B.3.2 Dam Safety. Although construction of dams dates back many years, the history of dam safety covers a much shorter time span. Only a limited number of states had any laws regulating dam safety prior to 1900. The failure of the South Fork Dam in 1889 at Johnstown, Pennsylvania, resulting in 2,209 deaths, had limited influence on dam safety programs. California initiated a dam safety program following failure of the St. Francis Dam in 1928. Failure of the Buffalo Creek Dam in West Virginia and the Canyon Lake Dam in South Dakota in 1972 contributed to Congress passing "The National Dam Inspection Act" in 1972. "The Reclamation Safety of Dams Act" in 1977 followed failure of Teton Dam in Idaho in 1976. Failure of the Laurel Run Dam in Pennsylvania and the Kelly Barnes Dam in Georgia in 1977 set in motion the development of the "Federal Guidelines for Dam Safety" issued in 1979 by the Federal Coordinating Council for Science, Engineering, and Technology (FCCSET) (reference A.71).

B.3.3 Interagency Committee on Dam Safety. Although the Interagency Committee on Dam Safety (ICODS) was created in 1980, the Water Resources Development Act (WRDA) of 1996 codified it as a permanent forum for the various government agencies to advise FEMA on institutional, managerial, technical, legislative, and policy issues affecting national dam safety. The following Federal agencies serve on ICODS:

Department of Agriculture
Department of Defense
Department of Energy

Department of Interior
Department of Labor
Federal Emergency Management Agency
Federal Energy Regulatory Commission
International Boundary and Water Commission (U.S. Section)
Nuclear Regulatory Commission
Tennessee Valley Authority

B.3.3.1 ICODS encourages the establishment and maintenance of effective Federal programs, policies, and guidelines intended to enhance dam safety for the protection of human life and property. This is accomplished through (1) coordination and information exchange among Federal agencies and State dam safety agencies; (2) coordination and information exchange among Federal agencies concerning implementation of the "Federal Guidelines for Dam Safety" (reference A.59); (3) Federal activities that foster State efforts to develop and implement effective programs for the safety of dams; (4) improved techniques, historical experience, and equipment for rapid and effective dam construction, rehabilitation, and inspection; and (5) devices for the continued monitoring of the safety of dams. ICODS has an Operations Subcommittee, which focuses on activities essential to carrying out the operating activities of ICODS.

B.3.3.2 The Director of the Federal Emergency Management Agency was designated coordinator of the National Dam Safety Program in WRDA96, and is the Chair of the ICODS and the National Dam Safety Review Board.

B.3.4 National Dam Safety Review Board. The Water Resources Development Act of 1996 established the National Dam Safety Review Board (NDSRB). The NDSRB monitors state implementation of dam safety programs, and advise the Director of FEMA in national dam safety policy. The Director of FEMA based on their dam safety expertise selects nominees to the NDSRB. The USACE Dam Safety Officer recommends a qualified individual to serve on the NDSRB. Five subcommittees serve under NDSRB and focus on activities essential to carrying out the goals of the Program. These subcommittees are:

Dam Safety Research Work Group
Dam Safety Training Work Group
National Inventory of Dams Work Group
Guidelines Development Work Group
Dam Security Work Group

APPENDIX C

Summary of the Federal Guidelines for Dam Safety

C.1 1977 Presidential Memorandum. In 1977, President Carter issued a memorandum directing three actions.

C.1.1 That all Federal agencies having responsibility for dams conduct a thorough review of their practices that could affect the safety of these structures and report their findings to the Federal Coordinating Council for Science, Engineering, and Technology (FCCSET).

C.1.2 That FCCSET prepare the “Federal Guidelines for Dam Safety” for use by all Federal agencies.

C.1.3 That an Interagency Committee on Dam Safety (ICODS) be established to promote and monitor Federal and state dam safety programs.

C.2 Publication of Guidelines. In 1979, the “Federal Guidelines for Dam Safety” was published, and ICODS was given oversight responsibility for dam safety. The key management practices outlined in the guidelines (FEMA 93, (reference A.71)) are

C.2.1 Establish a Dam Safety Officer and appropriate staff,

C.2.2 Maintain an updated inventory of dams,

C.2.3 Document design criteria and construction activities,

C.2.4 Prepare initial reservoir filling plans and reservoir regulation criteria,

C.2.5 Prepare operation and maintenance instructions and document activities,

C.2.6 Maintain a training and awareness program,

C.2.7 Prepare and maintain Emergency Action Plans (EAP's) for each dam,

C.2.8 Establish a program of periodic inspections and evaluation of dams, and

C.2.9 Monitor and evaluate the performance of each dam and appurtenant structure and provide remedial construction as necessary.

C.3 Implementation of Guidelines. The “Federal Guidelines for Dam Safety” (reference A.71) requires each agency responsible for the design, construction, operation, or regulation of a dam project to be structured with a single identifiable, technically qualified head responsible for ensuring that all management and technical safety aspects of dam engineering are adequately considered throughout the development

and operation of the project. That position must have continuity of guidance and direction, and authority and resources to ensure these responsibilities can be carried out. To comply with this portion of the Guidelines, the Chief of Engineers has designated a USACE Dam Safety Officer by General Order. This regulation further defines the requirements and responsibilities of the Dam Safety Officers at each level of the command.

