparedness actions that can be taken before an emergency. A list of materials, equipment and

manpower available to moderate or alleviate the effects of a dam failure or spillway release should be included in this section.

5. **Inundation Map.** An inundation map delineating the areas that will be flooded as a result of dam failure is a key component of the EAP. The inundation map is used by both the dam owner and emergency management officials to assist in identifying the area that would need to be notified and evacuated as the result of a dam failure or flooding condition. These maps are a useful tool to graphically display the flooded areas, travel times for a wave front and flood peaks at critical locations.
6. **Appendices.** The appendices contain information that supports and supplements the material used in the development and maintenance of the EAP.

Because emergency management agencies rely on the inundation map to develop evacuation procedures, both a “sunny day” failure and a failure during the worst case flood flow conditions should be analyzed and shown on the inundation maps. If a dam is located upstream, failure scenarios with the upstream dam shall also be evaluated. Flood control dams, which have experienced a first fill to the spillway crest, may request a waiver from the “sunny day” failure scenario if adequate justification is provided. The inundation maps should be prepared to show the time and distance from the dam when the flood wave will arrive at critical areas in relation to the beginning of the dam failure hydrograph, the maximum discharge (Q_p) and the depth of flow. Critical public facilities (e.g. water supplies, hospitals, electric utilities, etc.) that would be affected by the flooding should be identified. The dam breach analysis and flood inundation maps shall be submitted to the State Engineer for approval before the EAP is finalized.

APPENDIX A

GLOSSARY OF TERMS

Abutment – That part of the valley side against which the dam is constructed. The left and right abutments of dams are defined with the observer viewing the dam looking in the downstream direction, unless otherwise indicated.

Acre-foot – A unit of volumetric measure that would cover one acre to a depth of one foot. It is equal to 43,560 cubic feet.

Appurtenant structure – Ancillary features of a dam such as outlets, spillways, power plants, tunnels, etc.

Axis of Dam – The vertical plane or curved surface, chosen by a designer, appearing as a line, in plan or in cross-section, to which the horizontal dimensions of the dam are referenced.

Base Thickness – Also referred to as base width. The maximum thickness or width of the dam measured horizontally between upstream and downstream faces and normal to the axis of the dam, but excluding projections for outlets, or other appurtenant structures.

Bedrock – The consolidated body of natural solid mineral matter which underlies the overburden soils.

Berm – A nearly horizontal step in the sloping profile of an embankment dam. Also a step in a rock or earth cut.

Borrow Area – The area from which material for an embankment is excavated.

Breach – An opening through a dam which drains the reservoir. A controlled breach is a constructed opening. An uncontrolled breach is an unintentional discharge from the reservoir.

Cavitation – The formation of a partial vacuum at the interface of fast-flowing water with a surface, typically at a point of turbulence such as a valve or impeller or immediately downstream from an obstruction or offset. Usually accompanied by noise and vibration, and is potentially destructive.

Channel – A general term for any natural or artificial facility for conveying water.

Cofferdam – A temporary structure to facilitate construction dewatering or to divert water away from construction, which is removed prior to completion of construction as part of construction phasing. Common types include steel sheet piles, earthen dikes, and water-filled bladders.

Compaction – Mechanical action which increases the density by reducing the voids in a material.

Conduit – A closed channel to convey water through, around, or under a dam.

Consequences of Failure – Potential loss of life or property damage downstream of a dam caused by floodwaters released at the dam or by waters released by partial or complete failure of dam; includes effects of landslides upstream of the dam on property located around the reservoir.

Construction Joint – The interface between two successive placings or pours of concrete where bond, and not permanent separation, is intended.

Contact Grouting – Filling, with cement grout, any voids existing at the contact of two zones of different materials, e.g. between a concrete tunnel lining and the surrounding rock.

Core – A zone of low permeability material in an embankment dam. The core is sometimes referred to as central core, inclined core, puddle clay core, rolled clay core, or impervious zone.

Core Wall – A wall built of relatively impervious material, usually of concrete or asphaltic concrete, in the body of an embankment dam to prevent seepage.

Crest of Dam – The lowest elevation of the uppermost surface of a dam, usually a road or walkway excluding any parapet wall, railing, etc.

Crest Width – The thickness or width of a dam at the crest level (excluding corbels or parapets). In general, the term thickness is used for gravity and arch dams, and width is used for other dams.

Cross Section – An elevation view of a dam formed by passing a plane through the dam perpendicular to the axis.

Cutoff Trench – A foundation excavation later to be filled with impervious material so as to limit seepage beneath a dam.

Cutoff Wall – A wall of impervious material usually of concrete, asphaltic concrete, or steel sheet piling constructed in the foundation and abutments to reduce seepage beneath and adjacent to the dam.

Dam – A barrier constructed across a watercourse or off channel for the purpose of storage, control, or diversion of water. Types of dams are listed below.

a. Arch Dam – A concrete or masonry dam, which is curved upstream so as to transmit the major part of the water load to the abutments.

b. Buttress Dam – A dam consisting of a watertight part supported at intervals on the downstream side by a series of buttresses. Buttress dam can take many forms, such as flat slab or massive head buttress.

c. Concrete Dam – A dam constructed primarily of concrete, usually cast-in place but possibly including precast or roller-compacted elements. Types of concrete dams include arch, buttress, and gravity, among others.

d. Live storage. The storage volume of a reservoir that is available for use and lies above the invert of the lowest outlet.

e. Reservoir storage capacity. The sum of the dead and live storage of the reservoir.

f. Earth Dam – An embankment dam in which more than 50% of the total volume is formed of compacted earth material generally smaller than 3-inch size.

g. Gravity Dam – A dam constructed of concrete and/or masonry which relies on its weight and internal strength for stability.

h. Masonry Dam – any dam constructed mainly of stone, brick or concrete blocks jointed with mortar. A dam having only a masonry facing should not be referred to as a masonry dam.

i. Multiple Arch Dam – a buttress dam comprised of a series of arches for the upstream face.

j. Rockfill Dam – An embankment dam in which more than 50% of the total volume is comprised of compacted or dumped cobbles, boulders, rock fragments, or quarried rock generally larger than 3-inch size.

k. Roller Compacted Concrete Dam – A concrete gravity dam constructed by the use of a dry mix concrete transported by conventional construction equipment and compacted by rolling, usually with vibratory rollers.

l. Saddle dam (or dike) – a subsidiary dam of any type of constructed across a saddle or low point on the perimeter of a reservoir. When a saddle dam is above the water surface for the permanent storage pool, it may be referred to as a saddle dike.

m. Tailings Dam – An industrial waste dam in which the waste materials come from mining operations or mineral processing. The waste products are conveyed as fine material suspended in water to the reservoir impounded by the embankment.

The embankment may be built of conventional materials but sometimes incorporates suitable waste products.

Dam Failure – The catastrophic breakdown of a dam, characterized by the uncontrolled release of impounded water. There are varying degrees of failure.

Design Water Level – The maximum water elevation including the flood surcharge, that a dam is designed to withstand.

Dike – See saddle dam.

Diversion Channel, Canal, or Tunnel – A waterway used to divert water from its natural course. The term is generally applied to a temporary arrangement, e.g. to by-pass water around a dam site during construction. “Channel” is normally used instead of “canal” when the waterway is short.

Drain, Blanket – A horizontal or gently sloping layer of pervious material placed to facilitate drainage of the foundation and/or embankment.

Drain, Chimney – A vertical or inclined layer of pervious material in an embankment to facilitate and control drainage of the embankment fill.

Drain. Toe – A system of pipe and/or pervious material along the downstream toe of a dam used to collect seepage from the foundation and embankment and convey it to a free outlet.

Drainage Area – The area draining to a particular point of study on a river or stream.

Drainage Curtain (also called drainage wells or relief wells) – A line of vertical wells or boreholes to facilitate drainage of the foundation and abutments and to reduce water pressure.

Drawdown – The difference between a water level and a lower water level in a reservoir within a particular time. Used as a verb, it is the lowering of the water surface.

Earthquake – A sudden motion or trembling in the earth caused by the abrupt release of accumulated stress along a fault.

Earthquake, Maximum Credible (MCE) – The most severe earthquake that can be expected to occur at a given site on the basis of geologic and seismological evidence.

Earthquake, Operating Basis (OBE) – The earthquake(s) for which the structure is designed to resist and remain operational. It reflects the level of earthquake protection desired for operational or economic reasons and may be determined on a probabilistic basis considering the regional and local geology and seismology.

Emergency Action Plan (EAP) – A plan of action to be taken to reduce the potential for property damage and loss of life in an area affected by a dam failure or large flood.

EAP Exercise – An activity designed to promote emergency preparedness; test or evaluate EAPs, procedures, or facilities; train personnel in emergency management duties; and demonstrate operational capability. Exercises consist of the performance of duties, tasks, or operations very similar to the way they would be performed in a real emergency. However, the exercise performance is in response to a simulated event.

EAP Exercise, Comprehensive – An in-depth exercise of an EAP that involves the interaction of the dam owner with the state and local emergency management agencies in a stressful environment with time constraints. Functional and full-scale EAP exercises are considered comprehensive EAP exercises.

Emergency Management Agency – The state and local agencies responsible for emergency operations, planning, mitigation, preparedness, response, and recovery for all hazards. Names of emergency management agencies may vary such as: Division of Emergency management, Comprehensive Emergency Management, Disaster Emergency Services, Civil Defense Agency, Emergency and Disaster Services.

Emergency Operations Center (EOC) – The location or facility where responsible officials gather during an emergency to direct and coordinate emergency operations, to communicate with other jurisdictions and with field emergency forces, and to formulate protective action decisions and recommendations during an emergency.

Energy Dissipator – A device constructed in a waterway to reduce the kinetic energy of fast flowing water.

Erosion – The wearing away of a surface (bank, streambed, embankment) by floods, waves, wind, or any other natural process.

Fault – A fracture or fracture zone in the earth crust along which there has been displacement of the two sides relative to one another.

Fault, Active – A fault which, because of its present tectonic setting, can undergo movement from time to time in the immediate geologic future.

Fault, Capable – An active fault that is judged capable of producing macro-earthquakes and exhibits one or more of the following characteristics:

a. Movement at or near the ground surface at least once within the past 35,000 years.

b. Macroseismicity (3.5 magnitude Richter or greater) instrumentally determined with records of sufficient precision to demonstrate a direct relationship with the fault.

c. A structural relationship to a capable fault such that movement on one fault could be reasonably expected to cause movement on the other.

d. Established patterns of microseismicity which define a fault, with historic macroseismicity that can be reasonably be associated with the fault.

Fetch – The straight line distance across a body of water subject to wind forces. The fetch is one of the factors used in calculating wave heights in a reservoir.

Filter (filter zone) – One or more layers of granular material graded (either naturally or by selection) so as to allow seepage through or within the layers while preventing the migration of material from adjacent zones.

Flood – A temporary rise in water surface elevation resulting in inundation of areas not normally covered by water. Hypothetical floods may be expressed in terms of average probability of exceedance per year such as one-percent-chance flood, or expressed as a fraction of the probable maximum flood or other reference flood.

Flood Inundation Zone – The downstream area that would be inundated or otherwise affected by the failure of a dam or by large flood flows.

Flood Routing – A process of determining progressively over time the amplitude of a flood wave as it moves past a dam and continues downstream.

Flood Storage – The retention of water or delay of runoff either by planned operation, as in a reservoir, or by temporary filling of overflow areas, as in the progression of a flood wave through a natural stream channel.

Freeboard – Vertical distance between the spillway crest and the lowest point of the top of dam, without chamber.

Gallery – A passageway in the body of a dam used for inspection, foundation grouting, and/or drainage.

Gate – A movable water barrier for the control of water.

a. Bulkhead gate. A gate used either for temporary closure of a channel or conduit before dewatering it for inspection or maintenance or for closure against flowing water when the head difference is small, e.g., for diversion tunnel closure.

b. Emergency gate – A standby or auxiliary gate used when the normal means of water control is not available. Sometimes referred to as guard gate.

c. Outlet gate – A gate controlling the flow of water through a reservoir outlet.

d. Regulating gate (regulating valve) – A gate or valve that operates under full pressure flow conditions to regulate the rate of discharge.

e. Slide gate (sluice gate) – A gate that can be opened or closed by sliding in supporting guides.

Gate chamber (valve chamber) – A room from which a gate or valve can be operated, or sometimes in which the gate is located.

Geotextiles – Any fabric or textile (natural or synthetic) when used as an engineering material in conjunction with soil, foundations or rock. Geotextiles have the following uses: drainage, filtration, separation of materials, reinforcement, moisture barriers, and erosion protection.

Groin – The area along the contact (or intersection) of the face of a dam with the abutments.

Grout – A fluidized material that is injected into soil, rock, concrete, or other construction material to seal openings and to lower the permeability and/or provide additional structural strength. There are four major types of grouting materials: chemical; cement; clay; and bitumen.

Grout Curtain – One or more zones, usually thin, in the foundation into which grout is injected to reduce seepage under or around a dam.

Hazard Potential Classification – A rating for a dam based on the potential consequences of failure. The rating is based on potential for loss of life and damage to property that failure of that dam could cause. Such classification is related to the amount of development downstream of a dam.

Head, Static – The vertical distance between two points in a fluid.

Heel – The junction of the upstream face of a gravity or arch dam with the ground surface. For an embankment dam the junction is referred to as the upstream toe of the dam.

Height – The maximum height from the lowest natural ground surface, which is typically on the downstream side, to the top of the dam.

Height, Structural – The vertical distance between the lowest point of the excavated foundation to the top of the dam.

Hydrograph, Breach or Dam Failure – A flood hydrograph resulting from a dam breach.

Hydrograph, Flood – A graphical representation of the flood discharge with respect to time for a particular point on a stream or river.

Hydrology – One of the earth sciences that encompasses the natural occurrence, distribution, movement, and properties of the waters of the earth and their environmental relationships.

Inflow Design Flood (IDF) – The flood flow above which the incremental increase in downstream water surface elevation due to failure of a dam or other water impounding structure is no longer considered to present an unacceptable additional downstream threat. The upper limit of the IDF is the probable maximum flood (PMF).

Instrumentation – An arrangement of devices installed into or near dams (i.e., piezometers, inclinometer, strain gauges, measurement points, etc.), which provide for measurements that can be used to evaluate the structural behavior and performance parameters of the structure.

Intake – Any upstream structure in a reservoir, dam or river through which water can be discharged.

Inundation Map – A map delineating the area that would be flooded by a particular flood event.

Jurisdictional Dam – A dam greater than 10 feet in height or storing greater than 10 acre-feet, that is not exempt under Section 72-5-32 NMSA.

Length of Dam – The length measured along the dam axis at the top of dam. This also includes the spillway, powerplant, navigation lock, fish pass, etc., where these form part of the length of the dam. If detached from the dam these structures should not be included.

Liquefaction – A condition whereby soil undergoes continued deformation at a constant low residual stress or with low residual resistance, due to the buildup and maintenance of high pore water pressures, which reduces the effective confining pressure to a very low value. Pore pressure buildup leading to liquefaction may be due either to static or cyclic stress applications and the possibility of its occurrence will depend on the void ratio or relative density of a cohesionless soil and the confining pressure.

Loss of Life – The likely number of human fatalities that would result from a dam failure flood event. No allowances for evacuation or other emergency actions by the population should be considered.

Meterology – The science that deals with the atmosphere and atmospheric phenomena, the study of weather, particularly storms and the rainfall they produce.

Minimum Operating Level – The lowest level to which the reservoir is drawn down under normal operating conditions.

Notification – To inform appropriate individuals about an condition so they can take appropriate action.

Observation Well – A hole used to observe the groundwater surface at atmospheric pressure within soil or rock.

One-Hundred Year Flood – A flood that has 1 chance in 100 of being equaled or exceeded during any year.

Outlet – An opening through which water can be discharged.

Outlet Works – A dam appurtenance that provides release of water (generally controlled) from a reservoir.

Parapet Wall – A solid wall built along the top of a dam (upstream or downstream edge) used for ornamentation, for safety of vehicles and pedestrians, or to prevent overtopping caused by wave runup.

Phreatic Surface – The free surface of water seeping at atmospheric pressure through soil and rock.

Piezometer – An instrument used for measuring fluid pressure (air or water) within soil, rock, or concrete.

Piping – The progressive development of internal erosion by seepage.

Probability – The likelihood of an event occurring.

Probable Maximum Flood (PMF) – The flood that may be expected from the most severe combination of critical meteorologic and hydrologic conditions that are reasonably possible in the drainage basin under study.

Probable Maximum Precipitation (PMP) – Theoretically, the greatest depth of precipitation for a given duration that is physically possible over a given size storm area at a particular geographical location during a certain time of year.

Purpose – The purpose for which the reservoir is used. Typical choices are: Irrigation, Hydroelectric, Flood Control, Water Supply, Recreation, Stock, Fish and Wildlife, and Tailings.

Reservoir – A body of water impounded by a dam and in which water can be stored.

Reservoir Inundation Zone – The area bounded by the water surface elevation associated with the routing of the IDF.

Reservoir Regulation (or operating) Procedure – Operating procedures that govern reservoir storage and releases.

Reservoir Rim – The boundary of the reservoir including all areas along the valley sides above and below the water surface elevation associated with the routing of the IDF.

Reservoir Surface Area – The area covered by a reservoir when filled to a specified elevation.

Riprap – A layer of large uncoursed stone, precast blocks, bags of cement or other suitable material, generally placed on the upstream slopes of an embankment or along a watercourse as protection against wave action, erosion or scour. Riprap is usually placed by dumping or other mechanical methods and in some cases is hand placed. It consists of pieces of relatively large size as distinguished from a gravel blanket.

Risk – The relationship between the consequences resulting from an adverse event and its probability of occurrence.

Slope – Inclination from the horizontal. Sometimes referred to as batter when measured from vertical.

Sluice – An opening for releasing water from below the static head elevation.

Spillway – A structure over or through which flow is discharged from a reservoir. If the rate of flow is controlled by mechanical means such as gates, it is considered a controlled spillway. If the geometry of the spillway is the only control, it is considered an uncontrolled spillway.

a. Auxilliary – Any secondary spillway which is designed to be operated very infrequently and possibly in anticipation of some degree of structural damage or erosion to the spillway during operation.

b. Principal (or service) – A spillway designed to provide continuous or frequent releases from a reservoir, without significant damage to either the dam or its appurtenant structures.

c. Emergency – A spillway that is designed to provide additional protection against overtopping of dams, and is intended for use under extreme flood conditions or misoperation or malfunction of the service spillway and/or the auxiliary spillway.

Spillway Channel – An open channel or closed conduit conveying water from the spillway inlet downstream.

Spillway Crest – The lowest level at which water can flow over or through the spillway.

Spillway Design Flood (SDF) – The required flood that a spillway must pass without failure of the dam.

Spillway Effective Length – The measured length of the crest of the spillway reduced by contraction of flow. Effective length is used to determine the spillway discharge.

Stilling Basin – A basin constructed to dissipate the energy of rapidly flowing water, e.g., from a spillway or outlet, and to protect the riverbed from erosion.

Storage – The retention of water or delay of runoff either by planned operation, as in a reservoir, or by temporary filling of overflow areas, as in the progression of a flood wave through a natural stream channel. Definitions of specific types of storage in reservoirs are:

a. Dead storage. The storage volume of a reservoir that lies below the invert of the lowest outlet and that, therefore, cannot readily be withdrawn from the reservoir.

b. Flood surcharge storage. The storage volume between the maximum operating level and the design water level.

c. Maximum storage. The sum of the reservoir storage capacity and flood surcharge storage.

Storm – The depth, area, and duration distribution of precipitation.

Sunny Day Failure – Failure from other than a large flood such as earthquake induced, structural weakness, piping, etc. The maximum operating water level is assumed.

Toe of Dam – The junction of the downstream slope of a dam with the ground surface; also referred to as the downstream toe. The junction of the upstream slope with the ground surface is called the heel or the upstream toe. For concrete dams, see heel.

Top of Dam – See crest of dam.

Top Thickness (top width) – See crest width.

Trashrack – A device located at an intake to prevent floating or submerged debris from entering the intake.

Tunnel – A long underground excavation with two or more openings to the surface, usually having a uniform cross section used for access, conveying flows, etc.

Type of Dam – See descriptions listed for Dam.

Upstream Blanket – An impervious blanket placed on the reservoir flood and abutments upstream of a dam. For an embankment dam, the blanket may be connected to the core.

Valve – A device fitted to a pipeline or orifice in which the closure member is either rotated or moved transversely or longitudinally in the waterway so as to control or stop the flow.

Volume of Dam – The total space occupied by the materials forming the dam structure computed between abutments and from top to bottom of dam. No deduction is made for small openings such as galleries, adits, tunnels, and operating chambers within the dam structure. Portions of powerplants, locks, spillway, etc., should be included only if they are necessary for the structural stability of the dam.

Wave Runup – Vertical height above the stillwater level to which water from a specific wave will run up the face of a structure or embankment.

Watershed – The region draining into a river, river system or body or water.

Weir – An overflow structure built across an open channel to raise or control the upstream water level and/or to measure the flow of water.

a. Weir, broad-crested. An overflow structure on which the nappe is supported for an appreciable length in the direction of flow.

b. Weir, measuring. A device for measuring the rate of flow of water. It generally consists of a rectangular, trapezoidal, triangular, or other shaped notch, located in a vertical, thin plate over which water flows. The height of water above the weir crest is used to determine the rate of flow.

c. Weir, ogee. An overflow structure with its cross-section in the form of a reverse curve, shaped like an elongated letter “S”. The downstream faces of overflow spillways are often made to this shape.

APPENDIX B

DAM SAFETY STATUTUES

Statutory Chapters in New Mexico Statutes Annotated 1978

CHAPTER 72 WATER LAW

ARTICLE 5 APPROPRIATION AND USE OF SURFACE WATER

72-5-9. Supervision; inspection; completion of works; alterations.

For the supervision of the construction of works for the storage, diversion or carriage of water there shall be in charge a registered professional engineer, whose qualifications have been approved by the State Engineer. This engineer shall have full authority to carry out such inspections and instructions that are deemed necessary by the State Engineer. On the date set for the completion of the work, or prior thereto, upon notice from the owner that the work has been completed, the State Engineer shall cause the work to be inspected, after due notice to the owner of the permit. Such inspection shall be thorough and complete, in order to determine the actual capacity of the works, their safety and efficiency. If not properly and safely constructed, as plans approved, the State Engineer may require the necessary changes to be made within a reasonable time, to be fixed by him and shall not issue his certificate of completion until such changes are made. If at or before the expiration of said time, good cause is shown why said change could not be made within said time, then additional time may be allowed in which to make said change. Failure to make such changes shall cause the postponement of the priority under the permit for such time as may elapse from the date for completing such changes until made to the satisfaction of the State Engineer, and applications subsequent in time shall have the benefit of such postponement of priority: the State Engineer, if he deems it necessary to the public safety, may bring in consulting engineers, geologists or other expert consultants, compensation for which will be paid for by the owner of the permit; provided, that for works involving the diversion of not exceeding twenty cubic feet of water per second or a dam not exceeding ten feet in height from the lowest natural ground surface elevation the State Engineer may, in his discretion, waive the above provisions and accept the report of the inspection by a registered professional engineer.

History: Laws 1907, ch. 49, § 30; Code 1915, § 5688; C.S. 1929, § 151-139; Laws 1937, ch. 178, § 4; 1941, ch. 126, § 12; 1941 Comp., § 77-508; 1953 Comp., § 75-5-8.

72-5-10. [State Engineer's certificate of construction.]

When the works are found in satisfactory condition, after inspection, the State Engineer shall issue his certificate of construction, setting forth the actual capacity of the works and such limitations on the water right as shall be warranted by the condition of the works, but in no manner extending the rights described in the permit.

History: Laws 1907, ch. 49, § 31; Code 1915, § 5689; C.S. 1929, § 151-140; 1941 Comp., § 77-509; 1953 Comp., § 75-5-9.

72-5-11. Inspection and correction of unsafe works.

If the State Engineer shall in the course of his duties find that any works constructed for the storage, diversion or carriage of water are unsafe and a menace to life or property, he shall at once notify the owner or agent, specifying the changes necessary and allowing a reasonable time for putting the works in safe condition. Upon the request of any party, accompanied by the estimated cost of inspection, the State Engineer shall cause any alleged unsafe works to be inspected. If they shall be found unsafe by the State Engineer, the money deposited by such party shall be refunded, and the fees for inspection shall be paid by the owner of such works; and, if not paid by him within thirty days after the decision of the State Engineer, shall be a lien against the property of such owner, to be recovered by suit instituted by the district attorney of the county at the request of the State Engineer. The State Engineer may, when in his opinion necessary, inspect any works under construction for the storage, diversion or carriage of water and may require any changes necessary to secure their safety; and the fees for such inspection shall be a lien on any property of the owner and shall be subject to collection as provided herein; provided that nothing contained in this section shall be construed to make works being constructed or owned by the United States while under supervision of officers of the United States subject to inspection by the State Engineer.

Nothing contained in this section and no action or failure to act under this section shall be construed:

A. to create any liability in the state or its officers or employees for the recovery of damages caused by such action or failure to act; or

B. to relieve the owner or operator of water impoundment works of the legal duties, obligations or liabilities incident to the ownership or operation of water impoundment works.

History: Laws 1907, ch. 49, § 32; Code 1915, § 5690; C.S. 1929, § 151-141; 1941 Comp., § 77-510; 1953 Comp., § 75-5-10; Laws 1979, ch. 314, § 1.

72-5-12. Failure to comply with State Engineer order; penalty.

Any owner of works for the diversion, storage, carriage or impoundment of water, his agent or employees, who, following notice to place such works in a safe condition as provided in Section 72-5-11 NMSA 1978, fails to take action specified by the State Engineer within the time allowed, shall be guilty of a misdemeanor. Any violation of this section shall be punishable by a fine of not more than two hundred fifty dollars ($250) for each offense or by imprisonment for a definite term not to exceed six months, or both. It is the duty of the State Engineer to give prompt notice to the district attorney of the county in which the works are located in case of such violation. The district attorney shall at once proceed against the owner and all parties responsible therefor.

History: Laws 1907, ch. 49, § 33; Code 1915, § 5691; C.S. 1929, § 151-142; 1941 Comp., § 77-511; 1953 Comp., § 75-5-11; Laws 1979, ch. 314, § 2.

72-5-32. Construction of dams exceeding ten feet in height. (1997)

Any person, association or corporation, public or private, the state or the United States hereafter intending to construct a dam shall meet the requirements of filing applications for appropriations and use of water pursuant to Section 72-5-1, 72-5-22, 72-5-23 or 72-5-24 NMSA 1978. Any person, association or corporation, public or private, the state or the United States intending to construct a dam that exceeds ten feet in height from the lowest natural ground surface elevation to the crest of the dam or impounds more than ten acre-feet of water shall submit on a form prescribed by the State Engineer detailed plans to the State Engineer for approval before construction. If the State Engineer finds that the dam design is safe, he shall approve the plans; provided that this section shall not apply to stock dams or erosion control structures whose maximum storage capacity does not exceed ten acre-feet or any dam constructed for the sole purpose of sediment and flood control under the supervision of the United States army corps of engineers.

History: Laws 1941, ch. 126, § 25; 1941 Comp., § 77-530; 1953 Comp., § 75-5-30; Laws 1979, ch. 114, § 1; 1997, ch. 66, § 1.

MANUAL OF RULES AND REGULATIONS GOVERNING THE APPROPRIATION AND USE OF THE SURFACE WATERS OF THE STATE OF NEW MEXICO

Revised August, 1953

(Copies of pertinent Sections Only)

I. CONSTITUTIONAL PROVISIONS AND GENERAL PRINCIPLES OF APPROPRIATION

All existing rights to the use of water for beneficial purposes in New Mexico were recognized and confirmed by the State Constitution at the time of its adoption.

The State Engineer is empowered to make all rules and regulations necessary to administer the duties devolved upon his office.

All natural waters flowing in streams and water courses in New Mexico are declared to be public and subject to appropriation for beneficial use.

Beneficial use is the basis, measure and limit of the right to use water. No water right, therefore, may be granted or claimed for more than the amount that can be beneficially used.

The unauthorized use of water to which another is entitled, or the willful waste of water to the detriment of another or of the public is a misdemeanor. Excessive, wasteful and otherwise non-beneficial uses do not constitute a valid water right.

Priority in time shall give the better right.

All water appropriated for irrigation purposes, except as otherwise provided by written contract between the owner of the land and the owner of any ditch, reservoir, or other works for the storage or conveyance of water, is appurtenant to the land upon which it is used and shall so continue as long as it can be beneficially used on or until it is lawfully severed from the land. Water which is appurtenant to certain lands may not be transferred to other lands or used for other beneficial purposes excepting with the consent of the owner of the land and as provided by law.

No appropriation of water shall be exercised to the detriment of anyone having prior, valid and existing rights to the use of the waters of the stream system.

Excepting for water rights acquired prior to March 19, 1907, any right to the use of public waters must originate by application to the State Engineer as provided by statute. Unauthorized use shall be a misdemeanor.

The public is notified of proposed appropriations by publication in a newspaper of general circulation in the stream system and any water right owner who feels that the use of water under such application would be detrimental to his prior right may file a protest thereto. After due consideration of the facts, the State Engineer shall approve or reject the application.

It is unlawful to commence any construction of works until the formal application to appropriate water has been approved and signed by the State Engineer.

The diversion and distribution of water for irrigation and domestic purpose in New Mexico is a public purpose, and an appropriator may exercise the right of eminent domain to acquire rights-of-way for canals, ditches, reservoirs, etc., necessary to accomplish such purpose.

License to appropriate water is issued by the State Engineer after the works are satisfactorily completed and the water is applied to beneficial use.

Excepting stored waters, failure of an owner to beneficially use all or any part of the water in which he has a vested right for a period of 4 consecutive years constitutes forfeiture and such unused water shall revert to the public; except that forfeiture does not necessarily occur should such non-use be caused by circumstances beyond the owner's control.

To the end that the waters of the several stream systems of the state may be so utilized as to prevent waste and damage and in order that the benefits of such waters be distributed among the land owners along said streams as equitably as possible without interfering with vested rights, the natural right of the people living in the upper valleys to impound and utilize a reasonable share of such waters has been recognized and declared, subject always to the provisions of the water right statutes.

The appropriation statutes do not apply to stockmen who shall build or construct tanks or ponds for watering stock which do not exceed 10 acre feet in capacity. The owners are, however, at all times responsible for any detriment or damage to prior water rights which may result from the construction of and storage of water in such stock ponds.

The State Engineer has the right and duty of supervision of the apportionment of water according to the licenses issued by his office and to the adjudications of the courts. Although water rights acquired prior to March 19, 1907, may be adjudicated only by the courts, all such rights are subject to regulation, adjudication and forfeiture for non-use as provided in the statutes; provided, that in all cases where the rights to the use of the waters in interstate streams of owners of land not included in conservancy districts, irrigation districts, or Federal reclamation projects have been the subject of litigation in

the State or Federal courts of an adjoining state, the State Engineer shall assume control of all or any part of such interstate stream and the diversions and distribution of the waters of the same in the public interest.

II. PROCEDURE FOR APPROPRIATING PUBLIC SURFACE WATERS

A. Initiation of Water Right---Filling Fees---Priority.

The right to appropriate the public surface waters of New Mexico may be acquired by any person, firm, association, corporation, the State of New Mexico or the United States of America. Excepting projects of the Bureau of Reclamation (see page 21), all rights acquired after March 19, 1907, must be initiated in the office of the State Engineer by filing an application to make such appropriation. Acceptance of the filing by the State Engineer gives the applicant a tentative right to proceed according to statute in establishing his water right. It is unlawful, however, to commence any construction of works prior to the formal approval of the application by the State Engineer. The necessary blank forms for making water right application will be furnished by the State Engineer upon request. All other regular blank forms will be sent to applicant as required.

A water right may be initiated by filing Notice of Intention, to be followed within a designated time by Formal Application; or the right may be initiated by filing Formal Application directly. In either case there is a filing fee which is a necessary part of the application. The fee for filing Notice of Intention is $25.00. The fee for filing Formal Application is graduated in amount and depends upon the size and complexity of the project (see Article VII Fees). Excepting as it may be changed by the provisions of Sections D, E, F or K of this Article, the priority date of any water right is the date of receipt of initial filing papers accompanied by proper fee.

B. Notice of Intention.

Notice of Intention to make Formal Application for Permit shall be filed in duplicate on the proper forms, accompanied by a $25.00 filing fee. Upon receipt of the Notice properly filled out, the State Engineer shall endorse thereon the date of receipt and shall establish the date for filing Formal Application. Initiation of a right by Notice of Intention is optional and is designed as the lawful means of establishing a priority date for a reasonable length of time sufficient to make surveys and prepare necessary maps, plans, etc., as required by statute. The time granted is usually 6 months but depends somewhat upon the size and complexity of the proposed project. Additional time may be granted at the discretion of the State Engineer in special or unusual cases where the original time allowance proves insufficient, but in no case may the time between filing of Notice of Intention and filing of Formal Application exceed an aggregate of 3 years.

C. Surveys---Maps---Plans.

Field surveys of the project shall be made and maps, plans, field notes, specifications, etc., of the proposed works prepared by a qualified registered professional engineer.

Small projects for simple diversion and distribution and which involve no planning or design of dams, canal structures, etc., may be prepared for filing by a registered surveyor, if qualified to do the work. The engineer is responsible for the reasonable correctness of maps, plans, etc., which he prepares for filing with the State Engineer.

The maps, plans, etc., must be prepared from actual field surveys and must be detailed and complete enough to determine the feasibility, safety and adequacy of the proposed works. In cases involving storage or diversion of large amounts of water, the State Engineer may require any additional information he deems necessary to describe and define the proposed use.

Description and details of the data, certificates, etc., which must be shown on the maps and plans will be found under Article VI, “Filing Maps, Plans, Specifications.”

D. Formal Application

Formal Application shall be filed in duplicate on the proper forms. If Formal Application is an initial filing, it shall be accompanied by the required filing fees; if it follows a Notice of Intention it shall be filed not later than the date set by the State Engineer for such filing and shall be accompanied by the required filing fees from which amount has been deducted the $25.00 fee paid at the time of filing such Notice of Intention. Upon receipt of the proper application forms, completed in every detail, the Notice of Publication shall be issued. The information, maps, field notes, and detail required in plans and specifications to be submitted with the application will depend upon the nature and complexity of the works and will be specified by the State Engineer in each case. In general, it will not be necessary to submit plans and specifications with the application. After receipt of the affidavit of Proof of such Publication and the end of the protest period (and hearing on said protested application if necessary said application shall be approved or denied. Application shall be approved only with the provision that complete plans and specifications shall be submitted within a reasonable length of time to be designated by the State Engineer, and that no construction of the works shall commence until such plans and specifications have been approved. Additional fees required for the examination and study of detailed plans and specifications are set forth in Article VII.

The date of receipt of Formal Application by the State Engineer shall be endorsed thereon and noted in his record. If Formal Application is filed later than the limiting date fixed by Notice of Intention or by subsequent extensions of time thereto, it shall, excepting as to filing fee, be treated as a new application and the priority date shall become the date of the filing of Formal Application.

Formal Application defines and limits the maximum amount of water which may be appropriated, and no subsequent act, excepting as provided by statute, can extend or amplify such appropriation. A right can be acquired for any amount less than that asked for in the Formal Application, however, it should be emphasized here, also, that proposed irrigated areas described in the Formal Application cannot be changed or

other areas substituted in lieu thereof, nor can the proposed point of diversion be changed, excepting as provided by law.

H. Fees for Examining Plans and Specifications.
Before he shall approve an application the State Engineer shall require the deposit of the fees prescribed by statute for the examination and study of the plans and specifications of the proposed works (see Article VII, "Fees"). These fees are graduated in amount and depend upon the size and complexity of the project, excepting that no fees are charged in the case of small, simple diversion projects where the submission of plans and specifications are not required, and no fees may be charged for studying plans and specifications in the case of projects initiated by the United States or its authorized agencies.

I. Approval---Permit.
In approving an application, the State Engineer shall sign his endorsement upon the Formal Application and shall set the time within which applicant shall construct the works and apply water to beneficial use, but not to exceed five years for construction of works and four years in addition thereto for application to beneficial use. If, in his opinion, sufficient unappropriated waters are not available to satisfy the project, the State Engineer may approve the application for a smaller amount of water than that applied for. In no case may the amount be increased excepting by a new or amended filing. Applications are always approved with the provision that they must not be exercised to the detriment of any appropriators having prior, valid and existing rights to the use of the water of the stream system. For special conditions, special additional provisions may be imposed.

Upon approval the application becomes a permit to appropriate water. A permit does not in itself constitute a water right but merely allows the permittee to demonstrate to the State and others that he can and will, in good faith and with due diligence, construct the works and apply water to beneficial use as provided by the terms thereof. The permit defines and limits the water right which may be required and should be filed of record with the clerk of the county within which the works are to be situated.

K. Construction of Works---Inspection.
The works shall be constructed by the permittee under the supervision of a qualified registered professional engineer unless this provision is specifically waived by the State Engineer. If he deems it necessary to the public safety, the State Engineer may call in consulting engineers or geologists to study and pass upon the project. Cost of such supervision and consulting work shall be borne by the permittee. Construction shall be carried on according to the plans and specifications approved by the State Engineer and no changes or alterations shall be made without his knowledge and consent. As soon as possible after notification of completion of works, the State Engineer, or a proper assistant, shall make a thorough inspection of the works to determine their actual capacity, their adequacy, safety and efficiency, and shall file his report thereon as a part of the permanent record; provided that, in the case of work involving the diversion of not to exceed 20 cubic feet of water per second of time or a dam not exceeding 10 feet in

height above stream bed, the State Engineer may appoint a registered engineer or land surveyor to make the inspection. If the works have been materially changed from the original plans on file, corrections shall be made on the originals, or amended plans shall be submitted for the record. If found to be improperly constructed or unsafe, the State Engineer shall require the making, within a reasonable time limit fixed by him, of all changes or repairs indicated as necessary. If the time allowed proves insufficient, the State Engineer may, upon sufficient showing by the permittee, grant additional time for making the required changes. Failure to make such corrections shall cause the postponement of the priority date of the permit for the length of time elapsing between the date set by the State Engineer and the date when the changes have been satisfactorily completed.

Upon completion, the permittee shall file in duplicate on the proper forms Proof of Completion of Works, which shall be duly sworn to and signed by the inspecting engineer after he has made a thorough field inspection. If not done previously, the owner shall at this time make affidavit or submit proof that he holds all necessary rights-of-way for his works without controversy. A fee of $25.00 for the issuance of a Certificate of construction shall accompany this filing.

L. Certificate of Construction.
The State Engineer shall then issue a Certificate of Construction which shall include the location of the point or points of diversion, the capacities of canals and reservoirs, and shall certify to the adequacy of the works for the intended use. Owner shall record the Certificate of Construction with the clerk of the county within which the works lie.

N. Final Inspection
Upon due notice to the owner of the permit, the State Engineer, one of his assistants, or a qualified registered professional engineer or land surveyor appointed by him shall make an inspection at the owner's expense and shall prepare and file as a part of the record a final report on the project, incorporating therein his recommendations of water use. Such report shall describe in detail by legal subdivision the land irrigated, giving acreages and as closely as possible the quantity of water applied on the lands. Such report is not required to determine losses in transit as they are uncertain and vary widely according to methods of delivery and character of soils thru which the works are constructed. A license to apply a given quantity of water on the land carries with it the right to divert from the stream an additional quantity sufficient to cover actual necessary losses in transit.

In the case of small diversion or storage projects, the State Engineer may in his discretion, when requested by the owner, cause the inspection of works and final inspection of application of water to beneficial use to be made at the same time.

V. ADDITIONAL PROVISIONS AND REQUIREMENTS

The following sections describe additional provisions and requirements of the law in connection with appropriation and use of the surface waters of the State. They are included herein to delineate more clearly certain rights and duties of the water users and of the State Engineer.

Federal Reclamation Projects
Whenever the proper officers of the United States authorized to construct reclamation projects under the terms of the Federal reclamation act shall notify the State Engineer that the United States intends to make use of certain unappropriated waters of the State, the waters so reserved shall not be subject to further appropriation for a period of three years, within which time such officers shall file comprehensive maps and plans of the proposed project. The waters so reserved are not subject to adverse claim or appropriation unless no plans have been filed within the 3-year period or unless such waters are formally released in writing by the proper officer of the United States.

This section involves only works initiated and built under the terms of the Federal Reclamation Law, and does not apply to other Federal agencies.

Unsafe Works---Inspection---Repair
If, upon the request of any party, accompanied by the estimated cost of inspection, or in the course of his regular duties, the State Engineer shall find by inspection that any works used for the storage, diversion or carriage of water are unsafe and a menace to life and property, he shall at once notify the owner thereof, specifying the changes necessary and allowing a reasonable time for putting the works in safe condition. The cost of such inspection shall be a lien upon the property, unless the works are found to need no repair or change, in which case the cost shall be borne by the party requesting the inspection. The continued use of unsafe works after notification by the State Engineer and contrary to his instructions shall be a misdemeanor.

Excepting for works under construction or being owned by the United States while under supervision of officers of the United States, the State Engineer may inspect any works under construction and may require any changes necessary to secure their safety, and the costs of such inspection shall be a lien upon the property.

VI. FILING MAPS, PLANS, SPECIFICATIONS

A. General Filing Requirements
TRACINGS---All filing maps, as well as supplementary plan and detail sheets, shall be original tracings, carefully and neatly done. If more than one sheet is required, they shall be properly numbered in sequence (example---Sheet 1 of 3 Sheets). In general the filing map shall be separate from the plans and detail sheets, excepting that, in the case of small simple diversion projects, all necessary information may be contained on a single sheet. All sheets shall conform to the standards given below.

DIMENSIONS---They shall be prepared on good quality tracing cloth, 24 inches by 36 inches, outside dimensions, with a one-inch margin on all sides. Tracings which vary from this standard size will not be accepted. Writing or other data must not appear in the margins of the sheets.

WATERPROOF INDIA INK---As all tracings are a part of the permanent record, they must be prepared with a good quality permanent black waterproof India drawing ink. This requirement also applies to all signatures, dates, acknowledgments, etc., appearing on the sheets. No sheets which do not fully comply with this provision can be accepted.

CARELESS OR UNSATISFACTORY WORK---CORRECTION---Illegible, mutilated, careless or otherwise poorly prepared maps and plans are not acceptable for filing purposes and may be returned to be redone and retraced. Maps and plan sheets upon which the data are incomplete, faulty or missing will be returned for correction or addition.

TRACINGS NOT FOLDED---Tracings must never be folded but should be rolled about a strong round stick or in a heavy cardboard mailing tube for transportation and handling purposes.

SCALE OF MAPS, PLANS AND DETAIL SHEETS---The scale or scales used on the filing sheets will, of course, vary according to requirements and space available. However, a standard engineer's scale of sufficient size to show all necessary data clearly and in detail should be chosen. All distances shall be shown in feet and decimals thereof; detail dimensions of structures, headgates, drops, etc., may be given in feet and inches. If part of the works is located on State or Federal lands over which right-of-way must be obtained, the scale chosen should preferably be the scale required by such agency, so that replatting to meet their requirements for obtaining right-of-way will not be necessary.

DIRECTION OF NORTH---Maps shall be platted to the true meridian and all bearings shown shall be true bearings. The direction of North shall be placed on the map. Magnetic declination should also be shown if used in making the field survey.

ENGINEER'S AND NOTARY'S SEALS---The impressions of the seals of the engineer or land surveyor preparing the filing and of the notary public shall be placed on the tracing cloth following or near the signatures thereof.

FIELD NOTES---TRAVERSES---Field notes showing courses and distances of canals or pipelines, or of extreme high water line of a reservoir, are a necessary part of a filing, particularly when the works lie on or cross lands thru which right-of-way must be acquired. As nearly as possible a station should be located on each public survey line wherever the traverse crosses such lines. Stations should be numbered consecutively from the point of beginning to the end of the works and bearings and distances shown

by tabulation on the filing map. Where traverses approach public survey corners along their routes, ties should be made to such corners as can be found. Corners which are located in the field and used in the survey should be indicated on the map by encircling them with a diamond or other mark to distinguish from corners not located.

HYDRAULIC PROPERTIES OF MAIN CANALS, PIPELINES, ETC.---All pertinent hydraulic properties of main canals, pipelines, etc., including their dimensions, gradients, coefficients of roughness, freeboard and working capacities, shall be determined and shown on the plan and detail sheets. All elevations, plans, sections, construction details, etc., necessary to properly describe the works shall be shown.

RESERVOIR AREA AND CAPACITY---The topography of any proposed reservoir site shall be determined with reasonable accuracy and a contour map thereof prepared and placed on the filing map, the contour intervals not to exceed 5 feet each in elevation. The State Engineer may require a smaller contour interval than 5 feet if necessary for obtaining reasonable accuracy. Detailed topography of the dam site including sufficient area upstream and downstream and at the sides to properly design spillways, outlets, coffer-dams, etc., shall be taken. An area and capacity table of each reservoir shall also appear on the map, the contour intervals of which may be designated as “feet above bottom of outlet,” or they may be given in “elevations above mean sea level,” or above some assumed datum. It is important that a permanent bench mark above high water line should be established and fully described in order that the established reservoir datum may be available at all times.

DESIGN OF DAMS---The design and specifications of any dam for the storage or diversion of water shall conform in all respects with the State Engineer's code of dam construction, a copy of which code will be sent applicants upon request. This requirement is essential, as much for the protection of the investment of the appropriator as it is for the protection of the lives and property of those living below the dam and for the conservation of the public water supply.

In general, earthen storage dams shall be constructed with a slope not less than 2: horizontal to 1 vertical on the upstream or water side and 2 horizontal to 1 vertical on the downstream side. Fill shall be placed in layers not to exceed 1 foot in thickness and each layer should be thoroughly compacted. In designing uncomplicated low earthen structures a suggested formula for computing width of crest is: Crest width = 2 /height + 3 feet, which width shall never be less than a minimum of 8 feet. The freeboard above high water line shall not be less than 5 feet. The upstream face shall be protected from wind and wave erosion by an adequate facing of rock, concrete or other suitable riprap material. Masonry and concrete dams shall be structurally safe as determined by acceptable design formulas. Foundations, cut-off walls, outlet works, etc., shall be adequate and properly designed. (Inspections made by the State Engineer's office indicate that many earlier earthen storage dams of the State had inadequate spillways, were constructed on steeper slopes than the above or were not properly compacted nor were the foundations properly prepared. As evidence that such construction is inadequate or worse, it may be mentioned here that perhaps half of the dams inspected

have failed either partially or completely, or else seep water so badly that their usefulness is impaired. It is poor economy to build storage structures which are not safe and adequate).

HIGH WATER LINE TRAVERSE---The extreme high water line of each reservoir (the maximum boundaries of the land temporarily covered by water when the spillway is discharging at maximum capacity) shall be determined by a closed transit traverse and included on the topographic map. A station should be located as nearly as possible on each public survey line wherever the traverse crosses such lines and the distance from that station to the nearest survey corner shown. Stations should be numbered consecutively from the point of beginning, and the courses and distances of the traverse tabulated on the map. Error of closure shall not exceed 1 foot per 5000 feet of distance measured. Such a traverse is necessary in procuring easements or rights-of-way.
With the approval of the State Engineer a high water line contour indicated on the topographic map may be substituted for the high water line traverse on ungated flood retention projects where reservoir basins will be drained within a specified time after each filling. Said contour to be obtained from actual field survey or by stereoplotting methods. Method used in obtaining the contours shall be noted on the map.

INITIAL POINT OF RESERVOIR TRAVERSE---POINT OF OUTLET---The location of the control gates (point of outlet from reservoir) shall be determined by course and distance from some known public survey corner. If the initial point of the high water line traverse does not coincide with this point, it also should be tied to a known survey corner or else tied to the point of outlet.

RESERVOIR DRAINAGE AREA---SPILLWAY CAPACITY---The drainage area above and tributary to the reservoir shall be determined with reasonable accuracy and a spillway of size adequate to handle the runoff therefrom shall be designed. It is desirable that the filing map shall show a small scale map of the basin above the dam which will indicate the length, size and shape of the contributing area, the location with respect to towns, railroads, highways, shipping points, etc. A proper design of the approach section of the spillway is important because any overflow section, no matter how large, is useless if the water cannot flow to it at a rate sufficient to safely carry away excess waters. A spillway of ample size is essential to protect the dam itself and it insure the safety of those living below the reservoir. The size and capacity of the spillway and of the outlet gates from the reservoir shall be indicated on the plans.

DIVERSIONS BELOW RESERVOIR---The point or points of diversion below a reservoir shall be determined and shown on the map by course and distance from some public survey corner. Traverses of main canals diverting below reservoirs, their directions of flow and their names or locations, if more than one, shall also be indicated.

STOCK-WATER DAMS---In general the following will govern the design and construction of stock-water dams impounding more than 10 acre-feet:

1. Preparation of Foundation All vegetation of every description together with all boggy or unstable materials within the area upon which the dam will rest shall be

removed and deposited outside the toes of the dam. The banks of the stream channel shall be dressed to a slope of about 12 horizontal to 1" vertical. A core trench, with sloping sides and a bottom width of not less than 5 feet and depth of 4 feet, shall be excavated along the center line for the full length of the dam and shall be refilled with the most impervious materials available. The foundation shall then be scarified or plowed lengthwise of the dam to secure proper bonding between the foundation and the embankment.

2. Embankment The fill material shall be placed in the core trench and the embankment in layers not exceeding 6 inches in thickness. Each layer shall be thoroughly compacted by a sheep's-foot roller, caterpillar treads, or trucks used during construction. The embankment material shall be placed in a horizontal plane for the full width and length of the work. No side dumping of material shall be permitted. When necessary, water shall be added to the fill material to obtain proper compaction. Puddling of material with water shall not be permitted. No frozen material, large clods, boulders, or organic matter shall be incorporated in the embankment. The upstream slope shall be constructed not steeper than 3 horizontal to 1 vertical and the downstream slope not steeper than 2 horizontal to 1 vertical. The crest width of the finished embankment depends upon the maximum height. Minimum crest widths are as follows:

Maximum height of dam (feet)	less than 10	10-14	14-18	16-22	22-26
Minimum crest width (feet)	8	9	11	12	13

The upstream two-thirds of the embankment section should consist of the most impervious materials available such as clay loam, or a mixture of clay and sand, and the downstream one-third of more previous materials, such as sand or gravel. On all dams where it is necessary to protect against wave action, the upstream face shall be adequately riprapped with stone or other suitable material.

3. Outlet Should the State Engineer so require, a pipe not less than 18 inches in diameter equipped with a suitable control gate and operating mechanism shall be installed. Such outlet pipe, when required, shall be provided with anti-seep collars of approved design. The pipe shall be placed in a trench and shall be completely surrounded with well compacted impervious material.

4. Spillway For the protection of the dam, an adequate spillway shall be constructed, of sufficient capacity to carry the entire discharge from the drainage basin above the dam during periods of excessive runoff. The spillway shall be located in stable material and shall discharge at a safe distance from the dam. The vertical distance from the crest of the spillway to the crest of the dam shall not be less than 5 feet. When necessary to provide the minimum free-board required (as specified below) this vertical distance may have to be increased. Unless the spillway is located in well-grassed earth, hard clay, shale, or rock the discharge velocity shall not exceed 3.5 feet per second. In earth this requires that the slope of the control section shall not exceed 0.25 foot per 100 feet. The freeboard (vertical distance between the water surface elevation at maximum discharge and the crest of the dam) shall be not less than 2.5 feet. The following

method shall be used to determine the minimum area of the control section (below maximum high water) based upon a maximum spillway slope of 0.25 foot per 100 feet and an assumed peak runoff of between 0.6 and 0.7 cubic feet per second per acre of drainage area:

Area of spillway control section (earth) in square feet = 0.2 x drainage area in acres.

Where a drainage basin is in hilly or rough country, with steep gradients or rocky ground cover, peak runoffs may considerably exceed those assumed above and the area of the spillway control section should be increased accordingly. If the spillway is located in shale or hard rock formation throughout its length, the cross sectional area of the control section may be reduced by increasing the velocity of discharge. The width of the entrance to the spillway should be one-third wider than the control section and the bottom should slope from this section toward the reservoir at a rate of approximately 1.0 foot per 50 feet.

5. Borrow Pits Borrow pits from which materials are taken shall be cleared of all vegetation and no material shall be borrowed within a distance of 50 feet of any part of the dam. Material excavated from the spillway, outlet works and core trench, when suitable, may be used in constructing the dam.

The above are considered to be the minimum requirements necessary for the construction of satisfactory stock-water dams. However, each structure will be considered upon its own merits. Depending on the magnitude of the structure and the proximity to downstream development, such as houses, roads, bridges, railways, etc., more stringent requirements may be imposed by the State Engineer. Water right filing procedures and the requirement of having a registered professional engineer prepare the plans and supervise construction will remain unchanged.

POWER PROJECTS---A map submitted in connection with a power project shall, in addition to the usual data, contain a statement of the effective head on the turbines, the maximum, minimum and average required flow in second feet and the effective horsepower to be developed.

PLANS---The plans sheets shall cover detailed information of the various works to be constructed, including plan, elevation, cross-section and profile of any dams and spillways with dimensions and construction details shown; also cross-sections, dimension and other pertinent detail of canals, headgates, flumes, siphons, measuring devices, pipelines, etc. All data necessary for the State Engineer to determine the safety and feasibility of the works shall be included.

SPECIFICATIONS---Specifications are usually necessary to supplement the plans of construction, defining and circumscribing the work to be done and the materials to be used. Simple projects involving little or no engineering may require no specifications. Projects of appreciable size or complexity, however, especially those involving contract work, shall be controlled by an adequate set of specifications covering work to be done,

methods of construction, types, qualities and sizes of materials, unit amounts to be used, supervision, inspection, etc. Such specifications should be clear, concise, definite and impartial to both owner and contractor. Arbitrary, unfair, ambiguous or unreasonable requirements should be carefully avoided.

Two copies of the specifications must accompany the formal application, maps and plans, and must receive the approval of the State Engineer. They should be typewritten or mimeographed on one side of legal size paper and firmly bound or clipped together. The project engineer's and the State Engineer's certificates should appear at the front or on the first sheet of the specifications. They shall contain a clause giving the State Engineer authority of inspection during construction and full power to act in the event specifications are not met, unless the appropriator is otherwise specifically exempted by law.

The designing engineer shall prepare detailed estimates of the cost of the construction, which shall be submitted to the State Engineer at the time of filing formal application.

The State Engineer may, in his discretion, waive the requirements for detailed plans and specifications in the case of small direct diversion or storage projects where there is no possibility of the constructed works being a menace to life or property.

CLAIMANT'S CERTIFICATE---A claimant's certificate shall be placed on and made a part of the filing map and shall be signed by the applicant and acknowledged by a Notary Public, using a permanent black India ink for the purpose. An alternate certificate is shown which should be used in case the applicant is a corporation. If the filing map (not including plan sheets) consists of more than one sheet, such certificate should be placed on the first sheet, due reference being made to all succeeding sheets.

ENGINEER'S CERTIFICATES---The qualified registered professional engineer or land surveyor (see Article II, Sec. C, “Surveys---Maps---Plans”) making the survey or under whose direction the survey was made, shall place on the filing map (or first sheet, if more than one) the engineer's certificate, which he shall sign before a notary public. The engineer's license number together with impressions of his seal and that of the notary public shall accompany this certificate.

The registered engineer preparing the plans and specifications shall also place upon the first sheets of the plans and of the specifications, certificates to the effect that they were prepared by him and such certificates shall be signed by him and witnessed by a notary public. The engineer's license number and the impressions of his and of the notary's seals shall accompany these certificates.

STATE ENGINEER'S CERTIFICATES---A certificate form for the State Engineer's approval shall be placed on the first sheet of the filing maps and similar certificates on the first sheet of the plans and of the specifications. These certificates are to be signed by the State Engineer after all necessary corrections or additions, if any, have been

made to the Formal Application, filing maps, plans, etc., and such endorsement is to certify his approval of the adequacy of the works for the proposed use.

B. Map Title, Statements and Affidavits

The following map title and statements shall be placed on and made a part of the filing map. They may be altered somewhat, if required, to fit the individual application.

MAP
of the

_____
(name of ditch, ditch and reservoir, irrigation, power, etc., system)

_____, Applicant
Located in _____County, State of New Mexico.
All courses true Magnetic Variation_____East*

Scale of Map, 1 In. = _____feet.

The undersigned, _____, claimant, whose post office address is _____, County of _____, State of _____has caused to be located by a qualified registered
_____
(professional engineer, land surveyor, or professional engineer and land surveyor)
the _____
(name of ditch, power, irrigation, etc., system)
as hereinafter described and indicated, hereby makes these several statements relative thereto and offers this map (these maps) **and statements for acceptance and filing in compliance with the laws of the State of New Mexico.**

* Include only if magnetic needle courses have been used in making survey.

For direct diversion system or diversion to an off-channel reservoir:

The headgate, which is the point of diversion from _____, from which the works derive their water supply,
(river, creek, spring, arroyo, etc.)
is located in the _____ quarter of the _____ quarter of section _____, Township _____ Range _____, N.M.P.M., (as projected, being on unsurveyed land), **at a point whence the _____ corner of section _____, Township _____, Range _____, bears _____ feet distant.**
(direction) (distance)

For any storage reservoir, for any power or similar project where the water returns to the stream undiminished in quantity, or for the location of any other important point of the works:

The _____ is located in the _____ quarter of the
(see note)
_____ quarter of section _____, Township _____, Range _____, N.M.P.M., (as projected, being on unsurveyed land) **at a point whence the _____ corner of section _____, Township _____, Range _____, bears _____ feet distant.**
(direction) (distance)

(Note: Use the following: (a) "outlet gate from the reservoir (or lake)"; (b) "initial point of the high water line traverse"; (c) "point of return to the stream," in the case of power or similar projects; (d) any other important point to be described and located.)

The main canal, pipeline, etc., from the stream in the case of a direct diversion project or diversion to an off-channel reservoir, and the main canal or canals carrying water to the lands below a reservoir shall be described according to the follow form:

The hydraulic properties of the _____ are as follows:
(name of canal)
bottom width, _____ feet; depth of water at full operating capacity, _____ feet; total depth (maximum water depth plus freeboard), _____ feet; side slopes, _____ horizontal to 1 vertical; diameter (in case of pipeline or circular flume), _____ feet; slope, _____ feet per 1000 feet; hydraulic radius, _____ feet; coefficient of roughness in (see Article VIII "Hydraulic Data"), _____; velocity at full operating capacity (see Article VIII), _____ feet per second; capacity _____ cubic feet per second.

(Note: This form shall be repeated for all main canals or conduits to be described.)

The storage dam or dams shall be described according to the following form:

The _____ has the following properties: maximum height
(name of storage dam)
above foundation, _____ feet; maximum length, _____ feet; maximum width at base, _____ feet; crest width, _____ feet; slope of upstream face, _____ horizontal to 1 vertical; slope of downstream face, _____ horizontal to 1 vertical; elevation (mean sea level or assumed datum) of spillway crest, _____ feet; elevation of bottom of outlet conduit (flow line) at upstream face of dam, _____ feet; _____ vertical distance between top of dam and

elevation to which water will rise when spillway is discharging maximum capacity, _____ feet; width of spillway, _____ feet; discharge capacity of spillway, _____ cubic feet per second. The outlet conduit is _____ (give size and character) **and has a maximum discharge capacity of _____cubic feet per second.**

Following the above, state the type of dam (arch, gravity, hollow arch, etc.), the construction material (concrete, masonry, earth and rock, etc), and the type of impermeable core or cut-off wall preventing percolation thru the dam.

The following area and capacity table shall follow the dam description:

Elevation (sea level or assumed datum), or Depth above Bottom of Outlet	**Water Surface Area, Acres**	**Cumulative Live Storage Capacity Acre-feet.**
_____	_____	_____
_____	_____	_____
_____	_____	_____
_____	_____	_____
_____	_____	_____

Dead storage (if any) below reservoir flow-line equals _____acre-feet.

Note: The first line shall show the water surface area at reservoir flow-line; the second line shall show area and capacity at the first contour above flow-line (may be an odd interval); the third and following lines shall show area and capacity at succeeding contour intervals; the last line shall show maximum live storage capacity at spillway crest elevation, unless automatic gates are placed in the spillway section for additional storage, in which case the last line shall show the maximum live storage at the tip of spillway gates.

The estimated cost of _____ is $_____
(canal or conduit)

(Repeat for each canal, lateral, etc.,in system)

The estimated cost of _____ is $_____
(storage or diversion dam)

(Repeat for each dam in system)

Total estimated cost of the works is $_____

The area to be irrigated consists of _____acres located and described by legal sub-division as follows:

Ownership	Sub-division	Sec.	Twp.	Rge.	Acreage
_____	_____	_____	_____	_____	_____
_____	_____	_____	_____	_____	_____
_____	_____	_____	_____	_____	_____
_____	_____	_____	_____	_____	_____

The efficient but not excessive duty of water in this area is _____acre feet per acre delivered on the land, claim for which is hereby made for irrigation purposes.

(Note: For appropriation of water for other proper purposes than irrigation, the above statements should be altered or revised to fit individual requirements.)

Following is the Dam Owner's certificate, to appear on the first sheet of the filing maps:

State of_____)
)ss.
County of_____)

I, _____, being first duly sworn, upon my oath, state that I have read and examined the accompanying map and statements (maps and statements consisting of _____ sheets) and know the contents thereof and representations thereon, and state that the same are true to the best of my knowledge and belief.

_____
Dam Owner.

Subscribed and sworn to before me this _____ day of _____, 20___.

_____
Notary Public.

My commission expires_____(SEAL)

If the Dam Owner is a corporation use the following:

State of_____)
)ss.
County of_____)

I, _____, being first duly sworn, upon my oath, state that I am the _____ (Officer) **of the _____, a corporation duly organized under the laws of the State of _____, that the accompanying map and statements (maps and statements consisting of _____ sheets) were made under authority of the Board of Directors of said corporation, and that, in their behalf, I have read and examined the statements and representations thereon and state that the same are true to the best of my knowledge and belief.**

_____
Dam Owner.

By_____

Subscribed and sworn to before me this _____ day of _____, 20___.

_____
Notary Public.

My commission expires_____ (SEAL)

Following is the engineer's certificate to be placed on the first sheet of the plans and the first sheet of the specifications:

State of New Mexico_____)
)ss
County of_____)

I, _____, being first duly sworn, upon my oath state that I am a registered professional engineer (or professional engineer and land surveyor), qualified in _____ engineering, and that the
(civil, mining, hydraulic, etc.)
accompanying _____ consisting of _____ sheets were
(plans, specifications)
prepared by me and are true and correct to the best of my knowledge and belief.

_____
Registered Professional Engineer (and Land Surveyor)

License No. _____ (SEAL)

Subscribed and sworn to before me this _____ day of _____, 20___.

_____

Notary Public.

My commission expires_____(SEAL)

Following is the surveyor's or engineer's certificate to be placed on the first sheet of the filing maps:

State of New Mexico_____)
)ss
County of_____)

I, _____, being first duly sworn, upon my oath state that I am the registered professional engineer and land surveyor (or registered professional engineer, or registered land surveyor) who made the map(s) of the _____ that such map was (maps consisting of _____
(name of irrigation or other system)
sheets were) prepared from field notes of actual surveys made by me or under my direction and that the same are true and correct to the best of my knowledge and belief.

_____
Registered Professional Engineer and/or Land Surveyor

License No. _____ (SEAL)

Subscribed and sworn to before me this _____ day of _____, 20___.

_____
Notary Public.

My commission expires_____(SEAL)

The State Engineer's approval of the filing maps, to appear on the first page thereof, follows:

State of New Mexico_____)
)ss
County of_____)

I hereby certify that the accompanying map(s) and statements have been examined by me and approved as to form and content, and were duly accepted for filing on the _____ day of _____, 20___.

_____
State Engineer.

The State Engineer's approval to be placed on the first sheets of the plans and the first sheet of the specifications, follows:

State of New Mexico_____)
)ss
County of_____)

I hereby certify that the accompanying _____ have been (plans, specifications)
duly examined by me and approved as to form and content, and were duly accepted for filing on the _____ day of _____, 20___.

_____
State Engineer.

VII. FEES

The State Engineer shall receive the following fees, to be paid by him into the general fund:

(a) For filing notice of intention to make formal application for permit to appropriate surface water, twenty-five dollars ($25.00), which shall be paid at the time of filing notice of intention.

(b) For filing a formal application for permit to appropriate water where the project is chiefly for diversion and direct use of the water, twenty-five dollars ($25.00) if the amount claimed does not exceed five (5) cubic feet of water per second, and five dollars ($5.00) for each cubic foot per second in excess of five (5); or if the project is chiefly for storage of excess and flood waters, ten dollars ($10.00) for each one thousand (1000) acre-feet or fraction thereon of storage capacity; or, if the project is for power purposes only, in which the water is returned to the river bed in substantially undiminished quantity, twenty-five dollars ($25.00), if the amount claimed does not exceed five (5) cubic feet of water per second, and one dollar ($1.00) for each cubic foot per second of time in excess of five (5); provided, however, that if application for permit is preceded by a notice of intention, the fee accompanying the notice of intention shall be applied on the subsequent fees. Fees included under this paragraph, which shall be paid to the State Engineer at the time of filing formal application for permit, shall include the filing of maps, plans, specifications, field notes, proof of publication and all other papers relating to the application, up to the issuing of the permit to appropriate water, and shall include the examination and study of all data therein with the exception of plans and

specifications, for the examination and study of which additional fees shall be collected as prescribed in this article.

(c) For examining in connection with any water right application the plans and specifications for a dam, two dollars ($2.00) for each one thousand dollars ($1,000) or fraction thereon of the estimated cost of such dam; for examining the plans and specifications for a canal or other water conduit, twenty-five dollars ($25.00), where the capacity does not exceed fifty (50) cubic feet of water per second, and ten dollars ($10.00) for each additional fifty (50) cubic feet per second or fraction thereof, the fees shall be paid to the State Engineer before he issues the permit to appropriate water; provided that no fee shall be paid for examining plans and specifications submitted by the United States or any agency or department of the United States.

(d) For issuing any certificate of construction or license to appropriate, twenty-five dollars ($25.00).

(e) For issuing a permit for an extension of time, fifty dollars ($50.00).

(f) For issuing any miscellaneous water right instrument or copy of any water right document filed in his office, one dollar ($1.00) for the first page thereof, and fifteen cents ($.15) for each additional page thereof.

(g) For filing any other paper necessarily forming a part of the permanent record of the water right application, permit or license, one dollar ($1.00).

(h) For a contact reproduction of any map or plan sheet accompanying an application for permit to appropriate water, three dollars ($3.00) for each sheet; for a negative of any map or plan sheet suitable to reproduce copies thereof, five dollars ($5.00) for each sheet.

(i) For inspecting dam sites, dams, irrigation systems or other construction work as required by law, one hundred dollars ($100.00) per day and actual and necessary traveling expenses. Fees for any inspection deemed necessary by the State Engineer and not paid on demand shall be a lien on any land or other property of the owner of the works and may be recovered by the State Engineer in any court of competent jurisdiction.

(j) For such other work as may be required of his office, such reasonable fees as in the judgment of the State Engineer the character and extent of the work justifies.

SUBMITTAL REQUIREMENTS FOR AN APPLICATION TO CONSTRUCT AND OPERATE A DAM

Office of the State Engineer
Engineering Review Project Check List
I. Design Report

Applicant: **File No.:**

I. Design Report	YES	NO	N/A
1. Design Report is stamped and signed by a NM Professional Engineer			
Hydrologic			
2. Hazard Classification including justification and supporting documentation			
3. Drainage Area tributary to a proposed reservoir			
4. Hydrologic Calculations, summary table, discussion of input parameters & assumptions			
5. Inflow and Outflow Hydrographs			
6. Hydraulic calculations including engineering data used to determine the capacities of the spillways and outlet conduits, stage/discharge			
7. Stage/Storage Curve or Table			
8. Flood control dam ungated and drains within 96 hours			
Geotechnical			
9. Geologic Investigation of dam site and reservoir basin			
10. Boring logs, geologic cross-sections, location and logs of test pits			
11. Laboratory testing and analysis of data			
12. Seepage Analysis			
13. Stability Analysis both static and dynamic, input and output listings, name of computer model			
14. Internal drainage design including instrumentation to monitor the drainage system, filter design to protect against piping			
15. Foundation treatment and abutment contact design			
16. Dam Geometry and Freeboard			
Other Design Elements			
17. Erosion control			
18. Instrumentation			
19. Designer's Operating Criteria			
20. Operation and Maintenance Manual			
21. Emergency Action Plan (required for high and significant hazard dams)			

Signature: _____ Date: _____

GENERAL INFORMATION

Purpose of the Dam and Reservoir

Explain the purpose of the dam and reservoir. For projects with more than one purpose, the primary purpose is listed with secondary purposes listed in order of importance.

Location and Access to the Dam

Provide a description of the stream on which the dam is located, the name of the county the dam is located in and the distance to the nearest town. Provide traveling directions to the site during both normal and flood conditions. A location map shall be included.

Project History

Provide a brief description of the history of the dam and reservoir including design engineer, construction engineer, contractor, original construction period and dates of modifications or major repairs. Describe State Engineer Orders or directives concerning the dam and the performance of the dam during any significant event such as flooding or earthquake.

Assignment of Responsibilities

Identify all areas of responsibility for the project and the specific personnel responsible for completing each assignment. This section shall also identify a Professional Engineer licensed in New Mexico that is available to advise the owner as needed. Areas of responsibility shall at a minimum include the following:

- Overall safety of the dam
- Operation of equipment
- Maintenance
- Collecting and Recording Instrumentation Data
- Evaluation of Instrumentation Data
- Submittal to State Engineer
- Engineer (Include Firm, address and phone number)

Description of the Dam and Appurtenances

All major project features shall be identified and the data shall be provided in tabular form. The following information shall be furnished if applicable:

Dam
- Type
- Height
- Crest Elevation
- Crest Length
- Crest Width
- Upstream Slope (H:V)
- Downstream Slope (H:V)

Reservoir
- Drainage Area
- Capacity at Spillway Crest (Provide separate tabulation for each spillway)
- Surface Area at Spillway Crest
- Maximum Elevation of SDF
- Dead Storage Capacity
- Dead Storage Elevation
- Reservoir Gage
- Sediment in Storage (if known)
- Sediment Storage Rate (if known)
- Date of most recent last area-capacity survey (if none, use original date)

Spillway (Provide separate tabulation for each spillway)
- Type (Include description of gates or other controls if applicable)
- Location
- Crest elevation
- Effective Length
- Discharge Capacity
- Maximum Discharge at SDF

Outlet Works
- Location
- Type of Intake
- Conduit size and material
- Invert Elevation
- Flow Controls (Size, type and location of gates)
- Type of Terminal Structure and Energy Dissipation Device
- Reservoir gage type(s)

PROJECT OPERATION

Reservoir Operation

A Reservoir Operation Section provides instruction to dam operators for both normal and emergency operations. An operating log shall be maintained to indicate the dates and times of operations (beginning and ending), adjustments, problems encountered and other data or observations as may be needed for the particular dam.

The first step in developing a reservoir operation plan is to determine and define what constitutes both normal operations and emergency operations, then procedures are developed for both situations. Procedures for both situations shall include the following minimum elements:

- Schedule of reservoir filling including maximum and minimum rates
- Release procedures (can vary with the season) including maximum and minimum rates
- Maximum storage level and drawdown limits
- Reservoir capacity allocations

Control Mechanisms and Other Equipment

The Control Mechanisms and Other Equipment Section provides equipment-operating instructions for all mechanisms associated with the dam and appurtenances. Step-by-step instructions for seasonal start up and shut down shall be included. Details on the correct method to open and close gates, proper sequence and gate usage shall be identified. Instructions for operating all equipment associated with the dam shall be included. This section shall also contain manufacturer-furnished operating and maintenance instructions, test procedures, shop drawings, catalog cut sheets, parts lists and replacement part sources.

INSTRUMENTATION AND MONITORING

Instrumentation at a dam provides critical data to evaluate the performance of the dam and identify potential problems. Dams with an Instrumentation Plan prepared during the design phase shall incorporate the recommendations in the instrumentation plan or provide justification why recommendations are not feasible. Minimum elements of the Instrumentation and Monitoring Plan are as follows:

- General description of instrumentation and a map showing the location of each instrument.
- Specifics for each installation
  - Purpose
  - Detailed description
  - Installations, repair and replacement procedures
  - Reading instructions
  - Maintenance instructions and schedule
  - Interpretation data including action thresholds and response measures up to and including implementing the EAP.
- Data submittal requirements to the State Engineer

MAINTENANCE

Preventive maintenance is necessary to ensure the dam will perform its intended function. Generally, the Maintenance Plan shall establish tasks, frequency and record keeping requirements. Typical tasks in a Maintenance Plan are as follows:

- Dam, Spillway, Reservoir and Outlet Channel
  - Woody vegetation control
  - Animal penetrations
  - Erosion
  - Concrete and metal protection
  - Unauthorized access
- Outlet Works
  - Exercise schedule
  - Lubrication routine for valves
  - Scheduled replacement of components
- Miscellaneous Maintenance Instructions

INSPECTION

Routine inspections by the dam owner are essential for timely identification of potential problems in order to maintain a safe dam. Minimum inspection frequency by the dam owner is monthly for water storage dams and after each large storm event but not less than every 3 months for flood control dams with no permanent pool. Site specific conditions may require a more frequent inspection schedule. Inspection forms shall be included in the Appendix.

Recommended inspection frequency of the interior of the outlet conduit by a Professional Engineer registered in New Mexico with experience in the operation of dams is every 5 years. Site-specific conditions may require a more frequent inspection schedule.

UPDATES AND REVISIONS

The O&M Manual shall be reviewed at least annually for updating needs. Generally, updates are required if there are changes of personnel, equipment or equipment operation, operation instructions, upstream or downstream conditions that require reservoir operation changes, contacts or procedures, or modification of the dam or its appurtenances. Revisions shall be submitted to the State Engineer for review and approval.

APPENDICES

The Appendices shall include any addition information needed to support the . The Designer's Operating Criteria and Instrumentation Plan prepared during the design phase shall be included in the Appendices along with Inspection Checklists.

Designer's Operating Criteria

The Designer's Operating Criteria (DOC) is prepared by the design engineer to ensure the dam and appurtenances are operated within any restrictions imposed by the design. All new dams are required to submit a DOC concurrent with the submittal of an Application to Construct and Operate a Dam. The DOC is a critical element of an O&M Manual, and is required for dams having Significant and High Hazard Potential Classification.

It is recognized that some existing dams may not have a DOC. If a dam has no prior-existing DOC, this shall be clearly stated in the O&M Manual. Any modification of the dam, mechanical equipment or appurtenances requiring approval from the State Engineer shall require the development of a DOC for the modification, including effects or limits that the modification may impose on existing structures or mechanical equipment that remain in service.

The DOC for a proposed dam shall be submitted concurrently with the Application to Construct and Operate a Dam. Each DOC shall be developed specifically to address the actual facility and conditions for operation. The following outline for the DOC is provided for general guidance.

DOC Title Page

Table of Contents

I. General Description

II. Dam Properties

III. Reservoir

- E. Reading Schedule

VII. Reference List

Appendices (as required)

Instrumentation Plan

An Instrumentation Plan provides a means to obtain data necessary to evaluate the performance of a dam. Generally, the dam design shall incorporate sufficient instrumentation to monitor horizontal and vertical movement of the dam and significant structures, seepage, and reservoir stage. Other instruments, such as piezometers, inclinometers, extensometers, strain gages, plumb lines, tape gages, crack measurement devices, flow gages and seismographs, may be required, depending upon the purpose and design of the specific dam and appurtenant structures.

Frequently, conditions at an existing dam will require installation of new instrumentation or replacement of existing instrumentation. In these cases, an amendment to the instrumentation plan shall be developed, incorporating all new instrumentation as well as any existing instrumentation that remains in service. The O&M Manual shall be updated to reflect the amended instrumentation plan.

The Instrumentation Plan shall: (1) include drawings showing the location of dam monitoring instruments; (2) provide specific information for each type of instrument; (3) establish instrumentation reading procedures and schedules for normal and emergency conditions, (4) provide descriptions of expected performance, and (5) provide instructions for dam operators in the case of a reading or readings that vary from expected performance.

Elements of the instrumentation plan shall be as follows:

- General Description of Instrumentation and Reading Schedule
- Identification of Unexpected Data
- Specifics for Each Installation
    - Detailed Description of Installations
    - Purpose
    - Reading and Maintenance Schedule Instructions
- Special Instrumentation/Monitoring Requirements

Inspection Checklists

Inspection Checklists tailored specifically to the dam are important for documenting observations. The owner for the life of the dam shall retain copies of the inspection checklists.

Dam emergency information for the emergency classifications

Name of person reporting the emergency: _____

Affiliation: _____

Phone Number: _____

Name & State ID number of dam: _____

Location of dam

County: _____

Municipality: _____

Stream: _____

Road(s): _____

Time and date of dam emergency: _____

Type of Emergency: _____

Phone and appropriate parties: *(refer to the Emergency Notifications Flow Chart)*

"This is (your name, title & affiliation).
There is a dam (Advisory, Warning, Emergency, or Breach) condition at (name of dam).
Observation was at (time).
The situation is (explain the condition).
What is your anticipated time of arrival at the dam and what are my instructions?"
(Refer to Site Description, page X, for directions to the dam)

Communication priority list:

1. Municipal Office of Emergency Management
2. County Office of Emergency Management
3. State Office of Emergency Management
4. State Dam Safety Agency
5. Owner's Engineer

II. Statement of Purpose

Purpose

This plan defines responsibilities and provides procedures designed to identify unusual and unlikely conditions, which may endanger _____ Dam in time to take mitigative action and to notify the appropriate emergency management officials of possible, impending, or actual failure of the dam. The plan may also be used to provide notification when flood releases will create major flooding.

Scope

This Emergency Action Plan:

1. Establishes a monitoring system, which can activate the Plan.
2. Identifies the officials, organizations, agencies, and their respective responsibilities for implementing the plan.
3. Identifies those areas, residences, facilities and roads, which might be affected by a dam failure.

III. Project Description

Project Site Description

Dam Name: _____ Hazard Potential Classification: _____

Project Site Drawings

*Provide/Attach project Site drawings

IV. Emergency Detection, Evaluation, and Classification

This section should discuss the procedures for timely and reliable detection, evaluation and classification of an existing or potential emergency condition. Preventative action shall be addressed for each condition. Suggested emergency classifications are:

Failure is imminent or has occurred
Potential failure situation is developing
Non-failure emergency condition

V. General Responsibilities Under the EAP

Dam Owner/Operator Responsibilities:

1. Identification of the emergency condition.
2. Notification of the State Office of Emergency Management and Office of the State Engineer Dam Safety Bureau. *(Refer to the Emergency Notification Flow Chart)*

Person responsible for the notification: _____

3. Implementation and direction of emergency repairs.
4. Update the emergency status to the State Office of Emergency Management and Office of the State Engineer Dam Safety Bureau.

Person responsible for the updates: _____

5. Provisions for security measures at the dam.
6. Provision of technical assistance to State Office of Emergency Management officials, when necessary.
7. Reporting termination of emergency situation on-site at the dam.

In non-emergency conditions, owner/operator must also provide for:

8. Routine maintenance and operations of the dam.
9. Routine surveillance of the dam.
10. Routine inspection of the dam.
11. Annual review, updating, and distribution of the EAP.

Owner/Operator's EAP Coordinator Responsibility:

Once the dam owner/operator has designated an EAP Coordinator, that person shall be responsible for EAP related activities including:

1. Inclusion and distribution of document revisions.
2. Establish training seminars.
3. Coordinate EAP exercises.
4. Contact person for any EAP related inquiries.

EAP Coordinator Name: _____
Phone Number: _____

Municipal Office of Emergency Management Responsibilities:

1. Warn the public of emergency conditions at the dam.
2. Implement and direct required evacuations of threatened areas.
3. Establish reception centers for evacuated people.
4. Secure and control access to evacuated areas.
5. Conduct rescue and recovery operations as required.
6. Determination and declaration of termination of an emergency/disaster response activity off-site.

County Office of Emergency Management Responsibilities:

1. Pass warning of emergency conditions at the dam to all affected municipalities.
2. Provide assistance to municipalities to help fulfill the emergency responsibilities.

State Office of Emergency Management Responsibilities:

1. Assumption of control and coordination (when appropriate) of all emergency actions in accordance with state statutes.
2. Provision of assistance to the affected municipalities and counties (when requested and beyond their capabilities).
3. Coordination of specialized assistance.
4. Notification of appropriate state agencies.
5. Notification of appropriate counties of any declared emergency condition.
6. Periodic testing of the emergency notification procedures.

Office of the State Engineer Dam Safety Bureau Responsibilities:

1. Provide technical assistance to the dam owner/operator.
2. Evaluation and acceptance of dambreak model and flood inundation map.
3. Assist in the evaluation and resolution of potential emergency conditions.
4. Has the authority to direct the owner/operator to take necessary safety measures.

Responsibility for Termination

The owner/operator is responsible for evaluating a declared emergency condition. The State Engineer is responsible for making the decision, when appropriate, that an emergency condition no longer exists on-site at the Dam. The State Office Of Emergency Management representatives are responsible for declaring termination of an emergency condition off-site. As such, it will be the responsibility of the owner/operator to notify the OEMs of an emergency condition termination promptly.

As part of the termination phase, the County/Municipal OEM will be responsible to conduct a critique of the overall emergency response and to prepare a report documenting emergency procedures and actions. The critique process will be a

discussion of the events that occurred prior to, during, and after a dam emergency. Participants review and evaluate their particular actions. The purpose of the critique is to determine what, if any, practicable improvements could be made for potential future emergencies, and conversely to identify deficiencies in procedures, manpower, materials and equipment.

Responsibility for Recovery

The basic goal of the recovery phase is to demobilize and return to the pre-emergency situation. The owner/operator is responsible for implementing all actions necessary to achieve this goal on-site at the dam. The State Office of Emergency Management has the responsibility to effectuate recovery off-site in the affected communities.

The owner/operator is responsible for directing all on-site recovery activities. The basic recovery actions common to the dam emergency classifications are:

- Secure access to emergency site,
- Restore basic facilities and services, and
- Assess damage.

_____

Direction to the Emergency Operations Center from the nearest State or County Highway:

_____

_____

_____

*Include a location map of the Emergency Operations Center.

Emergency Operations Center Location Map

Surveillance Checklist

The surveillance checklist must be specific to the site conditions of the dam and shall be approved by the State Engineer.

The surveillance checklist should be utilized by the Inspectors listed on the Emergency Notification Directory during their inspections. A record of these inspections and their findings should be kept by the owner/operator for ready reference.

Routine inspection intervals should be specified and individuals responsible for the inspection identified.

Access to the Site

A narrative description of primary and secondary access routes should be included. Attach map if necessary.

Response During Adverse Weather, Weekends, Darkness and Holidays

Supply a discussion of emergency response during periods other than office hours and during periods of adverse weather. Actions should be described in detail. The effects on response time should also be included.

Alternative Systems of Communication

Alternative channels of communication to be used in case of failure of the primary system or failure of other systems immediately available should be listed.

List of Contractors

It is the responsibility of the owner to maintain a current list of contractors that may be contacted during an emergency condition for equipment, materials, and repairs.

For each contractor on the list, the following must be provided:

1. Contractor:

   Contact Person: _____ Phone No.: _____
   Address: _____

   Services contracted for: _____

2. Contractor:

   Contact Person: _____ Phone No.: _____
   Address: _____

Equipment	Company & Location	Phone No.	Arrival Time to Dam (min.)

Other Site Specific Actions

Describe any other site-specific actions devised to moderate or alleviate the extent of potential emergencies.

VII. Inundation Maps

Description of Inundated Area

_____

_____

_____

_____

Attach map that delineates area of inundation.

The official inundation map attached to the EAP should be, whenever possible, in foldout format, no larger than 11 inches by 17 inches, and provide the most accurate, up-to-date data available. As such, it may be necessary to reduce the map scale once the inundated areas are identified.

VIII. Appendices

Appendix A. Investigations and Analysis of Dambreak Floods

Input data, printouts, and survey information from the dam failure analysis should be included in this section.

Appendix B. Plans for Training, Exercising, Updating, & Posting

The owner of the dam is responsible for the training of personnel, and the exercising and updating of the EAP. The training plan and exercise schedule should be included in this section. The revision schedule and distribution of the EAP should also be discussed. The location of each copy of the EAP and notification flowchart, if posted separately, should be stated in this section.

Appendix C. Definitions

Appendix D. Site Specific Concerns

This section of the appendix should provide a discussion of any site-specific concerns that provide valuable information affecting the EAP. The EAP should emphasize where appropriate structural drawings and flood data are maintained on-site.

Appendix E. Approval and distribution of the EAP

Once the EAP has been developed and approved by local and state emergency officers, the owner/operator shall submit the completed EAP to the State Engineer for approval. Once the State Engineer approves the EAP, the owner must distribute the EAP to all individuals who will be involved during an emergency. Any revisions to the EAP should be furnished to all individuals to whom the original EAP was distributed.

Each party receiving an EAP must sign and return a receipt to the distributor (owner/operator) of the EAP. The signed receipt is to assure that all parties are aware of and understand the EAP and agree to their assigned roles should an emergency occur. A standard distribution letter and receipt is included for reference.

The document holder and location of each copy of the up-to-date EAP should be included in this section of the EAP

Standard Distribution Letter & Receipt

(Date)

(Name of EAP document holder)
(Company or affiliation)
(Mailing address)

Re: EAP for (name of dam) Dam ID No.

Dear (Name of EAP holder):

(Name of the owner/operator) has (prepared or revised) the Emergency Action Plan for (name of the dam) Dam located within (name of township), (name of county). The EAP is a public safety regulatory required document. The (year) revisions are described in the REVISION SUMMARY.

Please insert the new material with the revision date in your controlled copy and remove the obsolete material (the effective dates generally are printed at the lower right corner of the pages). Please acknowledge your receipt of the controlled copy distribution by returning the obsolete pages to the undersigned with the attached acknowledgement, signed and dated.

We appreciate your continued cooperation in the revisions of the EAP. Should you have any recommendations or questions regarding the EAP, please do not hesitate to contact the undersigned.

Sincerely,

(Your Name)
(Affiliation)

I acknowledge receipt of the (revision date) revision to the (name of dam) EAP and have inserted the revision pages in my controlled copy. This EAP will be maintained at the designated location for use in the event of a drill or actual emergency declaration.

Controlled Document holder name: _____ Document No. _____

NEW MEXICO OFFICE OF THE STATE ENGINEER
Dam Safety Bureau
Hydrologic Analysis for Dams
August 15, 2008

Hydrologic analysis requirements for dams are cited in the Rules and Regulations Governing Dam Design, Construction and Dam Safety, which were filed with the New Mexico State Record Center as Title 19, Chapter 25, Part 12 of the New Mexico Administrative Code (19.25.12 NMAC). Hydrologic analysis shall be performed in accordance with Subsection C of 19.25.12.11 NMAC. The design life of a dam is much longer than the record retention period of most engineering firms and memories of most design engineers. It is important that the analysis stand on its own in a manner that is comprehensible to future engineers who may be involved with the structure. Therefore, the Office of the State Engineer (OSE) requires that the hydrologic analysis be fully documented and supported independent of computer programs or other computational methodology used in the analysis.

Most dams are constructed on a watercourse or have a contributing drainage area upstream from the dam. Intense rainfall creates inflow to the reservoir of the dam, which is routed through the reservoir and allowed to pass the dam through a spillway or multiple spillways. Earlier dams typically were provided with spillways that were sized to pass the largest observed floods. These dams frequently overtopped and failed, and roughly half of all known dam failures have been the result of flood overtopping. During the 20th Century, methods were developed to better evaluate infrequent or extreme flood events, and provide adequate spillway capacity to safely pass these floods. Hydrologic analysis is one of the most important aspects in the design of a safe dam, and will be closely reviewed by the New Mexico Office of the State Engineer (OSE) Dam Safety Bureau.

Presented below is an outline of the typical steps for completing a hydrologic analysis satisfying the requirements outlined in Subsection C of 19.25.12.11 NMAC. In order to facilitate review by the OSE Dam Safety Bureau the hydrologic analysis report must be organized in an easy to follow layout and format. Submittals that are not consistent with this document and the requirements outlined in Subsection C of 19.25.12.11 NMAC will cause a delay in the review by the OSE Dam Safety Bureau and may be returned to the owner with no review provided. Inadequate hydrology submittals may also require review fees to be resubmitted prior to subsequent review by the OSE Dam Safety Bureau.

The following steps are typically required in completing hydrologic analysis for dams for submittal to New Mexico Office of the State Engineer:

1. Determine hazard potential classification for the dam location.
2. Determine appropriate design storm requirements for location.
3. Determine geographic location, limits and area of watershed contributing to dam and reservoir.
4. Divide watershed into subbasins as appropriate, and determine subbasin areas, channel locations for routing, etc.
5. Determine basin or subbasin geometry such as longest flow path for each basin or subbasin, channel slope and cross section, highest and lowest points, basin centroid(s), mean basin elevation, etc. as required for methodology to be used.

6. Determine appropriate timing and routing parameters for the elements in the watershed model.
7. Determine reservoir characteristics including stage-storage and stage-discharge relationships.
8. Develop total watershed model by arranging subbasins, routing reaches, etc. in the proper sequence with appropriate parameters.
9. Derive the precipitation to be used for design.
10. Develop incremental precipitation from depth-duration relationship and arrange increments to create an appropriate temporal distribution of precipitation.
11. Develop spatial distribution of precipitation if appropriate.
12. Determine loss parameters or functions and apply to incremental precipitation.
13. Deduct losses from precipitation increments to estimate precipitation excess.
14. Select an appropriate transform methodology for converting excess rainfall to runoff.
15. Apply the transform methodology to each subbasin using incremental precipitation excess.
16. Add stream base flow, etc., to obtain flood hydrograph for each subbasin.
17. Combine and/or route subbasin hydrographs to determine the inflow design flood.
18. Route flood through reservoir and spillway to obtain estimates of reservoir peak stage, peak outflow, peak storage, flood duration, etc.
19. Review results for reasonableness, comparing to known floods or otherwise calibrating if possible.
20. Adjust model parameters, spillway characteristics, etc. as necessary and appropriate and repeat process.
21. Prepare hydrologic analysis report for OSE review and for the permanent record.

Discussion:

The steps taken in the analysis, along with assumptions made and parameters used, must be fully documented. Documentation requirements are discussed in the final section of this paper. Discussion of each of the steps for performing hydrologic analysis is as follows:

1. Hazard Potential Classification

Hazard Potential Classification is a function of dam location and downstream conditions, and is not a measure of the integrity of the dam or the adequacy of the design. High hazard potential classification applies if loss of life is probable if the dam fails catastrophically. This is usually fairly obvious, based on downstream development conditions. In some cases, breach and flood wave analysis is needed to establish hazard potential classification. If site is not High hazard potential, in most cases it will be Significant, due to substantial risk to property or assets (highways, barns, irrigation ditches, etc.) or potential for significant environmental consequences. Low hazard potential is typically limited to remote, small structures such as ranch ponds for cattle watering and limited irrigation. Flood control dams typically are High or Significant hazard potential, because the need to control flooding suggests life and/or assets being protected downstream. Evaluations for Low or Significant hazard potential dams must consider the potential for future downstream development.

2. Design Precipitation Requirements

Generally, high hazard potential dams require consideration of Probable Maximum Precipitation (PMP). Significant hazard potential dams require consideration of 50% PMP if 100 feet or less in height and having 50,000 acre-feet or less storage, or 75% PMP if greater than 100 feet in height or having over 50,000 acre-feet of storage. For significant hazard potential dams, percentages are applied to precipitation prior to hydrologic analysis. Low hazard potential dams require consideration of 100-year storm, expressed as a percentage of PMP. Therefore, most dams will require evaluation of PMP. In some cases, waiver of evaluation of PMP will be entertained for low hazard potential dams with no realistic possibility for future hazard potential change.

In addition to precipitation requirements for spillway design, flood control dams must be able to drain from spillway crest or 100-year, 24-hour peak reservoir level within 96 hours. This implies determination of 100-year, 24-hour precipitation in most cases. For high and significant hazard potential flood control dams conforming to local flood control authority or NRCS requirements for 100-year, 24-hour flood routing, OSE will defer to these requirements for determination of compliance with the 96-hour rule.

3. Watershed Location, Limits, and Area

Watershed location, limits and area have traditionally been obtained from 7-1/2 minute USGS quad maps by tracing the divide, and then determining the area by planimeter or other measurement. For smaller drainages, a site topo map is sometimes used. Recent analyses frequently use ArcView or other GIS software in conjunction with DEM or DTM. Determination of precipitation will require geographic location (latitude and longitude) of the approximate basin centroid or a georeferenced perimeter at an appropriate scale. Methodology used must be described and supported as appropriate. Drainage area for existing dams must be independently verified rather than relying on area indicated on drawings or in design report, particularly for older dams. Precipitation depths may require adjustment based on watershed area. Average elevation of the watershed is needed for determination of Local Storm PMP.

4. Subdivision of Watershed

Logical subdivision can be made where topography or surface features and development are dissimilar. SCS methodology would suggest maximum subbasin size of about 20 square miles. USBR – Cudworth recommends 500 square miles maximum area per subbasin. Subbasin areas should be reasonably similar – for example, don't combine 20 square mile and 0.5 square mile subbasins in the same model if you can help it. Avoid dividing into unnecessary subbasins, as this complicates the model and usually does not improve results. Particularly, avoid overdividing small basins, such as dividing 5 square miles into 20 subbasins. Subbasins should generally correspond with logical junction points and routing reaches.

5. Basin and Subbasin Geometry

Specific information required will depend on methodology used for timing parameters and runoff transform. Typical requirements might include length of longest watercourse, length to a point opposite the basin centroid, watercourse slope, average basin slope, estimated length of overland flow, length, slope, and cross-section of channel reaches, etc.

6. Timing and Routing Parameters

Typical parameters may include time of concentration, lag time, time-to-peak, time of travel, kinematic wave travel time, channel geometry and roughness, etc. depending on requirements of the transform methodology and channel routing used. To add to confusion, a parameter may be defined in different ways for different methodologies, even if the name is the same. The parameter(s) used must be appropriate for and compatible with transform methodology as defined within that methodology. Also, assumptions or limitations for the timing parameters must be consistent with the watershed being studied. These may include basin size or watershed length, channel condition (natural vs. improved or hardened), degree of development, etc. Method of determining timing and routing parameters must be indicated and justified as appropriate for location and transform methodology, with sample derivation and references.

7. Reservoir Characteristics

This may be developed as elevation-area or elevation-storage, depending on modeling requirements or input parameters for the method used. However, OSE Rules and Regulations require reservoir characteristics to be reported as elevation-storage table in one-foot intervals. Water storage reservoirs generally are assumed to be full to the point of uncontrolled discharge, e.g. spillway crest. Flood control dams with uncontrolled outlets and no permanent storage generally are assumed to be empty at the start of the modeling period.

8. Watershed Model

The basin and subbasin geometry and characteristics, routing reaches and parameters, reservoir characteristics, etc. are assembled to create the watershed model for the dam. It is useful to create a schematic or flow chart for the watershed model, particularly if software being used does not provide a graphical or schematic representation. A schematic or graphical representation of the model and tables of relevant model parameters will be required in the report submitted to OSE.

9. Precipitation Derivation

PMP east of the Continental Divide is derived using methodology of HMR 55A, PMP west of the Continental Divide is derived using HMR 49. Both HMR documents provide for 1) a Local Storm (thunderstorm), with 6 hours total duration, and 2) a General Storm, with 72 hours duration. Neither HMR includes procedures or allowances for durations less than the complete storm, such as a 1-hour thunderstorm or a 24-hour general storm. If a shorter duration is used, justification must be provided.

Concerning durations less than the complete storm, FEMA as quoted in City of Albuquerque *Development Process Manual* states, “FEMA’s position regarding the duration of rainfall is that the storm must extend for a period long enough to include all rainfall excess when the volume of the runoff hydrograph is an important consideration. This includes conditions when detention storage is involved, when sediment processes are a significant factor, and when combining and routing subbasin hydrographs to obtain watershed runoff. When the peak flow is the primary concern, and it is established that the use of a longer duration storm would not increase the peak flow, shorter duration storms are acceptable.” This would suggest that using the most intense 24 hours of the General Storm would only be appropriate if it can be shown that no excess

precipitation will occur outside of this period, or if it can be shown that the peak flow is not sensitive to storm volume if peak flow is the primary concern.

Both HMR documents require obtaining index precipitation from maps, and then adjusting precipitation depths for area, elevation, and orographic effects specific to the watershed being studied. The index precipitation depths are plotted against duration to develop a smooth depth-duration passing through the origin. Area adjustments typically are based on the total contributing area above the dam or other point of interest, rather than on individual subbasin areas. Since precipitation depth for PMP is adjusted for storm area during the derivation, no additional reductions should typically be taken during the hydrologic analysis.

The 1984 reprint of HMR 49 contains an Errata sheet following the title page. The entry for page 154 on this Errata sheet changes the basis for local storm elevation adjustments from the lowest elevation in the drainage to the mean elevation. This generally will result in greater reductions in precipitation depth for cases where the elevation adjustment applies. This change is not well documented anywhere else in the literature. Electronic versions of HMR 49 not containing this correction may still be available online.

Both Local and General Storm should be evaluated, unless clear evidence and justification can be provided showing that one storm or the other obviously controls. For example, in the Eastern portion of the New Mexico HMR 55A area, the 1- and 6-hour ordinates for the General Storm frequently are greater than the 1- and 6-hour ordinates of the Local Storm. Conversely, in certain locations of HMR 49 where the orographic component of General Storm precipitation is low, total storm volume for the General Storm can be less than the Local Storm. In most other cases, it is not sufficient to simply compare precipitation depths, since routing effects may result in greater spillway discharge from the General Storm, even though the Local Storm precipitation depths are greater at 1 and 6 hours.

Alternatives to HMR 49 and HMR 55A include site-specific analysis for PMP and Incremental Damage Assessment, either of which should be discussed first with OSE. In the future, an Extreme Precipitation Analysis Tool may be available for portions of the state, to provide an updated estimate of extreme precipitation.

Precipitation for frequency-based events, such as the 100-year storm, is obtained from NOAA Atlas 14, available online. Precipitation is obtained by latitude and longitude, and is point precipitation. The precipitation values from Atlas 14 are considered appropriate for storm areas of 10 square miles or less, and the full precipitation depth should be used for watersheds less than 10 square miles. For larger areas, an approved procedure for reducing precipitation based on area may be applied. The online documentation for Atlas 14 does not provide areal reduction factors specific to Atlas 14, but instead references three possible sources:

1. NOAA Atlas 2, *Precipitation-Frequency Atlas of the Western United States*, 1973. This method was originally presented in Technical Paper No. 40, *Rainfall Frequency Atlas of the United States*, U.S. Weather Bureau, 1961, and is incorporated into the Frequency Storm methodology in HEC-1 and HEC-HMS.

2. Technical Report 24, *A Methodology for Point-to-Area Rainfall Frequency Ratios*, NOAA, 1980.
3. Technical Memorandum HYDRO-40, "Depth-Area Ratios in the Semi-Arid Southwest United States," NOAA, 1984.

These methods will allow reductions for areas less than 10 square miles; however, Atlas 14 seems to recommend using the point precipitation values for 10 square miles or less. If areal reductions are made for drainage areas less than 10 square miles, justification must be provided. Areal reductions for frequency storms should be based on the total watershed contributing to the point of interest, and not on individual subbasin areas. For watersheds with total area exceeding the limits of the reduction method (400 square miles for NOAA Atlas 2/U.S. weather Bureau Technical Paper 40) the services of a qualified meteorologist may be necessary to determine appropriate reductions of point precipitation.

10. Precipitation Increments and Distribution

Precipitation increment size should generally correspond to the computational time step used, although this is not mandatory for many computer programs including HEC-HMS. Increments are obtained from the depth-duration curve by subdividing the curve by increment length and successively subtracting curve ordinates. For small, fast basins in particular it is important to use a sufficiently small increment size and computational time step to avoid under-prediction of peak runoff.

Once the increments have been determined, they must be arranged in an appropriate distribution. One of the most common arrangements sometimes called "center-peaking" or "balanced" distribution, places the largest increment at the center of the storm duration. The second largest increment is placed directly in front of the first, the third largest placed behind the first, and the procedure is continued with successively smaller increments until the distribution is filled. A similar distribution, favored by Bureau of Reclamation for 72-hour general storm PMP, can be termed "late-peaking." This distribution places the largest increment at the 2/3 point of the storm, then places the second and third largest increment successively in front of the largest increment, then the fourth largest increment immediately behind the largest increment, then continuing the sequence with two increments in front, one behind until the distribution is filled and all increments are used. Either the center-peaking or late peaking distribution will be acceptable for 72-hour General Storm PMP.

Both HMR 49 and HMR 55A refer to two recommended distributions for the 6-hour Local Storm. One is obtained from HMR 5, and the other from the USACE EM1110-2-1411. The distributions are similar, with the USACE EM1110-2-1411 distribution peaking later in the storm. HMR 49 states, "In application, the choice of either of these distributions is left to the user since one may prove to be more critical in a specific case than the other." This suggests that both methods should be evaluated and the more critical distribution should be used. In practice, the USACE EM1110-2-1411 appears to provide the higher peak discharge in the majority of cases. While not specifically discussed in either HMR 49 or HMR 55A, a center-peaking distribution of local storm PMP has been used in the past and is acceptable to OSE. In any case,

the distribution used must be justified as being appropriate for the specific drainage area being evaluated.

The center-peaking and late-peaking distributions described above are frequently approximated in HEC-HMS or HEC-1 using the Frequency Storm definition for precipitation. Using the Frequency Storm to distribute PMP can cause unintended consequences if one is not careful, and probably should be avoided by infrequent users. The Frequency Storm requires input of precipitation depths for durations corresponding to the frequency series of 5 min, 15 min, 1 hour, 2 hours, 3 hours, 6 hours, 24 hours, 48 hours, etc. The frequency series does not include a 72-hour duration, and so will not emulate the full General Storm PMP. The General Storm index values from HMR 55A do not include values for 5 min, 15 min, 2 hour, 3 hour, or 48 hour durations, and the index values from HMR 49 do not include 5 min, 15 min, 1, 2, or 3 hour values, requiring values to be interpolated or read from curve plots, introducing a possible source of error. The Frequency Storm method can result in unintended reductions of precipitation due to inappropriate use of Storm Area and Probability inputs in HEC-HMS and HEC-1. It is probably best to discuss with OSE before using the Frequency Storm to distribute PMP.

In cases where 100-year precipitation is required (primarily for low-hazard potential dams) the preferred distribution is a center-peaking distribution based on the frequency series from NOAA Atlas 14. The Frequency Storm functions in HEC-HMS, HEC-1, and possibly other programs, are suitable and are intended for this type of storm. Since the precipitation from Atlas 14 is point precipitation, reductions for storm area may be taken as appropriate. The common SCS Type II distribution used for most of the US east of New Mexico will not be appropriate in New Mexico in most cases. The Type IIA distributions used by NRCS in New Mexico may be appropriate, but it is recommended that their use be discussed with OSE prior to using these distributions.

The following distribution methods, which have all been used in submittals to OSE, are not generally appropriate:

- Using the depth-duration curve as the distribution.
- Straight-line distribution of equal increments throughout the storm or during peak periods of the storm.
- Using SCS Type II or NRCS Type II-a distribution for PMP.
- Compressing SCS or NRCS distributions for durations less than 24 hours
- Using a Huff distribution.

11. Spatial Distribution of Precipitation

Spatial distribution of precipitation intensity within a basin through use of isohyetal storm patterns is typically done only for relatively large basins. This method is not common in submittals to OSE, and the services of a qualified meteorologist is required if this method is used. The method is illustrated in HMR 52, which contains information for applying this method east of the 105th meridian, comprising roughly the eastern third of New Mexico.

The more typical submittal applies precipitation uniformly across the basin, with reductions in precipitation depth for larger areas as appropriate. The reductions in these cases are applied during the derivation of precipitation using HMR 49 or HMR 55A. When the isohyetal method

of spatial distribution is used, the full index precipitation is used without reduction, since reduction is effected by application of the isohyetal pattern.

12. Loss Function Parameters

Not all of the precipitation that falls is available to generate runoff. The primary losses to precipitation are interception, evaporation, retention, and infiltration. The first three of these are grouped, along with part of the infiltration loss, and termed "initial losses." For large, infrequent events such as the PMP, initial losses are relatively low compared to infiltration losses, and are assumed to have occurred due to antecedent rainfall prior to the start of the PMP. Therefore, initial losses are commonly neglected in evaluating PMP. Common loss characterizations include SCS curve numbers, initial/constant loss rates, exponential losses, and Green-Ampt method. Other methods are available as well. SCS curve numbers are typically used with SCS hydrograph methodology, and are not recommended for other hydrograph methods. Initial/Constant loss rate methodology is used with USBR and other unit hydrograph methods. Green-Ampt and exponential methods have not been frequently used in submittals to OSE. Parameters must be justified, both in terms of appropriateness for basin conditions (soil and vegetative cover or land use) and appropriateness with the selected transform methodology. For PMP, loss rates frequently are lower than those used with typical return frequency storms such as the 100-year event. Constant loss rates in excess of 0.5 inches/hour will require adequate supporting justification. Typical loss rates for the four SCS soil groups are as follows:

SCS Soil Group	Descriptive Characteristic	Ultimate Infiltration Rate
A	Low Runoff Potential	0.3 to 0.5 inches/hour
B	Moderate Infiltration Rate	0.15 to 0.30 inches/hour
C	Slow Infiltration Rate	0.05 to 0.15 inches/hour
D	High Runoff Potential	0 to 0.05 inches/hour

Source: USBR *Flood Hydrology Manual*, 1989, P. 112

13. Precipitation Excess

Determination of precipitation excess typically is embedded in hydrology software program, but is a straightforward step that can be assumed to be handled correctly with reputable software. The total rainfall excess must be determined and reported, in addition to instantaneous peak discharge. As a rule of thumb for General Storm PMP, rainfall excess less than 70% of total storm volume for 72-hour precipitation depth greater than 25 inches, or less than 60% of 72-hour storm volume for total precipitation depth less than 25 inches, will require justification. Loss parameters and precipitation increment size and distribution can have significant effect on rainfall excess.

14. Transform Methodology

The most common transform methodology is some sort of synthetic unit hydrograph procedure. SCS is fairly common, but may not be the best choice for PMP of extreme storms. SCS parameters are interrelated, and any deviation from the methodology (e.g. Initial-Constant loss rates rather than Curve Numbers) must be justified. The USBR *Flood Hydrology Manual* methodology is also commonly used. USBR is developed for the West, and has three regional unit hydrograph lag relationships that apply within New Mexico: "Great Plains," "Rocky

Mountains," and "Southwest Desert, Great Basin, and Colorado Plateau." Additionally, the Manual contains information for urban basins. It is important to select the correct relationship for the watershed being evaluated. Other unit hydrograph procedures include Clark's and Snyder's unit hydrographs. If these are used, parameters must be provided and justified. User-specified unit hydrographs or other relationships derived from gaging records are possible, but submittals to OSE using these methods have been rare. SCS, Clark's and Snyder's unit hydrographs are available in HEC HMS, and parameters must be provided and justified but unit hydrographs need not be provided. IF USBR methodology or other user-specified unit hydrographs are used, unit hydrograph ordinates must be provided. Kinematic Wave methodology is sometimes used, and is probably most suitable where the watershed can be conveniently be described as rectangular plane surfaces draining into lateral channels. Other distributed-model methodologies may exist or emerge, and should probably be discussed with OSE before submittal.

15. Application of Transform Methodology for Each Subbasin

For computer-based analysis, this is primarily a matter of properly configuring subbasin models and hydrologic parameters within the program.

16. Evaluation of Base Flow

In New Mexico, stream base flow is usually minimal or non-existent except in response to storm events. A possible exception might be snowmelt in mountainous regions. The USBR *Flood Hydrology Manual* discusses modeling base flow and snowmelt. If base flow in the stream will contribute significantly to the hydrograph, it should be considered, and base flow modeling assumptions documented. It may be desirable to model a token base flow if the resulting flood hydrograph will be analyzed in a program such as HEC-2 or HEC HMS for downstream water surface profiles under unsteady-flow conditions.

17. Hydrograph Combining and Routing to Determine IDF

Combining and routing is generally done by the computer model. Model input and output must be carefully scrutinized to make sure that the model is performing as intended

18. Reservoir Routing

Stage-storage information used in routing must be provided; the Rules and Regulations require this to be in elevation intervals of 1 foot. Outlet and spillway capacity rating curve or table must be developed and provided. Relying on older, previously generated rating curves without independently verifying their appropriateness is not acceptable. Spillway capacity is most frequently based on the Weir Equation, $Q = CL(H)^{1.5}$, Where Q is discharge, L is weir length perpendicular to flow, H is head on the weir typically taken as reservoir elevation minus weir elevation, and C is a discharge coefficient for the weir. The weir equation is only appropriate if flow passes through critical depth over the weir and supercritical flow will be present a sufficient distance downstream from the weir that backwater effects will not constrain flow over the weir. If supercritical flow is not assured, then a backwater analysis such as HEC-2 or HEC-RAS is needed to validate spillway capacity. Also if a significant channel exists between the weir and the reservoir, a backwater analysis is needed to confirm that the reservoir stage remains below the dam crest at the anticipated spillway capacity. Care must be exercised in selecting the coefficient C, as it is not constant with respect to flow depth and is sensitive to geometry of the

spillway crest and entrance. Textbook values for typical broad-crested and ogee weirs may not be appropriate. The most common error is to select too high of a coefficient, for example, 3.0 or 3.1 for an open-cut spillway for which 2.6 or 2.7 may be more appropriate.

19. Review of Results for Reasonableness

It is tempting to assume that if the computer program gives an answer and doesn't crash that this is the correct answer. In reality, the computer is not especially intelligent and will do exactly what you tell it to, whether this makes any sense or not. This is not just a matter of "garbage-in, garbage-out." Sometimes, parameters that are in the ballpark when taken individually can compound to skew results in one direction or another. Also, sometimes the program will perform functions not intended by the analyst, such as inappropriate reduction of precipitation for storm area, if you do not tell it exactly what you want and understand the significance of program defaults. Therefore, a review of intermediate steps and final results for reasonableness is important. Calibration of the hydrologic model for PMP is difficult since storms approaching this magnitude are rare. Calibrating against lesser storms such as the 100-year or smaller events may not be appropriate for PMP. Reasonableness of results compared to past experience with similar input parameters may be the best tool available. It is important not only to ensure that the spillway design flood is not underestimated for reasons of public safety, but also that it is not overestimated for reasons of economics. Often, the predicted flood is significantly less probable than the precipitation, which in the case of PMP already has an essentially indefinable but extremely low probability. In some cases, particularly for rehabilitation projects, this can have a substantial impact on project costs.

20. Adjustment of Model Parameters

Based on review of results for reasonableness, it may be appropriate to adjust parameters and recalculate. This will obviously be necessary if the selected spillway turns out not to be adequate for the computed flood. Sensitivity analysis with respect to critical parameters is sometimes useful in forming an opinion with regard to the appropriateness of the result.