APPENDIX D

Levels of USACE Responsibility for Dams

D.1 Involvement Categories. USACE involvement and responsibility related to dams and dam safety can be categorized into six areas (categories) based on the USACE involvement in design, construction, modification, operations, permitting, and ownership.

D.2 Category 1.

D.2.1 Involvement. Dams USACE owns, operates, and maintains. This includes appurtenant structures such as navigation locks, powerhouses and USACE owned levees that retain permanent pools, whose failure could potentially yield loss of life, or environmental or economic damage.

D.2.2 Responsibilities. USACE is responsible for dam safety.

D.3 Category 2.

D.3.1 Involvement: Dams USACE has designed and constructed, but responsibility for operation and maintenance rests with others.

D.3.2 Responsibilities: The primary dam safety responsibility is with the agency or sponsor responsible for performing operation and maintenance. USACE responsibility is to fulfill the requirements of the Project Cooperation Agreement (PCA), including periodically inspecting the project to evaluate its performance and maintenance.

D.4 Category 3.

D.4.1 Involvement. Dams designed, constructed, operated, maintained, and owned by others where flood control storage is provided at Federal expense under the authority of the 1944 Flood Control Act (Section 7 Dams).

D.4.2 Responsibilities. USACE maintains pertinent data on the project and participates in inspections to ensure that the Federal flood control interest is properly maintained.

D.5 Category 4.

D.5.1 Involvement. Dams designed, constructed, operated, maintained, and owned by others and later modified by USACE for the entity responsible for operation and maintenance.

D.5.2 Responsibilities. USACE assumes a limited responsibility for dam safety when work is accomplished by USACE to modify the dam.

D.6 Category 5.

D.6.1 Involvement. Dams where USACE has issued permits under its regulatory authority.

D.6.2 Responsibilities. USACE has no responsibility for dam safety.

D.7 Category 6.

D.8.1 Involvement. Dams inspected and evaluated by USACE under the authority of the National Program for the Inspection of Non-Federal Dams, PL 92-367.

D.8.2 Responsibilities. USACE has no responsibility for dam safety.

APPENDIX E

Essential Agency Guidelines

E.1 Policy. Essential Agency Guidelines are the state-of-practice for design, construction, operation, and maintenance of USACE dams as documented in current USACE regulations. The requirements specified in these USACE regulations must be met for a dam to achieve DSAC V (Adequately Safe) classification status. These regulations include Engineer Circulars, Engineer Regulations, Engineer Manuals, Engineer Pamphlets and Engineer Technical Letters; and Engineering and Construction Bulletins, and other official HQUSACE dam safety-related Policy Letters and guidance. Current USACE guidance reflecting the state-of-practice guidance is summarized in following paragraphs.

E.2 Hydrology and Hydraulics Minimum Requirements.

E.2.1 Hydrologic Design. Engineering analysis defining hydrologic capacity of the dam must be provided in accordance with Engineer Regulation 1110-8-2 (FR) (reference A.61). In order to be classified as DSAC V, analysis must demonstrate with a high degree of assurance that the dam can pass the inflow design flood without the dam failing. Current guidance is that this requirement is achieved by providing a hydrologic analysis concluding that the dam can pass 100% of the inflow design flood with freeboard or have an adequacy study showing it is specifically designed or analyzed to safely pass the overtopping flow. If the identified threshold flood is less than the inflow design flood requirements, the classification must reflect the deficiency.

E.2.2 Spillway Capacity. The existing capacity of the spillway must be demonstrated to be able to pass with a high degree of assurance, the inflow design flood in such a manner that downstream flows will not exceed unimpaired (without-project) discharges and ensure integrity of the structure (non-failure) during the design event. Current guidance is that the spillway capacity requirement is achieved by providing an analysis that concludes that it will pass the design flood with freeboard. There may be damage to the infrastructure, but the damage should not result in failure or uncontrolled release through the spillway. Beyond the design capacity of the spillway there must be a spillway adequacy study performed to assess the integrity of the spillway in the event that spillway flows are necessary. Many of USACE spillways have never been utilized and the potential for damage/failure under significant flow conditions is highly probable. The intent of design is that the spillway should operate in such a manner that the dam is not failed. The damage may be repairable but the dam must retain pool and operational functionality. In order to be classified as a DSAC V, a spillway adequacy study must be provided that documents expected performance of spillway for design conditions. If materials in the spillway are susceptible to erosion or expected performance is suspect, the classification should reflect that deficiency.

E.2.3 Outlet Works Capacity. The existing capacity of the outlet works must be able to pass the inflow design flood as required by the water control manual without

exceeding the design capacity. In order to be classified as a DSAC V, an outlet works adequacy study must be provided that documents the expected performance of the outlet works for design conditions OR the water control manual revised to reflect the outlet works will not be used for these conditions. If the outlet works is not safely designed to pass the required water control releases the classification should reflect that deficiency.