21. Hydrologic Analysis Report

Assuming the hydrologic analysis has included the required steps previously discussed, it is important that the methods and parameters used, the results obtained, and supporting justification be documented in a coherent report. This will allow OSE staff to verify that regulatory requirements for hydrology have been satisfied and evaluate whether the proposed design adequately addresses the required design storm. A secondary, but equally important purpose is to provide documentation of methods and assumptions to assist future engineering consultants and OSE staff in understanding the basis for design and assessing adequacy and safety of the structure. Personnel can turn over rapidly, analysis methods change over time, and the structure will almost certainly outlast both the designers and their methods. The hydrology report will serve as a guidance document to help future engineers understand the analysis. As a general principle, the information submitted must be adequate to allow an independent analyst, possibly at some point in the future, to replicate the analysis with comparable results. The information must be transparent and independent of the software program used for computation. The following are some of the items required in the report and supporting documentation:

1. Identification of the hazard potential classification, and any assumptions used in determining this classification. If the classification is anything other than High, supporting documentation, potentially including breach analysis and flood studies, may be required.
2. Determination of appropriate design precipitation based on hazard potential classification and size of structure. Provide detailed analysis report if design precipitation is based on incremental damage assessment or site-specific PMP study, either of which must be discussed with OSE in advance.
3. Location map and topographic map of drainage area contributing to the dam and reservoir, with drainage boundary and total area indicated.
4. Map indicating subbasin boundaries with areas indicated, hydrograph combination points, channels for routing, etc. This may be superimposed on the topographic map described in 3. above if of suitable scale.
5. Table of relevant basin and channel characteristics to be used in the analysis as dictated by the selected analysis methodology, including flow path lengths, centroid distances, mean basin elevations, channel slope, roughness, and cross-section, etc.
6. Discussion of timing and routing parameter derivation including methods or equations used and their applicability to this particular project, example calculations, and summary tables of input data and computed parameters.
7. Narrative discussion of watershed model accompanied by schematic showing the interrelation of various components of the model.
8. Elevation-storage and elevation-discharge tables for reservoir, outlets and spillways. These should be in 1-foot increments unless the dam is very high, in which case the appropriate interval must be discussed in advance with OSE.
9. Worksheets for Local Storm and General Storm PMP derivation from HMR 49 or 55A as appropriate. For Low hazard potential dams, copies of tables from NOAA Atlas 14 website, indicating latitude and longitude of point precipitation, must be included.
10. Table of distributed precipitation increments, distribution curve and/or hyetograph illustrating graphically how precipitation is distributed, and narrative describing and justifying the methodology for distributing precipitation.
11. If spatial distribution is used, full documentation of methodology and assumptions by qualified meteorologist is required.
12. Discussion of loss methodology and documentation of derivation of parameters, tables of soil and land use areas and percentages for each subbasin, and justification of the appropriateness of the parameters and methodology in the context of the overall analysis.
13. Table or graph of precipitation excess for each increment for which excess exists, and identification of total precipitation excess in inches and percentage of rainfall.
14. Discussion of transform methodology used. Coefficients or parameters for common synthetic unit hydrograph procedures (e.g. SCS. Snyder, Clark). If other than a common synthetic unit hydrograph procedure is used, unit hydrograph ordinates must be provided.
15. Table or computer echo of input parameters, with parameters identified or notated for each subbasin, routing reach, or other element.
16. Discussion of base flow or snowmelt methodology or considerations.
17. Table of combining and routing results, supported by computer output. Results must be concurrent with model schematic discussed in 7. above.

18. Elevation-storage and elevation-discharge tables for the reservoir in 1-foot increments, and table of routed hydrograph ordinates with peak inflow to reservoir and routed peak outflow identified. Inflow and outflow hydrographs plotted on same figure of appropriate scale.
19. Discussion of reasonableness of results, including any calibration or comparison information available.
20. Discussion of any parameter adjustments or sensitivity analysis performed in order to validate or improve reasonableness of results.

Special Case – Perimeter Dams:

An increasing number of dams regulated by OSE are perimeter embankments with no contributing watershed outside of the reservoir, interior slopes, and embankment crest. These dams may include wastewater pond dams, industrial evaporation pond dams, municipal raw water storage dams, tailings dams, etc. Water or potentially mobile contents are pumped or discharged to the reservoir as part of a controlled process.

For these perimeter dams, hydrology typically is greatly simplified. The contributing area (reservoir surface, interior slopes, and crest) is determined, and the design precipitation depth is applied to this area to determine the volume contribution of the storm to the reservoir. Where the design storm is all or a percentage of the PMP, the General Storm 72-hour index precipitation should be used. Losses are neglected, and the full precipitation depth is treated as excess contributing to the reservoir. In most cases, storage for this volume of water is provided above the normal maximum water level, with additional freeboard above flood stage to satisfy the freeboard requirements of OSE Rules and Regulations. In some cases, a spillway may be designed to allow routing and discharge of some of the flood volume, thereby reducing embankment height above normal maximum water level.

In addition to water from extreme precipitation events, perimeter embankments are susceptible to misoperation, where discharge into the reservoir continues past the design maximum reservoir level and eventually overtops the embankment, resulting in failure. For this reason, perimeter embankments must be provided with an overflow section with capacity equal to or greater than the discharge capacity into the reservoir, so that misoperation or failure of reservoir controls does not lead to embankment failure.

NOTICE OF PROPOSED REGULATIONS AND PUBLIC HEARING

OFFICE OF THE STATE ENGINEER
P.O. BOX 25102
SANTA FE, NEW MEXICO 87504-5102
(505) 827-6122
www.ose.state.nm.us

The State Engineer has released proposed amendments to Rules and Regulations Governing Dam Design, Construction and Dam Safety. The proposed amendments were developed to address changes to Section 72-5-32 NMSA effective on June 19, 2009 and to address improvements to the standards of dam design, construction and operation practice in New Mexico.

Amendments are proposed to the following sections of the Rules and Regulations Governing Dam Design, Construction and Dam Safety: (7) Definitions, (8) Fee Schedule, (9) Size Classification, (10) Hazard Potential Classification, (11) Design of a Dam, (12) Certifications, (13) Permit Conditions, (14) Proof of Completion of Works, (17) Operation and Maintenance Manual, (18) Emergency Action Plan, (19) Changes to an Existing Dam (20) Changes to an Existing Non-Jurisdictional Dam, and (21) Existing Dams.

The proposed regulations are available at the Office of the State Engineer in Santa Fe, Albuquerque, Las Cruces, Roswell, Deming, Aztec, and Cimarron. The proposed regulations are also posted on the Office of the State Engineer web site and may be accessed at www.ose.state.nm.us/water_info_dam_safety_rules.html. Click on the link under Proposed Rules and Regulations. To request that a copy of the rules and regulations be sent to you in the mail or by email, please contact Judy Leyba at 505-827-6111 or email judy.leyba@state.nm.us.

A public hearing will be held on the above described proposed and amended regulations at the State Capitol, Santa Fe, New Mexico, on October 29, 2010 beginning at 10:00 a.m. Any person who is or may be affected by these proposed rules and regulations may appear and testify. If you are an individual with a disability who is in need of special assistance or accommodation to attend or participate in the hearing, please contact Judy Leyba at (505) 827-6122. The Office of the State Engineer requests ten days advance notice to provide any special accommodation.

Written comments on the proposed regulations may be submitted to the Office of the State Engineer in Santa Fe or to any of the district offices. Written comments on the proposed rules and regulations may also be mailed to:

Office of the State Engineer
Dam Safety Bureau
Attention: Elaine Pacheco
P.O. Box 25102
Santa Fe, NM 87504

Please submit your written comments to the Office of the State Engineer no later than October 15, 2010. After October 15, 2010, written and oral comments must be submitted at the hearing in Santa Fe on October 29, 2010.

BEFORE THE NEW MEXICO STATE ENGINEER

IN THE MATTER OF THE PROPOSED	)
AMENDMENT OF RULES GOVERNING	)
DAM DESIGN, CONSTRUCTION AND	)
DAM SAFETY	)

FINDINGS OF FACT, ORDER
AND NOTICE OF PROPOSED RULEMAKING

COMES NOW John R. D'Antonio, Jr., P.E., State Engineer of the State of New Mexico, pursuant to NMSA 1978, Section 72-2-8(D), and makes the following **FINDINGS OF FACT**:

1. In accordance with NMSA 1978, Sections 72-2-8, 72-2-12 and 72-2-17, the State Engineer is authorized to adopt regulations, appoint hearing examiners, and conduct hearings on matters that are properly before him. A designated hearing examiner shall have such power as may be delegated by the State Engineer to regulate all proceedings before him, and to perform acts and take all necessary or proper measures for the efficient and orderly conduct of such proceedings.

2. The existing Rules and Regulations Governing Dam Design, Construction and Dam Safety do not adequately reflect and address:

a. The 2009 amendment to NMSA 1978, Section 72-5-32, which changed the definition of dams that are under the jurisdiction of the State Engineer;

b. Current state of the practice of the Office of the State Engineer concerning dam design, construction and dam safety; and

c. Industry standards relating to dam design, construction and dam safety.

3. It is necessary and appropriate to provide clear standards and regulations for the design, construction and safety of dams under the State Engineer's jurisdiction. Therefore, the existing rules should be amended so that consistent and detailed rules will be in place.

4. The proposed amendments have been reviewed by counsel for the State Engineer.

5. A detailed synopsis of the substantive proposed amendments is attached as Exhibit 1 to this Order and a list of references supporting the proposed amendments is attached as Exhibit 2.

6. A public hearing should be held on the proposed amendments to existing rules 19.27.12 NMAC (Dam Design, Construction and Dam Safety). Accordingly, the proposed amendments should be made publicly available, and a resume of the proposed amendments should be published together with notice of the public hearing pursuant to NMSA 1978, Section 72-2-8(D).

WHEREFORE, the State Engineer hereby **ORDERS:**

A. The proposed amended rules shall be filed for public inspection in the Office of the State Engineer in each District field office on or before August 23, 2010, and notice of the proposed rulemaking and public hearing shall be mailed to each person included in the file of interested persons in the Office of the State Engineer.

B. A resume of the substantive proposed amendments shall be published together with notice of public hearing in a minimum of five newspapers of general circulation once a week for two consecutive weeks, and notice shall also be published in the New Mexico Register. Publication shall be completed by October 8, 2010.

C. A public hearing on the proposed amendments shall be held in Santa Fe, New Mexico beginning at 10:00 a.m. on October 29, 2010.

Witness my hand and seal this 20th day of August, 2010.

John R. D'Antonio, Jr., P.E.
State Engineer of New Mexico

EXHIBIT 1

SYNOPSIS OF SUBSTANTIVE PROPOSED AMENDMENTS TO 19.25.12 NMAC
Dam Design, Construction and Dam Safety Rules and Regulations

Following is a synopsis of the sections of the substantive proposed amendments to rules and regulations governing dam design, construction and dam safety. Proposed procedural amendments are not included in this synopsis.

19.25.12.7 DEFINITIONS: The following definitions were added or amended.

19.25.12.7.A(2)
"**Aesthetic fill**: Cosmetic fill added to the downstream slope of a dam that is not required to address the safe design. Aesthetic fill shall not be considered when determining the properties of the dam for the purposes of evaluating the jurisdictional status and shall not be used to support the safe design."

19.25.12.7.D(1)(a)
"Jurisdictional dam" definition revised to conform to requirements of Section 72-5-32, NMSA 2009, as amended. See Exhibit 2, Reference 4.

19.25.12.7.D(1)(b)
"Non-jurisdictional dam" definition revised to conform to requirements of Section 72-5-32, NMSA 2009, as amended. Exemption for stock dams and erosion control dams as non-jurisdictional is no longer required. See Exhibit 2, Reference 4.

19.25.12.7.D(2)
"Dam crest" definition revised to recognize the crest is the entire uppermost surface and not a single location. The lowest elevation reference is moved to the dam height definition.

19.25.12.7.D(4)
"**Dam height**: The vertical distance from the lowest point on the downstream toe to the lowest point on the dam crest."

19.25.12.7.E(1)
"**Earthquake**: A sudden motion or trembling of the earth caused by the abrupt release of accumulated stress along a fault."

19.25.12.7.E(1)(a)
"**Operating basis earthquake**: The earthquake that can reasonably be expected to occur within the service life of the dam or appurtenant structures." See Exhibit 2, Reference 6.

19.25.12.7.E(1)(b)
"**Maximum credible earthquake**: The greatest earthquake that can reasonably be expected to be generated by a specific source on the basis of seismological and geological evidence." See Exhibit 2, Reference 6.

19.25.12.7.E(2)
"**Evacuation map**: A map prepared in collaboration with local emergency managers defining the area to be evacuated from a dam failure."

19.25.12.7.F(1)
"Fetch" definition amended to the more specific distance between the dam and farthest reservoir shore rather than the general distance across a body of water.

19.25.12.7.G
"**Geotextile**: Any fabric or textile (natural or synthetic) used as an engineering material in conjunction with soil, foundations or rock. Geotextiles provide the following uses: drainage, filtration, separation of materials, reinforcement, moisture barriers and erosion protection." See Exhibit 2, Reference 8.

19.25.12.7.I(1)
"**Incremental impacts**: Under a given flood, earthquake or other conditions, the difference in impacts that would occur due to failure or misoperation of the dam and appurtenant structures compared to those that would have occurred without failure or misoperation of the dam and appurtenant structures." See Exhibit 2.

19.25.12.7.N(3)
"North American vertical datum" definition corrected to reference the national geodetic vertical datum 1929 rather than the North American vertical datum 1927.

19.25.12.7.R
"**Residual freeboard**: The vertical distance between the high water line and the lowest point on the dam crest."

19.25.12.7.S(5)
"**Sunny day failure**: Dam failure with the reservoir at the normal operating level."

19.25.12.8 FEE SCHEDULE:

19.25.12.8.B
Fee for alter, repair or rehabilitation of a dam is added to the fee schedule.

19.25.12.8.H-I
Schedule of fees for all copies is replaced with a statement that fees will be charged to offset the cost of the service and consistent with state engineer policy adopted pursuant to the NM Inspection of Public Records Act.

19.25.12.9 SIZE CLASSIFICATION:

19.25.12.9.A
"Small" classification is revised to conform to requirements of Section 72-5-32, NMSA 2009, as amended.

19.25.12.11 DESIGN OF A DAM:

19.25.12.11
Introduction amendment adds an option to require a quality management plan if the supporting documentation does not meet acceptable engineering standards as determined by the state engineer.

19.25.12.11.C(1)(a)-(g)
Hazard potential classification amendments reorganize and describe in greater detail the information that must be included in the dam breach and flood routing analysis. See Exhibit 2, Reference 7.

19.25.12.11.C(2)(b)
Hydrologic analysis amendment requires a description of land treatment for the drainage area.

19.25.12.11.C(4)
Incremental damage assessment amendments clarify that the assessment is a process used when spillways cannot be designed to comply with the spillway design flood listed in 19.25.12.11.C(3). A detailed description of the process to assess incremental impacts is provided in the amendment. See Exhibit 2, Reference 2.

19.25.12.11.C(5)
Spillway capacity amendment deletes the option of performing an erosion study of the embankment to justify overtopping of a new dam due to inadequate spillway capacity.

19.25.12.11.C(6)(e)
Energy dissipation for spillway discharge amendment states: "<u>The design shall address energy dissipation to control erosion of the natural channel due to spillway discharge reasonably expected to occur during the life of the dam.</u>"

19.25.12.11.C(6)(g)
Training dikes amendment deletes the reference to compaction to "at least 70% relative density if Proctor testing is not appropriate."

19.25.12.11.C(8)(l)
Minimizing seepage along conduits amendment adds the following statement: "<u>Seepage collars are not an acceptable design standard for controlling seepage.</u>" See Exhibit 2, Reference 5.

19.25.12.11.C(11)
Seepage and internal drainage amendment requires the evaluation of seepage and internal drainage for dams with aesthetic fill on the downstream slope and removes the option of requesting a waiver for reservoirs with synthetic liners on that basis alone.

19.25.12.11.C(11)(d)
Seepage and internal drainage amendments replace the requirement for a specific device depending on flow rate to a more general requirement that the measuring device must be appropriate for the rate of flow. A requirement for an upstream catchment for the seepage collection device is also added.

19.25.12.11.C(12)
Stability analysis amendment requires the evaluation of stability for dams with aesthetic fill on the downstream slope and requires the stability of the reservoir rim to be evaluated if the slopes are steeper than 3 horizontal to 1 vertical.

19.25.12.11.C(12)(c)-(d)
Stability analysis amendment increases the factor of safety for rapid drawdown and end of construction loading conditions from 1.2 to 1.3. See Exhibit 2, Reference 9.

19.25.12.11.C(13)
Seismic design and analysis amendment adds the requirement of a seismic analysis for appurtenant structures. See Exhibit 2, Reference 6.

19.25.12.11.C(13)(a)
Seismological investigation amendment provides the criteria for the operating basis earthquake to be used in the seismological investigation study. See Exhibit 2, Reference 6.

19.25.12.11.C(13)(a)(i)
Seismological investigation amendment states: "Dams classified as high hazard potential other than flood control structures shall be designed for the maximum credible earthquake or for a 1% probability of exceedance in 50 years (approximately 5000-year return frequency)." See Exhibit 2, Reference 6.

19.25.12.11.C(13)(c)(i)
Pseudostatic analysis amendment deletes the reference to compaction of "at least 70% relative density if Proctor testing is not appropriate".

19.25.12.11.C(13)(c)(ii)
Pseudostatic analysis amendment states that a pseudostatic analysis is acceptable if the peak ground acceleration is 0.35g or less.

19.25.12.11.C(17)
Geotextile design amendment requires the geotextile design computations to be provided and clarifies the installation requirements for the geotextile.

19.25.12.11.C(19)
Utilities design amendment requires the evaluation of utilities in the spillway and seepage limits of the dam.

19.25.12.11.D(2)
Scale and size amendment allows drawings to range in size from 22 inches to 24 inches by 34 inches to 36 inches.

19.25.12.11.D(12)
Permanent bench mark amendment deletes the option of providing the location of the permanent bench mark based on the New Mexico state plane coordinate system.

19.25.12.11.E
Specifications amendments clarify that a specification package is required to be submitted for each project and that reference to standard specifications is not acceptable; however, inclusion of appropriate specifications from model specifications is appropriate. The amendment also requires the specifications to address frequency of testing and frequency of inspection.

19.25.12.11.E(4)
General conditions of the specifications amendment add the requirement that statements recognizing the authority of the state engineer to perform inspections during construction and acknowledging that the construction drawings and specifications cannot be changed without prior written approval from the state engineer be included in the specification package.

19.25.12.11.H
Instrumentation plan amendment adds the requirement that details of the instrumentation must be included in the construction drawings and that specifications must be consistent with the instrumentation plan. See Exhibit 2, Reference 1.

19.25.12.11.H(3)
Calibration amendment adds the requirement of including calibration and maintenance schedules, and instructions in the instrumentation plan. See Exhibit 2, Reference 1.

19.25.12.11.H(5)
Data reduction amendment adds the requirement of including data reduction and interpretation instructions in the instrumentation plan. See Exhibit 2, Reference 1.

19.25.12.12 CERTIFICATIONS:

19.25.12.12
Certifications introduction amendment adds the requirement for a certification from the local emergency management official.

19.25.12.12.D
Local and state emergency management official's certificate amendments revise the certification requirements to include a certification from the local emergency management official.

19.25.12.13 PERMIT CONDITIONS:

19.25.12.13.A(1)
Engineer supervising construction amendments add the requirements that the monthly construction report be signed and sealed by the engineer supervising construction and the monthly construction report includes a summary of construction activities and captioned and dated construction photographs.

19.25.12.13.A(4)(a)
Construction completion amendment requires the construction completion report to include signed certifications from the engineer and a certification for the state engineer.

19.25.12.13.A(4)(b)
Record mylar drawings amendments require the drawings to contain signed certifications from the owner and the engineer supervising construction and a certificate for the state engineer. The design engineer may also be required to sign a certification depending on the changes.

19.25.12.13.E
Operation condition amendment specifies a list of operation conditions that shall be included in the permit.

19.25.12.17 OPERATION AND MAINTENANCE MANUAL:

19.25.12.17
The amendment to the introduction first deletes the requirement that a professional engineer prepare the entire operation and maintenance manual and instead specifies that a professional engineer is only needed to prepare the complex technical aspects of the operation and maintenance manual if deemed appropriate by the state engineer. Second, the amendment clarifies that the state engineer may order storage restrictions if the operation and maintenance procedures are not followed.

19.25.12.17.A
General information amendment adds the requirement of including in the operation and maintenance manual information on access to the dam and the history of construction, repairs and performance. See Exhibit 2, Reference 1.

19.25.12.17.B(1)
Operation amendment adds the requirement of including the following information in the operation and maintenance manual: discharge information specific for the outlet conduit and spillway; an elevation, area and storage curve and table to the dam crest; and elevation of the high water line. See Exhibit 2, Reference 1.

19.25.12.17.B(3)
Operator safety amendment adds the requirement of including the following information in the operation and maintenance manual: confined space entry and permits; fall protection; lockout/tag out; and other applicable safety requirements.

19.25.12.17.C (2)-(7)
Instrumentation amendment revises this section to conform to the requirements of the instrumentation plan specified in 19.25.12.11.H. Under the amendment, the following additional information must be included in the operation and maintenance manual: detailed description of installation; calibration schedule and instructions; reading instructions; data reduction and interpretation; notification procedures; and schedule for reporting data with interpretations. See Exhibit 2, Reference 1.

19.25.12.17.H
Appendices amendment adds the requirement of including the following information in the appendices of the operation and maintenance manual: captioned and dated photographs; key sheets from the record construction drawings; instrumentation construction drawings; instrumentation rating tables and calibration details; monitoring and inspection forms; and copies of any relevant procedures.

19.25.12.18 EMERGENCY ACTION PLAN:

19.25.12.18
The introduction amendment adds the requirement of including in the emergency action plan a signed certification from the local emergency official and requires the dam owner to coordinate with emergency management officials to establish the evacuation limits.

19.25.12.18(D)
Preparedness amendment deletes the requirement for a professional engineer to prepare this element of the emergency action plan.

19.25.12.18(E)
Evacuation map amendment adds the requirement of including an evacuation map in the emergency action plan. The amendment specifies that the evacuation map is required to extend to a point where the consequences of dam failure no longer pose a threat to life and evacuation or restricting access is no longer required. See Exhibit 2, Reference 3.

19.25.12.18(E)(1)-(4)
Evacuation map amendment adds the requirement of including the following information in the evacuation map: distance downstream from the dam; arrival time of the leading edge of the flood wave; peak flow depth, incremental rise or water surface elevation in feet; and peak velocity in feet per second. See Exhibit 2, Reference 3.

19.25.12.18(F)
Inundation map amendment deletes the requirement that every dam breach and flood routing analysis report for preparing an emergency action plan be prepared to the same level as required for a design effort. The amendment specifies that the use of a simplified dam breach and flood routing analysis is acceptable if the consequences of failure justify a simplified process and the state engineer concurs. The amendment also specifies that the effects of flooding from dam failure must be routed until the flood no longer poses a threat to life and evacuation or restricting access are no longer required. See Exhibit 2, Reference 3.

19.25.12.18(F)(1)-(4)
Inundation map amendment adds the requirement of including the following information in the inundation map: distance downstream from the dam; arrival time of the leading edge of the flood wave; peak flow depth, incremental rise or water surface elevation in feet; and peak velocity in feet per second. See Exhibit 2, Reference 3.

19.25.12.19 CHANGES TO AN EXISTING DAM:

19.25.12.19.A
Proposed changes to an existing dam amendment adds the requirement that dam owners adding aesthetic fill to an existing dam obtain approval from the state engineer prior to undertaking any actions.

19.25.12.19.A(1)
Application amendment waives plan review fees for only the first review of plans to alter, repair or rehabilitate a dam.

19.25.12.19.B(2)
Removal or breach of a dam amendment adds the requirement that a breach be sized to pass the peak discharge without attenuation of the flood through the reservoir.

19.25.12.19.F
Proof of completion of works amendment clarifies that the requirement for a proof of completion of works form for changes to an existing dam will be made on a case by case basis by the state engineer.

19.25.12.20 CHANGES TO AN EXISTING NON-JURISDICTIONAL DAM:

19.25.12.20
The introduction amendment clarifies that a non-jurisdictional dam will no longer become jurisdictional if the purpose changes, but that a non-jurisdictional dam can become jurisdictional when the ownership changes from federal to non-federal.

19.25.12.21 EXISTING DAMS:

19.25.12.21.A
The introduction amendment adds the following statement: "Failure to comply with state engineer directives or these regulations may result in an order to reduce storage or to take corrective action."

19.25.12.21.B
Hazard classification change amendment deletes the following statement: "If the dam owner fails to address a deficiency, the state engineer may revoke the license to operate the dam and order the dam breached in accordance with Subsection B or C of 19.25.12.19 NMAC."

19.25.12.21.E
Operation and maintenance manual requirement amendment deletes compliance deadlines because the amendment will be promulgated on or after the deadlines and the deleted deadlines are no longer relevant. Existing owners of dams classified as high or significant hazard potential will be out of compliance if they have not complied with the requirements of 19.25.12.17 NMAC for an operation and maintenance manual.

19.25.12.21.F
Emergency action plan requirement amendment deletes compliance deadlines for all but significant hazard potential flood control dams and owners of 5 or more dams because the amendment will be promulgated on or after the deadlines and the deleted deadlines are no longer relevant.

TITLE 19 NATURAL RESOURCES AND WILDLIFE
CHAPTER 25 ADMINISTRATION AND USE OF WATER - GENERAL PROVISIONS
PART 12 DAM DESIGN, CONSTRUCTION AND DAM SAFETY

19.25.12.1 ISSUING AGENCY: New Mexico Office of the State Engineer
[19.25.12.1 NMAC - N, 3/31/2005]

19.25.12.2 SCOPE: These regulations apply to the design and construction of all jurisdictional dams in New Mexico and are intended to facilitate the continued safe operation and maintenance of all non-federal jurisdictional dams. These regulations govern the review and acceptance of plans for construction, alteration, modification, repair, enlargement and removal of a jurisdictional dam. These regulations ensure the continued safe operation, maintenance, site security and emergency preparedness for existing non-federal jurisdictional dams. These regulations do not authorize the appropriation or use of water pursuant to 19.26 NMAC and 19.27 NMAC.
[19.25.12.2 NMAC - N, 3/31/2005]

19.25.12.3 STATUTORY AUTHORITY: Section 72-5-32 NMSA requires any person, association or corporation, public or private, the state or the United States that is intending to construct a jurisdictional dam to submit detailed plans to the state engineer. Sections 72-5-9 and 72-5-10 NMSA establish the state engineer's authority over the construction of works and issuing certificates of construction. Sections 72-5-8 and 72-5-14 NMSA require construction to be completed in a time limit set by the state engineer and procedures for requesting an extension of time. Sections 72-5-11, 72-5-12 and 72-5-13 NMSA gives the state engineer jurisdiction over unsafe works, penalties for failure to comply with state engineer orders and priority of liens. Section 72-2-6 NMSA gives the state engineer the authority to assess fees. Section 72-2-8 NMSA gives the state engineer authority to adopt regulations and codes to implement and enforce any provision of any law administered by him. Section 72-8-1 NMSA gives the state engineer the authority to enter upon private property for the performance of his duties. Nothing in these rules shall be construed so as to limit the state engineer's authority to take lawful alternative or additional actions relating to the design, construction and safety of dams.
[19.25.12.3 NMAC - N, 3/31/2005]

19.25.12.4 DURATION: Permanent.
[19.25.12.4 NMAC - N, 3/31/2005]

19.25.12.5 EFFECTIVE DATE: March 31, 2005 unless a later date is cited at the end of a section.
[19.25.12.5 NMAC - N, 3/31/2005]

19.25.12.6 OBJECTIVE: To establish minimum design requirements, minimum submittal requirements and dam site owner responsibilities that shall be addressed to the state engineer's satisfaction in order to ensure a dam is designed, constructed, operated, maintained and secured in a safe manner.
[19.25.12.6 NMAC - N, 3/31/2005]

19.25.12.7 DEFINITIONS: Unless defined below or in a specific section of these regulations, all other words used herein shall be given their customary and accepted meaning.

A. Terms starting with the letter 'A' are defined as follows:

[~~A.~~] (1) Abutment: That part of the valley side against which the dam is constructed. The left and right abutments of dams are defined with the observer viewing the dam looking in the downstream direction.

(2) Aesthetic fill: Cosmetic fill added to the downstream slope of a dam that is not required to address the safe design. Aesthetic fill shall not be considered when determining the properties of the dam for the purposes of evaluating the jurisdictional status and shall not be used to support the safe design.

[~~B.~~] (3) Alteration, modification, repair, rehabilitation or enlargement of an existing dam: To change from the state engineer accepted construction drawings and specifications or current condition.

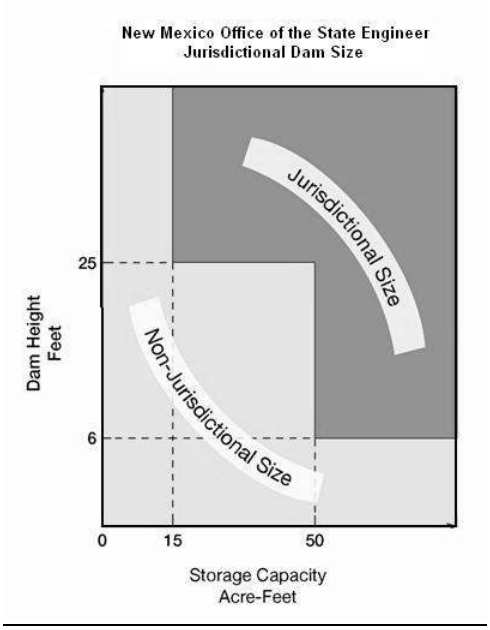
[~~C.~~] (4) Appurtenant structure: Auxiliary features of a dam such as outlets, spillways, access structures, tunnels and related housing at a dam.

[~~D.~~] (5) [~~American society for testing and materials (ASTM): An accepted standard for testing the properties of materials.~~] ASTM: Standards promulgated by ASTM international for testing the properties of materials. Methods cited in these regulations include laboratory compaction characteristics of soils.

B. Terms starting with the letter 'B' are defined as follows:

[~~E.~~] Breach: An opening through a dam or spillway that is capable of draining a portion of the reservoir or the entire reservoir. A controlled breach is a constructed opening. An uncontrolled breach is an unintentional discharge from the reservoir.

C. Terms starting with the letter 'C' are defined as follows:



[~~F.~~] (1) Consequences of failure: Potential loss of life or property damage downstream of a dam caused by waters released at the dam or by waters released by partial or complete failure of dam; includes effects of landslides upstream of the dam on property located around the reservoir.

[~~G.~~] (2) Crest width: The thickness or width of a dam at the crest level (excluding corbels or parapets). In general, the term thickness is used for gravity and arch dams and width is used for other dams.

D. Terms starting with the letter 'D' are defined as follows:

[~~H.~~] (1) Dam: A man-made barrier constructed across a watercourse or off-channel for the purpose of storage, control or diversion of water.

[~~(1)~~] (a) Jurisdictional dam: [~~A dam that is more than 10 feet in height measured from the lowest point on the downstream toe to the dam crest or impounds more than 10 acre-feet of water as measured from the lowest point on the downstream toe to the spillway crest. Dams constructed under the supervision of the U.S. army corps of engineers before May 19, 2004, become jurisdictional when such supervision by the U.S. army corps of engineers is terminated.~~] A dam 25 feet or greater in height, which impounds more than 15 acre-feet of water or a dam that impounds 50 acre-feet or more of water and is 6 feet or greater in height. For purposes of these regulations, reference to a dam means a jurisdictional dam unless otherwise noted.
See figure of jurisdictional dam size.

[~~(2)~~] (b) Non-jurisdictional dam: [~~Any dam less than or equal to 10 feet in height and having storage less than or equal to 10 acre-feet of water.~~] Any dam not meeting the height and storage requirements of a jurisdictional dam. The state engineer does not regulate the design, construction and operation of a non-jurisdictional dam unless the dam is unsafe and there is a threat to life or property, as determined by the state engineer. Waters impounded by a non-jurisdictional dam may not be exempt from water right permit requirements; therefore a separate state engineer water right permit for the water impounded in the reservoir created by a non-jurisdictional dam may be required. Non-jurisdictional dams shall meet the requirements of 19.26.2.15 NMAC unless otherwise exempt. The structures listed below are considered non-jurisdictional dams:

~~**[(a) Stock dam:** A stock dam constructed prior to May 19, 2004 with a storage capacity of 10 acre-feet or less regardless of the height of the dam.~~

~~**(b) Erosion control dam:** A dam for the sole purpose of erosion control constructed on a naturally dry watercourse as determined by the state engineer, with a storage capacity of 10 acre-feet or less as measured from the lowest point on the downstream toe to the spillway crest and the reservoir drains in 96 hours unless a quicker drain time is required by court decree.~~]

[~~(c)~~] (i) Levee or diversion dike: A structure where water flows parallel to the length of the levee or diversion dike as determined by the state engineer.

[~~(d)~~] (ii) Roadway embankment: A structure across a watercourse designed for the sole purpose of supporting a roadbed or other means of conveyance for transportation as determined by the state engineer; where the area upstream has not been enlarged to increase flood storage; and where the embankment is provided with an uncontrolled conduit of sufficient capacity to satisfy requirements of the appropriate state or local transportation authority. If no transportation authority has jurisdiction over the structure, the current drainage design criteria of the New Mexico department of transportation shall apply.

[~~I.~~] (2) Dam crest: The [~~lowest elevation of the~~] uppermost surface of a dam, usually a road or walkway excluding any parapet wall, railing, etc.

[~~J.~~] (3) Dam failure: The breakdown of a dam, characterized by the uncontrolled release of impounded water. [~~There are varying degrees of failure.~~]

[~~K.~~] (4) Dam height: The vertical distance from the lowest point on the downstream toe to the lowest point on the dam crest.

[~~L.~~] (5) Dam incident: An event at a dam that interrupts normal procedures and performance, affects the safety of the dam or results in a potential loss of life or damage to property.

E. Terms starting with the letter 'E' are defined as follows:

(1) Earthquake: A sudden motion or trembling of the earth caused by the abrupt release of accumulated stress along a fault.

(a) Operating basis earthquake: The earthquake that can reasonably be expected to occur within the service life of the dam or appurtenant structures.

(b) Maximum credible earthquake: The greatest earthquake that can reasonably be expected to be generated by a specific source on the basis of seismological and geological evidence.

(2) Evacuation map: A map prepared in collaboration with local emergency managers defining the area to be evacuated from a dam failure.

F. Terms starting with the letter 'F' are defined as follows:

[~~M.~~] (1) Fetch: The straight-line distance [~~across a body of water~~] between the dam and farthest reservoir shore subject to wind forces. The fetch is one of the factors used to calculate wave heights in a reservoir.

[~~N.~~] (2) Freeboard: The vertical distance between the spillway crest and the lowest point of the dam crest not including camber.

[~~O.~~] (3) Functional exercise: A meeting in a conference room environment involving the dam owner and state and local emergency personnel with responsibilities in the emergency action plan. The exercise takes place in a stress-induced environment with time constraints and involves simulation of a dam failure and other specific events. The exercise is designed to evaluate both the internal capabilities and responses of the dam owner and the workability of the information in the emergency action plan used by emergency management officials.

G. Terms starting with the letter 'G' are defined as follows: Geotextile: Any fabric or textile (natural or synthetic) used as an engineering material in conjunction with soil, foundations or rock. Geotextiles provide the following uses: drainage, filtration, separation of materials, reinforcement, moisture barriers and erosion protection.

H. Terms starting with the letter 'H' are defined as follows:

[~~P.~~] High water line: The highest water level elevation in the reservoir as determined from routing the spillway design flood or inflow design flood.

I. Terms starting with the letter 'I' are defined as follows:

(1) Incremental impacts: Under a given flood, earthquake or other conditions, the difference in impacts that would occur due to failure or misoperation of the dam and appurtenant structures compared to those that would have occurred without failure or misoperation of the dam and appurtenant structures.

[~~**Q. Inflow design flood:** The flood flow above which the incremental increase in downstream water surface elevation due to failure of a dam is no longer considered to present an unacceptable additional downstream threat. The upper limit of the inflow design flood is the flood resulting from the probable maximum precipitation and the lower limit is the flood resulting from the 100-year precipitation.~~]

[~~R.~~] (2) Inundation map: A map delineating the area that would be flooded by a particular flood event.

J. Terms starting with the letter 'J' [Reserved]

K. Terms starting with the letter 'K' [Reserved]

L. Terms starting with the letter 'L' are defined as follows:

[~~S.~~] (1) Length of dam: The length measured along the dam axis at the dam crest. This also includes the spillway, powerplant, navigation lock, fish pass, etc., where these form part of the length of the dam. If detached from the dam these structures [~~should~~] shall not be included.

[~~T.~~] (2) Loss of life: The likely number of human fatalities that would result from a dam failure flood event. No allowances for evacuation or other emergency actions by the population [~~should~~] shall be considered.

M. Terms starting with the letter 'M' [Reserved]

N. Terms starting with the letter 'N' are defined as follows:

[~~U.~~] (1) Naturally dry watercourse: A watercourse or portion thereof, which under normal conditions is dry, which flows only in direct response to precipitation and whose channel is at all times above the groundwater table.

[~~V.~~] (2) Normal operating level: The water level elevation corresponding to the maximum storage level that excludes any flood control or surcharge storage.

[~~W.~~] (3) North American vertical datum 1988 (NAVD 88): The current vertical control datum in use in North America established from nine space geodetic stations. This basis of establishing elevation provides a precise surface, [~~whereas the North American vertical datum 1927 (NAVD27)~~] whereas the national geodetic vertical datum 1929 (NGVD 29) is elevation established from mean sea level.

O. Terms starting with the letter 'O' are defined as follows:

[~~X.~~] (1) One-hundred year flood: A flood that has 1 chance in 100 of being equaled or exceeded during any year.

[~~Y.~~] (2) Owner: The individual, association or corporation, public or private, the state or the United States, owning the land upon which a dam is constructed; having a contractual right to construct, operate or maintain a dam; or the beneficiary of an easement to construct, operate or maintain a dam.

P. Terms starting with the letter 'P' are defined as follows:

(1) Probable: Likely to occur, reasonably expected, realistic.

[~~Z.~~] (2) Probable maximum precipitation: Theoretically, the greatest depth of precipitation for a given duration that is physically possible over a given size storm area at a particular location during a certain time of year.

Q. Terms starting with the letter 'Q' [Reserved]

R. Terms starting with the letter 'R' are defined as follows: Residual freeboard: The vertical distance between the high water line and the lowest point on the dam crest.

S. Terms starting with the letter 'S' are defined as follows:

[~~AA.~~] (1) Spillway: A structure over or through which excess flow is discharged from a reservoir. If the rate of flow is controlled by mechanical means such as gates, it is considered a controlled spillway. If the geometry of the spillway is the only control, it is considered an uncontrolled spillway. For purposes of these regulations, an uncontrolled outlet conduit that is used to drain the reservoir is not considered a spillway.

[~~BB.~~] (2) Spillway crest: The lowest level at which water can flow over or through the spillway.

[~~CC.~~] (3) Spillway design flood: The required flood that a spillway must pass without failure of the dam.

[~~DD.~~] (4) Storage: For purposes of determining whether a dam is jurisdictional, the storage is the volume of water impounded by the dam above the lowest elevation of the downstream toe to the elevation of the spillway crest. For dams with no spillway, storage is measured to the dam crest. Definitions of specific types of storage in reservoirs are:

[~~(1)~~] (a) Dead storage is the storage volume of a reservoir that lies below the invert of the lowest outlet and therefore, cannot readily be withdrawn from the reservoir.

[~~(2)~~] (b) Flood surcharge storage is the storage volume between the maximum operating level and the maximum water level during the spillway design flood.

[~~(3)~~] (c) Live storage is the storage volume of a reservoir that is available for use and lies above the invert of the lowest outlet.

[~~(4)~~] (d) Reservoir storage capacity is the sum of the dead and live storage of the reservoir.

[~~(5)~~] (e) Maximum storage is the sum of the reservoir storage capacity and flood surcharge storage.

(5) Sunny day failure: Dam failure with the reservoir at the normal operating level.

T. Terms starting with the letter 'T' are defined as follows:

[~~EE.~~] (1) Tabletop exercise: A meeting in a conference room environment involving the dam owner and state and local emergency personnel with responsibilities in the emergency action plan. The format is a discussion of an emergency event, response procedures to resolve concerns regarding coordination and responsibilities.

[~~FF.~~] (2) Toe: The contact line between the outer shell of the dam and the natural ground surface.

U. Terms starting with the letter 'U' [Reserved]

V. Terms starting with the letter 'V' [Reserved]

W. Terms starting with the letter 'W' are defined as follows:

[~~GG.~~] Wave runup: Vertical height above the water level to which water from a specific wave will run up the face of a structure or embankment.

X. Terms starting with the letter 'X' [Reserved]

Y. Terms starting with the letter 'Y' [Reserved]

Z. Terms starting with the letter 'Z' [Reserved]

[19.25.12.7 NMAC - N, 3/31/2005; A, xx/xx/2010]

19.25.12.8 FEE SCHEDULE: The state engineer assesses fees for filing forms, reviewing plans and specifications for dams and appurtenant structures and construction inspections.

A. For filing an application for permit to construct and operate a dam the fees shall be $25.

B. For filing an application to alter, repair or rehabilitate a dam the fee shall be $25.

[~~**B.**~~] **C.** For each review of design plans, construction drawings and specifications for a dam the fee shall be $2 per $1000 or fraction thereof of the estimated construction cost. For determination of fees, inclusion of contingencies, taxes and other permit fees is not required. Assessment of multiple review fees for the same application is at the sole discretion of the state engineer.

[~~C.~~] D. For issuing an extension of time for construction of a dam the fee shall be $50.

[~~D.~~] E. For inspecting construction of a dam the fee shall be $100/8-hour day and actual and necessary traveling expenses.

[~~E.~~] F. For filing a proof of completion of works for a dam the fee shall be $25.

[~~F.~~] G. For filing a change of ownership for a dam the fee shall be $5.

[~~G.~~] H. [~~For copies of dam safety records up to 11 inches by 17 inches the fee shall be $0.20 per copy.~~] The state engineer shall charge reasonable fees for copy and reproduction to offset the cost of the service, consistent with the state engineer's current policy adopted pursuant to the New Mexico Inspection of Public Records Act, NMSA 1978 Section 14-2 et seq.

[~~**H.** For copies of dam safety records greater than 11 inches by 17 inches the fee shall be $3.00 per copy.~~]

[19.25.12.8 NMAC - N, 3/31/2005; A, xx/xx/2010]

19.25.12.9 SIZE CLASSIFICATION: A dam shall be less than or equal to the maximum height and storage to qualify for the size classification.

A. Small: [~~A small dam is greater than 10 feet but less than or equal to 40 feet in height, or greater than 10 acre-feet but less than or equal to 1000 acre-feet of storage.~~] A small dam is 25 feet or greater but less than or equal to 40 feet in height, or 50 acre-feet or greater but less than or equal to 1000 acre-feet of storage.

B. Intermediate: An intermediate dam is greater than 40 feet but less than or equal to 100 feet in height, or greater than 1000 acre-feet but less than or equal to 50,000 acre-feet of storage.

C. Large: A large dam is greater than 100 feet in height[~~,~~] or greater than 50,000 acre-feet of storage.

[19.25.12.9 NMAC - N, 3/31/2005; A, xx/xx/2010]

19.25.12.10 HAZARD POTENTIAL CLASSIFICATION: The hazard potential classification is a rating for a dam based on the potential consequences of failure. The rating is based on loss of life, damage to property and environmental damage that is likely to occur in the event of dam failure. No allowances for evacuation or other emergency actions by the population [~~should~~] shall be considered. The hazard potential classification is not a reflection of the condition of the dam.

A. Low hazard potential: Dams assigned the low hazard potential classification are those dams where failure or misoperation results in no probable loss of life and low economic [~~and/or~~] or environmental losses. Losses are principally limited to the dam owner's property.

B. Significant hazard potential: Dams assigned the significant hazard potential classification are those dams where failure or misoperation results in no probable loss of human life but can cause economic loss, environmental damage, disruption of lifeline facilities, or can impact other concerns. Significant hazard potential classification dams are often located in predominantly rural or agricultural areas but could be located in populated areas with significant infrastructure.

C. High hazard potential: Dams assigned the high hazard potential classification are those dams where failure or misoperation will probably cause loss of human life.

[19.25.12.10 NMAC - N, 3/31/2005; A, xx/xx/2010]

19.25.12.11 DESIGN OF A DAM: Any person, association or corporation, public or private, the state, or the United States that is intending to construct a dam shall submit an application to construct and operate a dam and supporting documentation acceptable to the state engineer. This section primarily addresses the design and construction of embankment dams. Other types of dams shall conform to sound engineering principles and current state of the practice. Because each site, design and operating practice is unique, waivers of specific requirements in this section will be considered on a case-by-case basis. Request for waiver shall be in writing accompanied with documentation justifying the request. If the request is not justified to the satisfaction of the state engineer the request will be denied. If the supporting documentation for the design of a dam does not meet acceptable engineering standards and does not conform to these regulations, as determined by the state engineer, a quality management plan or third party review may be required by the state engineer. Construction shall not begin until the state engineer has accepted the supporting documentation and approved the application with [~~construction and operation~~] permit conditions. The application and supporting documentation shall include[~~:~~] the information described below.

A. Application: An application form shall be completed with original signature of the dam owner and accompanied with a filing fee in accordance with Subsection A of 19.25.12.8 NMAC. The form will be the only information available to the public before the project is approved for construction. All other supporting documentation is considered draft until accepted by the state engineer. A plan review fee in accordance with Subsection [~~B~~] C of 19.25.12.8 NMAC shall accompany the submittal of the design report, construction drawings and specifications. A detailed estimate of the construction cost for the proposed dam and appurtenant structures shall be submitted in support of the plan review fee.

B. Water right: A water right is required for water impounded by the dam. If the dam owner has a permit for the diversion of water, documentation addressing the necessity for storage, diversion periods and release conditions for the reservoir may be required. This requirement is waived for flood control dams that do not detain water longer than 96 hours in accordance with Subparagraph (b) of Paragraph (7) of Subsection C of 19.25.12.11 NMAC or provide documentation that a waiver by the state engineer has been granted. Flood control dams that do not drain within 96 hours require a water right for water permanently stored beyond the 96-hour drain time requirement and for associated losses due to evaporation and other potential depletions to the system unless a waiver in accordance with 19.25.12.11 NMAC is obtained.

C. Design report: A design report, which includes information to evaluate the safe design of the dam and appurtenant structures, shall be submitted in a form acceptable to the state engineer. [~~The design report shall contain the information described below and any other additional information determined necessary by the state engineer.~~] The final design report shall also be submitted in an electronic format acceptable to the state engineer. The design report may be submitted as a single report or as individual reports documenting the information described below. A professional engineer licensed in the state of New Mexico qualified in the design and construction of dams shall prepare or supervise the preparation of the design report. [~~The front cover shall show the name of the dam (identical to the application), the county in which the dam is located and type of report.~~] The front cover shall show the name of the dam, the county in which the dam is located, the dam owner and the type of report. [~~The first page behind the front cover shall show the name of the dam (identical to the dam name on the application), the county in which the dam is located and the signed certifications for the engineer and state engineer in accordance with Subsections B and E of 19.25.12.12 NMAC.~~] The first page behind the front cover shall show the name of the dam, the county in which the dam is located, a signed certification from the engineer and a certification for the state engineer in accordance with Subsections B and E of 19.25.12.12 NMAC. [~~The design report shall include:~~] The design report shall contain the information described below and any other additional information determined necessary by the state engineer to evaluate if the design is safe.

(1) Hazard potential classification. A hazard potential classification shall be based on the dam failure condition that results in the greatest potential for loss of life and property damage. If the state engineer concurs, the classification may be based on the judgment and recommendation of the professional engineer. For all other cases, a

low or significant hazard potential classification shall be supported by a dam breach and flood routing analysis, which includes calculations and data that supports the predicted dam failure flood. This analysis shall also address the potential for foreseeable future development. Evaluation of the effects of flooding from dam failure shall extend at least to the location downstream where the classification can be properly identified. The dam breach and flood routing analysis shall include, but not be limited to:

(a) [~~dam failure inundation maps;~~] description of the dam breach and flood routing methodology;

[~~(b)~~ ~~map of the water surface profiles;~~

~~(c)~~ ~~cross-sections drawn to scale showing water surface elevation at critical sections where structures are impacted and showing discharge in cubic feet per second, average velocity in feet per second, flood wave travel times, rate of rise and structures located in the flooded sections;~~]

[~~(d)~~] (b) a tabulation and justification of [~~assumed~~] parameters used in the analysis;

[~~(e)~~] (c) a sensitivity analysis of the [~~assumed~~] parameters used in the analysis;

[~~(f)~~] (d) references to all computer models, data and supporting justification used in the analysis; [~~and~~]

[~~(g)~~] (e) [~~appropriate data sheets and computer program output computations from computerized analysis shall be provided.~~] appropriate data sheets, computer program input and output computations and electronic files from computerized analysis;

(f) table of results for the flood routing for the sunny day failure and the failure and no failure scenarios for multiple flood events up to and including the spillway design flood as defined in Subparagraph (a) through (d) of Paragraph (3) of Subsection C of 19.25.12.11 NMAC; the table of results for all critical locations downstream shall include the depth of flow in feet, velocity of flow in feet per second, rate of flow in cubic feet per second and the incremental impacts; and

(g) dam failure inundation maps downstream of the dam for the sunny day failure and failure during the spillway design flood event showing the depth of flow in feet, average velocity in feet per second and rate of flow in cubic feet per second at critical locations downstream.

(2) Hydrologic analysis. The hydrologic analysis shall include a discussion of methodology used to calculate the spillway design flood for determining the available flood storage and spillway capacity. Consideration of how the dam will perform under these hypothetical flood conditions shall be evaluated. The hydrologic analysis shall include, but not be limited to:

(a) a topographic map of the drainage area above the dam with the drainage area and sub-basins delineated and presented on a map of appropriate scale and size;

(b) a description of the topography, soils and vegetative cover and land treatment of the drainage area;

(c) a discussion of the depth, duration and distribution of the spillway design storm;

(d) a tabulation, discussion and justification of all hydrologic parameters and methodology used to calculate runoff from rainfall;

(e) a discussion of the peak inflow, volume of runoff and maximum reservoir water level elevation for the inflow hydrograph;

(f) a plot of the reservoir inflow and outflow hydrographs extended until flow is negligible and plotted on the same figure of appropriate size and scale;

(g) a table showing the reservoir area (in acres) and storage capacity (in acre-feet) for each foot of elevation above the bottom of the reservoir to the dam crest; the table shall be determined from the reservoir topography map; indicate the amount of dead storage, elevation of the invert of the outlet and elevation of the crest of each spillway; all elevations shall be based on North American vertical datum 1988 or more recent adjustment; and

(h) appropriate data sheets and computer program output computations from computerized analysis [~~shall be provided~~].

(3) Spillway design flood. The spillway design flood is the flood that a spillway must be capable of conveying without dam failure. For perimeter embankment dams with no spillway and no external drainage area, the dam must be capable of impounding the spillway design flood without dam failure. A spillway design flood less than these requirements is acceptable to the state engineer if an incremental damage analysis is presented to justify the inflow design flood in accordance with Paragraph (4) of Subsection C of 19.25.12.11 NMAC. The spillway design flood is based on size classification and hazard potential classification of the dam as [~~follows~~] described below.

(a) Dams classified as low hazard potential, regardless of size, shall have spillways designed to pass a flood resulting from a 100-year precipitation event expressed as a percentage of the probable maximum precipitation.

(b) Dams classified as small and intermediate, with a significant hazard potential rating shall have spillways designed to pass a flood resulting from 50 percent of the probable maximum precipitation.

(c) Dams classified as large, with a significant hazard potential rating shall have spillways designed to pass a flood resulting from 75 percent of the probable maximum precipitation.

(d) Dams classified as high hazard potential, regardless of size, shall have spillways designed to pass a flood resulting from the probable maximum precipitation.

(4) Incremental damage assessment. [~~Where spillways are not in compliance with Paragraph (3) of Subsection C of 19.25.12.11 NMAC an incremental damage assessment shall justify the inflow design flood used to size the spillway. The assessment shall evaluate the consequences of dam failure. The assessment shall compare the impact of with failure and without failure conditions on downstream water levels and existing and known future development.~~] Where spillways cannot be designed to comply with Paragraph (3) of Subsection C of 19.25.12.11 NMAC an incremental damage assessment shall justify the spillway design flood used to size the spillway. The spillway design flood from an incremental damage assessment is the flood above which the incremental increase in downstream water surface elevation due to failure of a dam is no longer considered to present an unacceptable additional downstream threat when compared to the same flood without dam failure. The lower limit is the flood resulting from the 100-year precipitation. The assessment shall compare the incremental impacts on downstream areas including existing and foreseeable future development. The assessment shall include a dam breach and flood routing analysis in accordance with Subparagraphs (a) through (g) of Paragraph (1) of Subsection C of 19.25.12.11 NMAC for the failure and non-failure conditions. Methods for assessing the damage between failure and non-failure conditions shall be fully documented.

(5) Spillway capacity. The spillway capacity shall be adequate to pass the spillway design flood in accordance with Paragraph (3) of Subsection C of 19.25.12.11 NMAC or accepted inflow design flood in accordance with Paragraph (4) of Subsection C of 19.25.12.11 NMAC without failure of the dam. [~~If design calculations show that overtopping will occur, an erosion study of the embankment documenting that the dam will not breach is required.~~] If the outlet works are gated, the design discharge of the outlet works shall not be considered when routing the spillway design flood through the reservoir and spillway. The water level shall be at the normal operating level at the beginning of the spillway design storm. A spillway rating curve and table showing elevation in one-foot increments versus maximum discharge capacity shall be prepared. The rating curve and table shall include data from the crest of the spillway to the dam crest. The parameters used to calculate the spillway capacity shall be justified and appropriate data sheets and computer program output computations from computerized analysis shall be provided. Elevations shall be based on North American vertical datum 1988 or more recent adjustment.

(6) Spillway design. Spillways shall be evaluated for erosion potential during normal operation and the design flood event. Damage to a spillway during the design flood event is acceptable; however, a breach of the spillway is unacceptable. The spillway design shall address the [~~following~~] minimum requirements[~~:~~] described below.

(a) The material required for spillway lining depends on the spillway location, frequency of discharge and velocity of discharge to adequately address erosion and breach potential. The design shall provide adequate justification for the material selected.

(b) The design shall provide aeration of the nappe for cavitation control where control weirs are used at the spillway crest.

(c) The spillway must discharge away from the toe of the dam and abutment slopes.

(d) The design shall address the potential for the accumulation of debris that may block the spillway [~~shall be addressed~~].

(e) [~~Energy dissipation to control erosion of the natural channel due to spillway discharge shall be addressed.~~] The design shall address energy dissipation to control erosion of the natural channel due to spillway discharge reasonably expected to occur during the life of the dam.

(f) Channel lining shall be placed on a suitably prepared, stable subgrade. All edges and joints in channel lining material must be designed to prevent undermining and erosion. Concrete channel lining must be provided with adequate jointing to permit thermal expansion and contraction and adequate reinforcing to control thermal cracking. Adequate water stops are required at joints in the spillway lining. Concrete lining shall be

adequately anchored against displacement and uplift and shall be provided with adequate subdrainage to relieve hydrostatic pressure and prevent frost heave.

(g) Where training dikes are used to divert the water away from the dam, the dike shall be designed with a compaction to at least 95% of the maximum standard Proctor density, ASTM D 698, or at least 90% of the maximum modified Proctor density, ASTM D 1557[~~, or at least 70% relative density if Proctor testing is not appropriate~~]. Erosion protection for the dike shall be addressed in accordance with Paragraph (16) of Subsection C of 19.25.12.11 NMAC.

(7) Outlet works capacity. Dams shall be designed with a low level outlet to drain the entire contents above the elevation of the downstream toe of the dam. If environmental consequences prevent draining of the reservoir, the state engineer will grant a waiver if written justification is provided to the satisfaction of the state engineer. The outlet shall be sized to provide adequate capacity to satisfy water rights of downstream priority users. A stage discharge curve and table showing elevation in one-foot increments versus discharge capacity shall be prepared. The rating curve and table shall be from the invert of the outlet to the dam crest. The parameters used to calculate the outlet works capacity shall be justified and appropriate data sheets and computer program output computations from computerized analysis shall be provided. Elevations shall be based on North American vertical datum 1988 or more recent adjustment. The outlet works capacity shall meet the [~~following~~] minimum requirements [~~:~~] described below.

(a) Outlets for water storage [~~reservoirs~~] dams shall drain the reservoir in 45 days with supporting calculations provided.

(b) Outlets for flood control dams shall drain the reservoir in 96 hours unless a waiver is granted by the state engineer. The 96-hour time frame begins once the reservoir storage drops to the emergency spillway crest or reaches its peak during the 100-year, 24-hour event. Documentation supporting the waiver shall include the time to drain more frequent events.

(8) Outlet works design. The outlet works design includes the intake structure, conduit and terminal structure. The outlet works design shall meet the [~~following~~] minimum requirements [~~:~~] described below.

(a) Minimum conduit diameter is 18 inches unless a waiver is granted by the state engineer. Documentation supporting a waiver shall include identification of methods to inspect the interior of the conduit.