E.2.4 Gate Reliability. One of the significant findings of the risk assessment portfolio of USACE dams relates to the dependency on reliable gate operations for satisfactory performance of our dams. In particular many of our spillway gates have never been tested under design loads. If a dam depends on gates to pass inflow design floods there must be a gate reliability study performed addressing risk of failure or potential operating issues (such as debris) to receive a DSAC V classification. If a gate reliability is a potential failure mechanism, the classification should reflect that deficiency.

E.2.5 Water Control. Many of USACE projects have been operating for decades and have not updated their water control operating plans. As a minimum, the authorized water control plan/manual should be updated on a periodic basis. This update could be a simple assessment resulting in “no-change” or a complete update that reflects approved operational changes. In order to receive a DSAC V classification the water control manual must have been updated within the last 5 years. If the water control manual is outdated, the classification should reflect that deficiency.

E.2.6 Water Management Data. Generally speaking appropriate levels of monitoring and data collection must be available to make dam safety operational decisions. This data is primarily water volume and timing but it may also include water quality parameters that impact operations. In order to receive a DSAC V classification an assessment of the gage availability and operational availability of critical gages must be provided. If there are gaging shortfalls and/or gages are not dependable during extreme flood events, the classification should reflect that deficiency.

E.2.7 Sustainability Issues. USACE does not have a specific regulatory requirement to assess sustainability but there has always been recognition that we must consider impacts on operational functionality over time due to potential changes in the environment. Recently Congressional guidance has mandated additional emphasis on addressing sustainability and adaptive management opportunities. These considerations should include lake sedimentation, changes in inflow design flood (updating HMR’s), climate/global change, etc. In order to receive a DSAC V classification, a qualitative assessment/report should be provided addressing at least the near term potential for continued operations. As a minimum an engineering report must be provided addressing the basis for the inflow design flood (Note: This report should include potential for change (HMR, etc) which can be based on regional assessments) and impacts of lake sedimentation. As a minimum, results of most recent sedimentation surveys should be provided and projections for remaining life before impacting flood control storage or other project purposes.

E.2.8 Real Estate Interests. The Project should contain documentation or engineering analysis to demonstrate an adequate real estate interest downstream of the project in accordance with the guidance of ER 1110-2-1451 (reference A.54). In order to receive a DSAC V classification, all real estate interests downstream of USACE projects must be adequate to assure project purposes can be accomplished within the criteria outlined in ER 1110-2-1451 (reference A.54). If any modifications have been made to the original project it is important to insure adequate real estate interests have been obtained. This should include, but is not limited to lands below spillways, fuseplugs, saddle dams, outlet works or any surface designed to be overtopped. If additional real estate interests are necessary to insure a project can operated as designed, the classification should reflect this deficiency in terms of the risks it introduces.

E.2.9 Modeling and Mapping. The dam failure model and inundation mapping used to support the Emergency Action Plan should be reviewed and updated on a periodic basis. This update could be a simple assessment resulting in "no-change" or a complete update that reflects changes in the dam or downstream consequences of potential failure**.** In order to receive a DSAC V classification, the dam failure model and inundation mapping must have been updated within the last 10 years. If the dam failure model and/or inundation mapping is outdated, the classification should reflect this deficiency. (Note: Dam failure modeling and inundation mapping is required only for those dams whose failure could result in life loss, economic damage, or environmental consequences as a direct result of the dam failure flood. Dams with only indirect consequences (e.g. navigation, hydropower, or water supply impacts due to loss of the pool) generally do not require modeling or mapping.)

E.3 Geotechnical and Materials Minimum Requirements.

E.3.1 Geotechnical & Materials Design. Geotechnical engineering considerations must be addressed for all types of water-retaining structures, whether they are earth or rock fill embankments, concrete gravity dams, or concrete arch structures, due to the dependence of their engineering performance on both the host geology and the materials employed in the built structure. In order to be classified as DSAC V, geotechnical analysis of the anticipated response to impoundment of the reservoir in accordance with hydraulic and hydrologic design requirements must indicate that the dam and its foundation will retain the pool without progressive degradation of seepage control features, internal erosion leading to void formation, sliding of the dam on its foundation or at the abutment contacts, excessive deformation of the embankment leading to unacceptable loss of freeboard or damage to seepage control features, differential displacements within a concrete dam that affect waterstops or appurtenant structural or mechanical elements, or bearing capacity of dam-foundation or dam-abutment contacts. Current USACE guidance reflecting the state-of-practice guidance for engineering analysis defining geotechnical and materials capacity of the dam is provided in Engineer Regulations 1110-2-1150 (reference A.51), 1110-2-1806 (reference A.56), and 1110-2-1925 (reference A.57), through procedures described in numerous Engineering Manuals, including, but not limited to Engineer Manuals 1110-1-

1804 (reference A.9), 1110-1-2907 (reference A.10), 1110-1-2908 (reference A.11), 1110-2-1902 (reference A.13), 1110-2-1906 (reference A.14), 1110-2-1908 (reference A.15), 1110-2-1911 (reference A.16), 1110-2-2006 (reference A.19), 1110-2-2200 (reference A.23), and 1110-2-2201 (reference A.24).

E.3.2 Reservoir Rim. In addition to assurance of the integrity of the dam itself, stability of the reservoir rim upstream of the structure must be assured for anticipated loadings, whether of hydrologic, earthquake, or other hazards, man-made or natural.