(b) Metal conduits used in dams that are classified as significant hazard potential where the sole purpose of the dam is flood control, or in dams classified as low hazard potential, shall have adequate strength after corrosion for a minimum of 200 years, based on corrosivity testing of onsite soils. Cathodic or other protection of metal conduits is permissible and may be considered in this analysis. Metal conduits are not acceptable for dams classified as high hazard potential or dams classified as significant hazard potential with permanent water storage except as interior forms for cast-in-place concrete conduits.

(c) Outlet conduits for storage reservoirs shall be gated at the upstream end unless a waiver is granted by the state engineer. Where gates are located other than at the upstream end of the conduit, a guard gate or bulkhead shall be provided at the upstream end to allow draining of the conduit for inspection, maintenance and repair.

(d) Outlet conduits shall be adequately vented and shall include all supporting calculations. Where the outlet conduit ties directly to a downstream pipe, a by-pass valve shall be provided.

(e) Outlet controls and equipment shall be properly designed to be secure from damage due to vandalism, weather, ice, floating debris, wave action, embankment settlement and other reasonably foreseeable causes. The outlet control operators shall remain accessible during outlet works and spillway releases.

(f) Outlets for flood control structures shall be ungated. Where a gate is required to satisfy downstream release restrictions, a waiver from the state engineer is required. The written request for waiver shall include a plan for timely release of the floodwater.

(g) Outlet works intake structures shall be provided with trash racks or grates to prevent clogging with debris. Grate opening [~~size~~] area or bar spacing shall be adequate to satisfy applicable public safety requirements, if appropriate. Total [~~size~~] area of grate openings must be at least three times the cross-sectional area of the outlet conduit.

(h) The design of the outlet works terminal structure shall address energy dissipation to prevent erosion and shall include supporting calculations.

(i) Outlet conduits shall be designed for full embankment loading and for hydrostatic pressure equal to the maximum reservoir head, acting separately and in combination, with an adequate factor of safety for the

conduit material. If future increases in embankment height [~~and/or~~] or reservoir head are foreseeable, allowance shall be made in the design.

(j) The conduit together with all joints and fittings shall be watertight at the design pressure and shall be pressure tested prior to backfilling. Conduits shall be designed for all reasonably foreseeable adverse conditions including corrosion, abrasion, cavitation, embankment settlement and spreading, thermal effects and seismic loading. The ability of the conduit to withstand deflection and separation at the joints shall be addressed in the design of the outlet conduit.

(k) Outlet works shall be supported by stable, well-consolidated foundation materials. Where the conduit is placed in embankment fill or native overburden materials, settlement analysis shall be performed.

(l) Minimizing seepage along conduits shall be addressed including the methods for ensuring compaction of backfill around and beneath the conduit. Seepage collars are not an acceptable design standard for controlling seepage.

(m) All supporting documentation and calculations for the outlet works design shall be provided. The outlet works design shall include all foreseeable loading conditions, including but not limited to ice loading, debris buildup, wave action and embankment settlement. Structural design calculations for the intake structure, conduit and outlet structure shall be submitted.

(9) Geological assessment. A geological assessment of the dam and reservoir site is required for all dams classified as high or significant hazard potential. The geological assessment may be included in the geotechnical investigation or seismic study, or may be submitted as a separate document. The geological assessment shall address regional geologic setting; local and site geology; geologic suitability of the dam foundation; slide potential of the reservoir rim and abutment areas; and seismic history and potential.

(10) Geotechnical investigation. A geotechnical investigation shall assess site conditions and support the design. A professional engineer licensed in the state of New Mexico qualified to provide geotechnical expertise in the design and construction of dams shall prepare, stamp and sign the geotechnical investigation, which may be submitted as a separate report. The scope of the geotechnical investigation is dependent on the size classification, hazard potential classification, anticipated materials and construction methods, site geology and seismicity, anticipated soil strata and other site-specific conditions. The geotechnical investigation shall include a field investigation and laboratory testing. Results of field and laboratory testing shall be presented in a report, including recommended parameters to be used in design and construction of the dam and appurtenant structures. The field investigation and laboratory testing shall include but not be limited to the following:

(a) test borings in the footprint of the embankment, spillway excavations and appurtenant structures extending to bedrock or to a depth equal to at least the height of the dam; where appropriate, borings may include coring of bedrock materials to determine the quality and character of the rock;

(b) standard penetration tests or other field-testing to assess soil character and consistency;

(c) "undisturbed" sampling for further tests such as insitu density, shear strength and compressibility;

(d) supplemental test pits, if deemed necessary, to obtain bulk and undisturbed samples, assess soil layering and measure bedrock orientation;

(e) measurement of water level in drill holes;

(f) field permeability testing, if feasible;

(g) logs of test borings and test pits, location map and profile along dam axis with soil information shown;

(h) testing to determine the relevant properties of the material to be used in construction, including but not limited to shear strength, permeability, compressibility and filter characteristics; the testing method shall conform to accepted industry standards and be appropriate for the material being tested;

(i) evaluation of liquefaction potential and dynamic shear strength testing if deformation analysis is required; and

(j) identification of the location of the borrow material to be used during construction.

(11) Seepage and internal drainage. The effects of seepage and potential for internal erosion shall be evaluated. For dams with aesthetic fill on the downstream slope, the effects of seepage shall be evaluated with and without the aesthetic fill. A seepage analysis shall be performed to address the performance of the embankment under steady-state conditions for dams classified as high or significant hazard potential. All parameters and assumptions used in the analysis shall be summarized in a table and justified in the seepage analysis. A waiver may be requested in writing for flood control dams [~~or reservoirs with synthetic liners~~] that drain in 96 hours. The

seepage analysis and internal drainage design shall include [~~but not be limited to the following:~~] the minimum requirements described below.

(a) Flow nets of appropriate size and scale shall be prepared. The effects of anisotropy with respect to permeability shall be addressed. Ratios of horizontal to vertical permeability of less than 4 for constructed embankments and less than 9 for native deposits shall be supported by field and laboratory permeability tests. Appropriate data sheets and computer program output computations from computerized analysis shall be provided.

(b) The design shall address the effects of anticipated seepage beneath, around and through the dam. Seepage shall not exit on the dam face and excessive exit seepage gradients are unacceptable. All filter, transition and drainage zones within earth dams shall have a thickness adequate to address constructability and enhance seismic stability with a minimum thickness of 3 feet for each zone.

(c) Collector pipes and conduits for internal drains shall be made of non-corrodible material capable of withstanding the anticipated loads. If possible, pipes shall be located where they can be exposed for repair or replacement without threatening the stability of the dam. Collector pipes for drains shall be enveloped in a free-draining medium meeting filter criteria for adjacent embankment or foundation zones. Where surging or hydraulic gradient reversal is likely, perforation size must be less than the diameter at which 15 percent of the surrounding medium is finer. Where surging or hydraulic gradient reversal are unlikely, the perforation size must be less than the diameter at which 85 percent of the surrounding medium is finer.

(d) Drain pipes shall be sized to provide a flow depth no more than ¼ of the pipe diameter when carrying the anticipated discharge. Drain pipes shall be at least 6 inches in diameter unless the availability of technology for inspection and maintenance can be demonstrated. Individual pipes shall discharge to a gallery, well, manhole, or to daylight such that the flow of each pipe can be monitored and measured. Manifold connections, tees and wyes are not permitted. [~~If the anticipated flow from a drain line exceeds 10 gpm, a measuring flume or weir shall be provided for that line. If the anticipated flow from a drain line is less than 10 gpm, the outfall shall be designed to allow a 5 gallon bucket to be used to collect and measure discharge.~~] A seepage measuring device must be appropriate for the rate of anticipated flow. The measuring device must include an upstream catchment to detect any sediment in the seepage. Where pipes from internal drains are discharged to daylight, a rodent screen shall be provided.

(12) Stability analysis. Cross-sectional design for dams shall be supported by slope stability analysis. For dams with aesthetic fill on the downstream slope, the stability of the downstream slope shall be evaluated with and without the aesthetic fill. Dams classified as low hazard potential with upstream slopes no steeper than 3 horizontal to 1 vertical, downstream slopes no steeper than 2 horizontal to 1 vertical and which are 25 feet or less in height will not require slope stability analysis. Stability analysis of the reservoir rim is required where slopes are steeper than 3 horizontal to 1 vertical. The analysis model shall adequately represent the geometry and zoning, shear strength parameters, material unit weights, pore pressure and seepage conditions, external loading and other relevant factors of the critical cross section or sections. Manual computations in the analysis will be accepted if judged to be sufficiently rigorous. Where appropriate, the analysis shall consider noncircular or block and wedge type failure surfaces as well as circular failures. All parameters and assumptions used in the analysis shall be summarized in a table and justified in the geotechnical investigation. A scale drawing, utilizing the same scale for vertical and horizontal dimensions, shall be provided for each cross-sectional model used in the analysis, with the critical failure surface(s) identified. Appropriate data sheets and computer program output computations from computerized analysis shall be provided. Dams shall be designed to provide the following minimum factors of safety from the stability analysis:

(a) 1.5 for steady state long-term stability;

(b) 1.5 for operational drawdown conditions;

(c) [~~1.2~~] 1.3 for rapid drawdown conditions; and

(d) [~~1.2~~] 1.3 for end of construction.

(13) Seismic design and analysis. Dams and appurtenant structures classified as high or significant hazard potential shall be analyzed for seismic stability. Seismic analysis for water storage dams shall be based on full reservoir under steady state seepage conditions. Flood control dams with ungated outlets that satisfy Subparagraph (b) of Paragraph (7) of Subsection C of 19.25.12.11 NMAC without waiver shall be designed for earthquake loads under empty reservoir conditions and need not consider steady-state seepage. Dams sited on active faults shall obtain a waiver from the state engineer. To obtain a waiver the analysis shall show that the location of the dam is unavoidable and the dam must be designed to withstand anticipated fault movement without compromising its integrity. Appropriate data sheets and computer program output computations from computerized

analysis shall be provided. The seismic analysis shall meet the [~~following~~] minimum requirements [~~:~~] described below.

(a) A seismological investigation for the dam area and reservoir area shall be performed. This study may be part of the geological or geotechnical report for the structure, or may be a separate effort. The study shall determine and justify the appropriate seismic parameters to be used for design. The dam and appurtenant structures shall be capable of withstanding the operating basis earthquake without damage. The operating basis earthquake has a 50% probability of exceedance during the service life of the dam or appurtenant structures. In no case shall the service life be less than 100 years. The dam and appurtenant structures critical to the safety of the dam shall be capable of withstanding the design earthquake without failure. The seismic parameters shall be based on the [~~following~~] design earthquake [~~:~~] requirements described below.

(i) Dams classified as high hazard potential other than flood control structures shall be designed for the maximum credible earthquake or for [~~an earthquake with a 5000-year return frequency~~] a 1% probability of exceedance in 50 years (approximately 5000-year return frequency).

(ii) Dams classified as significant hazard potential or high hazard potential dams whose sole purpose is for flood control shall be designed for a 2% [~~chance of occurrence~~] probability of exceedance in 50 years (approximately 2500-year return frequency).

(b) An analysis of materials in the foundation, reservoir area and proposed embankment shall be completed to determine the potential for liquefaction, earthquake-induced sliding, or other seismic sensitivity, which may be accomplished as part of the geotechnical investigation.

(c) Pseudostatic analysis will be acceptable for the following cases:

(i) the embankment is to be mechanically compacted to at least 95% of the maximum standard Proctor density, ASTM D 698, or at least 90% of the maximum modified Proctor density, ASTM D 1557 [~~or at least 70% relative density if Proctor testing is not appropriate~~]; no materials prone to liquefaction are present in the foundation and peak [~~bedrock~~] ground acceleration is 0.20g or less; or

(ii) the embankment is to be mechanically compacted to at least 95% of the maximum standard Proctor density, ASTM D 698, or at least 90% of the maximum modified Proctor density, ASTM D 1557; potentially submerged portions of the embankment except for internal drain elements are constructed of clayey material; the dam is constructed on clayey soil or bedrock foundation and peak [~~bedrock~~] ground acceleration is 0.35g or less; and

(iii) all safety factor requirements in accordance with Subparagraphs (a) through (d) of Paragraph (12) of Subsection C of 19.25.12.11 NMAC are met;

(iv) minimum freeboard requirements in accordance with Subparagraphs (a) through (e) of Paragraph (15) of Subsection C of 19.25.12.11 NMAC are met; and

(v) the pseudostatic coefficient selected for analysis must be at least 50% of the predicted peak [~~bedrock~~] ground acceleration, but not less than 0.05g and the factor of safety under pseudostatic analysis shall be 1.1 or greater. In determining the factor of safety for pseudostatic analysis, a search for the critical failure surface shall be made.

(d) For dams not satisfying the requirements for pseudostatic analysis, a deformation analysis is required. The resulting embankment must be capable of withstanding the design earthquake without breaching and with at least 3 feet of freeboard remaining after deformation. The analysis shall also assess the potential for internal erosion as a result of cracking during deformation.

[~~**(e)** The seismic assessment shall also address the stability of appurtenant structures to the dam during the design earthquake as appropriate, unless failure of an appurtenance due to earthquake does not represent an immediate threat to the dam, in which case the operating basis earthquake may be used.~~]

(14) Dam geometry. The dam geometry shall be supported by the stability and seismic analysis and [~~meeting the following minimum requirements:~~] shall meet the minimum requirements described below.

(a) The crest width shall be at least equal to the dam height in feet divided by 5 plus 8 feet, with the minimum permissible crest width being 10 feet and the maximum required crest width being 24 feet.

(b) Roads located on the crest shall have appropriate surfacing to provide a stable base that resists rutting and provides adequate friction for safety in wet conditions.

(c) The crest design shall provide a minimum of 2 feet of cover or the depth of frost penetration; whichever is greater, above clay cores to prevent cracking of the core due to desiccation or frost penetration.

(d) Turnarounds [~~should~~] shall be provided on dead-end service roads on dam crests, located in such a manner that backing maneuvers longer than 300 feet are eliminated.

(e) The crest shall be provided with adequate cross slope to prevent ponding.

(f) The slope or slopes to which crest drainage is directed must be provided with adequate erosion protection to accept the crest drainage.

(g) The crest longitudinal profile shall be provided with adequate camber to maintain the profile after embankment settlement. Camber [~~should~~] shall be based on a settlement analysis and shall be at least 2 percent of the total embankment height, with a minimum of 1 foot at the highest point of the dam. The tops of internal core zones shall also be provided with camber in a similar manner to the crest of the dam.

(h) In the event that safety berms, street curbs, or other longitudinal features which block, control, or concentrate drainage are required on the dam crest, the design shall provide for collection and conveyance of accumulated water to discharge away from the embankment without erosion.

(15) Freeboard. Dams shall be provided with adequate freeboard. Wave runup shall be determined taking into consideration wind speed, reservoir fetch, embankment slope and roughness of the slope surface. Freeboard shall satisfy the [~~following conditions:~~] minimum requirements described below.

(a) Anticipated wave runup resulting from a 100 mph wind with reservoir level at the spillway crest will not overtop the dam.

(b) Anticipated wave runup resulting from a 50 mph wind with maximum reservoir level from routed spillway design flood will not overtop the dam.

(c) Clay core cover and capillary rise requirements in accordance with Subparagraph (c) of Paragraph (14) of Subsection C of 19.25.12.11 NMAC are satisfied.

(d) A minimum of 3 feet of freeboard remains after seismic deformation.

(e) In any case, at least 4 feet of freeboard shall be provided. The minimum of 4 feet of freeboard may be waived for perimeter [~~embankments~~] embankment dams with no spillway and no external drainage area, provided a written request is made to the state engineer accompanied with supporting justification.

(16) Erosion protection. Erosion protection shall be addressed to protect the dam and appurtenant structures from erosion that can threaten the safety of the structure. [~~At a minimum, the following areas of erosion shall be addressed:~~] Erosion protection shall address the minimum requirements described below.

(a) Wave erosion. The upstream slope shall be protected from wave erosion. The material selected and area of coverage shall be appropriate for the protection required with justification provided. Flood control dams in compliance with Subparagraph (b) of Paragraph (7) of Subsection C of 19.25.12.11 NMAC without waiver are exempt from wave protection.

(b) Surface erosion. The slope, crest, abutment and groins, toe areas and any other constructed areas associated with the dam and appurtenant structures shall be protected from [~~surface~~] wind erosion and erosion from concentrated and sheet flows. The material selected and area of coverage shall be appropriate for the protection required with justification provided.

(17) Geotextile design. Geotextiles are an acceptable material for use in dam design only if the geotextile is placed so that it does not jeopardize the dam or appurtenant structures during repair or failure of the geotextile. The geotextile [~~material~~] shall be used in accordance with the manufacturer's recommendations and intended use for the product. [~~Installation shall be by certified personnel and the completed installation certified by installer or manufacturer, if required by the manufacturer.~~] Geotextile design computations shall be provided. Where a geotextile is used for fluid containment the installation shall be performed by certified personnel and the completed installation shall be certified by a qualified independent entity.

(18) Structural design. The structural design information for all appurtenant structures, addressing water, earth, ice and any other applicable load shall be provided. Reinforced concrete design including assumptions for loads and limiting stresses and sample calculations shall be provided. Appropriate data sheets and computer program output computations from computerized analysis shall be provided.

(19) Utilities design. Utility placement or relocation shall be addressed as applicable. Utilities located in the vicinity of the proposed embankment [~~footprint should~~] and spillway footprint and seepage limits must be relocated and trenches backfilled and compacted with suitable material to the satisfaction of the state engineer. If utilities are allowed to remain, they will be required to satisfy applicable provisions for outlet conduits in accordance with Paragraph (8) of Subsection C of 19.25.12.11 NMAC.

(20) Miscellaneous design. Because each design is unique, all design elements not specifically addressed in these regulations shall be documented and justified with sample calculations and appropriate data sheets and computer program output computations from computerized analysis shall be included in the design report.

D. Construction drawings: Construction drawings shall be submitted in a form acceptable to the state engineer. The final construction drawings shall also be submitted in an electronic format acceptable to the state engineer. A professional engineer licensed in the state of New Mexico qualified in dam design and construction shall prepare the construction drawings. Illegible, mutilated, careless or otherwise poorly prepared drawings are not acceptable for filing with the state engineer. [~~Plan drawings and maps prepared with the aid of a computer require the submittal of the digital data files in tagged image file format or other format acceptable to the state engineer. The preparation of construction drawings is described below and shall include the following items:~~] Construction drawings shall contain the information described below and any other additional information determined necessary by the state engineer to evaluate if the construction drawings are consistent with the design.

(1) Quality. Construction drawings and maps shall be made from actual field or photogrammetric surveys of an accuracy acceptable to the state engineer. Construction drawings and maps shall be prepared with permanent black ink on mylar. All original signatures, dates and acknowledgments appearing on the sheet(s) shall be in permanent ink. [~~Plan~~] Construction drawings and maps shall always be rolled, never folded, for transmittal.

(2) Scale and size. Sheets shall [~~be~~] range in size from twenty-two (22) to twenty-four (24) inches by thirty-four (34) to thirty-six (36) inches with one (1) inch margins on all sides. The scale(s) used on the drawings may vary according to requirements and space available to show all necessary data in detail clearly in feet and decimals and to be clearly legible when the drawings are reduced to eleven (11) inches by seventeen (17) inches. Detailed dimensions of appurtenant structures shall be given in feet and inches. All sheets shall have bar scales in order to allow scaling of reduced drawings.

(3) Sheet numbers. Each sheet shall be numbered sequentially with the first sheet being sheet number one in conjunction with the total numbered sheets (example Sheet 1 of 5). The sheet number on the last sheet shall equal the total number of sheets.

(4) Engineer's seal and signature. Each sheet shall have the responsible engineer's seal and signature. Seals and signatures shall be presented in accordance with 16.39.3 NMAC.

(5) Orientation and date. The direction of north and the basis of bearings shall be shown on all maps. The date that field surveys are made or the date of the aerial photography used shall be shown on the maps.

(6) Title sheet. The first sheet of a set of [~~plans~~] construction drawings is the title sheet. The title sheet shall only contain sufficient information to summarize the scope of the project, [~~the title of the project and signed certifications for the dam owner, engineer and state engineer in accordance with Subsections A, B and E of 19.25.12.12 NMAC.~~] the title of the project, signed certifications from the dam owner, engineer and a certification for the state engineer in accordance with Subsections A, B and E of 19.25.12.12 NMAC. The title sheet shall summarize the properties of the dam and shall include the following information, as appropriate:

(a) name of the dam (same as shown on the application);
(b) type of dam (material);
(c) hazard potential classification;
(d) maximum height above the downstream toe in feet;
(e) maximum length in feet;
(f) crest width in feet;
(g) slope of the upstream face (horizontal to 1 vertical);
(h) slope of the downstream face (horizontal to 1 vertical);
(i) elevation of the dam crest in feet;
(j) elevation of spillway crest in feet;
(k) [~~elevation of outlet conduit flow line;~~] length of the conduit in feet;
(l) invert elevation of the upstream end of the conduit in feet;
(m) invert elevation of the downstream end of the conduit in feet;
[~~(l)~~] (n) freeboard in feet;
(o) residual freeboard in feet;
[~~(m)~~] (p) maximum spillway discharge capacity in cubic feet per second;
[~~(n)~~] (q) type of outlet conduit (give size and material);
[~~(o)~~] (r) maximum outlet conduit discharge capacity in cubic feet per second; and

[~~**(p)**~~] **(s)** location of the outlet works intake structure (using latitude and longitude [~~or to the New Mexico state plane coordinate system~~] in decimal degrees).

(7) Vicinity map. A vicinity map of sufficient scale and size to locate the pertinent area shall be shown on the title sheet or second sheet of the drawings.

(8) Site topography. A detailed topography of the dam site including sufficient area upstream and downstream and at the abutments shall be provided. Elevations shall be based on North American vertical datum 1988 or more recent adjustment.

(9) Design details. Detailed information of the various construction features including plan view, elevations, cross-sections at the maximum section and along the outlet works, profile along and section through the centerline of the dam showing the foundation materials, construction features and cross-sections and a profile of the emergency spillway with dimensions and construction details shall be provided. Any other information necessary for the state engineer to determine the feasibility and safety of the dam shall be [~~required~~] provided.

(10) Reservoir area, capacity and high water line traverse. The topography of any proposed reservoir site shall be determined to industry standards and a contour map with a contour interval of 1 foot shall be prepared. Elevations of the contours shall be tied to the North American vertical datum of 1988 or more recent adjustment. [~~The high water line at the elevation of the dam crest will be highlighted on the contour map.~~] The elevation of the high water line will be highlighted on the contour map. A curve [~~or~~] and table of elevation versus area and storage capacity for the reservoir shall be prepared from the contour map. The curve [~~or~~] and table shall be from the bottom of the reservoir to the dam crest. Area shall be provided in acres and storage capacity in acre-feet.

[~~**(11)** Point of outlet. A location of the outlet works shall be referenced using latitude and longitude or to the New Mexico state plane coordinate system.~~]

[~~**(12)**~~] **(11)** Permanent bench mark. A permanent bench mark shall be established above the high water line at a location unlikely to settle or be disturbed. The North American vertical datum of 1988 or more recent adjustment [~~and latitude and longitude or the New Mexico state plane coordinate system~~] for the bench mark elevation and the latitude and longitude in decimal degrees for the bench mark location shall be provided. A detail of construction of the permanent bench mark shall be provided.

E. Specifications: [~~Specifications~~] A specification package shall be prepared for each project describing work to be done and materials to be used to supplement construction drawings. [~~Specifications must be clear and concise and include detailed methods of construction, qualities and sizes of materials, unit amounts to be used and methods of testing and quality control, construction supervision and inspection.~~] Specifications shall be submitted in a form acceptable to the state engineer. The specifications shall also be submitted in an electronic format acceptable to the state engineer. Reference to standard specifications is not acceptable. Inclusion of appropriate specification sections derived from model specifications is acceptable. Specifications must be clear and concise. Specifications shall include detailed methods of construction, qualities and sizes of materials, unit amounts to be used, methods and frequency of testing and quality control, construction supervision and frequency of inspection. Specifications shall be prepared by a professional engineer licensed in the state of New Mexico qualified in the design and construction of dams. The specifications shall [~~meet the following requirements:~~] contain the information described below and any other additional information determined necessary by the state engineer to evaluate if the construction methods are consistent with the design and construction drawings.

(1) The front cover of the specifications shall show the name of the dam (identical to the application) and the county in which the dam is located. The first page behind the front cover shall show the name of the dam (identical to the dam name on the application), the county in which the dam is located, [~~signed certifications for the engineer and state engineer in accordance with Subsections B and E of 19.25.12.12 NMAC and a statement recognizing the authority of the state engineer. An approved model statement recognizing the authority of the state engineer is provided below. Changes to the model statement require prior approval of the state engineer. "All construction shall be performed in strict accordance with the accepted plans and specifications. Representatives of the state engineer shall have full authority to perform inspections during construction and shall have full power to act pursuant to the law and in accordance with Title 19, Chapter 25, Part 12, Dam Design, Construction and Dam Safety of the New Mexico Administrative Code if plans and specifications are not followed."~~.] a signed certification from the engineer and a certification for the state engineer in accordance with Subsections B and E of 19.25.12.12 NMAC.

(2) The specifications shall [~~be indexed~~] include a table of contents.

(3) The specifications shall be bound and submitted on [~~a good grade of white~~] 8 1/2-inch by 11-inch white paper.

(4) [~~The general conditions shall include statements that the construction drawings and specifications cannot be significantly changed without the prior written approval of the state engineer.~~] The general conditions shall include a statement that the construction drawings and specifications cannot be changed without the prior written approval of the state engineer and must recognize the authority of the state engineer to perform inspections during construction. An approved model statement is provided below. Changes to the model statement require prior approval of the state engineer. All construction shall be performed in strict accordance with the accepted construction drawings and specifications. Changes to the accepted construction drawings or specifications require prior written approval of the state engineer. Representatives of the state engineer shall have full authority to perform inspections during construction and shall have full power to act pursuant to the law and in accordance with Title 19, Chapter 25, Part 12, Dam Design, Construction and Dam Safety of the New Mexico Administrative Code if construction drawings and specifications are not followed."

F. Boundary, easement or right of way plat of survey: A plat of survey shall be submitted in a form acceptable to the state engineer. A professional surveyor licensed in the state of New Mexico shall prepare a plat of survey showing the dam owner's property boundaries or easement [~~and/or~~] or right of way granted by the land owner. The plat of survey shall be prepared in conformance with the requirements as set forth in the Minimum Standards for Surveying in New Mexico, 12.8.2 NMAC. The plat of survey shall clearly state to whom an easement is granted and what rights are conveyed with the easement. The plat of survey shall show the footprint of the dam and appurtenant structures and the high water line in the reservoir. The plat of survey shall be [~~submitted with the construction drawings and~~] recorded with the county clerk of the county or counties in which the survey is located. A certificate signed by the surveyor in accordance with Subsection C of 19.25.12.12 NMAC shall appear on the plat of survey. A certified copy of the recorded plat of survey bearing the recorded page and endorsement of the county clerk shall be submitted to the state engineer for filing [~~upon completion of construction~~]. Adequate property ownership, easement or right of way shall be required for the following conditions:

(1) to access the dam and outlet controls during normal and flood events;

(2) to prevent development encroachment into the reservoir area defined by normal operation and the spillway design flood that adversely affects the performance of the dam;

(3) to prevent development in the approach, control and discharge section of the spillway that may restrict flow through the spillway;

(4) to return outlet works and spillway discharge to the natural drainage and allow the outlet works to discharge freely; and

(5) to perform maintenance on the dam, appurtenant structures and surrounding areas to ensure the safe performance of the dam.

G. Dam site security: Dams classified as high or significant hazard potential shall address security at dams to prevent unauthorized operation or access. If in the opinion of the state engineer, the failure of the dam will result in catastrophic consequences, a security and risk management program for the dam will be required. Elements of a security and risk management program are:

(1) threat, vulnerability and risk assessments;

(2) physical security plans; and

(3) integration of security operational procedures.

H. Instrumentation plan: An instrumentation plan shall be submitted in a form acceptable to the state engineer. An instrumentation plan providing the ability to monitor and evaluate the performance of a dam is required for dams classified as high or significant hazard potential. Instrumentation details must be included on the construction drawings and specifications must be consistent with the instrumentation plan. The instrumentation plan may be submitted as a separate report or as part of the [~~operation and maintenance manual~~] design report. Minimum requirements of the instrumentation plan shall include:

[~~**(1)** general description of instrumentation;~~

~~**(2)** reading schedule;~~

~~**(3)** identification of critical readings;~~

~~**(4)** specifics for each installation including;~~

~~**(a)** detailed description of installations;~~

~~**(b)** purpose of the instrumentation;~~

~~**(c)** reading and maintenance schedule instructions; and~~

~~**(5)** special instrumentation or monitoring requirements.~~]

(1) description and purpose;

(2) detailed description of installations;
(3) calibration and maintenance schedule and instructions;
(4) reading schedule and instructions;
(5) data reduction and interpretation instructions; and
(6) identification of critical readings.

I. Operation and maintenance manual: An operation and maintenance manual is required for dams classified as high or significant hazard potential. The operation and maintenance manual identifies activity necessary to address the continued safe operation, maintenance and overall performance of the dam. Any restrictions imposed by the design shall be addressed in the operation and maintenance manual. The operation and maintenance manual shall conform to the requirements set forth in 19.25.12.17 NMAC.

J. Emergency action plan: An emergency action plan is required for dams classified as high or significant hazard potential. The emergency action plan identifies potential emergency conditions at a dam and specifies preplanned actions to be followed to minimize property damage and loss of life. The emergency action plan shall conform to the requirements set forth in 19.25.12.18 NMAC.

[19.25.12.11 NMAC - N, 3/31/2005; A, xx/xx/2010]

19.25.12.12 CERTIFICATIONS: Signed certifications by the dam owner, engineer, surveyor, [~~state office of emergency management~~] local and state emergency management officials and the state engineer are required by these regulations on specific documents. Approved model certifications for the dam owner, engineer, surveyor, [~~state office of emergency management~~] local and state emergency management officials and state engineer are provided below. Changes to the model certifications require prior approval of the state engineer.

A. DAM OWNER'S CERTIFICATE: A certificate followed by the dated signature of the dam owner and notary public acknowledgment is required on the title sheet of the construction drawings and first page behind the front cover of the operation and maintenance manual and emergency action plan. The following model certification is considered to be an example of the minimum that the dam owner shall certify. If the dam owner is a corporation, political subdivision or other governmental entity a model certificate is also provided.

[~~state of _____)~~
~~_____) ss.~~
~~county of _____)~~]

I, (dam owner's name), being first duly sworn, upon my oath, state that I have read and examined the accompanying _____ (construction drawings consisting of ____ sheets, operation and maintenance manual, or emergency action plan) and know the contents and representations therein for _____ dam and all that is shown herein is done with my free consent and in accordance with my wishes and state that the same are true and correct to the best of my knowledge and belief.

_____
Dam owner signature Date

Subscribed and sworn to before me this _____ day of _____ , 20__.

_____
Notary public

My commission expires _____ (SEAL)

If a claimant is a corporation, political subdivision or other governmental entity the following shall be used:

[~~state of _____)~~
~~_____) ss.~~
~~county of _____)~~]

I, (representative's name), being first duly sworn, upon my oath, state [~~than~~] that I am the _____ (officer) of the _____, a _____ [~~corporation~~] (corporation or political subdivision) duly organized under the laws of the state of _____, that the accompanying

_____ (construction drawings consisting of ____ sheets, operation and maintenance manual, or emergency action plan) for _____ dam were made under authority of the board of directors of said [~~corporation~~] (corporation or political subdivision) and that, in their behalf, I have read and examined the statements and representations and all that is shown herein is done with their free consent and in accordance with their wishes and state that the same are
true and correct to the best of my knowledge and belief.

_____
Representative signature, title Date

Subscribed and sworn to before me this _____ day of _____ , 20__.

_____
Notary public

My commission expires _____ (SEAL)

B. ENGINEER'S CERTIFICATE: A certificate followed by the dated signature, license number and seal of the engineer responsible for preparing the [~~design~~] report, construction drawings, specifications, operation and maintenance manual and engineering elements of the emergency action plan is required. The certificate shall be placed on the title sheet of the construction drawings and first page behind the front cover of the [~~design~~] report, specifications, operation and maintenance manual and emergency action plan. The following model certification is considered to be an example of the minimum that the engineer [~~should~~] must certify to:

[~~state of _____)~~
~~_____) ss.~~
~~county of _____)~~]

I, (engineer's name), hereby certify that I am a professional engineer licensed in the state of New Mexico, qualified in _____ (civil, geotechnical, etc.) engineering; that the accompanying _____ ([~~design~~] report, construction drawings consisting of ____ sheets, specifications, _____ elements of the operation and maintenance manual, or _____ elements of the emergency action plan) for _____ dam was prepared by me or under my supervision; that the accompanying _____ ([~~design~~] report, construction drawings consisting of ____ sheets, specifications, _____ elements of the operation and maintenance manual, or _____ elements of the emergency action plan) is in compliance with the Dam Design, Construction and Dam Safety Regulations (19.25.12 NMAC) and that the same are true and correct to the best of my knowledge and belief.

(Engineer's signature) _____, License number _____, (SEAL)
Engineer's name

Date [~~submitted~~]: _____

C. SURVEYOR'S CERTIFICATE: The professional surveyor licensed in the state of New Mexico preparing the plat of survey showing property boundaries, acquired easements or rights-of-way shall include a certificate on the plat of survey as modeled in Paragraph (2) of Subsection J of 12.8.2.9 NMAC, the Minimum Standards for Surveying in New Mexico. The following model certificate is considered to be an example of the minimum that the surveyor [~~should~~] must certify to:

I, (surveyor's name), New Mexico professional surveyor no. (surveyor's license number), do hereby certify that this (boundary, easement, or right of way) plat of survey and the actual survey on the ground upon which it is based were performed by me or under my direct supervision; that I am responsible for this survey; that this survey meets the Minimum Standards for Surveying in New Mexico; and that it is true and correct to the best of my knowledge and belief. I further certify that this survey is not a land division or subdivision as defined in the New Mexico Subdivision Act and that this instrument is a (boundary, easement, or right of way) plat of survey of _____ dam.

(Surveyor's signature)_____, License number_____, (SEAL)
Surveyor's name

Date [~~submitted~~]: _____

D. [~~**STATE OFFICE OF EMERGENCY MANAGEMENT:** A certificate form for the state office of emergency management acceptance shall be placed on the first page behind the front cover of the emergency action plan. This certificate is to be signed by state office of emergency management after all necessary corrections or additions, if any, have been made.~~
~~state of _____)~~
~~_____) ss.~~
~~county of _____)~~] **LOCAL AND STATE EMERGENCY MANAGEMENT OFFICIAL'S CERTIFICATE:** Certificate forms for the local and state officials responsible for emergency management shall be placed at the front of the emergency action plan and immediately after the engineer's certificate. The local official's certificate shall be placed in front of the state official's certificate.

I hereby certify that the accompanying emergency action plan for _____ dam has been duly examined by me and accepted for filing on the _____ day of _____, 20__.

[~~_____~~
~~State office of emergency management~~]
(Official's signature)_____
(Print official's name)
(Print name of local or state emergency management entity)

E. STATE ENGINEER'S CERTIFICATE: A certificate form for the state engineer acceptance shall be placed on the title sheet of the construction drawings and first page behind the front cover of the [~~design~~] report, specifications, operation and maintenance manual and immediately after the state official responsible for emergency management in the emergency action plan. This certificate is to be signed by the state engineer or his representative after all necessary corrections or additions, if any, have been made.

[~~state of _____)~~
~~_____) ss.~~
~~county of _____)~~]

I hereby certify that the accompanying _____ ([~~design~~] report, construction drawings, specifications, operation and maintenance manual or emergency action plan) for _____ dam and appurtenant structures has been duly examined by me and accepted for filing on the _____ day of _____, 20__.

_____
State engineer

[19.25.12.12 NMAC - N, 3/31/2005; A, xx/xx/2010]

19.25.12.13 [~~CONSTRUCTION AND OPERATION~~] PERMIT CONDITIONS: After reviewing the required documentation, the state engineer will notify the dam owner if any deficiencies are found with the submittal to construct and operate a dam. The dam owner will be given an opportunity to correct any deficiencies noted in the review process. Once all deficiencies have been addressed the state engineer will approve the application for permit to construct and operate a dam with conditions under which construction and operation shall occur. Failure to comply with conditions of the approved permit may result in the state engineer issuing an order to redesign, reconstruct or restrict operation of the dam and reservoir until conditions are met. Construction must be completed within two years of approving the application unless an extension of time for the construction is requested and approved by the state engineer. [~~The conditions of construction and operation shall include, but not be limited to the~~

~~following:~~] The permit conditions are described below and may include additional conditions determined necessary by the state engineer to ensure the dam is constructed and operated in a safe condition.

A. Engineer supervising construction: Prior to initiation of construction, the dam owner shall designate a professional engineer licensed in the state of New Mexico qualified in the design and construction of dams to supervise construction. If the state engineer finds the engineer acceptable, an order is issued approving the engineer and setting forth conditions under which the engineer will supervise construction. [~~Conditions shall include, but shall not be limited to:~~] Construction supervision conditions are described below.

(1) The engineer supervising construction shall submit monthly progress reports [~~including summary of test results, problems encountered and their solutions.~~] that are signed and sealed. The report shall include:

(a) summary of construction activities;

(b) summary of test results;

(c) captioned and dated construction photographs; and

(d) a discussion of problems encountered and their solutions.

(2) Construction shall be in accordance with accepted drawings and specifications. State engineer approval of any modifications to the accepted drawings or specifications is required prior to undertaking the modifications. Requests for changes or modifications by the engineer supervising construction shall be submitted in writing, supported with appropriate documentation.

(3) The engineer supervising construction shall provide the state engineer a minimum of 72 hours notice to perform inspections as specified in the conditions of construction.

[~~**(4)** Upon completion of construction, the engineer supervising construction shall submit to the state engineer the following items:~~

~~**(a)** a completion report, which shall include descriptions of problems and their solutions;~~

~~**(b)** a summary of materials test data and labeled and dated construction photographs;~~

~~**(c)** record mylar construction drawings including signed certifications on the title sheet; and~~

~~**(d)** a certificate that the dam was constructed in accordance with the accepted drawings and specifications and is in satisfactory condition. An approved model certificate for the engineer supervising construction is shown below. Changes to the language in the certification require prior approval by the state engineer.~~]

(4) Upon completion of construction, the engineer supervising construction shall submit to the state engineer the items described below.

(a) A construction completion report, which shall include a signed certification from the engineer supervising construction and a certification for the state engineer in accordance with Subsections B and E of 19.25.12.12 NMAC. The construction completion report shall also include:

(i) description of construction activities including problems and their solutions;

(ii) a summary of materials test data; and

(iii) captioned and dated construction photographs.

(b) Record mylar construction drawings including a signed certification on the title sheet from the dam owner and a certification for the state engineer in accordance with Subsections A and E of 19.25.12.12 NMAC. The record mylar drawings shall also contain a signed certificate from the engineer supervising construction that the dam was constructed in accordance with the record drawings and specifications and is in satisfactory condition. If design changes are made during construction, the design engineer may also be required to sign a certification in accordance with Subsection B of 19.25.12.12 NMAC. An approved model certificate for the engineer supervising construction is shown below. Changes to the language in the certification require prior approval by the state engineer.

[~~state of _____)~~
~~_____) ss.~~
~~county of _____)~~

~~I, _____, (engineer's name) state that I am a qualified professional engineer licensed in the state of New Mexico, that I have inspected the _____ dam and appurtenant structures and find them to be completed in accordance with the record construction drawings and specifications and are now in a satisfactory condition for acceptance.~~]

I, (engineer's name) , state that I am a qualified professional engineer licensed in the state of New Mexico, that I have supervised the (construction, repair, rehabilitation) of dam and appurtenant structures and find them to be completed in accordance with the record construction drawings and specifications and are now in a satisfactory condition for acceptance.

(Engineer's signature) License number , (SEAL)
Engineer's name

Date [~~submitted~~]: _____

B. State engineer's authority during construction: The state engineer may perform inspections at any time during construction of the dam and appurtenant structures. Inspections will vary with each project, based on the complexity of the design. Inspection of specific construction items are standard construction conditions in the permit and require the engineer supervising construction to provide the state engineer with a minimum of 72 hours advanced notice. If the state engineer receives a minimum of 72 hours advanced notice, a delay of construction to schedule a state engineer inspection is not required. State engineer inspection fees are charged in accordance with Subsection [~~D~~] E of 19.25.12.8 NMAC. Fees for inspection of construction by the state engineer not paid on demand shall become a lien on any land or other property of the dam owner and may be recovered by the state engineer.

C. Completion of construction: Upon completion of construction, a proof of completion of works form for the dam shall be submitted in accordance with 19.25.12.14 NMAC. Owners of dams classified as high or significant hazard potential shall submit to the [~~state engineer an updated operation and maintenance manual in accordance with 19.25.12.17 NMAC and an updated emergency action plan~~] state engineer any required updates to the operation and maintenance manual in accordance with 19.25.12.17 NMAC and any required updates to the emergency action plan in accordance with 19.25.12.18 NMAC incorporating any modifications made during construction. Upon the satisfactory completion of all conditions in the permit, pending the issuance of a certificate of construction and license to operate a dam, use of the reservoir shall require written permission from the state engineer. Use of the dam and reservoir are restricted until the state engineer accepts the updated operation and maintenance manual and emergency action plan, if required.

D. Extension of time for construction: The state engineer will grant an extension of time for completing construction upon proper showing by the dam owner of due diligence or reasonable cause for delay and accompanied with a fee in accordance with Subsection [~~C~~] D of 19.25.12.8 NMAC. An affidavit by a professional engineer licensed in the state of New Mexico qualified in the design and construction of dams shall be filed with the state engineer providing evidence that the design of the dam meets or exceeds the design requirements in accordance with 19.25.12.11 NMAC. An extension of time may be granted for a period not to exceed five (5) years. No extension of time shall be granted which in combination extend the time allowed by the permit beyond ten (10) years from the initial date of approval of the application, unless the state engineer in his discretion expressly waives this limitation pursuant to NMSA 1978, Section 72-5-14. Failure to request an extension of time shall result in cancellation of the permit by the state engineer.

E. Operation conditions: Operation conditions will be identified in the permit to construct and operate a dam. Operation conditions are described below:

(1) The owner shall comply with the office of the state engineer rules and regulations for dams.

(2) Changes to the easements require prior approval from the state engineer.

(3) Changes, alterations, or modifications to the dam or sediment removal or dredging not outlined in the operation and maintenance manual requires state engineer approval prior to making the change.

(4) The dam owner shall provide access to the state engineer for periodic dam safety inspections.

(5) The dam owner must comply with all state engineer safety orders issued for the dam.

(6) Owners of dams classified as low and significant hazard potential shall have the hazard classification periodically evaluated by a professional engineer licensed in New Mexico if downstream development occurs to ensure the dam design is not deficient.

(7) Operation of the dam must be in compliance with the approved operation and maintenance manual and emergency action plan.

(8) The dam owner shall operate the dam in compliance with any specific condition, requirement, or limitation established by the design engineer or otherwise applicable to the dam.

(9) Failure by the dam owner to comply with operation conditions may result in revocation of the permit or license to operate and an order to breach the dam in accordance with Subsection B or C of 19.25.12.19 NMAC.
[19.25.12.13 NMAC - N, 3/31/2005; A, xx/xx/2010]

19.25.12.14 PROOF OF COMPLETION OF WORKS: Upon completion of [~~all~~] the construction conditions a proof of completion of works for the dam shall be filed on a form provided by the state engineer with appropriate fees in accordance with Subsection [~~E~~] F of 19.25.12.8 NMAC. The proof of completion of works for the dam shall be filed with original signature of the dam owner and engineer supervising construction. The proof of completion of works form shall be provided to the state engineer as a separate submittal.
[19.25.12.14 NMAC - N, 3/31/2005; A, xx/xx/2010]

19.25.12.15 CERTIFICATE OF CONSTRUCTION OF A DAM: Upon receipt of the proof of completion of works form, the state engineer will determine if all construction conditions of the permit were met. Upon a determination by the state engineer that all construction conditions have been complied with, the state engineer shall issue a certificate of construction. The certificate of construction shall address the general properties of the dam and appurtenant structures. The dam owner shall record the certificate of construction with the county clerk of the county within which the works are located.
[19.25.12.15 NMAC - N, 3/31/2005]

19.25.12.16 LICENSE TO OPERATE A DAM: Upon issuance of a certificate of construction the state engineer shall issue a license to operate a dam. The license to operate a dam shall address operation conditions and dams shall be operated in accordance with the operation conditions. In addition, dams classified as high and significant hazard potential shall operate in accordance with the operation and maintenance manual and emergency action plan prepared in accordance with Sections 17 and 18 of 19.25.12 NMAC. Failure to comply with the conditions of the license to operate a dam may result in a state engineer order that limits operation, requires specific action by the owner and if necessary the license to operate a dam may be revoked by the state engineer. If a license to operate a dam is revoked the state engineer may order the dam breached in accordance with Subsections B or C of 19.25.12.19 NMAC.
[19.25.12.16 NMAC - N, 3/31/2005]

19.25.12.17 OPERATION AND MAINTENANCE MANUAL: Owners of dams classified as high or significant hazard potential shall prepare, maintain and adhere to an operation and maintenance manual that addresses the continued safe operation, maintenance and performance of the dam. Because each site, design and operating practice is unique, waivers of specific requirements in this section will be considered on a case-by-case basis. Request for waiver shall be in writing accompanied with documentation justifying the request. If the request is not justified to the satisfaction of the state engineer the request will be denied. [~~A professional engineer licensed in the state of New Mexico qualified in the design and construction of dams shall prepare the operation and maintenance manual. The front cover shall show the name of the dam (identical to the application), the county in which the dam is located and type of report. The first page behind the front cover shall show the name of the dam (identical to the dam name on the application), the county in which the dam is located and signed certifications for the dam owner, engineer and state engineer in accordance with Subsections A, B and E of 19.25.12.12 NMAC.~~] If deemed appropriate, the state engineer may require the owner to obtain the services of a professional engineer licensed in the state of New Mexico qualified in the design and construction of dams to prepare complex technical aspects of the operation and maintenance manual. The operation and maintenance manual shall be submitted in a form acceptable to the state engineer. The operation and maintenance manual shall also be submitted in an electronic format acceptable to the state engineer. The front cover shall identify the document as an operation and maintenance manual and shall show the name of the dam, the county in which the dam is located and the dam owner. The first page behind the front cover shall show the name of the dam, the county in which the dam is located, signed certifications from the dam owner, engineer if required and a certification for the state engineer in accordance with Subsections A, B and E of 19.25.12.12 NMAC. Operation or maintenance of the dam in violation of the procedures presented in the accepted operation and maintenance manual that affect the safety of the dam will result in an order being issued requiring the dam owner to address the problem. The state engineer may also issue an order restricting storage in order to improve the unsafe condition. Failure to comply with orders issued by the state engineer may result in the license to operate the dam being revoked and the dam being ordered breached in accordance with

Subsection B or C of 19.25.12.19 NMAC. [~~Generally, the~~] The operation and maintenance manual shall [~~address the following, with modification depending on the specific dam application:~~] contain the information described below, if relevant to the project, and any other additional information determined necessary by the state engineer to evaluate if the dam will be operated and maintained in a safe condition.

[~~**A. Project Information:** General information on the project including the purpose, location, history, responsibilities and description and properties of the dam and appurtenant structures shall be required.~~]

A. General information: Information on the project shall include but not be limited to the following:

(1) location and access;

(2) purpose and description;

(3) table of properties; and

(4) history of construction, repairs and performance.

B. Operation: Operation instructions, frequency of operation and operator safety for the project shall include but not be limited to the following:

(1) Reservoir:

(a) water right storage allocations;

(b) [~~spillway design flood water level~~] elevation, area and storage curve and table to the dam crest;

(c) [~~emergency reservoir evacuation procedures and maximum discharge rate; and~~] elevation of the high water line;

(d) discharge rating table for the outlet conduit;

(e) discharge rating table for the spillway;

(f) emergency reservoir evacuation procedures; and

[~~(d)~~] (g) first filling criteria and monitoring requirements.

(2) Outlet works:

(a) first operation;

(b) seasonal startup;

(c) seasonal shutdown;

(d) installation and removal of bulkhead;

(e) operation procedures for specific equipment; and

(f) electrical systems and controls.

(3) Operator safety:

(a) confined space entry and permits;

(b) fall protection;

(c) lockout/tag out; and

(d) other applicable safety requirements;

C. Instrumentation: [~~The following elements for monitoring instrumentation shall be addressed~~

[~~**(1)** general description~~

~~**(2)** purpose~~

~~**(3)** critical readings~~

~~**(4)** reading and maintenance procedures; and~~

~~**(5)** reading schedule.~~] Instrumentation for the project shall include but not be limited to the following;

(1) description and purpose;

(2) detailed description of installation;

(3) calibration and maintenance schedule and instructions;

(4) reading schedule and instructions;

(5) data reduction and interpretation;

(6) identification of critical readings and notification procedures; and

(7) schedule for reporting data with interpretations to the state engineer.

D. Security: Projects that include security measures shall describe the security measures along with instructions for monitoring, maintaining and inspection.

[~~**D.**~~] **E.** Maintenance: Maintenance requirements and [~~schedule~~] frequency shall be included.

[~~**E.**~~] **F.** Inspection: Inspection requirements, [~~schedule~~] frequency and recommended checklist shall be included.

[~~**F.**~~] **G.** Updates and revisions: An update and revision procedure shall be included.

[~~G.~~] **H.** Appendices: [~~Appendices to include any design consideration and the instrumentation plan to ensure any restrictions imposed by the design are incorporated into the operation and maintenance manual shall be included. Copies of inspections forms and any other information that supports and supplements the material used in the development and maintenance of the operation and maintenance manual.~~] Appendices shall include documentation that supports and supplements the manual. The appendices shall include but not be limited to the following:

(1) captioned and dated photographs;

(2) key sheets from the record construction drawing set;

(3) instrumentation construction drawings;

(4) instrumentation rating tables and calibration details;

(5) monitoring and inspection forms;

(6) instrumentation plan to ensure any restrictions imposed by the design are incorporated into the operation and maintenance manual; and

(7) copies of any relevant procedures.

[19.25.12.17 NMAC - N, 3/31/2005; A, xx/xx/2010]

19.25.12.18 EMERGENCY ACTION PLAN: Owners of dams classified as high or significant hazard potential shall prepare, maintain and exercise an emergency action plan for immediate action in the event of a potential dam failure. [~~The emergency action plan shall follow the format provided by the state engineer or a format that has prior approval of the state engineer.~~] Because each site and operating practice is unique, waivers of specific requirements in this section will be considered on a case-by-case basis. Request for waiver shall be in writing accompanied with documentation justifying the request. If the request is not justified to the satisfaction of the state engineer the request will be denied. The emergency action plan shall follow the format provided by the state engineer or a format that has prior approval of the state engineer. The emergency action plan shall also be submitted in an electronic format acceptable to the state engineer. The front cover shall identify the document as an emergency action plan and shall show the name of the dam [~~(identical to the application)~~], the county in which the dam is located and [~~type of report~~] the dam owner. [~~The pages immediately behind the front cover shall show the name of the dam (identical to the dam name on the application), the county in which the dam is located and signed certifications for the dam owner, engineer, local and state office of officials responsible for emergency management and state engineer in accordance with Subsections A, B, D and E of 19.25.12.12 NMAC.~~] The pages immediately behind the front cover shall show the name of the dam, the county in which the dam is located, signed certifications from the dam owner, engineer, local and state officials responsible for emergency management and a certification for the state engineer in accordance with Subsections A, B, D and E of 19.25.12.12 NMAC. The dam owner shall coordinate with the local emergency management office in preparing the emergency action plan. The coordination is required to ensure that there is an agreement on the evacuation limits and responsibilities. The dam owner shall submit a copy to the local and state [~~office of~~] officials responsible for emergency management for acceptance prior to submittal to the state engineer. The dam owner shall review the emergency action plan annually, update as necessary and furnish a copy of updates to [~~the state engineer, state office of emergency management and~~] all official copyholders. The dam owner shall exercise the emergency action plan to verify those involved in its implementation know their roles and responsibilities. [~~It is recommended the~~] The dam owner shall conduct a functional exercise of the emergency action plan every 5 years with a table top exercise conducted 2 to 3 years before the functional exercise. The exercise may result in updates to ensure the emergency action plan maintains operational readiness, timeliness and responsiveness. Failure to act in accordance with the accepted emergency action plan that affects [~~the safety of the dam~~] public safety will result in an order being issued requiring the dam owner to address the problem. Failure to comply with orders issued by the state engineer may result in the license to operate the dam being revoked and the dam being ordered breached in accordance with Subsection B or C of 19.25.12.19 NMAC. A professional engineer licensed in the state of New Mexico qualified in the design and construction of dams shall prepare engineering [~~elements of~~] information for the emergency action plan as specified below. An emergency action plan shall [~~contain the following minimum elements:~~] contain the information described below and any other additional information determined necessary by the state engineer or emergency management official to evaluate the planned response to an emergency situation by the dam owner.

A. Notification flowchart: A notification flowchart showing who is to be notified, by whom and in what priority.

B. Emergency detection, evaluation and classification: Procedures for reliably and timely identifying an emergency situation to ensure that an appropriate course of action is implemented. A professional engineer licensed in the state of New Mexico qualified in the design and construction of dams shall prepare this element.

C. Responsibilities: A list designating responsibilities for the emergency action plan related tasks including, but not limited to developing, maintaining, exercising, implementing, warning, evacuation and termination of the emergency.

D. Preparedness: A list of materials, equipment and manpower available to moderate or alleviate the effects of a dam failure or spillway release. [~~A professional engineer licensed in the state of New Mexico qualified in the design and construction of dams shall prepare this element.~~]

E. Evacuation map: An evacuation map delineating the areas that will be evacuated as a result of dam failure. The evacuation map shall extend to a point where the consequences of dam failure does not pose a threat to life and evacuation or restricting access is not required. If available, shape files from geographic information system software of the evacuation map shall be submitted. Evacuation maps shall include the following information at critical locations downstream as required by the local official responsible for emergency management:

(1) distance downstream from the dam;

(2) arrival time of the leading edge of the flood wave;

(3) peak flow depth, incremental rise or water surface elevation in feet; and

(4) peak velocity in feet per second.

[~~E.~~] F. Inundation map: An inundation map delineating the areas that will be flooded as a result of dam failure. [~~The dam breach analysis shall be prepared in accordance with Subparagraphs (a) through (g) of Paragraph (1) of Subsection C of 19.25.12.11 NMAC for the failure with the water level at the reservoir storage capacity and at the maximum water level during the spillway design flood event. If a dam is located upstream, failure scenarios with the upstream dam shall also be evaluated. Flood control dams that have not experienced a fill to the spillway crest shall prepare a failure scenario with the water level at the spillway crest. Flood inundation maps shall also be prepared for the maximum release without failure of the dam. Evaluation of the effects of flooding from dam failure shall extend at least to the location downstream where the flood no longer poses a threat to life or property.~~] The inundation map shall be supported by a dam breach and flood routing analysis report. The dam breach and flood routing analysis shall evaluate the sunny day failure, failure at the high water line and any additional event deemed appropriate by the dam owner. If appropriate considering the consequences of dam failure, a simplified dam breach and flood routing analysis may be used with approval from the state engineer. If a dam is located downstream, failure scenarios with the downstream dam shall also be evaluated. Evaluation of the effects of flooding from dam failure shall extend at least to the location downstream where the consequences of dam failure does not pose a threat to life and evacuation or restricting access is not required. A professional engineer licensed in the state of New Mexico qualified in the design and construction of dams shall prepare this element. If available, shape files from geographic information system software of the inundation map shall be submitted. Inundation maps shall include the following information at critical locations downstream;

(1) distance downstream from the dam;

(2) arrival time of the leading edge of the flood wave;

(3) peak flow depth, incremental rise and water surface elevation in feet; and

(4) peak velocity in feet per second.

[~~F.~~] G. Appendices: All information that supports and supplements the material used in the development and maintenance of the emergency action plan. The dam breach and flood routing analysis report shall be submitted as a separate document.

[19.25.12.18 NMAC - N, 3/31/2005; A, xx/xx/2010]

19.25.12.19 CHANGES TO AN EXISTING DAM: A dam owner proposing to reconstruct, enlarge, modify, restore reservoir capacity, repair, remove or breach an existing dam must make application to and receive approval from the state engineer prior to undertaking any such action. The current condition of the dam, the type of repair or modification and the proposed means to achieve the repair or modification shall dictate the detail of the information provided to the state engineer in order to obtain approval. Because each site, design change and operating practice is unique, waivers of specific requirements in this section will be considered on a case-by-case basis. Request for waiver shall be in writing accompanied with documentation justifying the request. If the request is not justified to the satisfaction of the state engineer the request will be denied. Existing dams present the same hazards to life and

property downstream as new dams. Therefore, owners of dams classified as high or significant hazard potential shall evaluate the current condition of the dam and address in the submittal to the state engineer whether the dam is in compliance with the design requirements in Subsection C of 19.25.12.11 NMAC. If the state engineer determines compliance with requirements in Subsection C of 19.25.12.11 NMAC are critical to the safety of the dam, the state engineer shall issue an order requiring the deficiency be addressed as part of the proposed change. Owners of dams classified as low hazard potential shall comply with the design requirements in Subsection C of 19.25.12.11 NMAC for the proposed change only. Maintenance activity performed in accordance with 19.25.12.17 NMAC does not require prior state engineer approval. Dam owners shall not abandon a dam without breaching or removing the dam to ensure the dam no longer poses a risk to life, property, the environment surrounding the dam or downstream of the dam. In the event of any changes of ownership affecting the title to a dam, the new owner shall file a change of ownership form for a dam with the state engineer. Recognition of the responsibility and liability associated with dam ownership is required along with fees for filing the change in ownership form for a dam in accordance with Subsection [~~F~~] G of 19.25.12.8 NMAC. This section exempts federal dams if no change to the water storage permit is required. [~~In general, the following minimum submittal is required to make changes to an existing dam:~~] A proposed change to an existing dam shall require the submittal of the information described below and any other additional information determined necessary by the state engineer to evaluate if the change to the dam is safe.

A. Proposed changes to an existing dam: For dam owners proposing to reconstruct, enlarge, modify, restore reservoir capacity, [~~or~~] repair or add aesthetic fill to an existing dam, the [~~following supporting documentation~~] information described below is required prior to undertaking any such action[~~:~~].

(1) An [~~amended~~] application [~~if properties of~~] to alter, repair or rehabilitate the dam and appurtenant structures [~~change~~]. Fees for filing the [~~amended~~] application and for reviewing drawings and specifications shall be in accordance with Subsections [~~A~~] B and [~~B~~] C of 19.25.12.8 NMAC. [~~Fees~~] Review fees identified in Subsection C of 19.25.12.8 NMAC are waived for the first review if the state engineer requires the change to address a dam safety deficiency.

(2) Documentation of sufficient water rights if changes in storage or release requirements are proposed in accordance with the requirements of Subsection B of 19.25.12.11 NMAC.

(3) A design report addressing the proposed change in accordance with the requirements of Subsection C of 19.25.12.11 NMAC. Owners of dams classified as high or significant hazard potential shall submit a design report addressing whether the existing condition of the dam is in compliance with the design requirements listed in Subsection C of 19.25.12.11 NMAC. Where the existing condition of the dam is not in compliance with the design requirements of Subsection C of 19.25.12.11 NMAC, the design report shall propose changes to address compliance with the design requirements of Subsection C of 19.25.12.11 NMAC or request a waiver that the deficiency is not critical to the safety of the dam and provide adequate justification for the waiver.

(4) Construction drawings and specifications addressing the proposed change in accordance with the requirements of Subsections D and E of 19.25.12.11 NMAC.

(5) A plat of survey showing the dam owner's property boundaries, easement, or right of way. The plat of survey shall be in accordance with the requirements of Subsection F of 19.25.12.11 NMAC.

(6) For dams classified as high or significant hazard potential, a dam site security assessment in accordance with the requirements of Subsection G of 19.25.12.11 NMAC.

(7) For dams classified as high or significant hazard potential, an instrumentation plan in accordance with the requirements of Subsection H of 19.25.12.11 NMAC.

(8) For dams classified as high or significant hazard potential, an updated operation and maintenance manual and emergency action plan in accordance with the requirements of Sections 17 and 18 of 19.25.12 NMAC.

B. Removal or breach of dams classified as high or significant hazard potential: Dam owners intending to breach or remove a dam classified as high or significant hazard potential shall submit a plan to the state engineer for approval prior to breaching or removing the dam. The plan shall evaluate the potential effects of the dam removal or breach on life, property and the environment downstream. A professional engineer licensed in the state of New Mexico qualified in the design and construction of dams shall prepare the plan. The state engineer will revoke the license to operate a dam upon completion of all construction conditions. The plan shall meet the [~~following~~] conditions[~~:~~] described below.

(1) The reservoir shall be emptied in a controlled manner, which will not endanger lives or damage property downstream.

(2) The dam or breach area shall be excavated down to the level of natural ground and the breach shall be of sufficient width to safely pass the 100-year, 24-hour flood peak discharge without attenuation of the flood through the reservoir.

(3) The side slopes of the breach shall be excavated to a stable angle.

(4) The breach shall be armored as necessary to prevent erosion of the breach area.

(5) The plan shall address the control of sediment previously deposited in the reservoir.

(6) Drawings and specifications shall be prepared in accordance with the appropriate requirements listed in Subsections D and E of 19.25.12.11 NMAC and shall include a title sheet with required certifications and signatures, the location, dimensions and lowest elevation of the breach and any other detail to sufficiently describe the proposal.

(7) Designation of the professional engineer licensed in the state of New Mexico qualified in the design and construction of dams that will supervise construction of the breach or dam removal. Submittal of the professional engineer's qualifications for state engineer approval is required.

C. Removal or breach of dams classified as low hazard potential: Owners of dams classified as low hazard potential shall submit a written notice to the state engineer of intent to breach the dam. The state engineer will revoke the license to operate a dam upon completion of all construction conditions. The breach notice shall meet the [~~following~~] minimum requirements[~~:~~] described below.

(1) The bottom width elevation of the breach shall be to original ground.

(2) The bottom width of the breach shall be a minimum of one-half the height of the dam but not less than 10 feet.

(3) The side slopes shall not be steeper than one horizontal to one vertical.

(4) The excavated material shall not be placed in the streambed.

D. Closure of a tailings facility: A closure plan [~~is~~] must be prepared to address the closure of a tailings facility. State engineer approval is required before any modification occurs to a jurisdictional tailings dam. A professional engineer licensed in the state of New Mexico qualified in the design and construction of tailings dams shall prepare the closure plan, which shall include a design report, drawings and specifications prepared in accordance with the appropriate requirements listed in Subsections C, D and E of 19.25.12.11 NMAC. The state engineer will revoke the license to operate a dam upon completion of all construction conditions. The plan shall address the following issues:

(1) long-term stability under static and dynamic conditions;

(2) control of surface runoff to avoid erosion;

(3) plan for long term monitoring, if appropriate; and

(4) identification of an engineer licensed in the state of New Mexico qualified in tailings dam design and construction to supervise implementation of the closure plan; submittal of the engineer's qualifications for state engineer approval is required.

E. Construction and operating conditions: After reviewing the required documentation, the state engineer will notify the dam owner if any deficiencies are found with the submittal. The dam owner will be given an opportunity to correct any deficiencies noted in the review process. Once all deficiencies have been addressed the state engineer will approve the amended application or proposed change with conditions under which construction and operation shall occur. Action by the state engineer will be in accordance with 19.25.12.13 NMAC, appropriately modified to address the proposed changes.

F. Proof of completion of works, certificate of construction and license to operate: [~~Requirement~~] The requirement for a proof of completion of works form for the dam, certificate of construction and license to operate a dam for changes to a dam will be made on a case by case basis by the state engineer. The proof of completion of works form for the dam, certificate of construction and license to operate a dam, if required, shall be in accordance with the Sections 14, 15 and 16 of 19.25.12 NMAC, appropriately modified to address the proposed changes. If the dam is breached, the state engineer will cancel the permit and revoke the license to operate a dam.

[19.25.12.19 NMAC - N, 3/31/2005; A, xx/xx/2010]

19.25.12.20 CHANGES TO AN EXISTING NON-JURISDICTIONAL DAM: A dam owner proposing to reconstruct, enlarge, or modify a non-jurisdictional dam, resulting in a jurisdictional dam after construction is completed, shall comply with 19.25.12.11 NMAC before construction begins. If the [~~purpose~~] ownership of a non-jurisdictional dam changes, resulting in a jurisdictional dam, [~~or if ownership changes, resulting in a jurisdictional~~

~~dam,~~] the owner shall comply with 19.25.12.11 NMAC. The state engineer will give the owner a reasonable amount of time to comply with 19.25.12.11 NMAC. If the owner fails to comply with 19.25.12.11 NMAC, the dam will be ordered breached in accordance with Subsection B or C of 19.25.12.19 NMAC.
[19.25.12.20 NMAC - N, 3/31/2005; A, xx/xx/2010]

19.25.12.21 EXISTING DAMS: The state engineer [~~inspects~~] may inspect existing dams to verify dams are operated and maintained in a safe manner. Access to the dam site shall be made available to the state engineer upon request. If a critical dam safety problem is observed by the state engineer or reported to the state engineer, an order [~~will~~] may be issued requiring the dam owner to address the problem. If a dam incident occurs at a dam, the dam owners shall report the incident to the state engineer within 72 hours. If a major repair is required at an existing dam, the plan to repair the dam shall be in accordance with 19.25.12.19 NMAC. Minor repairs not identified as maintenance activity in accordance with 19.25.12.17 NMAC require state engineer approval. Failure to comply with state engineer directives or these regulations may result in an order to reduce storage or to take corrective action. Failure to comply with orders issued by the state engineer may result in the license to operate a dam being revoked and the dam ordered breached in accordance with Subsection B or C of 19.25.12.19 NMAC. Owners of existing dams shall comply with the [~~following:~~] requirements described below.

A. Owners acquiring property with a dam shall promptly notify the state engineer on a form provided by the state engineer of the change in ownership. Recognition of the responsibility and liability associated with dam ownership is required along with fees for filing the change in ownership form for a dam in accordance with Subsection [~~F~~] G of 19.25.12.8 NMAC.

B. Owners of dams classified as low or significant hazard potential shall evaluate the hazard classification if downstream development occurs. The dam owner shall submit the results of the hazard potential evaluation prepared in accordance with Paragraph (1) of Subsection C of 19.25.12.11 NMAC to the state engineer for approval [~~and a plan for addressing design deficiencies~~]. If the hazard potential classification changes due to downstream development, the state engineer shall give the dam owner a time limit to address deficiencies. Deficiencies shall be addressed in accordance with [~~Paragraphs (3), (12) and (13) of~~] Subsection C of 19.25.12.11 NMAC and Sections 17 and 18 of 19.25.12 NMAC. [~~If the dam owner fails to address a deficiency, the state engineer may revoke the license to operate the dam and order the dam breached in accordance with Subsection B or C of 19.25.12.19 NMAC.~~]

C. Dams classified as high or significant hazard potential shall be inspected on an interval no greater than 5 years by a professional engineer licensed in the state of New Mexico qualified in the design and construction of dams. The owner is responsible for securing the services of the professional engineer. The professional engineer shall provide a signed and sealed report to the state engineer describing the findings of the inspection and recommendations for corrective action or changes to the operating procedures. Routine inspection by the state engineer as described in 19.25.12.21 NMAC satisfies this requirement.

D. Owners of dams classified as high or significant hazard potential in an unsafe condition may receive an order from the state engineer to address the deficiency pursuant to NMSA 1978, Section 72-5-11 (1979). The state engineer may also issue an order to an owner of a non-jurisdictional dam if the dam is unsafe and a threat to life or property, as determined by the state engineer. Owners shall comply with orders issued by the state engineer pursuant to NMSA 1978, Section 72-5-12 (1979).

E. Owners of dams classified as high or significant hazard potential shall comply with 19.25.12.17 NMAC requiring an operation and maintenance manual. Upon compliance with 19.25.12.17 NMAC the state engineer will issue a license to operate the dam. [~~Dams classified as high hazard potential shall comply by December 31, 2008. Dams classified as significant hazard potential shall comply by December 31, 2010.~~]

F. Owners of dams classified as high or significant hazard potential shall comply with 19.25.12.18 NMAC requiring an emergency action plan. [~~Dams classified as high hazard potential shall comply by December 31, 2008 unless the dam is for flood control purposes with no permanent storage, then compliance by December 31, 2010 is required. Dams classified as significant hazard potential shall comply by December 31, 2010 unless the dam is for flood control purposes with no permanent storage, then compliance by December 31, 2012 is required.~~] Dams classified as significant hazard potential for flood control purposes with no permanent storage shall comply by December 31, 2012. Owners of 5 or more dams classified as high or significant hazard potential may propose a schedule for compliance with the emergency action plan requirement. [~~The schedule must be submitted by the owner to the state engineer by December 31, 2005 and is subject to review and approval or modification by the state engineer. The schedule must propose compliance dates for each dam. The first dam must be in compliance by December 31, 2008 and at least an additional dam must be in compliance each year thereafter. All dams must be in~~

~~compliance by December 31, 2015. Upon failure to meet an approved compliance schedule all dams will revert to compliance dates shown above.~~] The schedule must propose compliance dates for each dam and all dams must be in compliance by December 31, 2015. The compliance schedule is subject to review and approval or modification by the state engineer.

G. Dam owners that transfer the entire water right out of the reservoir shall have their license to operate a dam revoked and [~~may~~] will receive from the state engineer an order to breach the dam in accordance with Subsection B or C of 19.25.12.19 NMAC.

H. Dam owners that fail to obtain state engineer approval prior to construction of a dam shall comply with all conditions imposed by the state engineer within a time limit established by the state engineer or the state engineer may order the dam breached in accordance with Subsection B or C of 19.25.12.19 NMAC.

[19.25.12.21 NMAC - N, 3/31/2005; A, xx/xx/2010]

19.25.12.22 SEVERABILITY: If any portion of this part is found to be invalid, the remaining portion of this part shall remain in force and not be affected.

[19.25.12.22 NMAC - N, 3/31/2005]

History of 19.25.12 NMAC: [RESERVED]

NEW MEXICO OFFICE OF THE STATE ENGINEER
Dam Safety Bureau
Hydrologic Analysis for Dams
August 15, 2008

Hydrologic analysis requirements for dams are cited in the Rules and Regulations Governing Dam Design, Construction and Dam Safety, which were filed with the New Mexico State Record Center as Title 19, Chapter 25, Part 12 of the New Mexico Administrative Code (19.25.12 NMAC). Hydrologic analysis shall be performed in accordance with Subsection C of 19.25.12.11 NMAC. The design life of a dam is much longer than the record retention period of most engineering firms and memories of most design engineers. It is important that the analysis stand on its own in a manner that is comprehensible to future engineers who may be involved with the structure. Therefore, the Office of the State Engineer (OSE) requires that the hydrologic analysis be fully documented and supported independent of computer programs or other computational methodology used in the analysis.

Most dams are constructed on a watercourse or have a contributing drainage area upstream from the dam. Intense rainfall creates inflow to the reservoir of the dam, which is routed through the reservoir and allowed to pass the dam through a spillway or multiple spillways. Earlier dams typically were provided with spillways that were sized to pass the largest observed floods. These dams frequently overtopped and failed, and roughly half of all known dam failures have been the result of flood overtopping. During the 20th Century, methods were developed to better evaluate infrequent or extreme flood events, and provide adequate spillway capacity to safely pass these floods. Hydrologic analysis is one of the most important aspects in the design of a safe dam, and will be closely reviewed by the New Mexico Office of the State Engineer (OSE) Dam Safety Bureau.

Presented below is an outline of the typical steps for completing a hydrologic analysis satisfying the requirements outlined in Subsection C of 19.25.12.11 NMAC. In order to facilitate review by the OSE Dam Safety Bureau the hydrologic analysis report must be organized in an easy to follow layout and format. Submittals that are not consistent with this document and the requirements outlined in Subsection C of 19.25.12.11 NMAC will cause a delay in the review by the OSE Dam Safety Bureau and may be returned to the owner with no review provided. Inadequate hydrology submittals may also require review fees to be resubmitted prior to subsequent review by the OSE Dam Safety Bureau.

The following steps are typically required in completing hydrologic analysis for dams for submittal to New Mexico Office of the State Engineer:

1. Determine hazard potential classification for the dam location.
2. Determine appropriate design storm requirements for location.
3. Determine geographic location, limits and area of watershed contributing to dam and reservoir.
4. Divide watershed into subbasins as appropriate, and determine subbasin areas, channel locations for routing, etc.
5. Determine basin or subbasin geometry such as longest flow path for each basin or subbasin, channel slope and cross section, highest and lowest points, basin centroid(s), mean basin elevation, etc. as required for methodology to be used.

6. Determine appropriate timing and routing parameters for the elements in the watershed model.
7. Determine reservoir characteristics including stage-storage and stage-discharge relationships.
8. Develop total watershed model by arranging subbasins, routing reaches, etc. in the proper sequence with appropriate parameters.
9. Derive the precipitation to be used for design.
10. Develop incremental precipitation from depth-duration relationship and arrange increments to create an appropriate temporal distribution of precipitation.
11. Develop spatial distribution of precipitation if appropriate.
12. Determine loss parameters or functions and apply to incremental precipitation.
13. Deduct losses from precipitation increments to estimate precipitation excess.
14. Select an appropriate transform methodology for converting excess rainfall to runoff.
15. Apply the transform methodology to each subbasin using incremental precipitation excess.
16. Add stream base flow, etc., to obtain flood hydrograph for each subbasin.
17. Combine and/or route subbasin hydrographs to determine the inflow design flood.
18. Route flood through reservoir and spillway to obtain estimates of reservoir peak stage, peak outflow, peak storage, flood duration, etc.
19. Review results for reasonableness, comparing to known floods or otherwise calibrating if possible.
20. Adjust model parameters, spillway characteristics, etc. as necessary and appropriate and repeat process.
21. Prepare hydrologic analysis report for OSE review and for the permanent record.

Discussion:

The steps taken in the analysis, along with assumptions made and parameters used, must be fully documented. Documentation requirements are discussed in the final section of this paper. Discussion of each of the steps for performing hydrologic analysis is as follows:

1. Hazard Potential Classification

Hazard Potential Classification is a function of dam location and downstream conditions, and is not a measure of the integrity of the dam or the adequacy of the design. High hazard potential classification applies if loss of life is probable if the dam fails catastrophically. This is usually fairly obvious, based on downstream development conditions. In some cases, breach and flood wave analysis is needed to establish hazard potential classification. If site is not High hazard potential, in most cases it will be Significant, due to substantial risk to property or assets (highways, barns, irrigation ditches, etc.) or potential for significant environmental consequences. Low hazard potential is typically limited to remote, small structures such as ranch ponds for cattle watering and limited irrigation. Flood control dams typically are High or Significant hazard potential, because the need to control flooding suggests life and/or assets being protected downstream. Evaluations for Low or Significant hazard potential dams must consider the potential for future downstream development.

2. Design Precipitation Requirements

Generally, high hazard potential dams require consideration of Probable Maximum Precipitation (PMP). Significant hazard potential dams require consideration of 50% PMP if 100 feet or less in height and having 50,000 acre-feet or less storage, or 75% PMP if greater than 100 feet in height or having over 50,000 acre-feet of storage. For significant hazard potential dams, percentages are applied to precipitation prior to hydrologic analysis. Low hazard potential dams require consideration of 100-year storm, expressed as a percentage of PMP. Therefore, most dams will require evaluation of PMP. In some cases, waiver of evaluation of PMP will be entertained for low hazard potential dams with no realistic possibility for future hazard potential change.

In addition to precipitation requirements for spillway design, flood control dams must be able to drain from spillway crest or 100-year, 24-hour peak reservoir level within 96 hours. This implies determination of 100-year, 24-hour precipitation in most cases. For high and significant hazard potential flood control dams conforming to local flood control authority or NRCS requirements for 100-year, 24-hour flood routing, OSE will defer to these requirements for determination of compliance with the 96-hour rule.

3. Watershed Location, Limits, and Area

Watershed location, limits and area have traditionally been obtained from 7-1/2 minute USGS quad maps by tracing the divide, and then determining the area by planimeter or other measurement. For smaller drainages, a site topo map is sometimes used. Recent analyses frequently use ArcView or other GIS software in conjunction with DEM or DTM. Determination of precipitation will require geographic location (latitude and longitude) of the approximate basin centroid or a georeferenced perimeter at an appropriate scale. Methodology used must be described and supported as appropriate. Drainage area for existing dams must be independently verified rather than relying on area indicated on drawings or in design report, particularly for older dams. Precipitation depths may require adjustment based on watershed area. Average elevation of the watershed is needed for determination of Local Storm PMP.

4. Subdivision of Watershed

Logical subdivision can be made where topography or surface features and development are dissimilar. SCS methodology would suggest maximum subbasin size of about 20 square miles. USBR – Cudworth recommends 500 square miles maximum area per subbasin. Subbasin areas should be reasonably similar – for example, don't combine 20 square mile and 0.5 square mile subbasins in the same model if you can help it. Avoid dividing into unnecessary subbasins, as this complicates the model and usually does not improve results. Particularly, avoid overdividing small basins, such as dividing 5 square miles into 20 subbasins. Subbasins should generally correspond with logical junction points and routing reaches.

5. Basin and Subbasin Geometry

Specific information required will depend on methodology used for timing parameters and runoff transform. Typical requirements might include length of longest watercourse, length to a point opposite the basin centroid, watercourse slope, average basin slope, estimated length of overland flow, length, slope, and cross-section of channel reaches, etc.

6. Timing and Routing Parameters

Typical parameters may include time of concentration, lag time, time-to-peak, time of travel, kinematic wave travel time, channel geometry and roughness, etc. depending on requirements of the transform methodology and channel routing used. To add to confusion, a parameter may be defined in different ways for different methodologies, even if the name is the same. The parameter(s) used must be appropriate for and compatible with transform methodology as defined within that methodology. Also, assumptions or limitations for the timing parameters must be consistent with the watershed being studied. These may include basin size or watershed length, channel condition (natural vs. improved or hardened), degree of development, etc. Method of determining timing and routing parameters must be indicated and justified as appropriate for location and transform methodology, with sample derivation and references.

7. Reservoir Characteristics

This may be developed as elevation-area or elevation-storage, depending on modeling requirements or input parameters for the method used. However, OSE Rules and Regulations require reservoir characteristics to be reported as elevation-storage table in one-foot intervals. Water storage reservoirs generally are assumed to be full to the point of uncontrolled discharge, e.g. spillway crest. Flood control dams with uncontrolled outlets and no permanent storage generally are assumed to be empty at the start of the modeling period.

8. Watershed Model

The basin and subbasin geometry and characteristics, routing reaches and parameters, reservoir characteristics, etc. are assembled to create the watershed model for the dam. It is useful to create a schematic or flow chart for the watershed model, particularly if software being used does not provide a graphical or schematic representation. A schematic or graphical representation of the model and tables of relevant model parameters will be required in the report submitted to OSE.

9. Precipitation Derivation

PMP east of the Continental Divide is derived using methodology of HMR 55A, PMP west of the Continental Divide is derived using HMR 49. Both HMR documents provide for 1) a Local Storm (thunderstorm), with 6 hours total duration, and 2) a General Storm, with 72 hours duration. Neither HMR includes procedures or allowances for durations less than the complete storm, such as a 1-hour thunderstorm or a 24-hour general storm. If a shorter duration is used, justification must be provided.

Concerning durations less than the complete storm, FEMA as quoted in City of Albuquerque *Development Process Manual* states, “FEMA’s position regarding the duration of rainfall is that the storm must extend for a period long enough to include all rainfall excess when the volume of the runoff hydrograph is an important consideration. This includes conditions when detention storage is involved, when sediment processes are a significant factor, and when combining and routing subbasin hydrographs to obtain watershed runoff. When the peak flow is the primary concern, and it is established that the use of a longer duration storm would not increase the peak flow, shorter duration storms are acceptable.” This would suggest that using the most intense 24 hours of the General Storm would only be appropriate if it can be shown that no excess

precipitation will occur outside of this period, or if it can be shown that the peak flow is not sensitive to storm volume if peak flow is the primary concern.

Both HMR documents require obtaining index precipitation from maps, and then adjusting precipitation depths for area, elevation, and orographic effects specific to the watershed being studied. The index precipitation depths are plotted against duration to develop a smooth depth-duration passing through the origin. Area adjustments typically are based on the total contributing area above the dam or other point of interest, rather than on individual subbasin areas. Since precipitation depth for PMP is adjusted for storm area during the derivation, no additional reductions should typically be taken during the hydrologic analysis.

The 1984 reprint of HMR 49 contains an Errata sheet following the title page. The entry for page 154 on this Errata sheet changes the basis for local storm elevation adjustments from the lowest elevation in the drainage to the mean elevation. This generally will result in greater reductions in precipitation depth for cases where the elevation adjustment applies. This change is not well documented anywhere else in the literature. Electronic versions of HMR 49 not containing this correction may still be available online.

Both Local and General Storm should be evaluated, unless clear evidence and justification can be provided showing that one storm or the other obviously controls. For example, in the Eastern portion of the New Mexico HMR 55A area, the 1- and 6-hour ordinates for the General Storm frequently are greater than the 1- and 6-hour ordinates of the Local Storm. Conversely, in certain locations of HMR 49 where the orographic component of General Storm precipitation is low, total storm volume for the General Storm can be less than the Local Storm. In most other cases, it is not sufficient to simply compare precipitation depths, since routing effects may result in greater spillway discharge from the General Storm, even though the Local Storm precipitation depths are greater at 1 and 6 hours.

Alternatives to HMR 49 and HMR 55A include site-specific analysis for PMP and Incremental Damage Assessment, either of which should be discussed first with OSE. In the future, an Extreme Precipitation Analysis Tool may be available for portions of the state, to provide an updated estimate of extreme precipitation.

Precipitation for frequency-based events, such as the 100-year storm, is obtained from NOAA Atlas 14, available online. Precipitation is obtained by latitude and longitude, and is point precipitation. The precipitation values from Atlas 14 are considered appropriate for storm areas of 10 square miles or less, and the full precipitation depth should be used for watersheds less than 10 square miles. For larger areas, an approved procedure for reducing precipitation based on area may be applied. The online documentation for Atlas 14 does not provide areal reduction factors specific to Atlas 14, but instead references three possible sources:

1. NOAA Atlas 2, *Precipitation-Frequency Atlas of the Western United States*, 1973. This method was originally presented in Technical Paper No. 40, *Rainfall Frequency Atlas of the United States*, U.S. Weather Bureau, 1961, and is incorporated into the Frequency Storm methodology in HEC-1 and HEC-HMS.

2. Technical Report 24, *A Methodology for Point-to-Area Rainfall Frequency Ratios*, NOAA, 1980.
3. Technical Memorandum HYDRO-40, "Depth-Area Ratios in the Semi-Arid Southwest United States," NOAA, 1984.

These methods will allow reductions for areas less than 10 square miles; however, Atlas 14 seems to recommend using the point precipitation values for 10 square miles or less. If areal reductions are made for drainage areas less than 10 square miles, justification must be provided. Areal reductions for frequency storms should be based on the total watershed contributing to the point of interest, and not on individual subbasin areas. For watersheds with total area exceeding the limits of the reduction method (400 square miles for NOAA Atlas 2/U.S. weather Bureau Technical Paper 40) the services of a qualified meteorologist may be necessary to determine appropriate reductions of point precipitation.

10. Precipitation Increments and Distribution

Precipitation increment size should generally correspond to the computational time step used, although this is not mandatory for many computer programs including HEC-HMS. Increments are obtained from the depth-duration curve by subdividing the curve by increment length and successively subtracting curve ordinates. For small, fast basins in particular it is important to use a sufficiently small increment size and computational time step to avoid under-prediction of peak runoff.

Once the increments have been determined, they must be arranged in an appropriate distribution. One of the most common arrangements sometimes called "center-peaking" or "balanced" distribution, places the largest increment at the center of the storm duration. The second largest increment is placed directly in front of the first, the third largest placed behind the first, and the procedure is continued with successively smaller increments until the distribution is filled. A similar distribution, favored by Bureau of Reclamation for 72-hour general storm PMP, can be termed "late-peaking." This distribution places the largest increment at the 2/3 point of the storm, then places the second and third largest increment successively in front of the largest increment, then the fourth largest increment immediately behind the largest increment, then continuing the sequence with two increments in front, one behind until the distribution is filled and all increments are used. Either the center-peaking or late peaking distribution will be acceptable for 72-hour General Storm PMP.

Both HMR 49 and HMR 55A refer to two recommended distributions for the 6-hour Local Storm. One is obtained from HMR 5, and the other from the USACE EM1110-2-1411. The distributions are similar, with the USACE EM1110-2-1411 distribution peaking later in the storm. HMR 49 states, "In application, the choice of either of these distributions is left to the user since one may prove to be more critical in a specific case than the other." This suggests that both methods should be evaluated and the more critical distribution should be used. In practice, the USACE EM1110-2-1411 appears to provide the higher peak discharge in the majority of cases. While not specifically discussed in either HMR 49 or HMR 55A, a center-peaking distribution of local storm PMP has been used in the past and is acceptable to OSE. In any case,

the distribution used must be justified as being appropriate for the specific drainage area being evaluated.

The center-peaking and late-peaking distributions described above are frequently approximated in HEC-HMS or HEC-1 using the Frequency Storm definition for precipitation. Using the Frequency Storm to distribute PMP can cause unintended consequences if one is not careful, and probably should be avoided by infrequent users. The Frequency Storm requires input of precipitation depths for durations corresponding to the frequency series of 5 min, 15 min, 1 hour, 2 hours, 3 hours, 6 hours, 24 hours, 48 hours, etc. The frequency series does not include a 72-hour duration, and so will not emulate the full General Storm PMP. The General Storm index values from HMR 55A do not include values for 5 min, 15 min, 2 hour, 3 hour, or 48 hour durations, and the index values from HMR 49 do not include 5 min, 15 min, 1, 2, or 3 hour values, requiring values to be interpolated or read from curve plots, introducing a possible source of error. The Frequency Storm method can result in unintended reductions of precipitation due to inappropriate use of Storm Area and Probability inputs in HEC-HMS and HEC-1. It is probably best to discuss with OSE before using the Frequency Storm to distribute PMP.

In cases where 100-year precipitation is required (primarily for low-hazard potential dams) the preferred distribution is a center-peaking distribution based on the frequency series from NOAA Atlas 14. The Frequency Storm functions in HEC-HMS, HEC-1, and possibly other programs, are suitable and are intended for this type of storm. Since the precipitation from Atlas 14 is point precipitation, reductions for storm area may be taken as appropriate. The common SCS Type II distribution used for most of the US east of New Mexico will not be appropriate in New Mexico in most cases. The Type IIA distributions used by NRCS in New Mexico may be appropriate, but it is recommended that their use be discussed with OSE prior to using these distributions.

The following distribution methods, which have all been used in submittals to OSE, are not generally appropriate:

- Using the depth-duration curve as the distribution.
- Straight-line distribution of equal increments throughout the storm or during peak periods of the storm.
- Using SCS Type II or NRCS Type II-a distribution for PMP.
- Compressing SCS or NRCS distributions for durations less than 24 hours
- Using a Huff distribution.

11. Spatial Distribution of Precipitation

Spatial distribution of precipitation intensity within a basin through use of isohyetal storm patterns is typically done only for relatively large basins. This method is not common in submittals to OSE, and the services of a qualified meteorologist is required if this method is used. The method is illustrated in HMR 52, which contains information for applying this method east of the 105th meridian, comprising roughly the eastern third of New Mexico.

The more typical submittal applies precipitation uniformly across the basin, with reductions in precipitation depth for larger areas as appropriate. The reductions in these cases are applied during the derivation of precipitation using HMR 49 or HMR 55A. When the isohyetal method

of spatial distribution is used, the full index precipitation is used without reduction, since reduction is effected by application of the isohyetal pattern.

12. Loss Function Parameters

Not all of the precipitation that falls is available to generate runoff. The primary losses to precipitation are interception, evaporation, retention, and infiltration. The first three of these are grouped, along with part of the infiltration loss, and termed "initial losses." For large, infrequent events such as the PMP, initial losses are relatively low compared to infiltration losses, and are assumed to have occurred due to antecedent rainfall prior to the start of the PMP. Therefore, initial losses are commonly neglected in evaluating PMP. Common loss characterizations include SCS curve numbers, initial/constant loss rates, exponential losses, and Green-Ampt method. Other methods are available as well. SCS curve numbers are typically used with SCS hydrograph methodology, and are not recommended for other hydrograph methods. Initial/Constant loss rate methodology is used with USBR and other unit hydrograph methods. Green-Ampt and exponential methods have not been frequently used in submittals to OSE. Parameters must be justified, both in terms of appropriateness for basin conditions (soil and vegetative cover or land use) and appropriateness with the selected transform methodology. For PMP, loss rates frequently are lower than those used with typical return frequency storms such as the 100-year event. Constant loss rates in excess of 0.5 inches/hour will require adequate supporting justification. Typical loss rates for the four SCS soil groups are as follows:

SCS Soil Group	Descriptive Characteristic	Ultimate Infiltration Rate
A	Low Runoff Potential	0.3 to 0.5 inches/hour
B	Moderate Infiltration Rate	0.15 to 0.30 inches/hour
C	Slow Infiltration Rate	0.05 to 0.15 inches/hour
D	High Runoff Potential	0 to 0.05 inches/hour

Source: USBR *Flood Hydrology Manual*, 1989, P. 112

13. Precipitation Excess

Determination of precipitation excess typically is embedded in hydrology software program, but is a straightforward step that can be assumed to be handled correctly with reputable software. The total rainfall excess must be determined and reported, in addition to instantaneous peak discharge. As a rule of thumb for General Storm PMP, rainfall excess less than 70% of total storm volume for 72-hour precipitation depth greater than 25 inches, or less than 60% of 72-hour storm volume for total precipitation depth less than 25 inches, will require justification. Loss parameters and precipitation increment size and distribution can have significant effect on rainfall excess.

14. Transform Methodology

The most common transform methodology is some sort of synthetic unit hydrograph procedure. SCS is fairly common, but may not be the best choice for PMP of extreme storms. SCS parameters are interrelated, and any deviation from the methodology (e.g. Initial-Constant loss rates rather than Curve Numbers) must be justified. The USBR *Flood Hydrology Manual* methodology is also commonly used. USBR is developed for the West, and has three regional unit hydrograph lag relationships that apply within New Mexico: "Great Plains," "Rocky

Mountains," and "Southwest Desert, Great Basin, and Colorado Plateau." Additionally, the Manual contains information for urban basins. It is important to select the correct relationship for the watershed being evaluated. Other unit hydrograph procedures include Clark's and Snyder's unit hydrographs. If these are used, parameters must be provided and justified. User-specified unit hydrographs or other relationships derived from gaging records are possible, but submittals to OSE using these methods have been rare. SCS, Clark's and Snyder's unit hydrographs are available in HEC HMS, and parameters must be provided and justified but unit hydrographs need not be provided. IF USBR methodology or other user-specified unit hydrographs are used, unit hydrograph ordinates must be provided. Kinematic Wave methodology is sometimes used, and is probably most suitable where the watershed can be conveniently be described as rectangular plane surfaces draining into lateral channels. Other distributed-model methodologies may exist or emerge, and should probably be discussed with OSE before submittal.

15. Application of Transform Methodology for Each Subbasin

For computer-based analysis, this is primarily a matter of properly configuring subbasin models and hydrologic parameters within the program.

16. Evaluation of Base Flow

In New Mexico, stream base flow is usually minimal or non-existent except in response to storm events. A possible exception might be snowmelt in mountainous regions. The USBR *Flood Hydrology Manual* discusses modeling base flow and snowmelt. If base flow in the stream will contribute significantly to the hydrograph, it should be considered, and base flow modeling assumptions documented. It may be desirable to model a token base flow if the resulting flood hydrograph will be analyzed in a program such as HEC-2 or HEC HMS for downstream water surface profiles under unsteady-flow conditions.

17. Hydrograph Combining and Routing to Determine IDF

Combining and routing is generally done by the computer model. Model input and output must be carefully scrutinized to make sure that the model is performing as intended

18. Reservoir Routing

Stage-storage information used in routing must be provided; the Rules and Regulations require this to be in elevation intervals of 1 foot. Outlet and spillway capacity rating curve or table must be developed and provided. Relying on older, previously generated rating curves without independently verifying their appropriateness is not acceptable. Spillway capacity is most frequently based on the Weir Equation, $Q = CL(H)^{1.5}$, Where Q is discharge, L is weir length perpendicular to flow, H is head on the weir typically taken as reservoir elevation minus weir elevation, and C is a discharge coefficient for the weir. The weir equation is only appropriate if flow passes through critical depth over the weir and supercritical flow will be present a sufficient distance downstream from the weir that backwater effects will not constrain flow over the weir. If supercritical flow is not assured, then a backwater analysis such as HEC-2 or HEC-RAS is needed to validate spillway capacity. Also if a significant channel exists between the weir and the reservoir, a backwater analysis is needed to confirm that the reservoir stage remains below the dam crest at the anticipated spillway capacity. Care must be exercised in selecting the coefficient C, as it is not constant with respect to flow depth and is sensitive to geometry of the

spillway crest and entrance. Textbook values for typical broad-crested and ogee weirs may not be appropriate. The most common error is to select too high of a coefficient, for example, 3.0 or 3.1 for an open-cut spillway for which 2.6 or 2.7 may be more appropriate.

19. Review of Results for Reasonableness

It is tempting to assume that if the computer program gives an answer and doesn't crash that this is the correct answer. In reality, the computer is not especially intelligent and will do exactly what you tell it to, whether this makes any sense or not. This is not just a matter of "garbage-in, garbage-out." Sometimes, parameters that are in the ballpark when taken individually can compound to skew results in one direction or another. Also, sometimes the program will perform functions not intended by the analyst, such as inappropriate reduction of precipitation for storm area, if you do not tell it exactly what you want and understand the significance of program defaults. Therefore, a review of intermediate steps and final results for reasonableness is important. Calibration of the hydrologic model for PMP is difficult since storms approaching this magnitude are rare. Calibrating against lesser storms such as the 100-year or smaller events may not be appropriate for PMP. Reasonableness of results compared to past experience with similar input parameters may be the best tool available. It is important not only to ensure that the spillway design flood is not underestimated for reasons of public safety, but also that it is not overestimated for reasons of economics. Often, the predicted flood is significantly less probable than the precipitation, which in the case of PMP already has an essentially indefinable but extremely low probability. In some cases, particularly for rehabilitation projects, this can have a substantial impact on project costs.

20. Adjustment of Model Parameters

Based on review of results for reasonableness, it may be appropriate to adjust parameters and recalculate. This will obviously be necessary if the selected spillway turns out not to be adequate for the computed flood. Sensitivity analysis with respect to critical parameters is sometimes useful in forming an opinion with regard to the appropriateness of the result.

21. Hydrologic Analysis Report

Assuming the hydrologic analysis has included the required steps previously discussed, it is important that the methods and parameters used, the results obtained, and supporting justification be documented in a coherent report. This will allow OSE staff to verify that regulatory requirements for hydrology have been satisfied and evaluate whether the proposed design adequately addresses the required design storm. A secondary, but equally important purpose is to provide documentation of methods and assumptions to assist future engineering consultants and OSE staff in understanding the basis for design and assessing adequacy and safety of the structure. Personnel can turn over rapidly, analysis methods change over time, and the structure will almost certainly outlast both the designers and their methods. The hydrology report will serve as a guidance document to help future engineers understand the analysis. As a general principle, the information submitted must be adequate to allow an independent analyst, possibly at some point in the future, to replicate the analysis with comparable results. The information must be transparent and independent of the software program used for computation. The following are some of the items required in the report and supporting documentation:

1. Identification of the hazard potential classification, and any assumptions used in determining this classification. If the classification is anything other than High, supporting documentation, potentially including breach analysis and flood studies, may be required.
2. Determination of appropriate design precipitation based on hazard potential classification and size of structure. Provide detailed analysis report if design precipitation is based on incremental damage assessment or site-specific PMP study, either of which must be discussed with OSE in advance.
3. Location map and topographic map of drainage area contributing to the dam and reservoir, with drainage boundary and total area indicated.
4. Map indicating subbasin boundaries with areas indicated, hydrograph combination points, channels for routing, etc. This may be superimposed on the topographic map described in 3. above if of suitable scale.
5. Table of relevant basin and channel characteristics to be used in the analysis as dictated by the selected analysis methodology, including flow path lengths, centroid distances, mean basin elevations, channel slope, roughness, and cross-section, etc.
6. Discussion of timing and routing parameter derivation including methods or equations used and their applicability to this particular project, example calculations, and summary tables of input data and computed parameters.
7. Narrative discussion of watershed model accompanied by schematic showing the interrelation of various components of the model.
8. Elevation-storage and elevation-discharge tables for reservoir, outlets and spillways. These should be in 1-foot increments unless the dam is very high, in which case the appropriate interval must be discussed in advance with OSE.
9. Worksheets for Local Storm and General Storm PMP derivation from HMR 49 or 55A as appropriate. For Low hazard potential dams, copies of tables from NOAA Atlas 14 website, indicating latitude and longitude of point precipitation, must be included.
10. Table of distributed precipitation increments, distribution curve and/or hyetograph illustrating graphically how precipitation is distributed, and narrative describing and justifying the methodology for distributing precipitation.
11. If spatial distribution is used, full documentation of methodology and assumptions by qualified meteorologist is required.
12. Discussion of loss methodology and documentation of derivation of parameters, tables of soil and land use areas and percentages for each subbasin, and justification of the appropriateness of the parameters and methodology in the context of the overall analysis.
13. Table or graph of precipitation excess for each increment for which excess exists, and identification of total precipitation excess in inches and percentage of rainfall.
14. Discussion of transform methodology used. Coefficients or parameters for common synthetic unit hydrograph procedures (e.g. SCS. Snyder, Clark). If other than a common synthetic unit hydrograph procedure is used, unit hydrograph ordinates must be provided.
15. Table or computer echo of input parameters, with parameters identified or notated for each subbasin, routing reach, or other element.
16. Discussion of base flow or snowmelt methodology or considerations.
17. Table of combining and routing results, supported by computer output. Results must be concurrent with model schematic discussed in 7. above.

18. Elevation-storage and elevation-discharge tables for the reservoir in 1-foot increments, and table of routed hydrograph ordinates with peak inflow to reservoir and routed peak outflow identified. Inflow and outflow hydrographs plotted on same figure of appropriate scale.
19. Discussion of reasonableness of results, including any calibration or comparison information available.
20. Discussion of any parameter adjustments or sensitivity analysis performed in order to validate or improve reasonableness of results.

Special Case – Perimeter Dams:

An increasing number of dams regulated by OSE are perimeter embankments with no contributing watershed outside of the reservoir, interior slopes, and embankment crest. These dams may include wastewater pond dams, industrial evaporation pond dams, municipal raw water storage dams, tailings dams, etc. Water or potentially mobile contents are pumped or discharged to the reservoir as part of a controlled process.

For these perimeter dams, hydrology typically is greatly simplified. The contributing area (reservoir surface, interior slopes, and crest) is determined, and the design precipitation depth is applied to this area to determine the volume contribution of the storm to the reservoir. Where the design storm is all or a percentage of the PMP, the General Storm 72-hour index precipitation should be used. Losses are neglected, and the full precipitation depth is treated as excess contributing to the reservoir. In most cases, storage for this volume of water is provided above the normal maximum water level, with additional freeboard above flood stage to satisfy the freeboard requirements of OSE Rules and Regulations. In some cases, a spillway may be designed to allow routing and discharge of some of the flood volume, thereby reducing embankment height above normal maximum water level.

In addition to water from extreme precipitation events, perimeter embankments are susceptible to misoperation, where discharge into the reservoir continues past the design maximum reservoir level and eventually overtops the embankment, resulting in failure. For this reason, perimeter embankments must be provided with an overflow section with capacity equal to or greater than the discharge capacity into the reservoir, so that misoperation or failure of reservoir controls does not lead to embankment failure.

7	Existing Dams - Service Spillway Design Flood Criteria

1.0 INTRODUCTION

1.1 General

The Department of Environmental Conservation receives many requests for detailed information about designs for dams requiring a permit under Article 15, Section 0503 of the Environmental Conservation law. This brochure has been developed by the department for the general guidance of design engineers.

These guidelines represent professional judgment of the Dam Safety Section's staff engineers. The guidelines convey sound engineering practices in an average situation. Where unusual conditions exist and the guidelines are not applicable, it is the duty of the design engineer to notify the department which will then consider deviation from the guidelines.

Since these are only general guidelines for small dam construction in an average situation, compliance will not necessarily result in approval of the application. The determination by the department of the acceptability of the design and adequacy of the plans and specifications will be made on a case-by-case basis. The primary responsibility of proper dam design shall continue to be that of the applicant.

In the administration of this law, the department is concerned with the protection of both the health, safety and welfare of the people and the conservation and protection of the natural resources of the State. (See Reference 1 and 2).

Water stored behind a dam represents potential energy which can create a hazard to life and property located downstream of the dam. At all times the risks associated with the storage of water must be minimized. This document deals with the engineering guidelines for the proper design of a dam. In order for a dam to safely fulfill its intended function, the dam must also be constructed, operated and maintained properly.

Supervision of construction or reconstruction of the dam by a licensed professional engineer is required to insure that the dam will be built according to the approved plans. See Article 15-0503, Item 5 of the New York State, Environmental Conservation Law (Reference 1).

For the proper operation and maintenance of a dam, see "An Owners Guidance Manual for the Inspection and Maintenance of Dams in New York State" (Reference 6).

1.2 Application

A permit is required if the dam:

is at least 10 feet high or

stores 1 million gallons (3.07 acre feet) or

has a drainage area of 1 square mile.

Waste surface impoundments which are large enough to meet the above mentioned criteria shall not require an Article 15 dam permit. Hazardous waste surface impoundments will continue to be regulated by the Bureau of Hazardous Waste Technology, Division of Hazardous Substances

Regulation of the Department of Environmental Conservation, under 6NYCRR-Part 373, Hazardous Waste Management Regulation. Surface impoundments which are part of an approved waste water treatment process will be regulated within a SPDES permit issued by the Division of Water.

1.3 Application Forms

Applications, including the Supplement D-1 (hydrological, hydraulic and soils information), can be obtained from and should be submitted to the Regional Permit Administrator. The addresses of the Regional Permit Administrators are shown on page 31. Detailed information on application procedures is contained in the Uniform Procedures Regulations, Part 621.

Information on all pertinent items should be given. Construction plans and specifications should be prepared in sufficient detail to enable review engineers to determine if the proposed design and construction is in compliance with department guidelines. Thorough engineering review will be given each application. The time for this review and any additional time if revisions are necessary should be a consideration in each application.

2.0 DEFINITIONS

Appurtenant works are structures or materials built and maintained in connection with dams. These can be spillways, low-level outlet works and conduits.

Auxiliary spillway is a secondary spillway designed to operate only during large floods.

Cofferdam is a temporary structure enclosing all or part of the construction area so that construction can proceed in the dry.

Conduit is an enclosed channel used to convey flows through or under a dam.

Dam is any artificial barrier and its appurtenant works constructed for the purpose of holding water or any other fluid.

Department is the Department of Environmental Conservation (DEC).

Detention/Retention Basin is any structure that functions as a dam.

Earth Dam is made by compacting excavated earth obtained from a borrow area.

Energy Dissipator is a structure constructed in a waterway which reduces the energy of fast-flowing water.

Flood Routing is the computation which is used to evaluate the interrelated effects of the inflow hydrograph, reservoir storage and spillway discharge from the reservoir.

Freeboard is the vertical distance between the design high water level and the top of the dam.

Gravity Dam is constructed of concrete and/or masonry and/or laid-up stone that relies upon its weight for stability.

Height is the vertical dimension from the downstream toe of the dam at its lowest point to the top of the dam.

Low-Level Outlet is an opening at a low level used to drain or lower the water.

Major Size Dam is at least 25 feet high and holds at least 15 acre feet of water or is at least 6 feet high and holds at least 50 acre feet of water.

Maximum Impoundment Capacity is the volume of water held when the water surface is at the top of the dam.

Probable Maximum Flood (PMF) is the flood that can be expected from the severest combination of critical meteorologic and hydrologic conditions possible for the particular region. It is the flow resulting from the PMP.

Probable Maximum Precipitation (PMP) is the maximum amount of precipitation that can be expected over a drainage basin.

Seepage Collar is built around the outside of a pipe or conduit under an embankment dam to lengthen the seepage path along the outer surface of the conduit.

Service Spillway is the principal or first-used spillway during flood flows.

Service Spillway Design Flood(SSDF) is the flow discharged through the service spillway.

Spillway is a structure which discharges flows.

Spillway Design Flood(SDF) is the largest flow that a given project is designed to pass safely.

Toe of Dam is the junction of the downstream face of a dam and the natural ground surface, also referred to as downstream toe. For an earth dam the junction of the upstream face with the ground surface is called the upstream toe.

3.0 HAZARD CLASSIFICATION

3.1 General

The height of the dam, its maximum impoundment capacity, the physical characteristics of the dam site and the location of downstream facilities should be assessed to determine the appropriate hazard classification. Applications should include the design engineer's description of downstream conditions and his judgment of potential downstream hazards presented in the form of a letter designation and a written description.

3.2 Letter Designation

Class "A": dam failure will damage nothing more than isolated farm buildings, undeveloped lands or township or country roads.

Class "B": dam failure can damage homes, main highways, minor railroads, or interrupt use or service of relatively important public utilities.

Class "C": dam failure can cause loss of life, serious damage to homes, industrial or commercial buildings, important public utilities, main highways, and railroads.

3.3 Written Description

The written description is an elaboration of the letter designation. It includes descriptions of the effect upon human life, residences, buildings, roads and highways, utilities and other facilities if the dam should fail.

4.0 DESIGN AND CONSTRUCTION DOCUMENTS

4.1 Engineer Qualifications

The design, preparation of construction plans, estimates and specifications and supervision of the construction, reconstruction or repair of all structures must be done under the direction of a professional engineer licensed to practice in New York State. (See References 1 and 7).

4.2 Design Report

A design report, submitted with the application, should include an evaluation of the foundation conditions, the hydrologic and hydraulic design and a structural stability analysis of the dam. The report should include calculations and be sufficiently detailed to accurately define the final design and proposed work as represented on the construction plans. Any deviations from the guidelines should be fully explained.

4.3 Construction Plans

Construction plans should be sufficiently detailed for department evaluation of the safety aspects of the dam. The cover sheet should include a vicinity map showing the location of the dam. The size of the plans should be not less than 18 x 24 inches and no more than 30 x 48 inches. As-built plans of the project are required upon completion of construction.

4.4 Construction Inspection

The dam's performance will largely be controlled by the care and thoroughness exercised during its construction. Undisclosed subsurface conditions way be encountered which may materially affect the design of the dam. To ensure a safe design, the designer must be able to confirm design assumptions and revise the dam design if unanticipated conditions are encountered. Construction inspection is required in order to ensure that the construction work complies with the plans mid specifications and meets standards of good workmanship. Therefore, construction inspection of a dam is required by a licensed professional engineer to monitor and evaluate conditions as they are disclosed and to observe material placement and workmanship as construction progresses.

The engineer involved in the construction of the dam work will be required to submit a periodic construction report to the Department covering the critical inspection activities for the dam's construction/reconstruction. Prior to permit issuance the applicant shall submit, for review and approval, a proposed schedule of construction inspection activities to be performed by the applicant's engineer. Upon permit issuance, the approved schedule shall be part of the required work.

4.5 Specifications

Materials specifications will be required for items incorporated in the dam project. Materials specifications including format found acceptable are those issued by the following agencies and organizations.

State: New York State Department of Transportation

Federal: COE - Corps of Engineers
SCS - Soil Conservation Service

Industry: ASTM - American Society for Testing and Materials
ACI - American Concrete Institute
AWWA - American Water Works Association
CSI - Construction Specifications Institute

5.0 HYDROLOGIC CRITERIA

5.1 Hydrologic Design Criteria

A table of hydrologic design criteria giving the spillway design flood, the service spillway design flood and minimum freeboards for various hazard classifications can be found in Table 1.

5.2 Design Flood

The National Weather Service has published data for estimating hypothetical storms ranging from the frequency-based storm to the Probable Maximum Precipitation event. For the frequency-based storms Technical Paper TP-40 (Ref 17) and TP-49 (Ref 18) will be used to determine rainfall. For the Probable Maximum Precipitation event, Hydrometeorological Report HMR-51 (Ref 16) will be used.

When using the above mentioned TP's and HMR's, the minimum storm duration will be six hours. For large drainage areas in which the time of concentration exceeds six hours, the precipitation amounts must be increased by the applicable duration adjustment.

The Soil Conservation Service (SCS) has developed Technical Release 55 (TR-55) "Urban Hydrology for Small Watersheds". TR-55 presents simplified procedures for estimating runoff and peak discharge and is an acceptable procedure for designing spillways for small watersheds. In developing TR-55 the SCS uses a storm period of 24 hours for the synthetic rainfall distribution.

Although the "rational method" (Q=CIA) is used for estimating design flows for storm drains and road culverts, it normally is not an acceptable method for determining peak discharge for the design of a dam spillway. The rational method should not be used for watershed areas larger than 200 acres because of its inaccuracy above that range. The greatest weakness of the "rational method" for predicting peak discharges lies in the difficulty of estimating the duration of storms that will produce peak flow. The greatest probability for error, both as to magnitude and understanding relates to the term "intensity" or "rate of rainfall". Although the units are inches per hour, the term does not mean the total inches of rain falling in a period of one hour. "Intensity" should be related to the time of concentration. "Intensities" would be higher for storms of short duration and would be lower for storms of longer duration.

Table I indicates that the appropriate Spillway Design Flood will be a percentage of the 100 year flood or the PMF. Therefore, in order to correctly determine the peak flow, the rainfall values used will be for the 100 year flood or the PMF and the appropriate peak discharge will be computed. After the peak discharge has been found, this value will then be multiplied by the appropriate percentages. For example a small dam in the Class "B" hazard category will have the discharge based on the

rainfall from a 100 year flood and this discharge will then be multiplied by 2.25 to obtain the peak discharge. The percentages should be applied to the discharge vllues in the final step of the calculations. It is incorrect to apply the percentages to the rainfall values.

5.3 Existing Dams - Design Flood

Existing dams that are being rehabilitated should have adequate spillway capacity to pass the following floods without overtopping:

Hazard Classification	Spillway Design Flood (SDF)
A	100 year
B	150% of 100 year
C	50% of PMF

The Service Spillway Design Flood (SSDF) for existing dams is the same as shown for the new dams on Table 1.

TABLE 1 - NEW DAMS

HYDROLOGIC DESIGN CRITERIA TABLE

HAZARD CLASSIFICATION	SIZE DAM	SPILLWAY DESIGN FLOOD (SDF)	SERVICE SPILLWAY DESIGN FLOOD (SSDF)	MINIMUM FREEBOARD (FT.)
"A"	*SMALL	100 year	5 year	1
"A"	*LARGE	150% of 100 yr.	10 year	2
"B"	SMALL	225% of 100 yr.	25 year	1
"B"	LARGE	40% of PMF	50 year	2
"C"	SMALL	50% of PMF	25 year	1
"C"	LARGE	PMF	100 year	2

*SMALL

Height of dam less than 40 feet. Storage at normal water surface less than 1000 acre feet.

*LARGE

Height at dam equal to or greater than 40 feet. Storage at normal water surface equal to or greater than 1000 acre feet.

NOTE:

Size classification will be determined by either storage or height, whichever gives the larger size category.

6.0 HYDRAULICS OF SPILLWAYS

6.1 Spillways

Spillways protect the dam from overtopping. Consideration must be given to dams and reservoirs upstream of the dam in question when designing the spillway. A dam should be provided with either a single spillway or a service spillway-auxiliary spillway combination.

6.2 Single Spillway

For a single spillway, the structure should have the capacity and the durability to handle sustained flows as well as extreme floods and be non-erodible and of a permanent-type construction. Free overall spillways, ogee spillways, drop inlet or morning glory spillways, and chute spillways are common types. An earth or grass-lined spillway is not durable under sustained flow and should not be used as a single spillway.

6.3 Criteria for a single spillway are as follows:

6.3.1 Sufficient spillway capacity should be provided to safely pass the spillway design flood with flood routing through the reservoir. (See Table 1 for spillway design flood).