E.3.3 Conduits. Conduits passing through soil within or beneath the dam require additional investigation to assure that their embedment conditions preclude development of seepage paths that are conducive to piping of soil materials. Anti-seep collars or flanges were installed in many dams; it is difficult to compact soils around these features, and under-consolidation with time may lead to detrimental seepage along the conduit; presence of these collars may serve to justify changing the assignment of DSAC V to DSAC IV.

E.3.4 Drainage Features. Relief wells, drainage blankets, chimney drains and other design components intended to convey seepage downstream of waterstops or the earthen core of a dam must be free of contaminants or clogging that would impede their function. Clogged drainage features, whether by organic/bacterial attack, mechanical disturbance or constriction, or siltation, preclude assignment of DSAC V unless and until such contamination is cleared and surveillance reveals that contamination is not recurrent. This infers that a DSAC V dam will not have internal drainage elements that cannot be inspected and validated as to proper function, nor that may not be remediated in the event that such elements may be rendered ineffective at some time.

E.3.5 Filters. Piping of soil materials may result if transitions between fine-grained soils forming an impervious core and surrounding, supportive shell zones or drainage features are not designed and constructed with properly graded filter zones. Damage to the impounding capability of the dam would likely remain unseen until substantial and invasive remedial action is required; the absence of these filter zones precludes assignment as a DSAC V dam. Turbid or muddy seepage must be investigated to rule out internal erosion of dam or foundation soils as the source of the soil fines; a DSAC V dam must have no history of such unattributed sediments in downstream seepage. The presence of slumps, sinkholes or voids within the embankment or beneath or around any conduits or diaphragms such as facing or spillway armoring concrete or training/retaining structures is indicative of soil movement from some mechanism, whether seepage-related or from consolidation settlement, and precludes assignment as a DSAC V dam, unless the causative mechanism is fully determined and permanently resolved.

E.3.6 Earthquake Resistance. Earthquake response of site soils within and beneath the embankment to earthquake ground motions are unpredictable and may even cause damage to well-designed structures. Excess pore water pressures, above hydrostatic, may result during moderate to strong ground shaking in saturated soils;

these may reduce effective shear strength and lead to sliding or permanent deformations within or beneath any dam on a soil foundation. Well-compacted earth or rock fill embankments constructed on an intact rock foundation typically perform satisfactorily during earthquakes exhibiting peak ground accelerations less than about 0.2 g. If the design ground motion anticipated for a given dam is less severe than this, and if the dam otherwise meets all requirements from the engineering disciplines for which it is evaluated, it may be considered safe enough for the DSAC V designation. Hydraulic fill embankments, which are placed without engineering consideration other than expedience of constructability, should not be assigned as DSAC V unless dynamic seismic analysis indicates satisfactory performance.

E.3.7 Summary. If loads less than or equal to the design loads create critical distress (unsatisfactory performance that leads to loss of pool or loss of function that leads to loss of life or large economic consequences), the classification must reflect the deficiency.

E.4 Structural Minimum Requirements.

E.4.1 Structural Data. Historical structural design documents, including as-built drawings and material specifications must be available or adequate field surveys, sampling and testing performed to fully define critical geometric and physical properties of any structural component whose failure would adversely affect the performance of the project. If data on structure geometry and physical properties need to be assumed, or the accuracy of existing data is suspect, the classification should reflect that deficiency.

E.4.2 Structural Condition Assessment. All structures, whose failure would adversely affect the performance of the project, must be current with all required inspections, including underwater and/or dewatered inspections. All potentially significant deterioration must be located and quantified with a high level of confidence. This includes assessment of internal conditions such as presence of alkali-silica reaction in concrete or loss of post-tensioning in anchor rods. If inspections are not current or in accordance with guidance, or if there is not a high confidence level that all significant deterioration has been located, the classification should reflect that deficiency.

E.4.3 Structural Stability Evaluation. All structural units or monoliths, whose failure would adversely affect the performance of the project, must have a stability evaluation performed in accordance with EM 1110-2-2100 (reference A.20) and EM 1110-2-6053 (reference A.31) and meet all mandatory requirements stated in those documents. If evaluation methods or results are not in accordance with current guidance, the classification should reflect that deficiency.

E.4.4 Structural Strength and Serviceability Evaluation. All structures, whose failure would adversely affect the performance of the project, must have strength and serviceability evaluated in accordance with current guidance. Guidance for reinforced-

concrete hydraulic structures is contained in EM 1110-2-2104 (reference A.21). Guidance for hydraulic steel structures is contained in EM 1110-2-2105 (reference A.22). Additional guidance for specific structure types is included in EM 1110-2-2200 (reference A.23) for gravity dams, EM 1110-2-2201 (reference A.24) for arch dams, EM 1110-2-2400 (reference A.26) for outlet works, EM 1110-2-2701 (reference A.27) for vertical lift gates, EM 1110-2-2702 (reference A.28) for tainter gates, and EM 1110-2-2703 (reference A.29) for lock gates. If strength and serviceability have not been evaluated for all structures whose failure would adversely affect the performance of the project, or evaluation methods or results do not comply with current guidance, the classification should reflect that deficiency.

APPENDIX F

Background Information on the USACE Dam Safety Action Classification System

F.1 Policy.

F.1.1 The Dam Safety Action Classification process is intended to provide consistent and systematic guidelines for appropriate actions to address the Dam Safety issues and deficiencies of USACE dams. USACE dams are placed into Dam Safety Action Classes (DSAC) based on their individual Dam Safety risk considered as probability of failure and potential failure consequences. Consequences of the dam failure considered are lives lost, economic, environmental, and other impacts. All dams will be evaluated with a screening assessment and classified according to the DSAC. Dams will be reclassified as new dam safety related information about the dam is developed through monitoring or studies. The intent is that the classification of a dam is dynamic, changing as project characteristics change or as more refined information becomes available.

F.1.2 The structure and make-up of the DSAC table resulted from the need to formally recognize different levels and urgencies of actions that are commensurate with the different safety status of USACE dams. These actions range from immediate recognition of an urgent and compelling situation requiring extraordinary action through to normal operations and Dam Safety activities for safe dams.

F.1.3 In the past, the USACE Dam Safety program essentially recognized two categories of actions those for dams considered safe, which comprised routine Dam Safety activities, normal operation and maintenance; and those for dams that were considered in need of remediation, for which investigations, remediation funding justification documents, and design and construction of remediation measures were additional activities. However, these two categories do not provide formal recognition of an adequate range of actions and degrees of urgency, especially for dams with Dam Safety issues that are very high or extremely high risk, which warrant heightened actions that are not provided for in the current business-as-usual procedures. Three action classes are termed “unsafe” and two are termed “safe”. The choice of three “unsafe” action classes is to provide adequate separation in the range of levels of actions. These five action classes are now included in the USACE Dam Safety program and summarized in the DSAC table. At the top, DSAC I is for those dams considered to be critically near failure and for which urgent actions are needed to avoid catastrophe in the near-term. DSAC II is for dams with confirmed (unsafe) and unconfirmed (potentially unsafe) dam safety issues; failure could begin during normal operations or be initiated as the consequence of an event. The likelihood of failure from one of these occurrences, prior to remediation, is too high to assure public safety. DSAC III is for dams with confirmed and unconfirmed dam safety issues where the combination of life or economic consequences with probability of failure is moderate to high. DSAC IV is for dams that are not declared safe because they don’t meet current guidelines, but which are not considered unsafe enough to warrant heightened attention and for which

remediation is considered to be quite low priority, although investigations to confirm their DSAC classification should be given normal priority. At the bottom is DSAC V for dams that are determined to be safe. Examples of Dam Safety Action Classifications are given in following sections of this appendix.

F.2 Dam Safety Action Classes. Five classes of action were selected to portray the range of actions district Dam Safety officers are to take in executing their Dam Safety responsibilities. The USACE dams are to be placed into Dam Safety Action Classes (DSAC) based on their individual Dam Safety risk considered as probability of failure and potential failure consequences.

F.2.1 DSAC I – Urgent and Compelling (Unsafe).

F.2.1.1 Characteristics. Dams in this class are CRICTICALLY NEAR FAILURE OR EXTREMELY HIGH RISK under normal operations. These dams are ones where progression toward failure is confirmed to be taking place and are almost certain to fail under normal operations any time within a few years without intervention**;** or the dams have Extremely High Risk with a combination of life or economic consequences with high probability of failure.

F.2.1.2 Actions. A summary of the actions to be considered and pursued by the district for this class of dams are:

F.2.1.2.1 Take immediate action to avoid failure.

F.2.1.2.2 Validate classification through an external peer review.

F.2.1.2.3 Implement interim risk reduction measures, including operational restrictions, and ensure that emergency action plan is current and functionally tested for initiating event.

F.2.1.2.4 Conduct heightened monitoring and evaluation.

F.2.1.2.5 Expedite investigations to support justification for remediation using all resources and funding necessary.

F.2.1.2.6 Initiate intensive management and situation reports.

F.2.1.3 Examples of Critically Near Failure Dams.

F.2.1.3.1 Dam A. Dam A is experiencing foundation, abutment, and embankment piping or internal erosion due to seepage through these features under normal pool elevations. All of the seepage items may lead to the formation of piping, which can quickly progress to rapid breaching of the embankment. Loss of strength in the foundation or embankment may result in a slope stability failure which could result in dam overtopping though the lowered dam crest. Recent subsurface investigations have

revealed significant degradation of the foundation and embankment soils. Extremely soft zones were found in multiple borings. Piezometers within the embankment downstream of the existing cutoff wall show significantly higher than expected pressures in reaction to the pool. Movement monuments have indicated continual and increasing settlement of portions of the embankment crest. A temperature survey of the piezometers shows cooler zones in the rock foundations which indicate direct seepage from the pool. Numerous and excessive wet areas persist in areas just downstream of the embankment. These wet areas have progressively increased over the years.