6.3.2 Assuming no inflow, the spillway should have sufficient discharge capacity to evacuate 75% of the storage between the maximum design high water and the spillway crest within 48 hours.

6.3.3 The spillway will have an energy dissipater at its terminus.

6.3.4 A drop inlet or morning glory spillway, as a single spillway, is only acceptable on a Hazard Class "A" structure with a drainage area of less than 50 acres. In this case, sufficient storage capacity should be provided between the spillway crest and top of dam to contain 150% of the entire spillway design flood runoff volume.

6.4 Service Spillway - Auxiliary Spillway Combination:
In the case of the service spillway - auxiliary spillway combination, the service spillway discharges normal flows and the more frequent floods, while the auxiliary spillway functions only during extreme floods.

Service spillways must be durable under conditions of sustained flows; whereas auxiliary spillways do not. Service spillways should have sufficient capacity to pass frequent floods and thus reduce the frequency of use of the auxiliary spillway. The service spillway usually does not have sufficient capacity to pass the entire spillway design flood. Drop inlet or morning glory spillways are common types of service spillways. This type of structure will consist of a vertical inlet riser connected to a service spillway conduit with an energy

dissipator at the outlet. An auxiliary spillway is capable of handling high but short duration flows. It may be an excavated grass-lined channel if the designer is able to limit velocities to the non-erodible range for grass. It cannot carry prolonged flows because of eventual deterioration of the grass linings. For spillways which will be required to discharge flows at a high velocity, a more permanent type of material such as concrete will be required. An auxiliary spillway may be located adjacent to a dam abutment or anywhere around the rim of the reservoir. It should be located sufficiently apart from the dam to prevent erosion of any embankment materials. A spillway over the dam is not acceptable. It may either discharge back into the natural watercourse below the dam, or so long as a flood hazard is not created, into a watercourse within an adjacent drainage basin.

6.5 Criteria for an auxiliary spillway-service spillway combination are as follows:

6.5.1 Sufficient service spillway capacity should be provided to safely pass the service spillway design flood with flood routing through the reservoir. (See Table 1 for service spillway design flood).

6.5.2 The service spillway normally should be provided with an energy dissipater at its outlet end.

6.5.3 The auxiliary spillway crest must be placed at or above the service spillway design high water, and not less than 1 foot above the service spillway crest.

6.5.4 The auxiliary spillway-service spillway combination must provide sufficient discharge capacity to safely pass the spillway design flood with flood routing through the reservoir (See Table 1 for spillway design flood).

6.5.5 Assuming no inflow, the auxiliary spillway-service spillway combination should have sufficient capacity to evacuate the storage between the maximum design high water and the auxiliary spillway crest within 12 hours.

6.5.6 Assuming no inflow, the service spillway should have sufficient capacity to evacuate 75% of the storage between the auxiliary spillway crest and the service spillway crest within 7 days.

6.5.7 Auxiliary spillways shall not be placed on fill.

6.5.8 Velocities in auxiliary spillways should not exceed the maximum permissible velocities (non-erodible velocities) of the spillway materials.

6.5.9 If an auxiliary spillway is located near an embankment,it should be located so as not to endanger the stability of the embankment. The following criteria will help guard against damage to the embankment:

a. Discharge leaving the exit channel should be directed away from the embankment and should be returned to a natural watercourse far enough downstream as to have no erosive effect on the embankment toe.

b. The spillway exit channel, from the spillway crest to a section beyond the downstream toe of dam, should be uniform in cross-section, contain no bends, and be longitudinally perpendicular to the spillway crest. Curvature may be introduced below the toe of dam if it is certain that the flowing water will not impinge on the toe of dam.

6.0 A FLASHBOARD POLICY

Background

Flashboards are used to raise the water surface of an impoundment. However, the installation of flashboards along the crest of a spillway may permanently reduce the size of the spillway opening. Our records indicate that in some instances the reduction of spillway capacity with the installation of flashboards has resulted in overtopping and subsequent dam failure. Two examples are the Tillson Lake Dam (#1942420) in Ulster County and the Lake Algonquin Dam (#171-2700) in Hamilton County.

In 1939 flashboards were placed across the spillway of the 40 foot high Tillson Lake Dam in such a manner as to greatly reduce the spillway opening. Storm flow caused dam overtopping which eroded the earth slope in front of the 100 foot wide, 30 foot high concrete core wall. Failure of the core wall resulted in a tremendous amount of erosion to farm land, loss of farm machinery, chickens, several local bridges and basement flooding. The dam was rebuilt and failed in 1955 because flashboards were again in place and did not fail during storm flow.

In 1949 the Lake Algonquin Dam failed because flashboards were not removed for the winter. A January storm caused overtopping and subsequent dam failure at the right abutment. The dam failure resulted in the loss of a home, several farm buildings and a road.

When wood flashboards are installed properly they will be

supported by steel pins. These steel pins will be designed to fail when the depth of flow over the top of the flashboards reaches a certain level. Critical to the design of the flashboard system are the diameter of the steel pin, the ultimate strength of the steel and the spacing of the pins. In very few cases is the Consulting Engineer or Contractor who designed the flashboards able to provide sufficient quality control to ascertain that the as-built condition is similar to the design proposal.

Many field maintenance personnel do not understand the need for flashboards to fail when the depth of flow over the flashboards reaches a certain level. Therefore, there is a tendency to insert the flashboards in such a manner so that they will never fail, thus permanently reducing spillway capacity and increasing the possibility of dam failure by overtopping. This is what nearly happened at the Gore Mountain Dam at North Creek. During the period of 1977-1980 DEC operations personnel installed wide flange beams to support the wood flashboards. The approved design for the flashboard supports were one inch diameter steel pins. However, operations personnel decided they would have less maintenance problems if they permanently secured the wood flashboards between the six inch wide flange beams. Under this support the flashboards would never fail.

Around February 15, 1981 a sudden thaw and rain caused the water level at Gore Mountain Dam to rise within eight inches of the top of dam. This level was about two feet, four inches over the top of the flashboards. The extra sturdy wide flange beam support system precluded any chance of flashboard failure. Fortunately this abnormally high level was reported to the DEC by a local resident while he was snowmobiling. During the fall of 1981, DEC revised the flashboard support system so that the flashboards were properly supported by one inch diameter steel pins and the steel pins would fail in bending when the depth of flow over the top of the flashboards reached one foot.

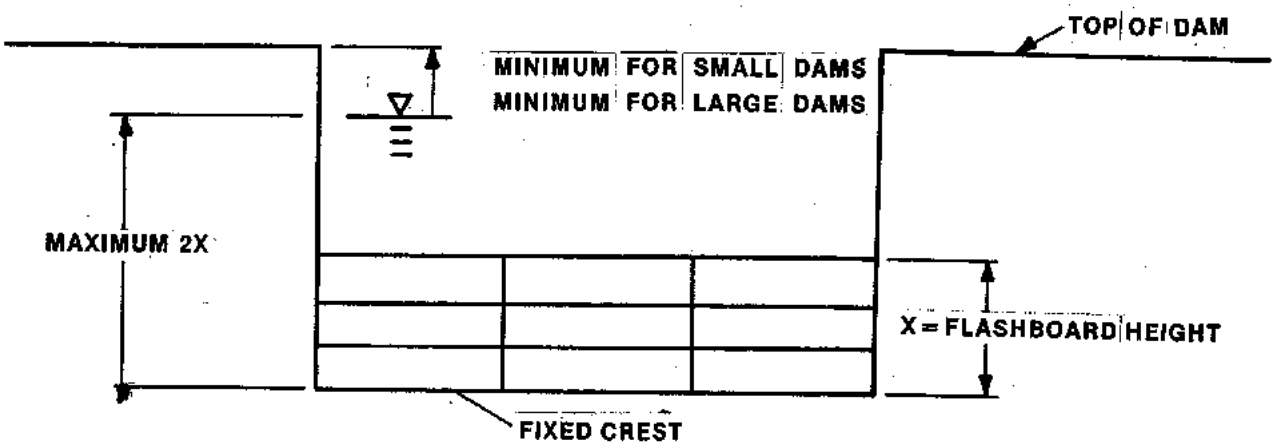
For the foregoing reasons the Dam Safety Section has developed the following policy regarding the installation of flashboards on dams.

New Dams

Flashboards shall not be installed on any new dams. The dam owner or hydroelectric developer shall determine the normal pool elevation for the proposed impoundment and provide a permanently fixed spillway crest at the selected elevation. If pool elevation fluctuations are desired, they should be achieved by means of adequately sized gates, drains, siphons or other acceptable methods.

Existing Dams

A permanently fixed spillway crest is the preferred method of establishing normal pool elevation.



The installation or continued use of flashboards on existing dams will be considered on a case by case basis. Flashboards on existing dams will only be acceptable if the dam is able to satisfy the hydraulic and structural stability criteria contained in the Guidelines for Design of Dams. If the flashboards are designed to fail in order to satisfy either criterion, detailed failure calculations must be submitted for Department review and approval. The maximum pool elevation the flashboards are designed to fail at shall be the lower of:

1. Two times the height of the flashboards measured from the bottom of the flashboards, or

2. Two times the freeboard specified in Table 1 of these Guidelines, for a dam of the pertinent size and hazard classification, measured downward from the top of dam.

The maximum pool elevation that would be reached under Spillway Design Flood conditions, without the flashboards failing, shall also be determined.

Flashboards shall be installed, operated and maintained as intended in their design and in accordance with the terms and/or conditions of any permits or approvals. The approved flashboard configuration (pin spacing, pin size, board height, board size, etc.) shall not be modified without prior Department approval.

7.0 OUTLET WORKS AND CONDUITS

7.1 Outlet Works

A low-level outlet conduit or drain is required for emptying or lowering the water in case of emergency; for inspection and maintenance of the dam, reservoir, and appurtenances; and for releasing waters to meet downstream water requirements. The outlet conduit may be an independent pipe or it may be connected to the service spillway conduit. The low level drain is required to have sufficient capacity to discharge 90% of the storage below the lowest spillway crest within 14 days, assuming no inflow into the reservoir.

7.2 Control

Outlet conduits shall have an upstream control device (gate or valve) capable of controlling the discharge for all ranges of flow.

7.3 Conduits

Only two types of conduits are permitted on Hazard Class "B" and "C" structures; precast reinforced concrete pipe and cast-in-place reinforced concrete.

On Hazard Class "A" structures, welded steel pipe or corrugated metal pipe may be used providing the depth of fill over the pipe does not exceed 15 feet and the pipe diameter does not exceed 24 inches.

All outlet conduits shall be designed for internal pressure equal to the full reservoir head and for the superimposed embankment loads, acting separately.

The minimum size diameter conduit used as the barrel of a drop inlet service spillway shall be 12 inches.

The joints of all pipe conduits shall be made watertight.

Any pipe or conduit passing through an embankment shall have features constructed into the embankment whereby seepage occurring along the pipe or conduit is collected and safely conveyed to the downstream toe of the embankment. This can be accomplished by using a properly designed and constructed filter and drainage diaphragm. The filter and drainage diaphragm will be required unless it can be shown that antiseep collars will adequately serve the purpose.

Antiseep collars will not be permitted for dams with a height in excess of 20 feet. If antiseep, collars are used in lieu of a

drainage diaphragm, they shall have a watertight connection to the pipe. Collar material shall be compatible with pipe materials. The antiseep collars shall increase the seepage path along the pipe by at least 15%.

A means of dissipating energy shall be provided at the outlet end of all conduits 12 inches or more in diameter. If a plunge pool is used, the conduit should be cantilevered 8 feet over a concrete, steel or treated timber support located near or at the downstream toe of the embankment. The plunge pool should be riprap-lined if a conduit 18 inches or more in diameter is used. The foregoing may apply to smaller pipes if the embankment's downstream slope is steep and the soil erodible.

8.0 GEOTECHNICAL INVESTIGATION

8.1 Foundations

8.1.1 Subsurface explorations (drill holes, test pits and/or auger holes) should be located along the centerline of the dam, at the proposed service and auxiliary spillway locations, and in other critical areas. The depth of the subsurface explorations should be sufficient to locate and determine the extent and properties of all soil and rock strata that could affect the performance of the dam, the reservoir and appurtenant structures. Referring to information such as geologic bulletins, soil survey maps, groundwater resources bulletins, etc., may aid the designer in determining the scope of the exploration program needed and interpreting the results of the program. For even the smallest low hazard dams, at least three explorations should be made along the centerline of the dam, one in the deepest part of the depression across which the dam will be built and one on each side. At least one exploration should be made at the proposed auxiliary spillway location. For small low-hazard dams, to be built on a foundation known from the geology of the area to be essentially incompressible and impervious to a great depth, the minimum depth of explorations should be 5 feet unless bedrock is encountered above this depth. In other cases the minimum depth of explorations should be 10 feet, with one or more borings extending to a depth equal to the proposed height of the dam. If it is proposed to excavate in the reservoir area, the possibility of exposing pervious foundation layers should be investigated by explorations or a review of the geology of the area. If rock is encountered in explorations, acceptable procedures, such as coring, test pits, or geologic information, should be used to verify whether or not it is bedrock.

8.1.2 Sufficient subsurface explorations should be made to verify the suitability of encountered rock for use as a foundation

and/or construction material. Testing of the rock materials shall ascertain its strength, compressibility, and resistance to degradation, and its ability to safely withstand the loads expected to be imposed upon it by the proposed project.

8.1.3 Soils encountered in explorations should be described accurately and preferably classified in accordance with the Unified Soil Classification System.

8.1.4 For Hazard Class "C" dams, appropriate field and/or laboratory tests should be performed in order to aid in evaluating the strength, compressibility, permeability, and erosion resistance of the foundation soils. Also, appropriate laboratory tests should be performed on samples of the proposed embankment materials in order to ascertain their suitability for use in the dam. Field and/or laboratory tests may be required also for dams of lower hazard classification in the case of critical foundation strength or permeability conditions.

8.1.5 Stability of the foundation under all operating conditions should be evaluated.

8.1.6 Settlement of the dam and appurtenant works should be evaluated and provisions made in the design to counteract the effects of any anticipated settlements.

8.1.7 Whenever feasible, seepage under the dam should be controlled by means of a complete cutoff trench extending through all pervious foundation soils into a relatively impervious soil layer. If the dam is to be built on an impervious foundation, the cutoff or key trench should be excavated to a depth of at least 3 feet into the foundation soils and backfilled with compacted embankment material. Where the final depth of cutoff cannot be established with certainty during design, a note should appear on the plans stating that the final depth of the cutoff trench will be determined by the engineer during the time of construction. Backfilling of the cutoff or key trench should be performed in the dry, unless special construction procedures are used. The bottom width of the trench should be at least 8 feet and should be increased in the case of dams more than 20 feet high. The widths of complete cutoffs my be made considerably less if the cutoff is extended vertically a minimum distance of 4 feet into impervious material. In the case of a cutoff or key trench extending to bedrock, the trench does not have to extend into rock. However, all shattered and disintegrated rock should be removed and surface fissures filled with cement grout. The need for pressure grouting rock foundations should be evaluated and, if necessary, adequately provided for.

8.2 Borrow Sources for Embankment Materials

Sufficient subsurface explorations should be made in borrow areas to verify the suitability and availability of an adequate supply of borrow materials. Logs of explorations should be included for review with the plans and specifications. Exposure of pervious soils and fissured rock below normal water surface of the proposed pond, at borrow areas located in or connected to the reservoir area, should be avoided.

If pervious soils or fissured rock conditions are encountered during borrow operations these exposed areas should be sealed with a sufficient thickness of compacted impervious material. In no case should this seal be less than two feet thick and consideration should be given to utilizing a greater thickness where site conditions and hazard classifications dictate.

Borrow areas should be located with due consideration to the future safety of the dam and should be shown on the plans. In general, no borrow should be taken within a distance measured from the upstream toe of the dam equal to twice the height of the dam or 25 feet, whichever is greater.

9.0 EARTH DAMS

9.1 Geometry

9.1.1 The downstream slope of earth dams without seepage control measures should be no steeper than 1 vertical on 3 horizontal. If seepage control measures are provided, the downstream slope should be no steeper than 1 vertical on 2 horizontal.

9.1.2 The upstream slope of earth dams should be no steeper than 1 vertical on 3 horizontal.

9.1.3 The side slopes of homogenous earth dams may have to be made flatter based on the results of design analyses or if the embankment material consists of fine grained plastic soils such as CL, MH or CH soils as described by the Unified Soil Classification System.

9.1.4 The minimum allowable top width (W) of the embankment shall be the greater dimension of 10 feet or W, as calculated by the following formula:

$W = 0.2H + 7$; where H is the height of the embankment (in feet)

9.1.5 The top of the dam should be sloped to promote drainage and minimize surface infiltrations and should be cambered so that the design freeboard is maintained after post-construction settlement takes place.

9.2 Slope Stability

Where warranted and especially for new Hazard Class "C" dams, the department may require that slope stability analyses be provided for review. The method of analyses and appropriate factors of safety for the applicable loading conditions shall be as indicated by U. S. Army Corps of Engineers publications (latest edition) (Ref. 11).

Earth dams, in general, should have seepage control measures, such as interior drainage trenches, downstream pervious zones, or drainage blankets in order to keep the line of seepage from emerging on the downstream slope, and to control foundation seepage. Hazard Class "A" dams less than 20 feet in height and Hazard Class "B" dams less than 10 feet in height, if constructed on and of erosion-resistant materials, do not require special measures to control seepage.

In zoned embankments, consideration should be given to the relative permeability and gradation of embankment materials. No particle greater in size than six inches in maximum dimension should be allowed to be placed in the impervious zone of the dam.

9.3 Compaction Control and Specifications

Before compaction begins, the embankment material should be spread in lifts or layers having a thickness appropriate to the type of compaction equipment used. The maximum permissible layer thickness should be specified in the plans or specifications.

Specifications should require that the ground surface under the proposed dam be stripped of all vegetation, organic and otherwise objectionable materials. After stripping, the earth foundation should be moistened, if dry, and be compacted before placement of the first layer of embankment material. Inclusion of vegetation, organic material, or frozen soil in the embankment, as well as placing of embankment material on a frozen surface is prohibited and should be so stated in the specifications.

For all dams, compaction shall be accomplished by appropriate equipment designed specifically for compaction. The type of compaction equipment should be specified in the plans or specifications.

The degree of compaction should be specified either as a minimum number of complete coverages of each layer by the compaction equipment or, in the case of higher or more critical dams, based on standard ASTM test methods.

When the degree of compaction is specified as a number of complete coverages or passes, the final number of passes required shall be determined by the engineer during construction.

In order to insure that the embankment material is compacted at an appropriate moisture content, a method of moisture content control should be specified. For Hazard Class "A" dams less than 20 feet high, the moisture content may be controlled visually by a qualified inspector. Hand tamping should be permitted only in bedding pipes passing through the dam. All other compaction adjacent to structures should be accomplished by means of manually directed power tampers.

Backfill around conduits should be placed in layers not thicker than 4 inches before compaction with particle size limited to 3 inches in greatest dimension and compacted to a density equal to that of the adjacent portion of the dam embankment regardless of compaction equipment used.

Care should be exercised in placing and compacting fill adjacent to structures to allow the structures to assume the loads from the fill gradually and uniformly. Fill adjacent to structures shall be increased at approximately the same rate on all sides of the structures.

The engineer in charge of construction is required to provide thorough and continuous testing to insure that the specified density is achieved.

9.4 VEGETATION CONTROL - TREES AND BRUSH

9.4.1 Trees and Brush

Trees and brush are not permitted on earth dams because:

a. Extensive root systems can provide seepage paths for water.

b. Trees that blow down or fall over can leave large holes in the embankment surface that will weaken the embankment and can lead to increased erosion.

c. Brush obscures the surface limiting visual inspection, provides a haven for burrowing animals and retards growth for grass vegetation.

Stumps of cut trees should be removed so grass vegetation can be established and the surface mowed. Stumps should be removed either by pulling or with machines that grind them down. All woody material should be removed to about 6 inches below the ground surface. The cavity should be filled with well compacted soil and grass vegetation established.

9.4.2 Grass Vegetation

Grass vegetation is an effective and inexpensive way to prevent erosion of embankment surfaces. It also enhances the appearance of the dam and provides a surface that can be easily inspected.

10.0 STRUCTURAL STABILITY CRITERIA FOR GRAVITY DAMS

10.1 Application

These guidelines are to be used for the structural stability analysis of concrete and/or masonry sections which form the spillway or non-overflow section of gravity dams.

These guidelines are based on the "Gravity Method of Stress and Stability Analysis" as indicated in Reference 13.

If the gravity dam has keyed or grouted transverse contraction joints, then the "Trial-Load Twist Method of Analysis" (Reference 13) may be used for the stability analysis.

Elastic techniques, such as the finite element method, my be used to investigate areas of maximum stress in the gravity dam or the foundation. However, the finite element method will only be permitted as a supplement to the Gravity Method. The Gravity Method will be required for the investigation of sliding and overturning of the structure.

10.2 Non-Gravity Dams

For non-gravity structures such as arch dams, the designer is required to present calculations based on appropriate elastic techniques as approved by the Dam Safety Section.

10.3 Loads

Loads to be considered in stability analyses are those due to: external water pressure, internal water pressure (pore pressure or uplift) in the dam and foundation, silt pressure, ice pressure, earthquake, weight of the structure.

10.4 Uplift

Hydrostatic uplift pressure from reservoir water and tailwater act on the dam. The distribution of pressure through a section of the dam is assumed to vary linearly from full hydrostatic head at the upstream face of the dam to tailwater pressure at the downstream face or zero if there is no tailwater. Reduction in the uplift pressures might be allowed in the following instances:

10.4.1 When foundation drains are in place. The efficiency of the drains will have to be verified through piezometer readings.

10.4.2 When a detailed flow net analysis has been performed and indicates that a reduction in uplift pressures is appropriate. Any reduction of pressure of more than 20% must be verified by borings and piezometer readings.

10.4.3 When a sufficient number of borings have been progressed and piezometer readings support the fact that actual uplift pressures are less than the theoretical uplift pressures.

10.5 Loading Conditions

Loading Conditions to be analyzed.

Case 1 - Normal loading condition; water surface at normal reservoir level.

Case 2 - Normal loading condition; water surface at normal reservoir level plus an ice load of 5,000 pounds per linear foot, where ice load is applicable. Dams located in more northerly climates, may require a greater ice load.

Case 3 - Design loading condition; water surface at spillway design flood level.

Case 3A- Maximum hydrostatic loading condition; maximum differential head between headwater and tailwater levels as determined by storms smaller in magnitude than the spillway design flood. This loading condition will only be considered when the is submerged under Case 3 loading condition.

Case 4 - Seismic loading condition; water surface at normal reservoir level plus a seismic coefficient applicable to the location.

10.6 Stability Analysis for New Dams

10.6.1 Field Investigation

Subsurface investigations should be conducted for new dams. Borings should be made along the axis of the dam to determine the depth to bedrock as well as the character of the rock and soils under the dam. The number and depth of holes required should be determined by the design engineer based on the complexity of geological conditions. The depth of holes should be at least equal to the height of the dam. Soil samples and rock cores should be collected to permit laboratory testing. The values of cohesion and internal friction of the foundation material should be determined by laboratory testing.

On proposed sites where the foundation bedrock is exposed, the requirements for borings may be waived in some cases. An engineering geologist's professional opinion of the rock quality and the acceptability of the design assumptions will be required in those cases.

10.6.2 Overturning

The resultant force from an overturning analysis should be in the middle third of the base for all loading conditions, except for the seismic analysis (Case 4), where the resultant shall fall within the limits of the base.

10.6.3 Cracking

The resultant force falling outside the middle third of the base and its resulting tension cracks will not be accepted in the design of new dams, except for the seismic loading condition (Case 4).

10.6.4 Sliding

Sliding safety factors may be computed using the Shear-Friction method of analysis when shear values are based on either the results of laboratory testing or an engineering geologist's professional opinion. When the Shear-Friction method is used, the structure should have a minimum safety factor of 2.0 for all loading conditions except for Case 4 (seismic loading) where the minimum acceptable sliding safety factor shall be 1.5.

Designs which are not based on laboratory testing or an engineering geologist's professional opinion must be analyzed using the Friction Factor of Safety. This analysis assumes that the value of shear or cohesion is zero. The minimum safety factor using this method should be 1.5 for all loading conditions except Case 4 where the minimum safety factor shall be 1.25.

10.7 Stability Analysis for Existing Dams

10.7.1 Field Investigations

Subsurface investigations should normally be conducted as part of a detailed structural stability investigation for an existing dam and should provide information regarding the materials of the dam and its foundation. The number and depth of holes required should be determined by the engineer based on the complexity of the composition of the dam and foundation. Samples should be collected and tested to determine the material properties. The program should also measure the uplift pressures at several locations along the base of the dam.

In cases where no subsurface investigations are conducted conservative assumptions regarding material properties and uplift pressures will be required.

10.7.2 Overturning

The resultant force from an overturning analysis should be in the middle third of the base for normal loading conditions (Case 1) and within the middle half of the base for the ice loading condition (Case 2) and the spillway design flood loading condition (Case 3). For the seismic loading condition (Case 4), the resultant force should fall within the limits of the base.

10.7.3 Cracking

If the overturning analysis indicates that the resultant force is outside the middle third, then tension exists at the heel of the dam which may result in the cracking of the concrete. For existing dams cracking will be permitted for all loading conditions except the normal loading condition (Case 1). If the criteria specified above in Overturning for the location of the resultant force are not satisfied, further study and/or remedial work will be required. The Bureau of Reclamation's Cracked Section Method of analysis is acceptable for investigating the stability of the dam for the above mentioned loading conditions. When the Cracked Section Method of analysis is used, the criteria for the minimum sliding factor of safety will have to be satisfied.

10.7.4 Sliding

Sliding safety factors may be computed using the Shear-Friction method of analysis when shear values are based on the results of laboratory testing of samples from subsurface investigations. When the Shear-Friction method is used, the structure should have a minimum safety factor of 2. 0 for Case 1 and Case 2; a value of 1.5 for Case 3 and a value of 1.25 for Case 4.

If no subsurface explorations are performed, the sliding safety factors must be computed using the Friction Factor of Safety. The minimum safety factor using this method should be 1.5 for Case 1; a value of 1.25 for Case 2 and Case 3; and a value of 1.0 for Case 4.

11.0 EXISTING DAMS: REHABILITATION AND MODIFICATION

Additional data should be submitted for dam rehabilitations or dam modifications, including a report by a professional engineer describing the performance and maintenance history of the existing dam. In addition, all data regarding construction, such as existing subsurface explorations, construction materials used for the dam, and plans and specifications should be submitted. If this information is not available, the engineer should inspect and evaluate the structure as to its condition, performance, maintenance history and other information regarding foundation soils and existing conditions.

The engineer should also assess the safety and adequacy of the existing structure against those criteria for spillway capacity and structural stability, indicated in the appropriate sections of these guidelines.

Where a new embankment is to be constructed against an existing dam embankment, the existing slope shall be benched as the new fill is spread and compacted in layers as described in the plans and specifications. This benching is done to provide an interlock between the existing and new embankments. Benching shall not be done in the upstream-downstream direction.

All topsoil and sod shall be stripped from the surface of the existing embankment before placing new material within the area of reconstruction.

Remove or seal all existing drainage structures which are not to be operative in the proposed design, in order to prevent a plane of seepage from developing through the dam.

12.0 COFFERDAMS

A cofferdam in most cases is a temporary structure enclosing all or part of the construction area. The purpose of the cofferdam is to provide protection so that construction can proceed in the dry.

12.1 When using a cofferdam the following criteria must be met:

12.1.1 Flood Plain Management

A hydraulic analysis must be performed to determine the backwater effect of the cofferdam. A range of flood discharges up to and including the 100 year return frequency flood shall be evaluated to determine the potential flood damages to lands and improvements upstream of the cofferdam not owned or otherwise controlled by the applicant. The analysis shall focus on determining if the project meets the flood plain management criteria of 6NYCRR-Part 500, if applicable, or regulations adopted by the local jurisdiction for participation in the National Flood Insurance Program.

12.1.2 Dam Safety

The applicant will have to demonstrate that cofferdam failure will not adversely impact lives and property. The evaluation will focus on the potential for flooding, loss of life and damage to properties downstream of the cofferdam not owned or otherwise controlled by the applicant.

If cofferdam failure could adversely impact properties downstream of the cofferdam, not controlled by the applicant, or if the cofferdam failure could adversely impact lives, then more specific information regarding the geotechnical, structural and hydraulic aspects of the cofferdam design will be required. The determination by the department of the acceptability of the cofferdam design will be made on a case-by-case basis.

13.0 MISCELLANEOUS

The earth embankment, earth spillways, and all disturbed earth adjacent to the embankment or other appurtenances should be seeded, except where riprap or other slope protective materials are specified.

Where destructive wave action is expected, the upstream slope of the embankment should be protected with rock riprap or other suitable material for effective erosion control.

A trash rack designed to prevent debris from entering and obstructing flow in the conduit should be provided on the vertical riser for any drop inlet spillway.

An anti-vortex device is required on the vertical riser for any drop inlet spillway with riser diameter greater than 12 inches.

Instrumentation

1.Piezometers - All earth dams 40 feet high or higher shall have at least two piezometers on the downstream slope of the embankment to measure saturation levels and hydrostatic pressures. All concrete dams 40 feet or higher should have at least two piezometers along the crest of the dam.

2.Weirs - on all dams with toe drains, weirs are required at the downstream end of the drain. The weirs measure the amount of seepage water through the embankment. Measurements of the seepage should be documented and correlated with the reservoir surface elevation. See Reference 6, pages 55-56.

14.0 EMERGENCY ACTION PLAN

An emergency action plan (EAP) should be developed by the owner of a high hazard dam (Class "C").

A copy of this EAP is to be provided to the Dam Safety Section of the department during the initial permit review period for new dams and for existing dams, if a copy of the EAP has not been previously submitted. See Reference 6, pages 69-73.

15.0 APPROVAL TO FILL RESERVOIR OF A NEW DAM

Before any water can be impounded by the dam, the dam owner shall adhere to the following:

15.1 For all Hazard Class "C" and [major size] Hazard Class "B" dams.

Within two weeks after completion of dam construction the permittee shall notify the Regional Permit Administrator in writing by certified mail of its completion and shall include a notarized statement from the owner's engineer that the project has been completely constructed under his care and supervision in accordance with plans and specifications as approved by the department. Any changes in the construction of the dam from the approved plans will be reflected in the "As-Built" plans.

The department will inspect the completed dam with the owner's engineer. During the inspection, the owner's engineer will submit "As Built" drawings and other construction records for review, such as foundation data and geological features, properties of embankment and foundation materials, concrete properties and construction history. Upon review of the data and the determination of the adequacy of the structure the "Approval to Fill" letter will be issued, permitting the owner to store water.

15.2 For all Hazard Class "A" and [Below Major Size] Hazard Class "B" dams.

Within two weeks after completion of dam construction the permittee shall notify the Regional Permit Administrator in writing by certified mail of its completion and shall include a notarized statement from the owner's engineer stating that the project has been completely constructed under his care and supervision in accordance with plans and specifications as approved by the department. Any changes in the construction of the dam from the approved plans will be reflected in the "As-Built" plans that will be submitted to the Department.

No water shall be impounded for at least 15 days subsequent to the notification to the Regional Permit Administrator.

DOW 3.1.4 – GUIDANCE FOR
DAM ENGINEERING ASSESSMENT REPORTS

New York State Department of Environmental Conservation

DEC Program Policy

Issuing Authority: Mark Klotz	**Title:** GUIDANCE FOR DAM ENGINEERING ASSESSMENT
Date Issued:	**Latest Date Revised: New**
Originator: Alon Dominitz – Dam Safety Section	

***** N O T I C E *****

This document has been developed to provide Department staff with guidance on how to ensure compliance with statutory and regulatory requirements, including case law interpretations, and to provide consistent treatment of similar situations. This document may also be used by the public to gain technical guidance and insight regarding how the department staff may analyze an issue and factors in their consideration of particular facts and circumstances. This guidance document is not a fixed rule under the State Administrative Procedure Act section 102(2)(a)(I). Furthermore, nothing set forth herein prevents staff from varying from this guidance as the specific facts and circumstances may dictate, provided staff's actions comply with applicable statutory and regulatory requirements. This document does not create any enforceable rights for the benefit of any party.

Preliminary DRAFT

Table of Contents

I. Summary: 1
II. Policy: 1
III. Purpose and Background: 2
IV. Responsibility: 2
V. Procedure: 2
VI. Related References: 7

I. Summary:

Title 6 of New York Rules and Regulations, Part 673.13 ("Part 673.13") requires the preparation of an Engineering Assessment Report, which must be submitted to the New York State Department of Environmental Conservation ("Department").

This policy provides guidance to dam owners and engineers on the preparation of, and DEC staff on the review of, Engineering Assessment Reports pursuant to Part 673.13.

II. Policy:

The life-cycle of a dam consists of several phases, starting with construction and initial filling and transitioning to alternating periods of normal operation and maintenance, repairs, and upgrades. This cycle continues until the dam is breached or removed, or fails. For a dam to continue to serve its intended function, it must be maintained. As conditions change over time, repairs and perhaps reconstruction and/ or upgrade of the dam, for example increasing the spillway capacity, may become necessary.

A dam is a part of a dynamic system, with various forces continuously acting upon it, such as ice, flooding, earthquakes, erosion, animal burrowing, woody root penetration, and sediment accumulation. Downstream developments can affect the hazard class of a dam, upstream developments can change the way the watershed behaves during runoff events, and science and technology evolve to modify best practices and regulatory criteria over time.

The release of water stored by a dam in an uncontrolled manner represents a potential danger to downstream lives, property and the environment. As such, the dam owner must develop and implement a dam safety program. Part 673 requires that an owner's dam safety program that is appropriate to the dam's hazard classification. Those for Class C (High Hazard) or Class B (Intermediate Hazard) dams consist of periodic safety inspections and engineering assessments, along with an Inspection and Maintenance Plan ("I&M Plan") and an Emergency Action Plan ("EAP"). An I&M Plan template is available on the Department's web site. Requirements for the preparation of an EAP are described in the Department's publication "DOW 3.1.3 – Emergency Action Plans for Dams". Periodic safety inspections and engineering assessments are intended to provide an independent review of an existing structure and the owner's dam safety program, identify any deficiencies or gaps in knowledge, and determine the steps and schedule necessary to correct the deficiencies.

When deficiencies are identified, the dam owner must categorize them either as issues that can be resolved through regular or enhanced maintenance, or whether repairs and/or upgrades are required. Conditions requiring additional or continued monitoring should also be identified. Maintenance is work involved in the routine or regular upkeep of a dam, and includes, for example, debris removal, mowing grass, cleaning trash racks, and exercising valves. Repairs or upgrades generally consist of more extensive or intrusive work, which if performed improperly could endanger the structure, and therefore must be performed under the supervision of a professional engineer ("PE"), in accordance with a formal design, and require a dam safety permit issued by the Department through its Division of Environmental Permits, in pursuant to Parts 608 and 621. Although maintenance does not require a Dam Safety permit, it could require other types of permits, such as a Construction Stormwater permit, from the DEC.

Safety inspections and engineering assessments include many of the components that would be required as part of a permit application for repair or upgrading of the dam. The difference is that regular inspections and assessments are an evaluation of the *existing* structure against current dam safety criteria, whereas the Engineering Design Report, plans and specifications required for a permit must evaluate the *proposed* repairs and/or upgrades to the structure. In either case, the dam and appurtenant structures should be considered as part of an integrated system, and must function together to safely fulfill their water impounding function.

III. Purpose and Background:

It is the purpose of this guidance to inform owners, engineers, and DEC staff regarding the procedures, content, and format for dam safety engineering assessment reports as required by 6NYCRR Part 673.

Part 673 requires owners of Hazard Class B (Intermediate Hazard) and Class C (High Hazard) dams, and, at the Department's discretion, dams assigned a Condition Rating of Unsafe or Unsound, to perform an Engineering Assessment of their dam on a regular basis.

This guidance represents the professional judgment of the Department's Dam Safety Section's engineers. The guidance is applicable for the average dam in an average situation. Where unusual conditions exist, it is the duty of the dam owner's engineer to highlight any deviation from the Department's guidance and provide the specific engineering rationale for said deviation. Cost alone is not an acceptable rationale.

IV. Responsibility:

The dam safety program within the Bureau of Flood Protection and Dam Safety will interpret and maintain this policy.

V. Procedure:

The Engineering Assessment Report must, at a minimum, include the following:

1. Hazard classification evaluation
2. Complete Safety Inspection
3. Evaluation of the dam's spillway capacity
4. Evaluation of the dam's structural stability
5. Evaluate Outlet works (reservoir drain) capacity
6. Review of the dam's Emergency Action Plan, and
7. Provide a conclusion as to whether the dam is in conformance with current dam regulations and safety guidance.

The tasks normally associated with performing a dam safety Engineering Assessment can be divided as follows:

A. File review
B. On-site Engineering Inspection and Investigation

C. Engineering review, calculations, and conclusions
D. Engineering Assessment Report Generation
E. File report with Department and retain a copy with owner's records

The assessment should determine the condition of the dam relative to the appropriate safety criteria. It should identify deficiencies and recommend, as appropriate, remedial repairs, operational restrictions, monitoring, and/or modifications. The assessment should also identify any analyses and/or studies needed to assess and determine solutions to identified deficiencies.

The engineering assessment must be performed by a professional engineer registered to practice in New York State and possessing appropriate experience in evaluation of dams of type, size, and location to be assessed. The dam Engineering Assessment Report must be submitted to the Department in accordance with the schedule detailed in Part 673.13. The owner must retain a copy of the dam Engineering Assessment Report with their records of the dam.

A. Records Review

Perform a review of existing dam information. The engineer must analyze the dam's design, construction, and operational records to become fully acquainted with the present physical features as well as construction and performance history of the dam.

An owner may have a recently performed engineering assessment of the dam. At the owner's and engineer's option, the engineer may review the report for applicability to current standards and safety criteria and adopt all or parts of past reports. If an engineer does accept the analysis in any previous report, the engineer must state that the report's assumptions, analyses, or other accepted components have been reviewed and are acceptable to demonstrate compliance with selected criteria (as applicable). The engineer or owner may also choose to disregard previous assessments and perform a completely new assessment.

There may be multiple information sources, including, but not limited to, the following:

<u>Owner's Dam File:</u>

The owner should have a file for the dam that might contain dam design information and various reports generated when the dam was designed or rebuilt; hydrology, hydraulics, geology, inspections, etc. Operational records, if available, may contain vital information that should be reviewed in detail. The review should include review of the existing I&M Plan, results of past inspections, and maintenance work completed and/or planned. Finally, this part of the review should include a review of the dam's Emergency Action Plan, with particular attention to the inundation map. Part 673, effective August 19, 2010, requires the owner to retain pertinent records on a dam, and authorizes DEC to inspect those records.

<u>Department's Dam Safety File:</u>

The Department maintains a file for most dams in the state. While the DEC file may contain similar information to that contained in the owner's dam file, it can often provide supplementary information.

Note: Due to the security-sensitive nature of certain information on dams, the dam owner must submit a written request to the Department's Dam Safety Section ("DSS") asking for release of the specific file from Dam Safety to the owner's engineer. Contact information for DSS is available in Section E. of this document.

B. On-site Engineering Inspection and Investigation

The Engineer should perform at least two specific on-site activities; a hazard classification reconnaissance and a thorough dam safety inspection. Additional on-site investigations; i.e., soil borings, test pits, topographic and boundary surveys, etc., may be necessary dependent on what additional information is required to complete the engineering assessment. Interviews with maintenance personnel and other people familiar with the dam are also recommended.

Hazard Classification Reconnaissance

The dam's hazard classification influences the regulatory and design standards for the dam and is therefore a critical component to the assessment. A dam's hazard classification will typically dictate spillway capacity criteria, which in turn affects much of the remainder of the assessment, as well as the EAP requirements.

The first step in determining a dam's hazard classification is to perform a review of the downstream area of the dam. Before beginning the field reconnaissance, the engineer should become familiar with the dam's features and setting through a desktop review of the downstream area using readily accessible data such as USGS 7 ½ minute quadrangle maps, recent orthoimagery, and similar tools to determine potential downstream features that may be impacted by the dam's failure flood wave. The engineer can then perform the downstream field investigation to verify the buildings, roads, railroad, environmentally sensitive areas, etc. that will be within the flood wave's path. In most cases, field work will also be necessary to assess potential impacts and recommend a hazard classification.

The engineer should also review the local planning board's records to identify if proposed downstream development may impact the dam's future hazard classification. Draft planning documents will not impact the current hazard classification but may provide an indicator of future changes that could affect the classification and design standards.

The Engineering Assessment Report should include a written description of the hazard classification review, description of potential downstream impacts, and a recommended hazard classification in accordance with the hazard classification regulations at Part 673.5 and applicable NYS DEC guidance.

Dam Safety Inspection

The dam safety inspection is a comprehensive examination of the visible physical features of the dam and its appurtenant structures. The dam safety inspection requirements are presented in 6NYCRR Part 673.12(d). The visual inspection should comment on previously observed deficiencies, including the deficiencies' progression or advancement and identification of continuing or new corrective actions, as necessary,

with recommendations and a schedule. Corrective actions and recommendations may be deferred until after the technical analysis.
All observations and unusual features should be recorded, regardless of how insignificant they may seem. Photographs are a permanent record of the condition of the dam and provide a means to compare dam conditions at different points in time. Photographs are a required element of the Dam Safety Inspection Report.

A good source of information for conducting a dam safety inspection can be found in the Department's "An Owners Guidance Manual for the Inspection and Maintenance of Dams in New York State" which can be found at http://www.dec.ny.gov/lands/4991.html. Other references can be found on the Internet.

Underwater inspections may be required if the condition or design of underwater features is not well known. If necessary, an underwater inspection should be conducted as part of the Safety Inspection.

Other On-Site Investigations:

It may be necessary to conduct various investigations to verify assumptions that are used in the Engineering Assessment Report, i.e. subsurface investigation to obtain data for the dam's stability assessment, or determining the source of potential seepage.

C. Engineering Review, Calculations, and Conclusions

Following completion of the records review and on-site investigations, the engineering review can commence. The engineering review consists of:

1. Hazard Classification,
2. Hydrology Assessment,
3. Hydraulic Assessment,
4. Stability Assessment,
5. Conclusions and Recommendations.

Each of these tasks is described below.

1. Hazard Classification

Using information obtained during the on-site hazard classification reconnaissance and other information; i.e., topographic maps, orthoimagery, etc. (and following the Department hazard classification guidance) a hazard classification for the dam needs to be determined. If the dam is already classified as a Class C-high hazard dam, and there is no disagreement that there will be probable loss of life if the dam were to fail, it is not necessary to spend a great deal of effort on this portion of the assessment. If the assessment results in the dam's hazard classification changing, all documents supporting the hazard classification change must be included in the report. An electronic copy of all models used, not just the model's results, must be made a permanent part of the engineering assessment.

2. Hydrology Assessment

Given a dam's hazard classification, the inflow design storm can be determined, see Section 5.3 and Table 1 of the Department's *"Guidelines for the Design of Dams, Revised January 1989 ("Guidelines")"*. If existing dam documents contain a viable hydrologic study, that hydrologic study can be utilized. All assumptions and analyses used in the study need to be independently verified and all models employed need to include the latest hydrologic criteria applicable to the field of dam safety engineering, many of which are reflected in the *Guidelines*.

Note: As stated in the 1989 *Guidelines*, HMR-33 has been replaced by HMR-51 and 52, which are the applicable models for determining the Probable Maximum Flood in New York. If the dam is a high hazard dam and the hydrology model employed to determine the Probable Maximum Flood was HMR-33, the Probable Maximum Flood should now be determined using HMR- 51/52. HMR-33 is not accepted.

The Department does not have a preferred hydrology model for determining the inflow design storm, but any model used should be appropriate for the geographic and hydrologic setting of the dam being studied. The Engineering Assessment Report needs to include both the input and output pages for the model and should include an electronic copy of the model for the Department's review.

3. Hydraulic Assessment

If the dam's record contains a viable hydraulic assessment that uses the appropriate inflow design flood, that hydraulic study may be utilized. All assumptions and analyses used in previous reports must be verified by the engineer performing the new assessment, if the engineer wishes to rely on them. If the inflow design storm is different than the previous studies, a new hydraulic analysis will be necessary.

The design criteria for the hydraulics study can be found in Section 6.0 of the *"Guidelines"*. If a computer model is used to perform the hydraulic assessment, the input and output printout must be contained within the assessment and an electronic copy of the model must be provided to the department for its review.

4. Stability Assessment

If the dam's record contains a viable stability assessment, that stability study may be utilized. Even if previous loading assumptions are no longer valid, other parts of a previous stability assessment may be utilized if appropriate. Again, all assumptions and analyses used in previous reports must be verified by the engineer conducting the new assessment.

The design criteria for the stability study can be found in Section 10.0 of the *"Guidelines"*. If a computer model is used to perform the stability assessment, the model's name, model version, and the input and output printout should be placed in the assessment and an electronic copy of the model must be included within the assessment and an electronic copy of the model must be provided to the department for its review.

The stability analysis depends on the existing subsurface geology and often requires a geotechnical investigation. Previous geotechnical investigations may be available from which to gather soil or rock parameters. The need for additional or new geotechnical investigations may also be indicated. The engineer performing the Engineering

Assessment must judge whether existing information is sufficiently reliable to determine the dam's stability. If there is visual indication that the dam may be in distress because of stability reasons, additional geotechnical investigations may be needed.

5. Conclusions and Recommendations

The Assessment Report should have a summary section that briefly discusses the data reviewed and provides a conclusion as to whether the dam is in conformance with current dam safety criteria. A list of the proposed recommendations, if any, necessary to bring the dam into conformance with applicable dam safety criteria and a schedule for completing the recommendations must be provided. The report should be reviewed with the dam owner before it is submitted to the Department.

D. Engineering Assessment Report Generation

The Engineering Assessment Report should be compiled in a 3-ring binder and should contain the results of the on-site investigations, dam safety inspections, engineering assessments, and other data or reports. All previously published dam specific hydrology, geology, hydraulic, stability, etc. reports used or referenced should be made a part of the assessment report, and may be included as an appendix. The cover page must show the Dam Name, State Dam ID#, the town/city/village and county in which the dam is located, date of the Assessment, and the name and New York PE number of the engineer who performed the Assessment, and the name and signature of the dam owner.

The Assessment Report must be stamped and signed by a professional engineer registered to practice professional engineering in New York State.

E. File Report with Department and Retain a Copy with Owner's Records

One stamped and signed copy of the competed Engineering Assessment Report, as well as an electronic copy on CD, must be submitted to the following address:

New York State Department of Environmental Conservation
Division of Water - Dam Safety Section
625 Broadway, 4th Floor
Albany, NY 12233-3504

E.32. North Carolina

North Carolina Adminsitrative Code - Title 15A Department of Environment and Natural Resources of Subchapter 2K - Dam Safety

SECTION .0100 - GENERAL PROVISIONS

.0101 DEFINITIONS
.0102 DAM SAFETY ORDERS

History Note: Statutory Authority G.S. 143-215.25; 143-215.32; 143-215.34;
Eff. January 22, 1977;
Amended Eff. November 1, 1978;
Repealed Eff. June 15, 1980.

.0103 PURPOSE
The rules and regulations contained in this Subchapter are intended to carry out the purposes of the Dam Safety Law of 1967, as expressed in G.S. 143-215.24 which authorizes the implementation of a dam inspection and certification program in the interest of public health, safety and welfare.

History Note: Statutory Authority G.S. 143-215.31; 143-215.34;
Eff. June 15, 1980.

.0104 DEFINITIONS
As used in this Subchapter, the following terms have their stated meaning:
(1) "Applicant" means any person who has notified the department that he or she desires to construct, repair, alter, or remove a dam and requests approval by the department.
(2) "Appurtenance" means an accessory or integral subordinate structure associated with a dam, such as a spillway, conduit, walkway, valve, control gate, etc.
(3) "Articulation" means provisions for safe movement at the joint or juncture of sections of conduit.
(4) "As-built plans" means drawings, photographs, test data, and descriptions that clearly and accurately define the dam and its appurtenances after all construction is completed.
(5) "Conduit" means a natural or artificial channel or pipe through which water or other fluid is conveyed.
(6) "Critical circle" means the circle with the lowest factor of safety against mass movement in a circular arc analysis of slope stability.
(7) "Critical failure wedge" means the mass or block having the lowest factor of safety against mass movement in an analysis of slope stability along planar surfaces.
(8) "Director" means the Director of the Division of Land Resources, North Carolina Department of Natural Resources and Community Development.
(9) "Equipotential lines" means lines which represent points of equal energy level or head in a flow net.
(10) "Factor of safety" means the ratio of the forces or moments resisting mass movement to the forces or moments tending to produce mass movement.
(11) "Flow lines" means lines which represent the direction of flow in a flow net.
(12) "Flow net" means a graphical representation of flow lines and equipotential lines.
(13) "Hazard potential" means the probable damage that would occur if the

structure failed, in terms of loss of human life and economic loss or environmental damage.
(14) "Maintenance plan" means written instructions prepared by the engineer that prescribe the proper servicing and repair of mechanical equipment, appurtenances, spillways, vegetative cover, and other aspects related to the safety of the dam.
(15) "Owner" means the individual or association of individuals owning the property on which the dam exists or is to be constructed, and the persons financially responsible for the construction.
(16) "Phreatic surface" means the free-water surface of a zone of seepage; it is represented by the uppermost flow line, or seepage line, in a flow net.
(17) "Qualified engineer" means a professional engineer legally qualified to practice in North Carolina pursuant to Chapter 89C of the General Statutes of North Carolina, and having appropriate specialty expertise for the particular dam engineering problem with which he is involved.
(18) "Qualified geologist" means an earth scientist experienced in applied geology with respect to the interaction of lithologies, soils, and geologic structures with dams and impoundments, who can provide professional credentials such as certification by the American Institute of Professional Geologists or registration as a geologist in the United States.
(19) "Quality control" means that combination of testing, observation, and monitoring provided during construction to confirm that requirements stated or depicted in the plans and specifications are being achieved.
(20) "Rapid drawdown" means removal of liquid from a reservoir at a rate that is significantly faster than the rate of drainage of the materials composing the portions of the reservoir exposed by the fluid removal.
(21) "Seepage" means the movement of water in a porous material and the water exiting at the visible surface of the material.
(22) "Sliding base analysis" means an analysis of the safety of a structure against lateral movement along its foundation.
(23) "Waste treatment and mine refuse dam" means a structure for impounding, restraining, storing, or disposing of liquids, slurries, or materials capable of liquification, produced from industrial, commercial, municipal, agricultural, or mining activities.
(24) "Construction" means any action, other than by natural causes, that creates a structure capable of impounding water or other liquids, or which increases the impoundment capacity of an existing structure. For the purposes of 15A NCAC 2K .0222, it shall also mean the reduction of the height or impoundment capacity of a dam when the effect of such reduction will be to exempt the dam from the North Carolina Dam Safety Law of 1967.

.0105 CLASSIFICATION OF DAMS
(a) For the purposes of this Subchapter, dams shall be divided into three classes, which shall be known as class A (low hazard), class B (intermediate hazard), and class C (high hazard):
(1) Class A includes dams located where failure may damage uninhabited low value non-residential buildings, agricultural land, or low volume roads.
(2) Class B includes dams located where failure may damage highways or secondary railroads, cause interruption of use or service of public utilities, cause minor damage to isolated homes, or cause minor damage to commercial and industrial buildings. Damage to these structures will be considered minor only when they are located in back water areas not subjected to the direct path of the breach flood wave; and they will experience no more than 1.5 feet of flood rise due to breaching above the lowest ground elevation adjacent to the outside foundation walls or no more than 1.5 feet of flood rise due to breaching above the lowest floor elevation of the structure, the lower of the two elevations governing. All other damage potential will be considered serious.
(3) Class C includes dams located where failure will likely cause loss of life or serious damage to homes, industrial and commercial buildings, important public

utilities, primary highways, or major railroads.
(b) Classifications shall be proposed by the design engineer and are subject to approval by the Director.
(c) Probable future development of the area downstream from the dam that would be affected by its failure shall be considered in determining the classification.
(d) Dams will be subject to reclassification if the Director determines that the hazard potential has changed. Non-structural provisions of adequately demonstrated effectiveness and reliability such as flood plain zoning, and early warning systems may be considered by the Director in making this determination.
(e) When dams are spaced so that the failure of an upper dam would likely fail a lower dam, the consequence of the lower dam's failure shall be a determining factor for the upper dam's hazard classification.
(f) In assigning a hazard classification where a bridge or roadway is the only damageable property below a dam, consideration shall be given to the possibility of loss of human life, indirect economic impact through loss of service, and direct cost of damage to the bridge or roadway.

History Note: Statutory Authority G.S. 143-215.31; 143-215.34;
Eff. June 15, 1980.

SECTION .0200 - OBTAINING APPROVAL FOR DAM CONSTRUCTION: REPAIR OR REMOVAL

.0201 APPLICATIONS
(a) Any person(s) who proposes to construct, repair, alter or remove a dam must file with the Director a statement concerning the location of the dam, including the name of the stream and county, height, purpose, and impoundment capacity, 10 days before start of construction. If the Director determines that the proposed dam is exempt from the law, the applicant will be notified and he may then proceed with the construction.
(b) If the Director determines that the proposed dam is not exempt from the Dam Safety Law of 1967, the applicant will be so notified within 10 days of receipt of the statement described in (a) of this Rule and construction may not commence until a full and complete application has been filed and approved. This application must be filed at least 60 days before the proposed start of construction:
(1) When an application to construct a dam has been completed pursuant to Subsection (a) of this Rule, the department shall refer copies of the completed application papers to the Department of Human Resources, the Wildlife Resources Commission, the Department of Transportation, and such other state and local agencies as it deems appropriate for review and comment.
(2) Before commencing the repair, alteration, or removal of a dam, application shall be made for written approval by the department, except as otherwise provided by this Subchapter or in accordance with G.S. 143-215.27(b). The application shall state the name and address of the applicant; shall adequately detail the changes it proposes to effect; and shall be accompanied by maps, plans, and specifications setting forth such details and dimensions as the department requires. The department may waive such requirements in accordance with G.S. 143-215.27(a). The application shall give such other information concerning the dam and reservoir required by the department concerning the safety of any change as it may require, and shall state the proposed time of commencement and completion of the work. When an application has been completed, it may be referred by the department for agency review and report as provided by G.S. 143-215.26(b) in the case of original construction.
(c) The application for any dam shall include a preliminary report. (Filing of the preliminary report prior to filing the final design report, early in the site investigation and design schedule, is encouraged to assure the state's concurrence with the hazard classification, site investigation, and design concept. This is especially encouraged for class C dams.) The preliminary report shall be filed with the application and shall include the following information:
(1) a general description of the dam and appurtenances and a proposed classification as set forth in Rule .0105 of this Subchapter; The description shall include a statement of the purpose for which the dam is to be used;
(2) a description of properties located below the dam including number of homes, buildings, roads, utilities, and other property that, as determined by the engineer, would be endangered should failure of the dam occur;
(3) maps showing the location of the proposed structure that include the county, location of state roads, access to site, and outline of the reservoir; aerial

photographs or USGS maps may be used;
(4) preliminary drawings or sketches that include cross-sections, plans and profiles of the dam, proposed pool levels, and types of all spillways;
(5) preliminary design criteria and basis for selection including a description of the size, ground cover conditions, and extent of development of the watershed, drainage area, spillway design storm, geology and geotechnical engineering, assumptions for the foundation and embankment materials, and type of materials to be used in the principal spillways(s).
(d) The Final Design Report. A "Certificate of Approval" to construct will not be issued until the final design report is received and approved. The preliminary report as described in (c) of this Rule and the final design report may be submitted as one document. The final design report shall include:
(1) a report of the investigation of the foundation soils or bedrock and the borrow materials, including the location of borrow areas, that are to be used to construct the dam;
(2) criteria to indicate that the dam will be stable during construction and filling and under all conditions of reservoir operations;
(3) computations indicating that the dam is safe against overtopping during occurrence of the inflow design flood and wave action; Wave action need not be considered when the design flood is based on the probable maximum precipitation (pmp);
(4) criteria, design data or references to indicate that seepage flow through the embankment, foundation, and abutments will be controlled so that no internal erosion will take place and so there will be no sloughing in the area where the seepage emerges;
(5) calculations and assumptions relative to design of the spillway(s);
(6) provision to protect the upstream slope, crest, and downstream slope of earth embankments and abutments from erosion due to wind and rain;
(7) other design data, assumptions, and analysis data pertinent to individual dams and site conditions;
(8) a proposed construction schedule;
(9) a proposed filling schedule for the reservoir;
(10) a maintenance and operation plan;
(11) the estimated design life of the dam and the reservoir;
(12) provision for maintaining minimum stream flow requirements.
(e) The Plans and Specifications. Five sets of plans and specifications must be submitted. The plans shall be a detailed engineering design that consists of drawings and specifications and that include the following as a minimum:
(1) Sheet one shall show the name of the project; name of owner; hazard classification of the dam; designated access to the project; and location with respect to highways, roads, streams, and any dam(s) that would affect or be affected by the proposed structure;
(2) Maps shall be included showing the drainage area and outline of the reservoir and the ownership of properties covered by the reservoir or flood pool;
(3) Geologic investigation, cross-section, profiles, logs of borings, location of borrow areas, drawings of principal and emergency spillways, and other additional sheets shall be included and drawn in sufficient detail to clearly indicate the extent and complexity of the work to be performed; The degree of detail required shall be determined by the applicable provisions of Rules .0204 through .0212 of this Section;
(4) The technical provisions, as may be required, to describe the method of construction and quality control for the project;
(5) Special provisions, as may be required, to describe technical provision needed to ensure that the dam is installed according to the approved plans and specifications;
(6) General provisions that specify the rights, duties, and responsibilities of the applicant, applicant's engineer and builder and the prescribed order of work.
(f) The Director, within 60 days following receipt of a completed application, shall notify the applicant, by mail, that the application is either approved or disapproved. An approved application shall conform to the requirements of Rule .0202 of this Section.