F.2.1.3.2 Dam B. Dam B is experiencing foundation and abutment seepage and piping, and embankment piping along the conduit during all pool elevations. The conduit is founded on soil and constructed in soil materials. The periodic inspections indicated that a small amount of differential settlement has occurred at one of the conduit joints. It was constructed with seepage collars that likely prevented adequate compaction of the soil around the conduit and the seepage collars provide a seepage path along this interface that could lead to piping of the embankment. The left abutment is composed of granular glacial deposits and has experienced significant seepage during Normal pool events. The project has had several test fillings and subsequent seepage collection features were added after each test filling. The seepage is so severe that permanent operational restrictions have been imposed on the project to prevent high pools. The most likely mode of failure for this project is seepage and piping of foundation or abutment materials which may rapidly progress to breaching of the dam.

F.2.1.4 Example of Extremely High Risk Dam. Dam C. Items of concern include foundation and abutment seepage and piping under the embankment. The dam abuts highly karstic limestone formations. One documented cavity in the left rim is 77 feet deep and 15 feet wide. On the right rim, primary seepage pathways through the karst system have not been defined by previous subsurface investigations. In stream seepage measured downstream of the dam during zero releases have increased more than 40% from 90 cfs to 127 cfs in 15 years. Rim grouting has been performed twice previously with limited success. The seepage has potential to erode the earth embankment. There is a wet area downstream of the embankment that has appeared in the last 10 years. Initial foundation treatment, which consisted of minimal excavation and a single line grout curtain, is inadequate. The initial grout curtain and a curtain installed later encountered large clay-filled, solution features in the limestone. There is a potential for erosion of this clay-filled material, which would jeopardize the integrity of the embankment. Piezometer levels are higher than expected; however, some have steadily increased or decreased over the last 20 years indicating erosion of the foundation materials. There is a large metropolitan area (1,000,000 people) with high potential life loss and less than one hour of warning time for the flood wave. This project is considered to have extremely high risk.

F.2.2 DSAC II – Urgent (Unsafe or Potentially Unsafe).

F.2.2.1 Characteristics. Dams in this class are considered to have Failure Initiation Foreseen in that, for confirmed (unsafe) and unconfirmed (potentially unsafe) dam

safety issues, failure could be initiated during normal operations or from a hydrologic or seismic event. The likelihood of failure from one of these occurrences, prior to remediation, is too high to assure public safety. Or, dams in this class have Very High Risk in that the combination of life or economic consequences with probability of failure is very high.

F.2.2.2 Actions. A summary of the actions to be considered and pursued by the district for this class of dams are:

F.2.2.2.1 Implement interim risk reduction measures, including operational restrictions as justified, and ensure that emergency action plan is current and functionally tested for initiating event.

F.2.2.2.2 Conduct heightened monitoring and evaluation.

F.2.2.2.3 Expedite confirmation of classification.

F.2.2.2.4 Give very high priority for investigations to support justification for remediation.

F.2.2.3 Examples of Failure Initiation Foreseen Condition.

F.2.2.3.1 Dam D. The most likely mode of failure for this project is breaching of the dam by erosion or piping through cracks in the core caused by significant displacements of the upstream shell during an Operating Basis Earthquake (OBE) or greater earthquake. Foundation seepage may lead to the formation of piping, which can quickly progress to rapid breaching of the embankment. Detailed evaluation of the dam foundations indicates that a loose layer of alluvial materials will liquefy during an OBE earthquake or greater earthquake. The predicted large displacements during the earthquake will cause significant cracking or loss of the integrity of the dams' core section. The displacements are large enough to result in complete failure of the upstream shell of the dam. This will result in piping of the remaining dam embankment and will quickly progress to breach. The intake tower is located in the central part of the embankment just upstream of the core. Large displacement of the upstream shell will likely cause damage to the intake tower. The population at risk is located less than one hour travel time of the flood wave at the mouth of a narrow canyon. Loss of life is expected to be very high if the dam were to fail from an earthquake.

F.2.2.3.2 Dam E. The most likely failure mode is embankment, abutment, and foundation seepage and piping. Deficiencies in the design and construction techniques contribute to a condition of active piping at moderately high pools – 0.05 to 0.01 pool frequency. Most of the embankment is founded on alluvial and glacial soils without any seepage cutoff. Additionally, the rock below the foundation soils was not inspected or treated and has a history of solutioning. The grout curtain installed on the remainder of the foundation does not meet current standards. There is a history of seepage on the downstream embankment slope, the toe of the downstream embankment, zones

downstream of the toe, and along the abutment contacts with the higher pool levels. Piezometeric data show a 10 foot rise in the phreatic line over the last 20 years. There has been a continual and steady settlement of the dam crest to the left of the concrete section since at least 1978. It is likely that the settlement is the result of internal erosion caused by seepage. It is possible that seepage through the lift joints in the concrete section may be entering embankment materials.

F.2.2.4 Example of Very High Risk Condition. Dam G. Dam is overtopped by several feet at 80% of the probable maximum flood (PMF) and also has potential for foundation seepage creating a piping failure at pool levels for infrequent events. The very large population immediately downstream and a major downtown urban area within 10 miles of the dam has the potential for very high consequences and thus the risk for this project is considered to be very high even though the failure mode is driven by a near PMF event.

F.2.3 DSAC III – High Priority (Conditionally unsafe).

F.2.3.1 Characteristics. Dams in this class, for confirmed and unconfirmed Dam Safety issues, are considered to be Significantly Inadequate or have Moderate to High Risk in that the combination of life or economic consequences with probability of failure is moderate to high.