History Note: Statutory Authority G.S. 143-215.26,-27,-31;
Eff. June 15, 1980.

.0202 CERTIFICATE OF APPROVAL
(a) Approval of construction, repair, alteration, or removal of a dam will be contained in a certificate called a "Certificate of Approval" to be issued by the

Director. A Certificate of Approval is a letter from the Director constituting approval subject to written general stipulations and specific written stipulations deemed necessary by the Director on a case by case basis.
(b) No construction shall be performed until the certificate is issued. The Certificate of Approval period shall be valid for the construction schedule specified in the approved final design report. Construction must commence within one year after the certificate is issued.
(c) Notice by registered or certified mail shall be given to the Director at least 10 days before construction is commenced. When repairs are necessary to safeguard life and property, they may be started immediately; but the department shall be notified forthwith of the proposed repairs and of the work under way, and they shall be made to conform to its orders.
(d) If construction does not commence within one year after the certificate of approval is issued, the certificate shall expire and a new application shall be submitted. Upon written application and for good cause shown, the Director may extend the time for commencing construction.
(e) Certificates of Approval are revocable in the event that the terms of the certificate, including the written stipulations and those terms stated in G.S. 143-215.23, are violated or in the event that conditions develop during construction that are hazardous to life and property. If the certificate is revoked due to development of hazardous conditions, the Director will issue an order requiring the owner or owners of the dam to make at his or their expense maintenance, alterations, or removal as deemed necessary within a time limited by the order; provided, any dam covered by a certificate issued under this Rule is considered to be within the definition of dams in G.S. 143-215.25 and .0104 of this Subchapter.
(f) Certificates of Approval are revocable in the event that the approved construction schedule is deviated from without prior written approval of a substitute construction schedule submitted in writing. Such approval of a substitute construction schedule shall be in the form of an Addendum to the Certificate of Approval to be issued by the Director.

History Note: Statutory Authority G.S. 143-215.26,-27,-31;
Eff. June 15, 1980.

.0203 PROFESSIONAL ENGINEER REQUIREMENTS
The design, preparation of the plans and specifications, inspection of the construction of or on the dam, and certification that the dam was constructed, repaired, altered, or removed according to the plans approved by the Director and that the dam or its remains are safe shall be done by a legally qualified engineer and shall bear his professional seal unless exempted under the provisions of G.S. 89C-25.

History Note: Statutory Authority G.S. 143-215.29,-31;
Eff. June 15, 1980.

.0204 INVESTIGATIONS
(a) General. The applicant shall be required to complete all investigations prior to submission of the final plans and application. The scope and the degree of precision that will be required for a specific project will depend on the conditions of the site and the hazard created by the proposed structure.
(b) Foundations and Abutments. The foundation and abutments investigation shall consist of borings, test pits, and other subsurface exploration necessary to assess the soil, rock, and groundwater conditions. Geologic profiles and a geologic report prepared by a qualified geologist may be required for class B dams and shall be required for class C dams.
(c) Construction Materials. Specifications for construction materials shall establish minimum acceptance criteria so that design properties are achieved. If the use of on site borrow materials is specified, exploration, testing, and calculations should be performed to indicate that there are sufficient quantities of material available that meet the design criteria.
(d) Surveys. Surveys shall be made with sufficient accuracy to locate the proposed construction and to define the volume of the storage in the reservoir. The downstream area shall be investigated in order to delineate the area of potential damage in case of failure. Locations of centerlines, and other horizontal and vertical control points, shall be shown on a map of the site.
(e) Hydrologic Investigation. The drainage area shall be determined. Both present and projected future land use shall be considered in determining the runoff

characteristics of the drainage area. The most severe of these two conditions shall be used in the design. All hydrologic assumptions and design calculations shall be included in the report.

History Note: Statutory Authority G.S. 143-215.26,-27,-31;
Eff. June 15, 1980.

.0205 SPILLWAY DESIGN

(a) All dams shall have a spillway system with capacity to pass a flow resulting from a design storm indicated in (e) of this Rule for a hazard classification appropriate for the dam, unless the applicant provides calculations, designs, and plans to show that the design flow can be stored, passed through, or passed over the dam without failure occurring.

(b) A vegetated earth or unlined emergency spillway will be approved when computations indicate that it will pass the design storm without jeopardizing the safety of the structure. The risk of recurring storms, excessive erosion, and inadequate vegetative cover will be considered acceptable in such a spillway when its average frequency of use is predicted to be no more frequent than once in 25 years for existing class B and for class A dams except for small class A dams designed in accordance with all design criteria established by the U.S.D.A, Soil Conservation Service, and as contained in Engineering Standard 378 of the U.S.D.A., Soil Conservation Service; once in 50 years for new class B, small and medium new class C, and existing class C dams; and once in 100 years for large and very large new class C dams. The dam sizes referred to in this Subsection are defined in (e) of this Rule.

(c) Lined Spillways and Channels. The design report shall include design data criteria for open channel, drop, ogee, and chute spillways and other spillway types that include crest structures, walls, channel lining, and miscellaneous details. All masonry or concrete structures shall have joints that are relatively water-tight and shall be placed on foundations capable of sustaining applied loads without undue deformation. Provisions must be made for handling leakage from the channel or underseepage from the foundation which might cause saturation of underlying materials or uplift against the undersurfaces.

(d) Within 15 days following passage of the design storm peak, the spillway system shall be capable of removing from the reservoir at least 80 percent of the water temporarily detained in the reservoir above the elevation of the primary spillway.

(e) It is recognized that the relationships between valley slope and width, total reservoir storage, drainage area, other hydrologic factors, and specific cultural features have a critical bearing on determining the safe spillway design flood. Rational selection of a safe spillway design flood for specific site conditions based on quantitative analysis is acceptable. The spillway should be sized so that the increased downstream damage resulting from overtopping failure of the dam would not be significant as compared with the damage caused by the flood in the absence of dam overtopping failure. A design storm more frequent than once in 100 years will not be acceptable for any class C dam. In lieu of quantitative analysis, the following tables shall be used as criteria for spillway design storms and permissible velocities for vegetated earth spillways:

Criteria For Spillway Design Storm[1] Size Classification

Size	Total Storage (Ac-Ft)[1]	Height (Ft)[1]
Small	less than 750	less than 35
Medium	equal to or greater than 750 and less than 7,500	equal to or greater than 35 and less than 50
Large	equal to or greater than 7,500 and less than 50,000	equal to or greater than 50 and less than 100
Very Large	equal to or greater than 50,000	equal to or greater than 100

[1]The factor for determining the largest size shall govern.

Minimum Spillway Design Storms

Hazard	Size	Spillway Design Flood (SDF)
Low (Class A)	Small	50 year
	Medium	100 year
	Large	1/3 PMP
	Very Large	1/2 PMP
Intermediate (Class B)	Small	100 year
	Medium	1/3 PMP
	Large	1/2 PMP
	Very Large	3/4 PMP
High (Class C)	Small	1/3 PMP
	Medium	1/2 PMP
	Large	3/4 PMP
	Very Large	PMP

Permissible Velocities for Vegetated Earth Spillways

Permissible velocity[2] - feet per second				
	Erosion-resistant soils		Easily erodable soils	
	Percent slope of exit channel		Percent slope of exit channel	
Vegetation	0 to 5	5 through 10	0 to 5	5 through 10
Bermuda grass Bahia grass	8	7	6	5
Tall fescue Kentucky bluegrass Reed canary	7	6	5	4
Sod-forming grass mixture	5	4	4	3
Lespedeza sericea Weeping lovegrass Alfalfa Crabgrass	3.5	Do not use	2.5	Do not use

[2]Increase values 10 percent when the anticipated average use of the spillway is not more frequent than once in 50 years or 25 percent when the anticipated average use is not more frequent than once in 100 years.

History Note: Statutory Authority G.S. 143-215.26; 143-215.27; 143-215.31; Eff. June 15, 1980.

.0206 CONDUITS

(a) A conduit shall be provided to drain each reservoir. The conduit design shall include the computation of the minimum time required to drain the reservoir.

(b) All pipe conduits shall convey water at the design velocity without damage to the interior surface.

(c) Protection shall be provided to prohibit unsafe seepage along conduits through the dam, abutments, and foundation. The specific design for seepage protection along conduits shall be shown in the drawings and specifications.

(d) Adequate allowances shall be incorporated in the design to compensate for differential settlement and possible elongation of the pipe conduit.

(e) Trash racks shall be installed at the intake of conduits to prevent clogging the conduit.

(f) Pipe Conduit Spillway Materials

(1) Pipe conduits shall be designed to support the total external loads in addition to the total internal hydraulic pressure without leakage.

(2) Reinforced or Prestressed Concrete Pipe Conduits

(A) All conduits are to be designed and constructed to remain watertight under maximum anticipated hydraulic pressure and maximum probable joint opening, including the effects of joint rotation and extensibility.

(B) Provisions for safe movement of the barrel are to be provided at each joint in

the barrel and at the junction of the barrel and riser or inlet. Cradles are to be articulated if constructed on a yielding foundation.

(C) The engineer shall submit the final design details of the proposed pipe to be used for all class A dams where the height of the dam exceeds 35 feet and all class B and C dams.

(3) Corrugated Metal Pipe Conduits

(A) Corrugated metal pipe shall not be used in class A dams over 35 feet high or in class B and C dams, except for special cases when the design engineer can adequately demonstrate satisfactory performance.

(B) Corrugated metal pipe may be used in class A dams which are less than 35 feet high.

(C) Corrugated metal conduits shall have watertight connecting bands designed and installed to remain watertight under maximum anticipated hydrostatic head and joint rotation.

(D) Flange type couplings shall not be used for corrugated metal pipe or corrugated steel pipe where the diameter exceeds 12 inches unless the applicant produces computations to verify that the flanges and the pipe conduit are of such design to safely support the total external loads in addition to the total internal hydraulic pressure without leakage.

(g) Dissipating Devices. All gates, valves, conduits and concrete channel outlets shall be provided with a dissipator designed and constructed to control erosion and prevent damage to the embankment or the downstream outlet or channel.

(h) In the case of repair to an existing dam, the engineer may determine that the conduit should not be repaired or replaced and shall submit reasoning to support this determination in the application for the Certificate of Approval to repair. The Director shall approve, disapprove, or approve in part this determination.

History Note: Statutory Authority G.S. 143-215.26; 143-215.27; 143-215.31; Eff. June 15, 1980.

.0207 SEEPAGE CONTROL

(a) All dams shall be designed and constructed to prevent the development of instability due to excessive seepage forces, uplift forces, or loss of materials in the embankment, abutments, spillway areas, or foundation. Seepage analysis for design shall identify areas having high internal uplift or exit gradients.

(b) The design may include an embankment internal drainage system, a zoned embankment, a foundation cut-off, an upstream blanket, a sufficiently wide homogeneous section, or other methods to protect against instability from excessive seepage forces or high hydraulic gradients.

(c) For class C dams, a flow net analysis shall be made to determine the location of the phreatic surface, flow lines, and equipotential lines within the embankment and its foundation. This analysis may be based on graphical construction, electrical or liquid analogs, soil prototype methods, or other accepted methods. The flow net and stability analysis shall use the maximum operating pool level with not less than five feet of clear water at the surface. Possible fluctuations in tail water elevation shall be included in the analysis. The flow net and seepage analysis shall be documented in the final design report, as required by .0201(d)(4) of this Section.

(d) Piezometers for confirming the location of the phreatic surface assumed for seepage and slope stability analyses should be considered by the design engineer for class A and class B dams and shall be required for class C dams. Where piezometers are required, their design, depths, and locations shall be provided as required in .0201(d) and .0212(b) of this Section.

History Note: Statutory Authority G.S. 143-215.26; 143-215.27; 143-215.31; Eff. June 15, 1980.

.0208 STRUCTURAL STABILITY AND SLOPE PROTECTION

(a) Design and construction of dams to assure structural stability shall be consistent with modern engineering practice. The scope and degree of precision that will be required for a specific project will depend on the conditions of the site and the damage potential of the proposed structure. Consideration in design for structural stability shall include, but are not necessarily limited to, the following:

(1) the hazard potential of the dam under present downstream conditions and under conditions which would likely develop during the life of the reservoir;

(2) foundation bearing capacity, compressibility, and permeability; the extent and reliability of the site investigation; and the predictability of the site and foundation conditions;

(3) the reliability of construction materials, such as borrow soils, in terms of sufficient volume to complete construction without unanticipated interruption and in terms of predictability of physical properties such as strength, permeability, and compressibility;
(4) durability of construction materials;
(5) construction conditions at the site;
(6) the degree of quality control to be exercised during construction;
(7) pore pressure build-up during construction;
(8) the rate of filling the reservoir and the rate of possible reservoir drawdown;
(9) tailwater conditions and the impact of tailwater drawdown;
(10) possible effects of landslides and subsurface solution activity on the structural stability of the dam and spillway structures;
(11) the extent of piezometers and other devices which will be used to monitor the completed dam and the degree of access for inspections.
(b) Slope stability analyses should be considered by the design engineer for all embankment dams and may be required for class B and class C dams. Where slope stability analyses are required, documentation in the final design report shall include the design cross section(s) showing the soil parameters assumed for analysis, the location of the phreatic surface assumed for analysis, stability computations, and the location and computed safety factor(s) for the most critical circle(s) or failure wedge(s). A minimum factor of safety of 1.5 for slope stability for normal loading conditions, and 1.25 for quick drawdown conditions and for construction conditions, shall be required unless the design engineer provides a thoroughly documented basis for using other safety factors.
(c) Foundation bearing capacity and sliding base analyses should be considered for all dams and may be required for class B and C dams. Where bearing capacity or sliding base analyses are required, documentation of assumptions, computations, and safety factors shall be included in the final design report. A minimum factor of safety against bearing capacity and sliding wedge failure of 2.0 shall be required unless the design engineer provides a thoroughly documented basis for using other safety factors.
(d) Resistance of appurtenant structures against flotation uplift shall be provided for all dams. If the structures are anchored by dead weight alone, the buoyant weight shall be used for analysis and the minimum factor of safety shall be 1.15. If the structures are anchored to soil or rock, the minimum factor of safety for that portion of the resistance provided by soil or rock anchorage shall be 2.0 unless the design engineer provides a thoroughly documented basis for using a lower safety factor.
(e) For concrete, masonry, or other similar dams of relatively narrow cross section, resistance against overturning under maximum design loading conditions shall be considered; overturning stability computations shall be required for class B and class C dams. Where overturning analyses are required, the computations shall be included in the final design report. The minimum safety factor against overturning under maximum design loading conditions shall be 1.5 unless the design engineer provides a thoroughly documented basis for using a lower safety factor.
(f) The anticipated reservoir and tailwater drawdown conditions shall be considered in all stability computations and shall be included in the design documents provided in the final design report.
(g) The slopes must be protected against erosion by wave action, and the crest and downstream slope must be protected against erosion due to wind and rain. Riprap and other erosion protection shall be provided over the full range in stage between the lowest drawdown elevation and at least two feet above full normal pool. Exceptions for slowly rising reservoirs, such as waste storage facilities, may be approved in writing by the Director.

History Note: Statutory Authority G.S. 143-215.26; 143-215.27; 143-215.31; Eff. June 15, 1980.

.0209 DESIGN LIFE OF A DAM AND RESERVOIR
(a) The selection of materials and equipment to be used in a dam and all of its appurtenant features shall either be based on sufficient quality and durability to satisfactorily function throughout the design life or shall provide for safe and economical replacement within the design life span.
(b) The design life of a dam and reservoir is the period of time the dam and reservoir can be expected to perform effectively as planned. The design life of a dam shall be determined by the following:
(1) the time required to fill the reservoir with sediment from the contributing watershed,

(2) the durability of appurtenances and materials used to construct the dam,
(3) the time required to permanently fill a waste treatment or storage facility with waste,
(4) the time required to perform the specific function for which the dam was designed.

History Note: Statutory Authority G.S. 143-215.27; 143-215.31;
Eff. June 15, 1980.

.0210 SEDIMENT CONTROL
Sediment control related to earth moving activities involved in construction or repair of dams shall be provided in accordance with the North Carolina Sediment Pollution Control Act of 1973 (G.S. 113A-50 through 113A-66). Devices for sediment control during drainage of a reservoir shall be provided; exceptions for emergency drainage of a reservoir may be approved by the Director.

History Note:Statutory Authority G.S. 143-215.31, -113A-54;
Eff. June 15, 1980.

.0211 WASTE TREATMENT AND MINE REFUSE DAMS
(a) Waste treatment and mine refuse dams and reservoirs shall conform to all requirements of this Subchapter. In addition to the requirements of Rule .0105 of this Subchapter, a waste treatment or mine refuse dam may be classified A, B, or C on the basis of potential environmental damage.
(b) Mine refuse dams that are designed to be constructed in stages shall include an emergency spillway system that is capable of safely passing the required storm frequency below the top of the dam for each stage of construction. The refuse facility shall not be used until each stage of construction is completed and approved by the Director.

History Note: Statutory Authority G.S. 143-215.31;
Eff. June 15, 1980.

.0212 ADDITIONAL DESIGN REQUIREMENTS
(a) All elements of the dam and reservoir shall conform to good engineering practice. The safety factors, design standards, and design references that are used shall be included with the final design report.
(b) Monitoring or inspection devices may be required by the Director for use by inspectors or owners in the inspection during construction and filling and after completion of construction. The Director may also require that such monitoring or inspection devices, existing or installed by requirement, be read and documented at specified intervals and that copies of such be forwarded to his office.

(c) The plans, construction schedule, and construction specification shall assure that the downstream flow satisfies minimum quality and quantity standards as defined in G.S. 143-215.25(4) during the period of construction, filling, and life of the dam and reservoir.

History Note: Statutory Authority G.S. 143-215.26; 143-215.27; 143-215.31;
Eff. June 15, 1980.

.0213 CONSTRUCTION SCHEDULE
The applicant shall submit a construction schedule that includes:
(1) Techniques and work force to be used to insure that the dam is constructed according to the plans and specifications;
(2) A construction schedule that includes the estimated time to complete the construction activities;
(3) Techniques to be used to divert the stream flow to prevent interference with construction and hazard to life, health, or property;
(4) The extent and method of quality control shall be subject to approval of the Director.

History Note: Statutory Authority G.S. 143-215.26; 143-215.27; 143-215.31;
Eff. June 15, 1980.

.0214 PROPOSED CHANGES IN DESIGN
The owner shall notify the director of any proposed changes in design, plans, and specifications that will affect the stability of the dam. Approval must be obtained from the Director prior to installation. This approval shall be in the form of a written addendum to the Certificate of Approval.

History Note: Statutory Authority G.S. 143-215.26; 143-215.27; 143-215.31;
Eff. June 15, 1980.

.0215 AS-BUILT PLANS
Two complete sets of as-built plans shall be submitted to the Director within 30 days of completion of the project.

History Note: Statutory Authority G.S. 143-215.30; 143-215.31;
Eff. June 15, 1980.

.0216 ENGINEER'S CERTIFICATION
The engineer who has inspected the construction of or on the dam shall submit written certification bearing his professional seal, unless exempted under the provisions of G.S. 89C-25, that the dam and all appurtenances have been built, repaired, altered, or removed in conformance with the plans, specifications, and drawings approved by the Director and that the dam is safe.

History Note: Statutory Authority G.S. 143-215.30; 143-215.31;
Eff. June 15, 1980.

.0217 AUTHORITY FOR INSPECTION
Authorized personnel of the department may make inspection during construction as deemed necessary to ensure that the structure is being built in conformance with the Certificate of Approval issued. Said inspections do not relieve the engineer in charge from the responsibility of providing adequate inspection of the work.

History Note: Statutory Authority G.S. 143-215.29; 143-215.30; 143-215.31;
Eff. June 15, 1980.

.0218 EXEMPTIONS

History Note: Statutory Authority G.S. 143-215.21; 143-215.31;
Eff. June 15, 1980;
Amended Eff. November 1, 1985;
Repealed Eff. July 1, 1988.

.0219 ACCEPTABLE DESIGN: PROCEDURES AND TECHNICAL REFERENCES
The following represent acceptable design procedures and references:
(1) the design procedures, manuals, and criteria used by the United States Corps of Engineers;
(2) the procedures, manuals, and criteria used by the United States Soil Conservation Service;
(3) the procedures, manuals, and criteria used by the United States Department of Interior, Bureau of Reclamation;
(4) other procedures that are approved by the Director.

History Note: Statutory Authority G.S. 143-215.31; 143-215.34;
Eff. June 15, 1980.

.0220 GRANTING OF FINAL APPROVAL
(a) Unless the Director has reason to believe that the dam, as completed, is unsafe or not in compliance with any applicable requirement, regulation, or law, the Director, upon completion of construction and upon receipt of the engineer's certification pursuant to Rule .0215 of this Section, shall grant final approval of the work in accordance with the certificate, subject to such terms as he/she deems necessary for the protection of life and property.
(b) Pending issuance of final approval, a new dam or the addition to an existing dam shall not be used except on written consent of the Director and subject to conditions he/she may impose relating to safety of life and property and the

satisfaction of minimum stream flow requirements.

History Note: Statutory Authority G.S. 143-215.3; 143-215.30;
Eff. June 15, 1980.

.0221 DELEGATION OF AUTHORITY
The Director has the authority to:
(1) issue approval, disapproval, or approval subject to conditions for proposed construction, repair, alteration or removal of dams;
(2) require progress reports, issue notices of non-compliance and orders to comply, order a halt in construction in the event of non-compliance;
(3) receive notices of completion, specify details of description, grant final approval;
(4) assess civil penalties; and
(5) perform other related functions.

History Note: Statutory Authority G.S. 143-215.3; 143-215.3(a)(4); 143-215.28; 143-215.29; 143-215.30;
143-215.36(b);
Eff. June 15, 1980;
Amended Eff. November 1, 1982.

.0222 APPLICATION PROCESSING FEES
(a) A nonrefundable minimum application processing fee, in the amount stated in Paragraph (d)(1) of this Rule, shall be paid when an application for construction or removal of a dam is filed in accordance with 15A NCAC 2K .0201. Each application for construction or removal of a dam shall be deemed incomplete and shall not be reviewed until the minimum application processing fee is paid.
(b) A nonrefundable additional application processing fee, in the amount stated in Paragraph (d)(2) of this Rule, shall be paid when the as-built plans are submitted to the Director in accordance with 15A NCAC 2K .0215. Final approval to impound, pursuant to 15A NCAC 2K .0220, shall not be granted until the owner's certification and the accompanying documentation are filed in accordance with Paragraph (e) of this Rule, and the additional processing fee is paid.
(c) The application processing fee for the construction or removal of a dam shall be based on the actual cost of construction or removal of the applicable dam.
(1) The actual cost of construction or removal of a dam shall include all labor and materials costs associated with the construction or removal of the dam and appurtenances.
(2) The actual cost of construction or removal of a dam shall not include the costs associated with acquisition of land or right of way, design, quality control, electrical generating machinery, or constructing a roadway across the dam.
(d) Schedule of Fees:
(1) The minimum application processing fee shall be two hundred dollars ($200.00).
(2) The additional application processing fee shall be the following percentages of the cost of construction or removal:
(A) 2 percent of the actual costs between ten thousand and one dollars ($10,001) and one hundred thousand dollars ($100,000);
(B) 1.5 percent of the actual costs between one hundred thousand and one dollars ($100,001) and five hundred thousand dollars ($500,000);
(C) 1.0 percent of the actual costs between five hundred thousand and one dollars ($500,001) and one million dollars ($1,000,000);
(D) 0.5 percent of the actual costs over one million dollars ($1,000,000).
In no case, however, shall the additional application fee be more than fifty thousand dollars ($50,000).
(e) Immediately upon completion of construction or removal of a dam, the owner shall file with the Director a certification, on a form prescribed by the Department, and accompanying documentation, which shows the actual cost incurred by the owner for construction or removal of the applicable dam.
(1) The owner's certification and accompanying documentation shall be filed with the as-built plans and the engineer's certification in accordance with 15A NCAC 2K .0215 and 15A NCAC 2K .0216, respectively.
(2) If the Director finds that the owner's certification and accompanying documentation contain inaccurate cost information, the Director shall either withhold final impoundment approval, or revoke final impoundment approval, until the owner provides the accurate documentation and that documentation has been verified by the Department.
(f) Payment of the dam application processing fee shall be by check or money

order made payable to the "N.C. Department of Environment, Health, and Natural Resources". The payment should refer to the applicable dam.
(g) In order to comply with the limit on fees set forth in G.S. 143-215.28A, the Director shall, in the first half of each state fiscal year, project revenues for the fiscal year from fees collected pursuant to this Rule. If this projection shows that the statutory limit will be exceeded, the Director shall order a pro rata reduction in the fee schedule for the remainder of the fiscal year to avoid revenue collection in excess of the statutory limits.

Eff. January 1, 1991.

.0223 DAM HEIGHT AND STORAGE DETERMINATION
(a) For the purpose of determining size classification, the height of a dam shall be measured from the highest point on the crest of the dam to the lowest point on the downstream toe.
(b) The total storage capacity of a dam shall be that volume which would be impounded at the elevation of the highest point on the crest of the dam.

SECTION .0300 - INSPECTIONS: DAM SAFETY ORDERS

.0301 INSPECTION BY THE DEPARTMENT
(a) Schedule of Inspections
(1) All class A and B dams shall be inspected at least once every five years.
(2) Class C dams shall be inspected at least once every two years.
(b) At any time an inspection indicates that a dam may not perform satisfactorily or that the hazard classification has changed, the Director may require a detailed investigation at the owners expense to determine the required remedial action, if any.

History Note: Statutory Authority G.S. 143-215.31; 143-215.32;
Eff. June 15, 1980.

.0302 DAM SAFETY ORDERS
(a) The Director may issue an order directing the owner(s) of a dam to make, in not less than 90 days from issuance of the order and at the owner(s) expense, any maintenance, alteration, repairs, reconstruction, or change in construction upon a finding that the dam:
(1) is not sufficiently strong,
(2) is not maintained in good repair or operating condition,
(3) is dangerous to life or property, or
(4) does not satisfy minimum stream-flow requirements.
(b) The Director may issue an order directing the owner(s) of any dam to take such measures as may be essential, including lowering the level of the impounded water, drainage of the impoundment, and destruction of the dam or reservoir in whole or in part, immediately or within a time limited by the order if the condition of the dam is found to have become so dangerous to the safety of life or property, in the opinion of the Director, as not to safely permit sufficient time for issuance of an order in the manner provided by Subdivision (a) of this Rule.
(c) The Director may, if at any time the condition of any dam becomes so dangerous to the safety of life or property, in the opinion of the Director, as not to permit sufficient time for issuance of an order in the manner provided by Subdivision (a) or (b) of this Rule, immediately take such measures as may be essential to provide

emergency protection to life and property including the lowering of the level of a reservoir by releasing water impounded or the destruction in whole or in part of the dam or reservoir. Costs of such measures may be recovered from the owner(s) of the dam by appropriate legal action by the Commission.
(d) Orders issued by the Director may be conditioned so as to require the dam owner, if he is required or given the option to remove the dam, to undertake the removal in such a manner as to minimize the amount of sediment transported from the impoundment downstream.
(e) Dam safety orders issued by the Director in no way relieve the owner(s) of the dam from duties and obligations imposed by regulations in Section .0200 of this Subchapter, nor do they relieve the owner(s) of the dam from any liabilities or other legal obligations.

History Note: Statutory Authority G.S. 143-215.32; 143-215.34;
Eff. June 15, 1980.

SECTION .0400 - ADMINISTRATIVE HEARINGS

.0401 OPPORTUNITY FOR HEARING
An administrative hearing before the N.C. Office of Administrative Hearings shall be granted to any person:
(1) whose application for dam construction, repair, alteration, or removal has been disapproved by the Director or has been approved by the Director subject to conditions which are unacceptable to the applicant pursuant to Rule .0202 of this Subchapter;
(2) who has been denied final approval of a completed dam by the Director or who has been granted final approval by the Director subject to conditions which are unacceptable to the applicant pursuant to Rule .0219 of this Subchapter;
(3) against whom a dam safety order has been issued requiring the maintenance, alteration, repair, reconstruction, change in construction or location, or removal of a dam within 90 days, pursuant to Rule .0302(a) of this Subchapter, or the lowering of the level of the water impounded by the dam within a time period prescribed by the Director pursuant to Rule .0302(b) of this Subchapter; or
(4) who has been assessed a civil penalty pursuant to G.S. 143-215.36(b) and Subchapter 2J of this Chapter.

History Note: Statutory Authority G.S. 143-215.33; 150B-23;
Eff. June 15, 1980;
Amended Eff. July 1, 1988.

.0402 PROCEDURES
(a) Administrative hearings shall be conducted pursuant to 15A NCAC 1B .0200 et seq., and Chapter 150B of the General Statutes. Any person entitled to an opportunity for a hearing by Rule .0401 of this Section must request a hearing within ten days after receipt of the notice of the action taken under Rule .0401 of this Section.
(b) Copies of 15A NCAC 1B .0200 may be inspected in the offices of the Division of Land Resources, Land Quality Section, 512 N. Salisbury Street, Raleigh, N. C. 27611. Copies may also be inspected in the Division of Planning and Assessment, 512 N. Salisbury Street, 8th Floor, Archdale Building, Raleigh, N. C. 27611. Copies may be obtained at the previous locations or from the Rules Division of the N.C. Office of Administrative Hearings, Blount Street, Raleigh, N.C. 27611.

SECTION .0500 - MINIMUM STREAM FLOWS TO MAINTAIN AQUATIC HABITAT

.0501 DEFINITIONS

(a) Aquatic habitat shall be divided into three classes - "poor," "moderate," and "good."
(1) Streams with poor aquatic habitat are those which have a "poor" fish assemblage rating, and which are rated "poor" for at least two of the following three characteristics:
(A) Substrate;
(B) Cover; and
(C) Macro-invertebrate organisms.
(2) Streams with moderate aquatic habitat are those which exhibit physical conditions and biota which are intermediate between the poor and good categories.
(3) Streams with good aquatic habitat are those which receive at least two "good" ratings when the substrate, cover, and macro-invertebrate organism characteristics are evaluated. The fish assemblage also must receive a "good" rating.
(b) Cover means objects within or overhanging the stream channel which provide shelter for aquatic organisms. "Good" cover occurs when cover is widespread and diverse. "Poor" cover occurs when the amount of cover is small or non-existent.
(c) Substrate means the predominant particle size of the material which makes up the stream bed. "Good" substrate is composed of at least 50 percent silt free substrate with gravel or cobble. "Poor" substrate is composed of at least 80 percent silt, sand, or smooth bedrock.
(d) The macro-invertebrate organisms of the affected reach are rated as "good" if the affected reach is rated good or excellent in the Division of Environmental Management's (DEM) biological monitoring database, or by a site-specific survey according to Standard Operating Procedures for Biological Monitoring, 1995, Division of Environmental Management as defined in 15A NCAC 2B .0103(b). Macro-invertebrates are rated "poor" if the reach is rated fair or poor in DEM's biological monitoring database, or by a site-specific survey according to Standard Operating Procedures for Biological Monitoring, 1995, Division of Environmental Management as defined in 15A NCAC 2B .0103(b).
(e) The fish assemblage rating shall be based on the North Carolina Index of Biotic Integrity (IBI). Existing ratings from the DEM biological monitoring database shall be used where available. If no rating exists, then a site-specific survey shall be conducted according to Standard Operating Procedures for Biological Monitoring, 1995, Division of Environmental Management as defined in 15A NCAC 2B .0103(b). The fish assemblage shall be rated as "good" if the IBI rating is good, good-excellent, or excellent. The fish assemblage shall be rated as "poor" if the IBI rating is poor or lower.
(f) The affected reach of stream means that section of a stream downstream of a dam which experiences significant changes in hydrology. The exact delineation of the affected reach shall be site-specific and depend on factors including, but not limited to:
(1) volume of storage in the impoundment;
(2) upstream and downstream hydrologic characteristics of the stream;
(3) withdrawals from the impoundment; and
(4) downstream point source discharges to the stream.
For the purpose of evaluating aquatic habitat, the affected reach of a stream does not include any portion which is in the backwater of a downstream dam when the level of that downstream impoundment is at normal pool.
(g) "Special case" streams are those which exhibit at least one of the following characteristics:
(1) supplemental classification as an Outstanding Resource Water as defined in 15A NCAC 2B .0101(e)(4) and .0216;
(2) populations of aquatic species listed as threatened or endangered by the U.S. Fish and Wildlife Service, or species which are listed as threatened or endangered by the N.C. Wildlife Resources Commission;
(3) self-sustaining populations of wild trout; or
(4) exceptional non-game or fishery resources as determined by the Wildlife Resources Commission.

(h) The use of the regression equations in Rule .0502 of this Section shall depend on the geographic region of the state in which the stream is located. The geographic region shall be determined from the North Carolina Atlas, edited by Clay, Orr, and Stuart, published by the University of North Carolina Press, 1975.
(i) A continuous stream gage record means a continuous record of daily flows from a stream gage which:
(1) has at least 15 years of continuous daily records;
(2) has no significant hydrological effects caused by upstream regulation, withdrawals, or discharges;
(3) is no less than one-half and no more than one and one-half times the drainage area of the site in question; and
(4) has low flow and average flow yields which are comparable to the site in question.
(j) A site-specific instream flow study conducted by the applicant or his consultants, which is subject to approval by the Department, means a study performed according to the following conditions:
(1) A plan of study shall be developed in consultation with the Department and submitted to the Department for review and approval prior to commencement of the study.
(2) The plan of study shall identify the aquatic habitat parameters to be evaluated by the study. The selection of these parameters shall depend on factors including, but not limited to:
(A) the aquatic species being evaluated;
(B) the habitat quality of the affected reach; and
(C) existing or potential water shortages or water use conflicts.
(3) The Department shall have the option of participating in the collection of all field data, and shall be notified prior to collection of any set of data.
(4) The results of the study shall accurately determine the parameters identified during study design.
(5) The Department may review the field data and results of these studies to determine the stream flow needed to maintain aquatic habitat.

History Note: Statutory Authority G.S. 143-215.24; 143-215.25; 143-215.31; 143-215.32; 143-215.33;
143-215.36;
Eff. December 1, 1994;
Amended Eff. April 1, 1995.

.0502 REQUIRED MINIMUM FLOW FOR DAMS (NOT SMALL HYDRO PROJECTS)
(a) A dam operated by a small power producer, as defined in G.S. 62-3(27a), that diverts water from 4,000 feet or less of the natural stream bed, shall be exempt from this Rule.
(b) A dam proposed for a small stream with a mean annual daily flow less than or equal to 3.0 cubic feet per second (cfs) shall be subject to the following review process in determining the required minimum flow:
(1) If the mean annual daily flow is less than or equal to 3.0 cfs and the 7-day, 10-year low flow (7Q10) is less than or equal to 0.2 cfs; and if there are no existing point source discharges of wastewater to the affected stream reach; then no minimum release will be required.
(2) If the mean annual daily flow is less than or equal to 3.0 cfs and the 7Q10 is less than or equal to 0.2 cfs; and one or more existing point source discharges of wastewater enter the affected stream reach; then the minimum release shall be equal to the 7Q10.
(3) If the mean annual daily flow is less than or equal to 3.0 cfs and the 7Q10 is greater than 0.2 cfs, then the minimum release shall be equal to the 7Q10.
(c) If the mean annual daily flow is greater than 3.0 cfs, then the following procedures shall be used to determine the minimum flow requirement:
(1) The minimum flow for a dam on a stream with poor aquatic habitat shall be the 7Q10 flow determined by using U.S. Geological Survey procedures.
(2) The minimum flow for a dam on a stream with moderate aquatic habitat in the piedmont, as defined in Rule .0501(h) of this Section, shall be determined using regression equations provided in this Subparagraph.
(A) All flows used in regression equations shall be measured in cubic feet per second, all drainage areas shall be measured in square miles, and all logarithmic expressions shall refer to base 10 logarithms.
(B) The regression equation used to determine the minimum flow for a stream in the piedmont which exhibits moderate aquatic habitat, and for which no continuous

stream gage record, as defined in Rule .0501(i) of this Section, exists, shall be as follows:

LRF = (3.204 x M) - (2.618 x D)
LRF = LOG of regression flow
M = LOG of mean annual daily flow
D = LOG of drainage area

The regression flow (RF) is calculated by raising 10 to the power of the LRF. If the drainage area is greater than 95 square miles, the required minimum flow is 1.4 x RF. Otherwise the required minimum flow is equal to RF.

(C) The regression equation used to determine the minimum flow for a stream in the piedmont which exhibits moderate aquatic habitat, and for which a continuous stream gage record, as defined in Rule .0501(i) of this Section, does exist, shall be as follows:

LRF = (0.812 x M) + (8.111 x E92) - (4.806 x E85) - (3.275 x E95)
LRF = LOG of regression flow
M = LOG of mean annual daily flow
E85 = LOG of 85% annual exceedance flow
E92 = LOG of 92.5% annual exceedance flow
E95 = LOG of 95% annual exceedance flow

The regression flow (RF) is calculated by raising 10 to the power of the LRF. The required minimum flow is 1.1 x RF.

(3) The minimum flow for a dam on a stream with moderate aquatic habitat, located in a geographical region for which regression formulas are not provided, shall be determined by a site-specific instream flow study, as defined in Rule .0501(j) of this Section, conducted by the applicant or his consultants and subject to the approval of the Department.

(4) The minimum flow for a dam on a special case stream, or on a stream with good aquatic habitat, shall be determined by a site-specific instream flow study, as defined in Rule .0501(j). This study shall be conducted by the applicant or his consultants, and shall be subject to approval by the Department.

(5) If the applicant or owner disputes the minimum flow determined by the procedures described in Subparagraphs (c)(1) or (c)(2) of this Rule for streams with poor or moderate aquatic habitat, he may undertake a site-specific field study, as defined in Rule .0501(j) of this Section, subject to the review and approval of the Department. The final minimum release required will not exceed the amount determined by the procedures described in this Rule.

(6) The minimum release schedule for a water supply reservoir shall include provisions for reductions in the minimum flow which coincide with reductions in the usable water supply storage remaining in the impoundment and with reductions in the amount of water withdrawn from the reservoir.

(A) This system of tiered releases shall apply to new water supply reservoirs and any existing water supply reservoirs for which the minimum release is revised.

(B) The exact percentage of storage which triggers reductions in minimum flow will depend on several site-specific factors, including, but not limited to:

(i) size of the reservoir;

(ii) rate of the water supply demand;

(iii) hydrologic characteristics of the impounded stream; and

(iv) the impoundment levels which result in local efforts to reduce water usage through conservation measures.

(C) At least three levels of minimum releases shall be included in the release schedule for a water supply reservoir.

(D) When usable water supply storage has been reduced to a level which triggers the first reduction in minimum flow, then the average daily water withdrawal shall be reduced by at least 10 percent from the average daily withdrawal for the 60 day period immediately prior to the first reduction in the minimum flow. The water supply operator shall accomplish this reduction in withdrawal within two weeks of the reduction in the minimum release.

(E) When usable water supply storage has been reduced to a level which triggers the second reduction in minimum flow, then the average daily water withdrawal shall be reduced by at least 20 percent from the average daily withdrawal for the 60 day period immediately prior to the first reduction in the minimum flow. The water supply operator shall accomplish this further reduction in withdrawal within two

weeks of the second reduction in the minimum release.
(F) The water system operator shall document reduction in water withdrawals by submitting reports of daily water withdrawals to the Department. These shall be submitted every two weeks for as long as the minimum release is reduced below the amount normally required.
(G) An example is shown in the table below. (Note that the percentages of water supply storage which trigger the changes in minimum release are site-specific for this example and may vary according to the factors described in Part (B) of this Paragraph.)

Remaining Usable Water Level Supply Storage	Minimum Release	Water Use Reduction
between 70% and 100%	A	-------
between 40% and 70%	B	10%
below 40%	C	20%

A = Normal minimum release determined by a field study, regression equation, or use of the 7Q10
B = Intermediate reduction in minimum release
C = Low minimum release equal to no more than the 7Q10

(7) An existing dam which was built subject to review under the National or the State Environmental Policy Acts, and for which a minimum release has been established, will not have its minimum release changed under this Rule. However, the Department may review and adjust the minimum flow released by any other existing dam if there is evidence of any of the following conditions downstream of that dam:
(A) water quality standards not being maintained;
(B) water quality classifications which are being only partially supported or not being supported; or
(C) aquatic habitat not being maintained.
(8) If the minimum release required from an existing water supply reservoir is reviewed by the Department, any increase in minimum flow will be determined on a case-by-case basis in consideration of the following factors, including, but not limited to:
(A) availability of water to meet existing demands;
(B) rate of growth in water demand;
(C) planned development of alternative sources of water supply;
(D) structural difficulties;
(E) capital costs; and
(F) anticipated improvements in water quality and aquatic habitat in the affected reach resulting from the proposed change in minimum flow.

The change in minimum release shall be set no higher than an amount which would reduce the water supply safe yield, as determined by standard accepted engineering practices, by more than 10 percent.
(9) If a new minimum release requirement from an existing water supply reservoir is being delayed until a new source of water supply is developed, then this delay shall not exceed a period of five years from the written notification that a new minimum release will be required. This period may be extended by approval of the Environmental Management Commission in consideration of the following factors:
(A) delays in developing a new water supply source;
(B) changes in water quality and aquatic habitat in the affected reach; or
(C) availability of water to meet existing demands.

History Note: Statutory Authority G.S. 143-215.24; 143-215.25; 143-215.31; 143-215.32; 143-215.33;
143-215.36;
Eff. December 1, 1994;
Amended Eff. April 1, 1995.

.0503 REQUIRED MINIMUM FLOW FOR SMALL HYDROELECTRIC PROJECTS
(a) This Rule shall apply only to a dam operated by a small power producer, as defined in G.S. 62-3(27a), that diverts water from 4,000 feet or less of the natural stream bed. The length of the bypassed reach shall be measured from the toe of the dam to the point where the diverted water re-enters the natural channel,

following the centerline of the natural channel.
(b) The minimum release for a hydroelectric project subject to this Rule shall be determined according to the procedures described in Subparagraphs (1)-(5) of this Paragraph. If at any time the inflow just upstream of the dam is less than the minimum flow required in the bypassed reach, then the minimum flow may be reduced to a level equal to this inflow.
(1) If the aquatic habitat in the bypassed reach is rated poor, then the minimum release to the bypassed reach shall be determined as follows:
(A) If the 7Q10 is less than or equal to 10 percent of the mean annual daily flow, then the minimum release to the bypassed reach shall be the 7Q10 flow.
(B) If the 7Q10 is greater than 10 percent of the mean annual daily flow, and there are no existing point source discharges of wastewater to the bypassed reach, then the minimum release to the bypassed reach shall be 0.8 times the 7Q10.
(C) If the 7Q10 is greater than 10 percent of the mean annual daily flow, and one or more existing point source discharges of wastewater enter the bypassed reach, then the minimum release to the bypassed reach shall be the 7Q10 flow.
(2) If the bypassed reach does not have an aquatic habitat rating of "poor," is not on a special case stream, and is located in the piedmont region, as defined in Rule .0501(h) of this Section, then the minimum release to the bypassed reach shall be determined as follows:
(A) If the 7Q10 is less than or equal to six percent of the mean annual daily flow, then the minimum release to the bypassed reach shall be 3.0 times the 7Q10 flow.
(B) If the 7Q10 is greater than six percent of the mean annual daily flow, and less than or equal to 10 percent of the mean annual daily flow, then the minimum release to the bypassed reach shall be 2.2 times the 7Q10 flow.
(C) If the 7Q10 is greater than 10 percent of the mean annual daily flow, then the minimum release to the bypassed reach shall be 1.2 times the 7Q10 flow.
(3) The minimum flow determined by the procedures described in Subparagraphs (1) and (2) of this Paragraph may be adjusted downward by the Department if that adjustment would not result in significant loss of aquatic habitat. This adjustment may be based on factors including:
(A) the type of aquatic habitat present in the bypassed reach;
(B) the length of the bypassed reach.
(4) If the applicant or owner disputes the minimum flow determined by the procedures described in Subparagraphs (1) and (2) of this Paragraph, he may undertake a site-specific field study, as defined in Rule .0501(j) of this Section, subject to the review and approval of the Department. The final minimum release required will not exceed the amount determined by the procedures described in this Section.
(5) The minimum flow for a dam on a special case stream, or on a stream located in the mountain region, as defined in Rule .0501(h) of this Section, which does not exhibit poor aquatic habitat; shall be determined by a site-specific instream flow study, as defined in Rule .0501(j) of this Section. This study shall be conducted by the applicant or his consultants, and shall be subject to approval by the Department.
(c) A dam operated by a small power producer, as defined in G.S. 62-3(27a), which was operating to produce power as of October 13, 1994, and which is not under the jurisdiction of the Federal Energy Regulatory Commission, shall not be required by this Rule to increase its minimum flow above the amount required on October 13, 1994.

History Note: Statutory Authority G.S. 143-215.24; 143-215.25; 143-215.31; 143-215.32; 143-215.33;
143-215.36;
Eff. December 1, 1994;
Amended Eff. April 1, 1995.

.0504 MONITORING OF MINIMUM FLOW REQUIREMENTS
(a) An owner of a dam with a minimum flow requirement greater than 1.0 cfs shall install, calibrate, and maintain one or more stream staff gages following procedures described in U.S. Geological Survey Water Supply Paper 2175, "Measurement and Computation of Streamflow." Plans for such gages shall be submitted to the Department for approval prior to installation. Staff gages shall be calibrated to indicate the water surface elevations which correspond to the required flows. Calibration shall be verified at least every two years. All initial calibration and re-calibration measurements, including field data, shall be provided to the Department within 30 days of completion.
(b) If the minimum release from a dam is less than or equal to 1.0 cfs, then an

accurately calibrated release mechanism such as a gate or pipe opening shall be acceptable in lieu of a staff gage. Plans for making the required release shall be submitted to the Department for review and approval prior to construction, repair, or modification of the dam.

(c) An owner of a dam who does not comply with a minimum flow requirement may be required to install automated gaging which continuously monitors flow. Records from this type of gage shall be provided to the Department upon request, for the time period being investigated.

(d) Minimum release requirements may be modified or suspended for a term determined by the Department for reasons including pre-scheduled maintenance or construction involving the dam. The Department must approve a written request for such a change in the minimum flow requirement prior to any change in the minimum release.

(e) Reduction or cessation of the minimum flow as a result of emergency conditions or equipment failure shall not constitute a violation of the minimum flow requirement, so long as the event is reported to the Department within 48 hours. The Department may set forth a schedule for correcting the problem and restoring the required minimum flow. If the schedule is not met, and the problem continues to cause violation of the minimum flow requirement, then this violation may be subject to enforcement action.

History Note: Statutory Authority G.S. 143-215.24; 143-215.25; 143-215.31; 143-215.32; 143-215.33;
143-215.36;
Eff. December 1, 1994.

North Carolina

The Division of Land Resources

Dam Hazards Classification

Site Map

Hazard Classification	Description	Quantitative Guidelines
Low	Interruption of road service, low volume roads	Less than 25 vehicles per day
	Economic damage	Less than $30,000
Intermediate	Damage to highways, Interruption of service	25 to less than 250 vehicles per day
	Economic damage	$30,000 to less than $200,000
High	Loss of human life*	Probable loss of 1 or more human lives
	Economic damage	More than $200,000
	*Probable loss of human life due to breached roadway or bridge on or below the dam.	250 or more vehicles per day

NOTE: Cost of dam repair and loss of services should be included in economic loss estimate if the dam is a publicly owned utility, such as a municipal water supply dam.

Dam Safety Law of 1967

(As amended through 1995)

§ 143-215.23. Short title.

This Part shall be known and may be cited as the Dam Safety Law of 1967. (1967, c. 1068, s. 1.)

§ 143-215.24. Declaration of purpose.

It is the purpose of this Part to provide for the certification and inspection of dams in the interest of public health, safety, and welfare, in order to reduce the risk of failure of dams; to prevent injuries to persons, damage to downstream property and loss of reservoir storage; and to ensure maintenance of minimum stream flows of adequate quantity and quality below dams. (1967, c. 1068, s. 2; 1977, c. 878, s. 1; 1993, c. 394, s. 1.)

§ 143-215.25. Definitions.

As used in this Part, unless the context otherwise requires:

(1) "Dam" means a structure and appurtenant works erected to impound or divert water.

(2) "Minimum stream flow" or "minimum flow" means a stream flow of a quantity and quality sufficient in the judgment of the Department to meet and maintain stream classifications and water quality standards established by the Department under G.S. 143-214.1 and applicable to the waters affected by the project under consideration, and to maintain aquatic habitat in the length of the stream that is affected. (1967, c. 1068, s. 3; 1973, c. 1262, ss. 23, 38; 1977, c. 771, s. 4; c. 878, ss. 2, 4; 1983, c. 306; 1987, c. 827, ss. 154, 175; 1993, c. 394, s. 2.)

§ 143-215.25A. Exempt dams.

(a) Except as otherwise provided in this Part, this Part does not apply to any dam:

(1) Constructed by the United States Army Corps of Engineers, the Tennessee Valley Authority, or another agency of the United States government, when the agency designed or approved plans for the dam and supervised its construction.

(2) Constructed with financial assistance from the United States Soil Conservation Service, when that agency designed or approved plans for the dam and supervised its construction.

(3) Licensed by the Federal Energy Regulatory Commission, or for which a license application is pending with the Federal Energy Regulatory Commission.

(4) For use in connection with electric generating facilities under the jurisdiction of the North Carolina Utilities Commission.

(5) Under a single private ownership that provides protection only to land or other property under the same ownership and that does not pose a threat to human life or property below the dam.

(6) That is less than 15 feet in height or that has an impoundment capacity of less than 10 acre-feet, unless the Department determines that failure of the dam could result in loss of human life or significant damage to property below the dam.

(b) The exemption from this Part for a dam described in subdivisions (1) and (2) of subsection (a) of this section does not apply after the supervising federal agency relinquishes authority for the operation and maintenance of

the dam to a local entity. (1993, c. 394, s. 3.)

§ 143-215.26. Construction of dams.

(a) No person shall begin the construction of any dam until at least 10 days after filing with the Department a statement concerning its height, impoundment capacity, purpose, location and other information required by the Department. A person who constructs a dam, including a dam that is otherwise exempt from this Part under subdivisions (4) or (5) of G.S. 143-215.25A(a), shall comply with the malaria control requirements of the Department. If on the basis of this information the Department is of the opinion that the proposed dam is not exempt from the provisions of this Part, it shall so notify the applicant, and construction shall not be commenced until a full application is filed by the applicant and approved as provided by G.S. 143-215.29. The Department may also require of applicants so notified the filing of any additional information it deems necessary, including, but not limited to, streamflow and rainfall data, maps, plans and specifications. Every applicant for approval of a dam subject to the provisions of this Part shall also file with the Department the certificate of an engineer legally qualified in this State. The certificate shall state that the person who files the certificate is responsible for the design of the dam and that the design is safe and adequate.

(b) The Department shall send a copy of each completed application to the State Health Director, the Wildlife Resources Commission, the Department of Transportation, and other State and local agencies it considers appropriate for review and comment. (1967, c. 1068, s. 4; 1973, c. 476, s. 128; c. 507, s. 5; c. 1262, s. 23; 1987, c. 827, s. 176; 1989, c. 727, s. 163; 1993, c. 394, s. 4; 1995, c. 509, s. 80.)

§ 143-215.27. Repair, alteration, or removal of dam.

(a) Before commencing the repair, alteration or removal of a dam, application shall be made for written approval by the Department, except as otherwise provided by this Part. The application shall state the name and address of the applicant, shall adequately detail the changes it proposes to effect and shall be accompanied by maps, plans and specifications setting forth such details and dimensions as the Department requires. The Department may waive any such requirements. The application shall give such other information concerning the dam and reservoir required by the Department, such information concerning the safety of any change as it may require, and shall state the proposed time of commencement and completion of the work. When an application has been completed it may be referred by the Department for agency review and report, as provided by subsection (b) of G.S. 143-215.26 in the case of original construction.

(b) When repairs are necessary to safeguard life and property they may be started immediately but the Department shall be notified forthwith of the proposed repairs and of the work under way, and they shall be made to conform to its orders. (1967, c. 1068, s. 5; 1979, c. 55, s. 1.)

§ 143-215.28. Action by Commission upon applications.

(a) Following receipt of agency comments the Commission shall approve, disapprove, or approve subject to conditions necessary to ensure safety and to satisfy minimum stream flow requirements, all applications made pursuant to this Part.

(b) A defective application shall not be rejected but notice of the defects shall be sent to the applicant by registered mail. If the applicant fails to file a perfected application within 30 days the original shall be canceled unless further time is allowed.

(c) If the Commission disapproves an application, one copy shall be returned with a statement of its objections. If an application is approved, the approval shall be attached thereto, and a copy returned by registered mail. Approval shall be granted under terms, conditions and limitations which the Commission deems necessary to safeguard life and property.

(d) Construction shall be commenced within one year after the date of approval of the application or such approval is void. The Commission upon written application and good cause shown may extend the time for commencing construction. Notice by registered mail shall be given the Commission at least 10 days before construction is commenced. (1967, c. 1068, s. 6; 1973, c. 1262, s. 23; 1987, c. 827, s. 154.)

§ 143-215.28A. Application fees.

(a) In accordance with G.S. 143-215.3(a)(1a), the Commission may establish a fee schedule for processing applications for approvals of construction or removal of dams issued under this Part. In establishing the fee schedule, the Commission shall consider the administrative and personnel costs incurred by the Department for processing the applications and for related compliance activities. The total amount of fees collected in any fiscal year may not exceed one-third of the total personnel and administrative costs incurred by the Department for processing the applications and for related compliance activities in the prior fiscal year. An approval fee may not exceed the larger of two hundred dollars ($200.00) or two percent (2%) of the actual cost of construction or

removal of the applicable dam. The provisions of G.S. 143-215.3(a)(1b) do not apply to these fees.

(b) The Dam Safety Account is established as a nonreverting account within the Department. Fees collected under this section shall be credited to the Account and shall be applied to the costs of administering this Part. (1989 (Reg. Sess., 1990), c. 976, s. 1; 1991 (Reg. Sess., 1992), c. 1039, s. 15; 1993, c. 394, s. 5.)

§ 143-215.29. Supervision by qualified engineers; reports and modification during work.

(a) Any project for which the Commission's approval is required under G.S. 143-215.26, 143-215.27, and 143-215.28, and any project undertaken pursuant to an order of the Commission issued pursuant to this section or G.S. 143-215.32 shall be designed and supervised by an engineer legally qualified in the State of North Carolina.

(b) During the construction, enlargement, repair, alteration or removal of a dam, the Commission may require such progress reports from the supervising engineer as it deems necessary.