F.2.3.2 Actions. A summary of the actions to be considered and pursued by the district for this class of dams are:

F.2.3.2.1 Implement interim risk reduction measures, including operational restrictions as justified, and ensure that emergency action plan is current and functionally tested for initiating event.

F.2.3.2.2 Conduct heightened monitoring and evaluation.

F.2.3.2.3 Prioritize for investigations to support justification for remediation considering consequences and other factors.

F.2.3.3 Example of Significantly Inadequate Dam. Dam H. Two failure modes have been identified for this dam - overtopping and piping. The most probable is a piping failure of the foundation overburden materials, initiating at the left cut slope of the outlet channel. A pervious sand and gravel deposit overlying the bedrock is exposed in the outlet channel and does not have adequate seepage control filters. Dam is estimated to be overtopped by several feet by the probable maximum flood and the embankment is breached by erosion. During pools up to the record event, seepage has been observed downstream of the toe of the dam in the cut slopes on both sides of the outlet works stilling basin. Construction of remedial seepage control filters and relief wells were constructed several years after the dam was completed but appear to be insufficient to reduce the seepage to acceptable levels based on peizometer response. Seepage on the left cut slope is still occurring and is anticipated to increase in severity

under higher pool levels. The seepage being experienced along the outlet channel is occurring through a sand and gravel layer located immediately above the bedrock surface.

F.2.3.4 Example of a Moderate to High Risk Dam. Dam I. Dam has a long term history of downstream movement in the clay shale foundation. The piezometric data indicate high uplift in the foundation clays that are the result of the original loading by the embankment during construction. The available inclinometer data show distinct zones of movement at high pool levels as well as a very slow creep over time. The assessment shows the factors of safety for the more extreme pool elevations approach 1.0. The dam has been loaded to top of spillway gates for a pool of record, but there is still an additional 30 feet of storage above that elevation, thus the pool elevation of concern is a rare event. There is significant data to indicate a conditionally unsafe project (potential for failure only when the pool is very high) and the very large volume of water behind this dam at the higher pool elevations would create very high economic and environmental consequences with low to moderate loss of life consequences.

F.2.4 DSAC IV. Priority (Marginally Safe).

F.2.4.1 Characteristics. Dams in this class are considered to be inadequate with low risk. For confirmed and unconfirmed Dam Safety issues, the combination of life or economic consequences with probability of failure is low and may not meet all essential USACE guidelines.

F.2.4.2 Actions. A summary of the actions to be considered and pursued by the district for this class of dams are:

F.2.4.2.1 Conduct elevated monitoring and evaluation.

F.2.4.2.2 Give normal priority to investigations to validate classification, but no plan for interim risk reduction measures at this time.

F.2.4.3 Examples of Inadequate With Low Risk condition Dams.

F.2.4.3.1 Dam J. The embankment has a potentially preferential seepage path along the top of the outlet conduit and may result in piping of embankment materials during extreme hydrologic events. The dam does not have a foundation seepage cutoff system. Seepage has been apparent at the toe of the dam since the initial filling. High foundation seepage pressures are anticipated for the Extreme events. With the relief well system functional, it is estimated that the seepage pressure would be 2 feet above the ground surface at the toe during an Extreme event. It is likely that the high seepage pressures may cause some piping in the form of sand boils potentially causing embankment instability due to loss of foundation material. After the pool of record it was found that significant scouring occurred just below the outlet apron. There is currently a 140 foot long, 120 foot wide, and 13 foot (maximum) deep scour hole downstream of the outlet apron. There is potential for additional scouring and

undermining of the outlet apron and wing walls under Extreme conditions. The population centers downstream are all located on the elevated floodplain of a wide valley and the potential for economic consequences is low to moderate. The overall risk is considered low and some essential guidelines are met by this dam.

F.2.4.3.2 Dam K. An overtopping failure mode may result from inadequate freeboard based on existing routings. The resultant consequences are low because of a wide downstream valley, low population density, and ample warning time. Thus the risk is low.

F.2.5 DSAC V – Normal (Safe).

F.2.5.1 Characteristics. Dams in this class are considered to be adequately safe, meeting all essential USACE guidelines with no unconfirmed Dam Safety issues such that the residual risk is considered tolerable.

F.2.5.2 Actions. Continue routine Dam Safety activities, normal operation and maintenance.

F.2.5.3 Example of an Adequately Safe Dam. Dam L. Dam meets the requirements for hydrologic capacity to pass the most current inflow design flood (IDF), there is no known seepage and piping issue and seepage control features meet current standards, the seismic capacity and performance of all the features of the project are appropriate for the current seismic loads, and there are no operations and maintenance issues that impact the operations of the project for all pool and loading conditions. The project staff and water management staff are appropriately trained and qualified to deal with project operations under emergency and flood conditions. With this high level of readiness and low probability of unsatisfactory project performance a review of the project's residual risk indicates that the risk is tolerable for all design loads and the dam is "safe." Normal operations require due diligence by a district to perform the requisite monitoring, evaluation, maintenance, and training to actively manage the inherent residual risk associated with any dam with the goal to keep the residual risk at or below the that which is considered tolerable for the respective dam.