(c) If during construction, reconstruction, repair, alteration or enlargement of any dam, the Commission finds the work is not being done in accordance with the provisions of the approval and the approved plans and specifications, it shall give written notice by registered mail or personal service to the person who received the approval and to the person in charge of construction at the dam. The notice shall state the particulars in which compliance has not been made, and shall order immediate compliance with the terms of the approval, and the approved plans and specifications. The Commission may order that no further construction work be undertaken until such compliance has been effected and approved by the Commission. A failure to comply with the approval and the approved plans and specifications shall render the approval revocable unless compliance is made after notice as provided in this section. (1967, c. 1068, s. 7; 1973, c. 1262, s. 23; 1977, c. 878, s. 5; 1987, c. 827, s. 154.)

§ 143-215.30. Notice of completion; certification of final approval.

(a) Immediately upon completion, enlargement, repair, alteration or removal of a dam, notice of completion shall be given the Commission. As soon as possible thereafter supplementary drawings or descriptive matter showing or describing the dam as actually constructed shall be filed with the Department in such detail as the Commission may require.

(b) When an existing dam is enlarged, the supplementary drawings and descriptive matter need apply only to the new work.

(c) The completed work shall be inspected by the supervising engineers, and upon finding that the work has been done as required and that the dam is safe and satisfies minimum streamflow requirements, they shall file with the Department a certificate that the work has been completed in accordance with approved design, plans, specifications and other requirements. Unless the Commission has reason to believe that the dam is unsafe or is not in compliance with any applicable rule or law, the Commission shall grant final approval of the work in accordance with the certificate, subject to such terms as it deems necessary for the protection of life and property.

(d) Pending issuance of the Commission's final approval, the dam shall not be used except on written consent of the Commission, subject to conditions it may impose. (1967, c. 1068, s. 8; 1973, c. 1262, s. 23; 1987, c. 827, ss. 154, 177.)

§ 143-215.31. Supervision over maintenance and operation of dams.

(a) The Commission shall have jurisdiction and supervision over the maintenance and operation of dams to safeguard life and property and to satisfy minimum streamflow requirements. The Commission may adopt standards for the maintenance and operation of dams as may be necessary for the purposes of this Part. The Commission may vary the standards applicable to various dams, giving due consideration to the minimum flow requirements of the stream, the type and location of the structure, the hazards to which it may be exposed, and the peril of life and property in the event of failure of a dam to perform its function.

(b) The Department, consistent with rules adopted by the Commission, may impose any condition or requirement in orders and written approvals issued under this Part that is necessary to ensure that stream classifications, water quality standards, and aquatic habitat requirements are met and maintained, including conditions and requirements relating to the release or discharge of designated flows from dams, the location and design of water intakes and outlets, the amount and timing of the withdrawal of water from a reservoir, and the construction of submerged weirs or other devices intended to maintain minimum streamflows. The Commission shall adopt rules that specify the minimum streamflow in the length of the stream affected.

(c) The minimum streamflow in the length of the stream affected by a dam that is operated by a small power

producer, as defined in G.S. 62-3(27a), that diverts water from 4,000 feet or less of the natural streambed and where the water is returned to the same stream shall be:

(1) The minimum average flow for a period of seven consecutive days that would have an average occurrence of once in 10 years in the absence of the dam, or ten percent (10%) of the average annual flow of the stream in the absence of the dam, whichever is less, if prior to 1 January 1995 the small power producer was either licensed by the Federal Energy Regulatory Commission or held a certificate of public convenience and necessity issued by the North Carolina Utilities Commission.

(2) The minimum average flow for a period of seven consecutive days that would have an average occurrence of once in 10 years in the absence of the dam, or ten percent (10%) of the average annual flow of the stream in the absence of the dam, whichever is greater, if subdivision (1) of this subsection does not apply.

(3) To protect the habitat of the Cape Fear Shiner and other aquatic species, 28 cubic feet per second for any dam that diverts water from 2,500 feet or more of the natural streambed of any stream on which six or more dams operated by small power producers were located on 1 January 1995, notwithstanding subdivisions (1) and (2) of this subsection.

(d) Subsection (c) of this section establishes the policy of this State with respect to minimum streamflows in the length of the stream affected by a dam that is operated by a small power producer, as defined in G.S. 62-3(27a), that diverts water from 4,000 feet or less of the natural streambed and where the water is returned to the same stream, whether the dam is subject to or exempt from this Part. In its comments and recommendations to the Federal Energy Regulatory Commission regarding the minimum streamflow in the length of the stream affected by a dam that is operated by a small power producer, as defined in G.S. 62-3(27a), that diverts water from 4,000 feet or less of the natural streambed and where the water is returned to the same stream, the Commission and the Department shall not advocate or recommend a minimum streamflow that exceeds the minimum streamflow that would be required under subsection (c) of this section.

(e) The minimum streamflow in the length of the stream affected by a dam to which subsections (c) and (d) of this section do not apply shall be established as provided in subsection (b) of this section. Subsections (c) and (d) of this section do not apply if the length of the stream affected:

(1) Receives a discharge of waste from a treatment works for which a permit is required under Part 1 of this Article; or

(2) Includes any part of a river or stream segment that:

a. Is designated as a component of the State Natural and Scenic Rivers System by G.S. 113A-35.1 or G.S. 113A-35.2.

b. Is designated as a component of the national Wild and Scenic Rivers System by 16 U.S.C. § 1273 and 1274. (1967, c. 1068, s. 9; 1973, c. 1262, s. 23; 1987, c. 827, s. 154; 1993, c. 394, s. 6; c. 553, s. 80; 1995, c. 184, s. 1; c. 439, s. 1.)

§ 143-215.32. Inspection of dams.

(a) The Department may at any time inspect any dam, including a dam that is otherwise exempt from this Part, upon receipt of a written request of any affected person or agency, or upon a motion of the Environmental Management Commission. Within the limits of available funds the Department shall endeavor to provide for inspection of all dams at intervals of approximately five years.

(b) If the Department upon inspection finds that any dam is not sufficiently strong, is not maintained in good repair or operating condition, is dangerous to life or property, or does not satisfy minimum streamflow requirements, the Department shall present its findings to the Commission and the Commission may issue an order directing the owner or owners of the dam to make at his or her expense maintenance, alterations, repairs, reconstruction, change in construction or location, or removal as may be deemed necessary by the Commission within a time limited by the order, not less than 90 days from the date of issuance of each order, except in the case of extreme danger to the safety of life or property, as provided by subsection (c) of this section.

(c) If at any time the condition of any dam becomes so dangerous to the safety of life or property, in the opinion of the Environmental Management Commission, as not to permit sufficient time for issuance of an order in the manner provided by subsection (b) of this section, the Environmental Management Commission may immediately take such measures as may be essential to provide emergency protection to life and property, including the lowering of the level of a reservoir by releasing water impounded or the destruction in whole or in part of the dam or reservoir. The Environmental Management Commission may recover the costs of such measures from the owner or owners by appropriate legal action.

(d) An order issued under this Part shall be served on the owner of the dam as provided in G.S. 1A-1, Rule 4. (1967, c. 1068, s. 10; 1973, c. 1262, s. 23; 1977, c. 878, s. 3; 1987, c. 827, s. 154; 1993, c. 394, s. 7.)

§ 143-215.33. Administrative hearing.

A person to whom a decision or a dam safety order is issued under this Part may contest the decision or order by filing a contested case petition in accordance with G.S. 150B-23. A person to whom a decision is issued must file a contested case petition within 30 days after the decision is mailed to that person. A person to whom a dam safety order is issued must file a contested case petition within 10 days after the order is served. (1967, c. 1068, s. 11; 1973, c. 1262, s. 23; 1975, c. 842, s. 4; 1977, c. 878, s. 6; 1979, c. 55, s. 2; 1987, c. 827, s. 178; 1993, c. 394, s. 8.)

§ 143-215.34. Investigations by Department; employment of consultants.

The Department shall make such investigations and assemble such data as it deems necessary for a proper review and study of the design and construction of dams, reservoirs and appurtenances, and for such purposes may enter upon private property. The Department may employ or make such agreements with geologists, engineers, or other expert consultants and such assistants as it deems necessary to carry out the provisions of this Part. (1967, c. 1068, s. 12; 1973, c. 1262, s. 23; 1987, c. 827, s. 179.)

§ 143-215.35. Liability for damages.

No action shall be brought against the State of North Carolina, the Department, or the Commission or any agent of the Commission or any employee of the State or the Department for damages sustained through the partial or total failure of any dam or its maintenance by reason of any supervision or other action taken pursuant to or under this Part. Nothing in this Part shall relieve an owner or operator of a dam from the legal duties, obligations and liabilities arising from such ownership or operation. (1967, c. 1068, s. 13; 1973, c. 1262, s. 23; 1987, c. 827, s. 154.)

§ 143-215.36. Enforcement procedures.

(a) Criminal Penalties.

Any person who shall be adjudged to have violated this Article shall be guilty of a Class 3 misdemeanor and shall only be liable to a penalty of not less than one hundred dollars ($100.00) nor more than one thousand dollars ($1,000) for each violation. In addition, if any person is adjudged to have committed such violation willfully, the court may determine that each day during which such violation continued constitutes a separate violation subject to the foregoing penalty.

(b) Civil Penalties.

(1) The Secretary may assess a civil penalty of not less than one hundred dollars ($100.00) nor more than five hundred dollars ($500.00) against any person who violates any provisions of this Part, a rule implementing this Part, or an order issued under this Part.

(2) If any action or failure to act for which a penalty may be assessed under this Part is willful, the Secretary may assess a penalty not to exceed five hundred dollars ($500.00) per day for each day of violation.

(3) In determining the amount of the penalty, the Secretary shall consider the factors set out in G.S. 143B-282.1 (b). The procedures set out in G.S. 143B-282.1 shall apply to civil penalty assessments that are presented to the Commission for final agency decision.

(4) The Secretary shall notify any person assessed a civil penalty of the assessment and the specific reasons therefor by registered or certified mail, or by any means authorized by G.S. 1A-1, Rule 4. Contested case petitions shall be filed in accordance with G.S. 150B-23 within 30 days of receipt of the notice of assessment.

(5) Requests for remission of civil penalties shall be filed with the Secretary. Remission requests shall not be considered unless made within 30 days of receipt of the notice of assessment. Remission requests must be accompanied by a waiver of the right to a contested case hearing pursuant to Chapter 150B and a stipulation of the facts on which the assessment was based. Consistent with the limitations in G.S. 143B-282.1(c) and G.S. 143-282.1(d), remission requests may be resolved by the Secretary and the violator. If the Secretary and the violator are unable to resolve the request, the Secretary shall deliver remission requests and his recommended action to the Committee on Civil Penalty Remissions of the Environmental Management Commission appointed pursuant to G.S. 143B-282.1(c).

(6) If any civil penalty has not been paid within 30 days after notice of assessment has been served on the

violator, the Secretary shall request the Attorney General to institute a civil action in the Superior Court of any county in which the violator resides or has his or its principal place of business to recover the amount of the assessment, unless the violator contests the assessment as provided in subdivision (4) of this subsection. If any civil penalty has not been paid within 30 days after the final agency decision or court order has been served on the violator, the Secretary shall request the Attorney General to institute a civil action in the Superior Court of any county in which the violator resides or has his or its principal place of business to recover the amount of the assessment. A civil action shall be filed within three years of the date the final agency decision was served on the violator.

(7) The Secretary may delegate his powers and duties under this section to the Director of the Division of Land Resources of the Department.

(c) Injunctive Relief. - Upon violation of any of the provisions of this Part, a rule implementing this Part, or an order issued under this Part, the Secretary may, either before or after the institution of proceedings for the collection of the penalty imposed by this Part for such violations, request the Attorney General to institute a civil action in the superior court of the county or counties where the violation occurred in the name of the State upon the relation of the Department for injunctive relief to restrain the violation or require corrective action, and for such other or further relief in the premises as said court shall deem proper. Neither the institution of the action nor any of the proceedings thereon shall relieve any party to such proceedings from the penalty prescribed by this Part for any violation of the same. (1967, c. 1068, s. 14; 1973, c. 1262, s. 23; 1975, c. 842, s. 3; 1977, c. 771, s. 4; 1987, c. 827, ss. 154, 180; 1989 (Reg. Sess., 1990), c. 1036, s. 5; 1991, c. 342, ss. 10, 11; 1993, c. 394, s. 9; c. 539, s. 1021; 1994, Ex. Sess., c. 24, s. 14(c).)

§ 143-215.37. Rights of investigation, entry, access, and inspection.

The Commission shall have the right to direct the conduct of such investigations as it may reasonably deem necessary to carry out its duties prescribed in this Part, and the Department shall have the right to conduct such investigations, and for this purpose the employees of the Department and agents of the Commission have the right to enter at reasonable times on any property, public or private, for the purpose of investigating the condition, construction, or operation of any dam or associated equipment facility or property, and to require written statements or the filing of reports under oath, with respect to pertinent questions relating to the construction or operation of any dam: Provided, that no person shall be required to disclose any secret formula, processes or methods used in any manufacturing operation or any confidential information concerning business activities carried on by him or under his supervision. No person shall refuse entry or access to any authorized representative of the Commission or Department who requests entry for purposes of inspection, and who presents appropriate credentials, nor shall any person obstruct, hamper or interfere with any such representative while in the process of carrying out his official duties. (1967, c. 1068, s. 15; 1973, c. 1262, s. 23.)

CHAPTER 61-03
STATE ENGINEER

61-03-21. State engineer may require plan of operation - Adequate structure. Every operator of a water storage reservoir in North Dakota having a capacity of more than one thousand acre-feet [1233481.84 cubic meters] shall annually, between the first and fifteenth day of February, file with the state engineer an operating plan for such reservoir for the calendar year in which the same is filed. The operator of any such reservoir shall be required to cooperate with the state engineer to the end that all water releases shall be compatible with the best interest of the greatest number of downstream water users and affected landowners. In the event that the state engineer declares an emergency to exist in connection with the operation of any such reservoir, the operator thereof shall promptly submit to the state engineer a separate interim operating plan therefor in addition to the annual reservoir operating plan herein required. Such interim operating plan shall then be coordinated and integrated with the suggestions and plans of the state engineer to best serve the affected interests during such emergency. The state engineer may also require such operators to maintain adequate structures and to operate them in a manner that will prevent waste, promote the beneficial use of water and not endanger the general health and welfare of persons affected thereby. In the event such operator fails to maintain and operate adequate structures in the manner provided in this section, the state engineer shall set a place and time for hearing and shall serve notice upon such operator to show cause at such time and place why his water permit should not be declared terminated and canceled. A copy of any order terminating or canceling such water right shall be filed in the office of the recorder in the county or counties where the land to which the right is appurtenant is located. An appeal may be taken from the decision of the state engineer in accordance with the provisions of chapter 28-32.

History: Enacted 1957; amended 1963, 2001.

61-03-21.1. Inspection by state engineer. Whenever the state engineer is authorized or mandated by law to inspect or investigate an alleged violation of a statute under this title, the state engineer shall have the authority to enter upon land for the purposes of conducting such an inspection or investigation. Except in emergency situations as determined by the state engineer, the state engineer shall request written permission from the landowner to enter the property. If the landowner refuses to give written permission, or fails to respond within five days of the request, the state engineer may request the district court of the district containing the property for an order authorizing the state engineer to enter the property to inspect or investigate the alleged violation.

History: Enacted 1985; amended 1991.

61-03-21.2. Removal or modification of unsafe or unauthorized works. If the state engineer pursuant to the state engineer's authority under this title determines that works are unsafe or unauthorized, the state engineer shall notify the landowners by registered mail at the landowner's last known post-office address of record. A copy of the notice must also be sent to any tenant, if the state engineer has actual knowledge of the fact that a tenant exists. The notice must specify the nature and extent of the noncompliance, the modifications necessary for compliance, and must state that if the works are not modified or removed within the period stated in the notice, but not less than thirty days, the state engineer shall cause the removal or modification of the works and assess the cost thereof, or such portion as the state engineer shall determine, against the property of the landowner responsible. The notice must also state that the affected landowner may, within fifteen days of the date the notice is mailed, demand, in writing, a hearing upon the matter. The request for a hearing must state with particularity the issues, facts, and points of law to be presented at the hearing. If the state engineer determines the issues, facts, and law to be presented are well founded and are not frivolous and the request for a hearing was not made merely to interpose delay, the state engineer shall set a hearing date without undue delay. In the event of an emergency, the state engineer may immediately apply to the appropriate district court for an injunction prohibiting the landowner or tenant from constructing or maintaining the works, or ordering the landowner to remove or modify the works. Any assessments levied under the provisions of this section must be collected in the same manner as other assessments authorized by this title. If, in the opinion of the state engineer, more than one landowner or tenant has been responsible, the costs may be assessed on a pro rata basis in proportion to the responsibility of the landowners. Any person aggrieved by action of the state engineer under the provisions of this section may appeal the decision of the state engineer to the district court of the county in which the land is located in accordance with the procedures provided under chapter 28-32. A hearing as provided for in this section is a prerequisite to an appeal, unless the hearing was denied by the state engineer.

For purposes of this section, the term "works" includes dams, dikes, wells, or other devices for water conservation, flood control, regulation, storage, diversion, or carriage of water.

History: Enacted 1985; amended 1989, 1991.

CHAPTER 61-04
APPROPRIATION OF WATER

61-04-11. Inspections of works. If the state engineer, in the course of the state engineer's duties, shall find that any works used for the storage, diversion, or carriage of water are unsafe and a menace to life or property, the state engineer at once shall notify the owner or the owner's agent, specifying the changes necessary and allowing a reasonable time for putting the works in safe condition. Upon the request of any party, accompanied by the estimated cost of inspection, the state engineer shall cause any alleged unsafe works to be inspected. If they shall be found unsafe by the state engineer, the money deposited by such party shall be refunded, and the fees for inspection shall be paid by the owner of such works. If such fees are not paid by the owner of such works within thirty days after the decision of the state engineer, they shall be a lien against any property of such owner, and shall be recovered by a suit instituted by the state's attorney of the county at the request of the state engineer. The state engineer, when in the state engineer's opinion it is necessary, may inspect any works under construction for the storage, diversion, or carriage of water, and may require any changes necessary to secure their safety. The fees for such inspection shall be a lien on any property of the owner and shall be subject to collection as provided in this chapter but neither the United States nor the state of North Dakota nor any agency thereof shall be required to pay such fees.

History: Enacted 1905; amended 1961.

CHAPTER 61-16.1
OPERATION OF WATER RESOURCE DISTRICTS

61-16.1-38. Permit to construct or modify dam, dike, or other device required - Penalty - Emergency. No dikes, dams, or other devices for water conservation, flood control regulation, watershed improvement, or storage of water which are capable of retaining, obstructing, or diverting more than fifty acre-feet [61674.08 cubic meters] of water or twenty-five acre-feet [30837.04 cubic meters] of water for a medium-hazard or high-hazard dam, may be constructed within any district except in accordance with the provisions of this chapter. An application for the construction of any dike, dam, or other device, along with complete plans and specifications, must be presented first to the state engineer. Except for low-hazard dams less than ten feet [3.05 meters] in height, the plans and specifications must be completed by a professional engineer registered in this state. After receipt, the state engineer shall consider the application in such detail as the state engineer deems necessary and proper. The state engineer shall refuse to allow the construction of any unsafe or improper dike, dam, or other device which would interfere with the orderly control of the water resources of the district, or may order such changes, conditions, or modifications as in the judgment of the state engineer may be necessary for safety or the protection of property. Within forty-five days after receipt of the application, except in unique or complex situations, the state engineer shall complete the state engineer's initial review of the application and forward the application, along with any changes, conditions, or modifications, to the water resource board of the district within which the

contemplated project is located. The board thereupon shall consider, within forty-five days, the application, and suggest any changes, conditions, or modifications to the state engineer. If the application meets with the board's approval, the board shall forward the approved application to the state engineer. The state engineer shall make the final decision on the application and forward that decision to the applicant and the local water resource board. The state engineer may issue temporary permits for dikes, dams, or other devices in cases of an emergency. Any person constructing a dam, dike, or other device, which is capable of retaining, obstructing, or diverting more than fifty acre-feet [61674.08 cubic meters] of water or twenty-five acre-feet [30837.04 cubic meters] of water for a medium-hazard or high-hazard dam, without first securing a permit to do so, as required by this section, is liable for all damages proximately caused by the dam, dike, or other device, and is guilty of a class B misdemeanor.

History: Enacted 1981; amended 1985, 1997, 2003.

NORTH DAKOTA ADMINISTRATIVE CODE

ARTICLE 89-08
DAMS, DIKES, AND OTHER DEVICES

CHAPTER 89-08-01
DEFINITIONS

89-08-01-01. Definitions. The following definitions apply in this article:

1. "Appurtenant works" means all works incident or attached to a dam, dike or other device, including but not limited to:

   a. A spillway, either in the dam or separate from it;

   b. The reservoir and its rim;

   c. A low-level outlet; and

   d. A water conduit such as a tunnel, pipeline, or penstock, either through the dam, dike or other device or their abutments.

2. "Construction" or "construct" means any activity for which a permit is required by North Dakota Century Code section 61-16.1-38, including construction, alteration, enlargement, or modification of a dam, dike, or other device.

3. "Dam" means any artificial barrier or obstruction, including any appurtenant works, across a stream channel, watercourse, or an area that drains naturally or may impound water.

4. "Dike" means an embankment, including appurtenant works, constructed to protect real or personal property.

5. "District" means a water resource district.

6. "Engineer" means a person who has been duly registered and licensed as an engineer by the North Dakota state board of registration for professional engineers and land surveyors.

7. "Height" means the vertical distance in feet from the stream channel bottom at the centerline of the dam to the top of the settled embankment.

8. "High-hazard dam" means any dam located upstream of developed or urban areas where failure may cause serious damage to homes, industrial and commercial buildings, and major public utilities. There is potential for the loss of more than a few lives if the dam fails.

9. "Inspection" means a visual or mechanical check, a measurement, a boring, or any other method necessary for determination of the adequacy of construction techniques, conformity of work with approved plans and specifications, or the safety and operating performance of a dam, dike, or other device.

10. "Low-hazard dam" means a dam located in rural or agricultural areas where there is little possibility of future development. Failure of low-hazard dams may result in damage to agricultural land, township and county roads, and farm buildings other than residences. No loss of life is expected if the dam fails.

11. "Medium-hazard dam" means a dam located in predominately rural or agricultural area where failure may damage isolated homes, main highways, or railroads, or cause interruption of minor public utilities. The potential for the loss of a few lives may be expected if the dam fails.

12. "Other device" means a water control structure, other than a dam or dike, which may include, but is not limited to, diversion ditches, dugouts, lagoons, and holding ponds.

13. "Owner" means any person who owns, controls, operates, maintains, manages, or proposes to construct a dam, dike, or other device, except that for the purpose of signing the application for construction permit, "owner" means the person who owns the property or interest in property upon which the dam, dike, or other device will be built.

14. "State engineer" means the state officer provided for in North Dakota Century Code section 61-03-01 or any of the state engineer's employees or authorized agents.

History: Effective November 1, 1989.
General Authority: NDCC 28-32-02, 61-03-13
Law Implemented: NDCC 61-16.1-38

89-08-01-02. Definition of unsafe dam, dike, or other device. A dam, dike, or other device is unsafe if it threatens harm to life or property, or is improperly maintained.

History: Effective November 1, 1989.
General Authority: NDCC 28-32-02, 61-03-13
Law Implemented: NDCC 61-03-21.2

CHAPTER 89-08-02
CONSTRUCTION PERMITS

89-08-02-01. Determining the capacity of dams, dikes, or other devices. The impounding capacity of a dam is calculated based upon the top of the settled embankment of the dam. The diverting capacity of a dike is calculated based upon the area protected as measured from the top of the dike. If the absence of the dike could result in more than fifty acre-feet of water inundating the protected area, a permit is required. The diverting capacity of a diversion ditch is calculated based upon the runoff from a twenty-five year, twenty-four hour, precipitation event. No construction on the dam, dike, or other device can begin until a construction permit is obtained.

History: Effective November 1, 1989; amended effective April 1, 2004.
General Authority: NDCC 28-32-02, 61-03-13
Law Implemented: NDCC 61-16.1-38

89-08-02-02. Contents of application. A completed application for a construction permit must be submitted to the state engineer along with plans and specifications; evidence recognized in a court of law sufficient to establish a prima facie case of a property right in the property that will be affected by the construction of the dam, dike, or other device; and any additional data or information required by the state engineer.

History: Effective November 1, 1989; amended effective June 1, 1998; April 1, 2004.
General Authority: NDCC 28-32-02, 61-03-13
Law Implemented: NDCC 61-16.1-38

89-08-02-03. Permit does not absolve liability for damages. The receipt of a permit, including a permit for emergency construction, does not relieve an applicant from liability for damages resulting from any activity conducted pursuant to the permit.

History: Effective June 1, 1998.
General Authority: NDCC 28-32-02, 61-03-13
Law Implemented: NDCC 61-16.1-38

89-08-02-04. Temporary construction permits. If the state engineer determines an emergency exists, the state engineer may issue a temporary permit to construct a dam, dike, or other device capable of impounding, obstructing, or diverting more than fifty acre-feet. A temporary permit shall have a duration of not more than six months unless extended by the state engineer.

History: Effective April 1, 2004.
General Authority: NDCC 28-32-02, 61-03-13
Law Implemented: NDCC 61-16.1-38

CHAPTER 89-08-03
INSPECTIONS

89-08-03-01. Inspections and reports during construction of high-hazard dams, medium-hazard dams, and low-hazard dams over ten feet [3.05 meters] in height. In order to protect property and assure safety, the following are conditions to all permits for high-hazard dams, medium-hazard dams, or low-hazard dams over ten feet [3.05 meters] in height:

1. An engineer must be in charge of and responsible for inspections during construction.

2. Inspections during construction must be performed at intervals necessary to ensure conformity with the construction permit and the plans and specifications.

3. Within seven days after each inspection, the engineer in charge shall submit a written report to the state engineer specifying the information obtained pursuant to the inspection. The report will specify any changes necessary under this section.

History: Effective November 1, 1989; amended effective April 1, 2004.
General Authority: NDCC 28-32-02, 61-03-13
Law Implemented: NDCC 61-16.1-38

89-08-03-02. Monitoring during construction by the state engineer. The state engineer may monitor any dam, dike, or other device during construction to ensure conformity with the construction permit and the plans and specifications.

History: Effective November 1, 1989.
General Authority: NDCC 28-32-02, 61-03-13
Law Implemented: NDCC 61-04-11

89-08-03-03. Changes in construction. If, pursuant to an inspection under section 89-08-03-01 or section 89-08-03-02, the state engineer or engineer in charge determines changes in construction are necessary to insure safety, whether the changes are necessary because the dam, dike, or other device does not comply with the construction permit or plans and specifications, or an unforeseen condition is discovered, or for any other reason, the state engineer may order the appropriate changes and may order construction be stopped until the changes are made.

History: Effective November 1, 1989.
General Authority: NDCC 28-32-02, 61-03-13
Law Implemented: NDCC 61-04-11

89-08-03-04. Requested inspections.

1. Upon receipt of an affidavit complaining a dam, dike or other device is unsafe because of its construction, maintenance, or operation, the state engineer shall examine the available information and determine if the complaint is justified.

2. If the state engineer determines the complaint is unjustified, the state engineer shall notify the complainant in writing of that fact. If the complainant continues to request an inspection even though the state engineer determines the complaint is unjustified, the state engineer shall make the inspection upon receiving from the complainant a certified check or cashier's check in an amount sufficient to cover the total cost of inspection.

3. If the state engineer determines the complaint is justified, the state engineer shall make the inspection upon receiving from the complainant a certified check or cashier's check in an amount sufficient to cover the total cost of inspection.

4. If the dam, dike, or other device is defective, the state engineer shall require the owner of the dam, dike, or other device to pay the cost of inspection, and upon payment shall return the amount deposited by the complainant. If the cost of inspection is not paid within thirty days by the owner of the defective dam, dike, or other device, the cost of inspection shall become a lien against any of the owner's property.

5. If the dam, dike, or other device is not found defective, any money deposited by the complainant for the inspection may not be returned.

History: Effective November 1, 1989.
General Authority: NDCC 28-32-02, 61-03-13
Law Implemented: NDCC 61-04-11, 61-03-21.1, 61-03-21.2

89-08-03-05. Periodic inspections after construction. As a condition on all construction permits, the state engineer may require inspection of a dam, dike, or other device as often as necessary after construction to protect property and assure safety.

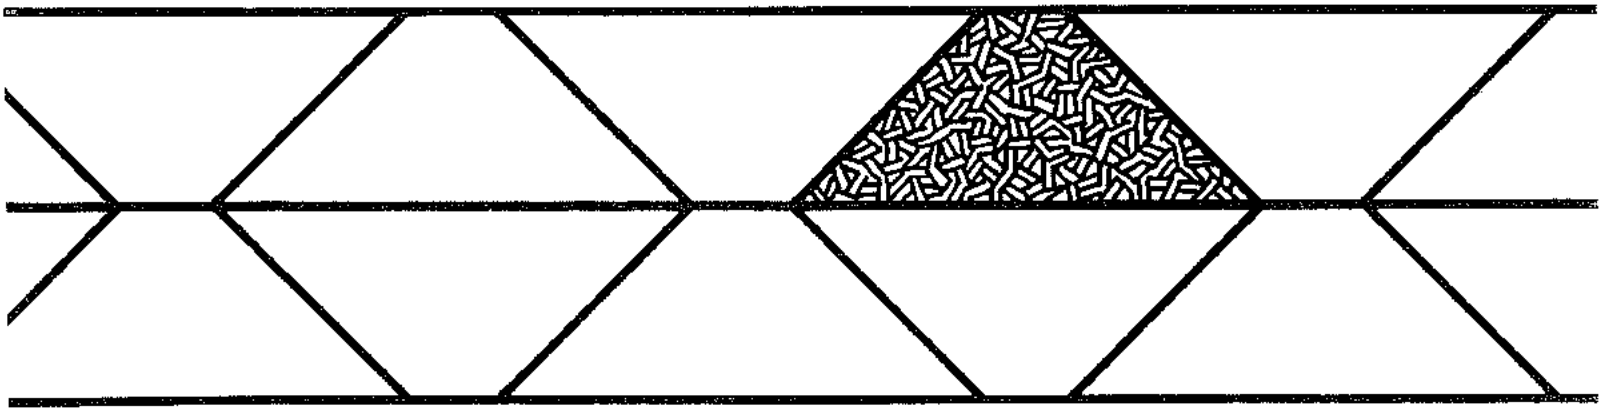
History: Effective November 1, 1989.
General Authority: NDCC 28-32-02, 61-03-13
Law Implemented: NDCC 61-04-11, 61-16.1-38

89-08-03-06. As built plans. As a condition on all construction permits, the owner of the dam, dike, or other device will provide the state engineer with "as built" plans after the dam, dike, or other device has been constructed.

History: Effective November 1, 1989.
General Authority: NDCC 28-32-02, 61-03-13
Law Implemented: NDCC 61-16.1-38

CHAPTER 89-08-04
OPERATING PLAN

89-08-04-01. Operating plan. By the fifteenth of February of each year, the operator of a reservoir with a capacity of more than one thousand acre-feet shall submit an operation plan for that year to the state engineer. The state engineer shall review the operating plan and if deficiencies or discrepancies exist, the state engineer shall notify the owner of the dam of the deficiencies or discrepancies within thirty days of discovering the deficiencies or discrepancies. The owner of the dam shall correct the deficiencies or discrepancies and return the corrected operating plan to the state engineer within fourteen days of receiving notice of the deficiencies or discrepancies. The operation plan must be approved by the state engineer prior to the operation of the dam. If the operator receives no response from the state engineer, the operation plan is approved. The operation plan must contain at a minimum:



1. A reservoir operation procedure;

2. A maintenance procedure for the dam and appurtenant works; and

3. Emergency procedures and warning plans.

History: Effective November 1, 1989.
General Authority: NDCC 28-32-02, 61-03-13
Law Implemented: NDCC 61-03-21

North Dakota Dam Design Handbook

North Dakota State Engineer
June 1985

CHAPTER I:

Purpose and Authority of Manual

The North Dakota State Engineer, under Section 61-02-14 of the North Dakota Century Code (NDCC), is charged with reviewing and approving construction drawings and specifications for dams constructed in North Dakota.

This handbook is primarily for use by engineers in the design and construction of earth dams in the state of North Dakota. Water resource districts may also find the handbook of assistance in their work. The handbook is a guide for the gathering of data, the design of the structure, the preparation of construction drawings and specifications, and the inspection of construction.

The handbook is not to be considered and does not represent a comprehensive step-by-step set of requirements for dam design. Its purpose is to outline the suggested standards for dam design in North Dakota, along with recommended methods and references. The engineering for each dam will be reviewed by the State Engineer on a case-by-case basis. Latitude will be provided to engineers allowing use of other methods producing a product of satisfactory quality.

CHAPTER II:

Liability

As a general rule, engineers have a duty to "exercise that degree of skill and knowledge normally exercised by members of the profession."

A design professional who plans and supervises a construction project will be liable to all persons who may foreseeably be injured if he does not fulfill his duty of properly exercising the skill he is assumed to possess. Design engineers have been found liable to the contractor, and to workmen for damages caused by defects in a design, if an exercise of the proper degree of skill would have prevented the defect.

Section 9-08-02.1 of the NDCC voids construction contracts with provisions making the contractor liable for "errors or omissions of the owner or his agents in the plans and specifications." Under this statute, the design professional will likely be either an owner or an owner's agent. Attempts to pass the liability for design defects to the contractor generally have been ineffective.

Owners of dams have a continuing duty to maintain their dams in a safe and hazard-free condition. Their duty also applies to the area adjacent to the dam. Liability may result if it is determined that injury or damages occurred as a result of an owner's negligence in maintaining a dam.

Section 43-19.1-28 of the NDCC requires the state or any political subdivision (including water resource boards, commissions, etc.) to hire a registered professional engineer to make all engineering drawings, specifications, estimates, and to supervise construction if the cost of the project exceeds $50,000.

CHAPTER III:

Permit Requirements

A. Authority

The North Dakota State Engineer, pursuant to Chapter 61-04 and Sections 61-16.1-38 and 61-16.1-53, North Dakota Century Code, and the North Dakota State Water Commission, pursuant to Section 61-02-14 of the North Dakota Century Code, have the power, authority and general jurisdiction to regulate, control and supervise the construction and operation of all dams within the state of North Dakota, both public and private, which they deem necessary or advisable. Also, the State Water Commission has the power and authority to work with the United States and any of its departments, agencies or officers with regard to dams, and to do what is necessary to carry out the expressed and implied purposes of Chapter 61-02, North Dakota Century Code.

B. Permits

1. Construction Permit

No dams which are capable of retaining or storing more than 12½ acre-feet of water may be constructed in North Dakota without a permit. An application for the construction of a dam must be submitted first to the State Engineer. The application must be on State Water Commission Form 110 (see Appendix A) and must include complete plans and specifications for the dam or reference to standard specifications. Upon receipt, the State Engineer will review the application. Except in unique circumstances, the State Engineer will complete his initial review within 45 days. He will forward the application, plans and specifications, along with any changes or conditions, to the water resource board of the district within which the contemplated dam is located. Within 45 days, the board shall consider the application and information forwarded by the State Engineer and return it to the State Engineer with its decision and comments regarding suggested changes, conditions and modifications. The State Engineer makes the final decision and forwards that decision to the applicant and the board (61-16.1-38, N.D.C.C.).

2. Water Permit

If water is to be appropriated and put to beneficial use as a result of the construction of a dam, a conditional water permit must be obtained prior to the initiation of construction. An application form 108 (see Appendix A) and instruction booklet, for the purpose of acquiring a conditional water permit, may be obtained from the State Engineer's office in Bismarck. Chapter 61-04, NDCC, establishes the procedures that must be followed prior to acquiring a conditional water permit.

3. Other Permits

The construction of a dam may require several other permits. The Corps of Engineers may require permits under the authority of Section 404 of the Clean Water Act and Section 10 of the Rivers and Harbors Act. The North Dakota Health Department requires a permit to discharge water into a stream. The State Engineer also requires a temporary water permit for water used during construction. Additional information on these permits can be obtained by contacting the respective agencies.

CHAPTER IV:

Classification of Dams

Dams shall be categorized according to the potential hazard to property or loss of life if the dam should suddenly fail. Existing development, as well as future downstream development, must be considered when categorizing a dam. The hazard category will be based solely on potential hazard from failure and not on the selected design criteria.

Although it is recognized that loss of life is possible with any dam failure, the following hazard categories of dams have been established for North Dakota:

Low — dams located in rural or agricultural areas where there is little possibility of future development. Failure of low hazard dams may result in damage to agricultural land, township and county roads, and farm buildings other than residences. No loss of life is expected if the dam fails;

Medium — dams located in predominantly rural or agricultural areas where failure may damage isolated homes, main highways, railroads or cause interruption of minor public utilities. The potential for the loss of a few lives may be expected if the dam fails;

High — dams located upstream of developed and urban areas where failure may cause serious damage to homes, industrial and commercial buildings and major public utilities. There is a potential for the loss of more than a few lives if the dam fails.

After a dam has been categorized according to failure hazard, it will also be classified for dam design criteria. Design criteria shall be based on the hazard classification and the height of the dam. ("Height of the dam" is defined as the distance in feet from the stream channel bottom at the centerline of the dam to the top of the settled embankment.)

Table 4-1 is based on dam height and hazard categories and outlines five classifications for dam design. Each classification will require varying degrees of intensity of investigation for hydrology, foundation and borrow explorations, soil testing, structural design, etc.

Table 4-1. Dam Design Classifications

Dam Height (Feet)	Hazard Categories		
	Low	Medium	High
Less than 10	I	II	IV
10 to 24	II	III	IV
25 to 39	III	III	IV
40 to 55	III	IV	V
Over 55	III	IV	V

CHAPTER V:

Standards for New Earthfill Dams

In general, earth dams should be designed in accordance with the following principles:

- the embankment shall not be overtopped by the design flood;
- the embankment phreatic line will not intercept the downstream face;
- the embankment slopes are stable under varying conditions;
- the embankment slopes are flat enough to limit shear stress in the foundation to the shear strength of the foundation materials with an adequate factor of safety;
- seepage water will not pass freely from the upstream embankment face to the downstream embankment face;
- seepage water passing through the embankment or the foundation shall have velocities lower than that required to move embankment or foundation materials; and
- the upstream face is protected against wave action and erosion and the downstream face is protected against erosion.

The criteria standards listed in this chapter are commensurate with the design classifications listed in Chapter IV. Thus, a low hazard dam will not require as extensive an investigation as a high hazard dam. It is recommended that the designer prepare a preliminary outline for review by the State Engineer prior to submitting the permit application. The outline shall set forth the dam classification, the general criteria to be used, and the degree of investigation and testing determined appropriate in the design of the proposed dam. The outline shall give the location, purpose, drainage area, owner, etc., of the proposed structure. The furnishing of this outline may eliminate unnecessary investigation expense.

This chapter is divided into eight sections, each covering a major component in the design of a dam. Each section includes a discussion of the general considerations along with suggested criteria standards. The majority of the suggestions are USDA-Soil Conservation Service criteria and guidelines with modifications. Deviations from these recommendations may be allowed, subject to the approval of the State Engineer, if there is a sound engineering basis for the change. The eight main sections in this chapter include:

A. Land Rights and Utilities
B. Hydrology
C. Sediment Storage
D. Geotechnical Exploration
E. Embankment and Foundation Design
F. Principal Spillway Design
G. Emergency Spillway Design
H. Design Documentation

A. Land Rights and Utilities

1. Land Rights

The need for fee title, easements and construction permits largely depends on the present and future ownership of the land involved in the dam and reservoir area. In general, stock and small irrigation dams are on the dam owner's land. In this case, land rights are usually unnecessary unless prior easements exist for other purposes. Larger dams, reservoirs and borrow areas may be located on land of several owners.

While it is the responsibility of the structure owner to obtain the necessary fee title, easements or construction permits, it is recommended that the designer prepare a land rights map for the owner and the State Engineer showing:

(a) the location of the structure (section, township, and range) on a county map which also shows prominent landmarks;

(b) a detailed site layout map showing both the land ownership, and the location of the dam, reservoir, borrow area(s) and ingress and egress routes (section, subdivisions, township and range);

(c) farmsteads and buildings;

(d) public roads;

(e) surface and buried utilities; and

(f) mines, oil wells, gravel pits, etc.

2. Utilities

Existing pipelines, cables, conduits, and materials are frequently encountered in proposed reservoir areas. Buried conduits are usually located at shallow depths in the floodplain. Utilities that represent a safety hazard should be relocated away from the site or modified to provide adequate safety assurances. Overhead cables or power lines should be relocated or raised as necessary to prevent damage or hazard to the public. All land rights, including subordination easements, should be obtained prior to bid letting or construction.

Every reasonable effort should be made to remove all conduits, cables and pipelines from the site. Most utility owners will want their facility removed from the site for easy maintenance. Only as a last resort, and

with concurrence of the affected utility owner and State Engineer, are conduits to be permitted to remain under an earth embankment.

Conduits permitted to remain under any part of the embankment are to be: (1) encased in concrete or otherwise treated to ensure durability and strength equal to that of the principal spillway; (2) properly articulated on all yielding foundations; (3) made watertight against leaking either into or out of the conduit; and (4) provided with anti-seep collars.

Enclosure of a conduit in another conduit is acceptable if the larger conduit meets the requirements of this section. The outside conduit must be positively sealed at the upstream end to prevent seepage and must extend the full distance under the embankment.

All plans for leaving utilities under the embankment or reservoir areas of a dam must have the approval of the utility owner and appropriate regulatory agencies.

B. Hydrology

One aspect in the investigation of a dam is the determination of the hydrologic performance of the project during flood events. These hydrologic investigations can usually be placed in two classes: (1) the investigations based on specific frequencies to determine the size of the principal spillway, and (2) the investigations based on Probable Maximum Precipitation (PMP) to determine the size of the emergency spillway. This section describes the procedures recommended for determining the required sizes of these two spillways.

1. Drainage Area Determination

(a) Principal Spillway Design

The contributing drainage area for principal spillway design can be adjusted for significant storage areas within the watershed. The available depressional storage may be estimated by a number of methods including field reviews, USGS topographic maps and aerial photography. It is recommended that 5-10 percent of the storage areas be randomly sampled to determine their approximate surface areas and depths. These samples should indicate both normal water levels and levels to the point of overflow. Normal water levels should be verified by landowner interviews or by examination of photographic records. Using this surface area and depth information, the volume of available storage may be estimated. If the volume of storage is large in relation to the design runoff volume, the storage areas may be considered non-contributing and may be deducted from the drainage area used to develop the design flood hydrograph for the principal spillway. Although the determination of significant storage is a judgment decision, storage should be at least 70 percent of the design runoff volume before areas are classified as non-contributing. Times of concentration and other watershed parameters should be based only on the contributing area.

(b) Emergency Spillway Design

The design storms for emergency spillway and freeboard design are critical to the safety of the dam. Also, runoff volumes are typically large, approaching the probable maximum values for high hazard structures. Because depressional storage areas may be periodically full, or partially full, reduction of the drainage area and associated runoff amounts are not recommended for the emergency spillway and freeboard design storms. Therefore, the total drainage area should be used for these design storms.

2. Rainfall and Snowmelt Design Data

Generally, principal spillway capacity and associated floodwater retarding storage is designed to meet the objectives of the dam; emergency spillway capacity is designed to provide the necessary safety requirements of the dam. The precipitation design amounts used to size these spillways is related to the dam design classifications. Table 5-1 shows the suggested hydrologic spillway criteria for both the principal and emergency spillways.

As indicated by footnote 3, Table 5-1, the State Engineer may allow adjustments to the PMP events on a case-by-case basis. One method that could be used to evaluate downstream impacts is risk analysis. Risk analysis can involve an assessment of several factors including incremental damage, depth of inundation in the downstream area and the opportunity to warn downstream areas. Incremental damage is the difference in damages, including loss of life, between two or more conditions. For example, incremental damage would be the difference in damages caused by a PMP event with a dam failure and the damages caused by a PMP event without a dam failure. The depth of inundation in the downstream area, including velocities, also merits consideration. In North Dakota, most natural floods do not produce high velocities in the inundation areas. These lower velocities reduce the risk of loss of life and, to some extent, loss of property. However, water depths and velocities resulting from a dam failure will likely be very high and, therefore, need careful review. The opportunity to warn downstream areas of a

Table 5-1. Suggested Precipitation Criteria For Spillway Design [1] [2] [3]

Dam Design Classification[4]	Principal Spillway[5]	Emergency Spillway Criteria	
		Velocity[6]	Freeboard[7]
I	—	P_{10}	P_{25}
II	—	P_{25}	P_{50}
III	P_{25}	P_{100}	.3 PMP
IV	P_{50}	.3 PMP	.5 PMP
V	P_{100}	.4 PMP	PMP

[1] Precipitation amounts by return period in years.

[2] PMP = Probable Maximum Precipitation.

[3] Each dam will have to be carefully evaluated to determine potential impact of dam failure. If the design engineer can show that damages and loss of life would not be significant as a result of failure, the State Engineer may allow a smaller event as the acceptable criteria.

[4] See Table 4-1, page 3.

[5] The requirement of the principal spillway event is to pass the flows without use of a non-structural emergency spillway.

[6] The requirement of the velocity hydrograph is to pass the flows within acceptable velocity limits (See Table 5-2, page 6).

[7] The requirement of the freeboard hydrograph is to pass the flows without overtopping the dam.

dam failure is also important. If the main impact area is only a few miles downstream, the amount of time available to warn people is short. On the other hand, the time available to warn areas 10 or 20 miles downstream is longer; therefore, the loss-of-life factor will be reduced. The development of a good warning system can significantly reduce loss-of-life impacts.

It is possible that an embankment can withstand overtopping without failing. This may be due to design features, construction methods and materials, and limited depth and duration of overtopping. If it can be shown that overtopping is not likely to result in the failure of the dam, then a smaller design event may be allowed.

(a) Principal Spillway Precipitation

The principal spillway precipitation events are used to determine the capacity of the principal spillway and the minimum elevation of the emergency spillway. Rainfall and snowmelt frequencies for design events of 100-year or less can be found in the USDA-SCS "North Dakota Hydrology Manual." The SCS soil cover complex number (curve number) procedure found in the manual is recommended for determining runoff volumes from rainfall precipitation.

Estimates of direct runoff volumes for design can be found in Soil Conservation Service's Technical Release Number 60, "Earth Dams and Reservoirs," and in the "North Dakota Hydrology Manual." Referenced volumes are for a 10-day duration and are used in the development of a principal spillway hydrograph.

The event that provides the maximum reservoir level should be used as the design event (i.e., 24-hour rainfall, 10-day rainfall or snowmelt). The critical event is dependent on the storage capacity and design of the dam. The 10-day events are the most common critical events, therefore, they should always be included in the analysis.

The time distribution of the precipitation events is also an important factor. The distribution tables found in the "North Dakota Hydrology Manual" are acceptable.

(b) Emergency Spillway Design Precipitation

The velocity precipitation amounts shown in Table 5-1 are the storm events that must be passed through the emergency spillway at a safe velocity. Allowable velocities depend on soils within the spillway. Table 5-2 lists the permissible velocities for vegetated emergency spillways. The values in Table 5-2 may be increased 10 percent when the anticipated use of the spillway is not more frequent than once in 50 years. They may be increased 25 percent when the anticipated use is not more frequent than once in 100 years. The freeboard precipitation amounts, shown in Table 5-1, are the minimum design storms that the structure must pass without overtopping the embankment. The velocity criteria does not apply to freeboard precipitation.

Hydrologic designs of emergency spillways for dam classifications III, IV and V require a determination of the PMP. These PMP amounts can be found in the U.S. Department of Commerce - National Oceanic and Atmospheric Administration (NOAA) "Hydrometeorological Report," Number 51.

For class V dams, it is suggested that the procedures outlined in NOAA "Hydrometeorological Report," Number 52 be followed in determining the Probable Maximum Flood (PMF). For lower class dams, it is adequate to determine the PMP rainfall amounts from the "North Dakota Hydrology Manual," adjust the amounts according to Table 5-1, and input this information directly into the hydrologic model.

Table 5-2. Permissible Velocities for Vegetated Emergency Spillways [1]

Cover[2]	Slope range (percent)	Permissible Velocity: Erosion resistant soils (ft/sec)	Permissible Velocity: Easily eroded soils (ft/sec)
Group 1	0-5	7	5
	5-10	6	4
	Over 10	5	3
Group 2	0-5	5	4
	5-10	4	3
Group 3	0-5	3.5	2.5
Group 4	0-5	3.5	2.5

[1] Use velocities exceeding five feet per second only where good covers and proper maintenance can be obtained. The values apply to average, uniform stands.

[2] Group 1: Sod formers used as mixture or as single species.

Creeping foxtail	Intermediate wheatgrass
Pubescent wheatgrass	Smooth bromegrass
Reed canarygrass	Streambank wheatgrass
Thickspike wheatgrass	Western wheatgrass
Big bluestem	Indiangrass
Prairie sandreed	Sand bluestem
Switchgrass	

Group 2: Mixtures composed of sod formers from Group 1 and bunch grasses from Group 3.

Group 3: Bunch grasses

Hard fescue	Tall wheatgrass
Green needlegrass	Slender wheatgrass
Blue grama	Little bluestem
Sideoats grama	

Group 4: Cover crops

Sudangrass	Oats
Spring wheat	Spring barley
Flax	Winter wheat
Rye	

3. Hydrograph Development and Infiltration Techniques

Acceptable procedures for hydrograph development are contained in the USDA-SCS "National Engineering Handbook," Section 4 - Hydrology. The Snyder and Clark unit hydrographs are also acceptable techniques.

Acceptable procedures for estimating the time of concentrations and the runoff curve numbers are outlined in the "North Dakota Hydrology Manual." The curve numbers for the 10-day rainfall event may be adjusted as shown in the SCS's Technical Release Number 60, "Earth Dams and Reservoirs." These adjustments do not apply to 24-hour and PMP rainfall events. It is recommended that an antecedent moisture condition of II or III be used in the SCS TR-20 computer model.

Base flow should also be included in hydrograph development at all sites where applicable. Base flow

amounts will be determined from available stream gage data or from regional data when site specific data are not available.

If a portion of the watershed is developed, or there is potential for development, it is recommended that the SCS's Technical Release Number 55, "Urban Hydrology for Small Watersheds," be used to make appropriate adjustments. This publication outlines procedures for increasing the runoff rates and flow velocities resulting from developed areas.

4. Routing Procedures

The purpose of flood routing is to determine what rate of flow will occur at specific times and locations in a stream or at a structure. There are two general types of flood routing as applied to dam design and evaluation: (1) stream flow routing; and (2) reservoir routing.

Stream flow or channel routing may be accomplished by several methods. The most common routing techniques are Muskingum, the modified puls, and techniques that use actual channel cross-section data.

Reservoirs can be routed by any number of level pool techniques. The basic requirements include reservoir elevation-storage information and a spillway rating curve. The principal spillway, the emergency spillway and the freeboard hydrographs should be routed through the reservoir with the starting water elevation at the normal water level. The principal spillway should also be adequate to draw down the reservoir pool level to 85 percent of the flood pool storage within a 10-day period. If the pool is not drawn down, the water level at the end of 10 days should be used as the starting water level for the design storm events. This may require an increase in either the spillway capacity or the volume of flood storage.

5. Computer Models

There are several computer models available for the hydrologic analyses in dam design. The Corps of Engineers' HEC-1 model and the SCS's TR-20 and Dams II computer models are recommended. If other models are used, the State Engineer may require model documentation. A hydrologic computer model is required for all design class IV and V dams.

When using a computer model, it is advisable to divide a watershed into subareas on the basis of size, drainage pattern, existing and proposed facilities, vegetation, soil and cover types, channel gradients and precipitation amounts. The subarea flows are connected and combined by channel routing.

It is advisable to calibrate the model results to historical flood events where adequate stream gage data is available. In this manner, the model timing, volume and peak flows can be checked. In areas where stream gage data is not available, it is recommended that alternate techniques be used to calibrate the model.

6. Dam Breach Analysis

Dam breach analysis requires a specific analytical approach rather than the use of procedures described for spillway design. A dam breach model analysis is required of all medium and high hazard dams. The suggested starting water elevation for a dam breach analysis is the elevation of the top of the dam. Although a specific modeling procedure is not required, the National Weather Service Dam Break Flood Forecasting Computer Model is suggested. There are several versions of this model. The SCS's TR-66 model, "Simplified Dam - Breach Routing Procedure," is also available for use.

7. Runoff Yield and Reliability

Where adequate stream gage data are available at a site, estimates will be based on that data. Where stream gage data are not available, it is recommended that estimates be based on procedures outlined in the SCS "North Dakota Hydrology Manual," Chapter VII.

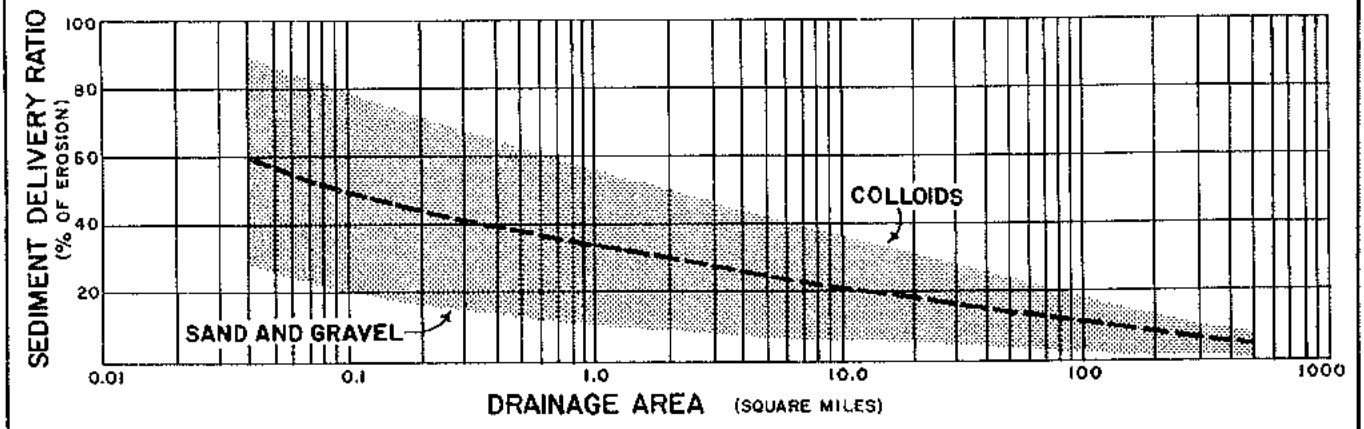
C. Sediment Storage

To assure the full effectiveness of a reservoir, capacity must be provided for sediment accumulation. There are several ways to determine sediment yields or rates of sediment accumulation in reservoirs. Two methods are discussed in this section: (1) the Sediment Delivery Ratio Method, and (2) the Reservoir Sedimentation Surveys Method. In general, the sediment delivery ratio method provides a higher level of sediment accumulation than the survey method. Reservoir sedimentation surveys may provide more accurate data for historical sediment accumulations in North Dakota reservoirs. However, it is advised that for design purposes, the engineer be conservative when using the survey method and apply a suitable factor of safety.

The criteria in this section do not apply to dams constructed as sediment ponds for coal mining operations. Those sediment ponds must be sized in accordance with North Dakota Public Service Commission criteria.

1. Sediment Delivery Ratio Method

The sediment delivery ratio method is well-adapted for estimating current sediment yields and predicting the influence of land treatment measures on future sediment yields. The following equation is employed.



$Y = E(DR)$

Where: Y = sediment yield (tons/acre/year)
E = gross erosion (tons/acre/year)
D.R. = sediment delivery ratio (percent)

The gross or total erosion in the drainage area of a reservoir is the summation of all water erosion occurring in the drainage area. It includes sheet and rill erosion, and channel-type erosion (gullies, valley trenches, streambank erosion, etc.). Procedures for the determination of quantitative values for each type of erosion are outlined in existing guides, handbooks, and technical releases. The SCS can provide valuable assistance in computing gross erosion.

The sediment delivery ratio is dependent on the topography, geology, and size of the drainage area. Any structures above the dam site (other dams, bridges, or culverts) that slow the runoff substantially will also affect sediment delivery. The most important variable is the size of the contributing drainage area. Figure 5-1 is a widely used curve depicting the relationship between sediment delivery ratio and drainage area.