F.3 Actions. The actions listed are an executive summary of the actions that a district Dam Safety officer should pursue based on the action classification assigned to each dam. The basic concept is that dams in classes I, II, and III shall be treated as unsafe until confirmed safe.

F.4 Documentation**.** It is recommended that a district document their decision for assigning a class to a given dam using a short fact sheet that addresses the available information in summary form to include the failure modes of concern, the loading conditions of concern, the probability of failure, the consequences, and DSAC assignment.

APPENDIX G

Dam Safety Program Management Tools

G.1 Purpose. The purpose for the Dam Safety Program Management Tools (DSPMT) is to facilitate agency wide data collection and monitoring of the USACE dam safety program and to track compliance against the "Federal Guidelines for Dam Safety" (reference A.71) and USACE criteria.

G.2 Introduction.

G.2.1 Since implementation of the USACE Dam Safety Program, it has become increasingly clear that there are broad information needs required to support dam safety. These data needs include:

G.2.1.1 Documenting the condition of the Agency's dams

G.2.1.2 Tracking the status and progress of the MSC's and District's dam safety programs

G.2.1.3 Reporting information regarding the Agency's inventory of dams periodically to the National Inventory of Dams (NID) and Congress.

G.2.2 Satisfying many of these data needs is the Dam Safety Program Management Tools (DSPMT). The DSPMT is an information collection and management system that is controlled locally by District dam safety program managers and which interacts with MSC's, Headquarters, and National external cooperative information resources for providing as-requested and periodic information on local dam safety information, program needs, and accomplishments within each organization's jurisdiction.

G.2.3 The purpose of the DSPMT is to provide dam safety program managers a tool to collect unbiased data about dams and dam safety programs, check selected data for accuracy, and then utilize the data to achieve an accurate local, regional, and National inventory of dams and to help address programmatic questions such as:

G.2.3.1 How well are our dam safety programs being implemented?

G.2.3.2 Are we doing too much in some areas and not enough in others?

G.2.3.3 Are we spending our scarce resources in the right places?

G.2.3.4 Are we improving?

G.2.4 The DSPMT consists of a set of interactive software programs which provide a resource to the dam safety data owners, managers, and data providers. The software

is under continual development and is evolving as needs are expressed by users. The DSPMT includes two distinct, complementary, and interoperable software programs:

G.2.4.1 The Dam Safety Program Performance Measures (DSPPM).

G.2.4.2 The National Inventory of Dams (NID) Electronic Submittal Workflow

G.2.5 Each of these programs is applicable to all levels of a dam safety organization. Output from the DSPPM at each level can be used individually and/or collectively as input at the next higher level to evaluate program performance on broader and broader scales (e.g., district, division, agency). By utilizing the tools provided by the DSPMT, data managers and providers can achieve the one-time-only data entry objective while maintaining an up-to-date, error-checked, consistent format database of dam inventory and program performance information.

G.3 Discussion. The overall objective of the DSPMT is to enable each user to have a computer program that interacts with the NID, local databases, and other external cooperative databases in a one-time-only data entry environment.

G.3.1 The vision is to eventually achieve:

G.3.1.1 One-time data entry for programs targeted at the different aspects of dam safety;

G.3.1.2 Efficient data extraction from local state and federal databases into a consistent user-friendly and user-managed inventory and performance measure database;

G.3.1.3 Automated error checking and identification of conflicting data;

G.3.1.4 Simple online exports of local inventory and performance measure (or indicator) data and import of national level data to/from a centralized server; and

G.3.1.5 Updating and reporting of inventory, performance measure, and incident information as frequently as desired.

G.3.2 The objectives of the DSPPM are also to provide simple, unbiased, quantitative data that are useful separately and/or collectively as metrics to help users:

G.3.2.1 Evaluate how well their dam safety programs are being implemented;

G.3.2.2 Determine whether they accomplished what they set out to accomplish;

G.3.2.3 Proactively “tell” their dam safety stories to others, both internal and external to their organizations; and

G.3.2.4 Encourage uniform and consistent application of laws, policies, and regulations.

G.4 DSPMT Overview.

G.4.1 DSPPM. The DSPPM is currently divided into seven subject areas:

G.4.1.1 Dam Safety Program Management Authorities and Practices,

G.4.1.2 Dam Safety Staff Size and Relevant Experience,

G.4.1.3 Inspections and Evaluations,

G.4.1.4 Identification and Remediation of Deficient Dams,

G.4.1.5 Project Response Preparedness,

G.4.1.6 Agency and Public Response Preparedness, and

G.4.1.7 Unscheduled Dam Safety Program Actions.

G.4.1.8 These broad performance measures are supported by detailed spreadsheets which are targeted at individual aspects of the performance measures. The following detailed additional spreadsheets are currently available within the DSPMT:

G.4.1.8.1 Staffing Spreadsheet

G.4.1.8.2 Deficiencies and Budgeting Prioritization Spreadsheet

G.4.1.8.3 Documentation Spreadsheet

G.4.1.9 These spreadsheets allow graphics of data to be generated that provide insight into the capabilities and challenges faced by the organization.

G.4.2 NID Submittal Workflow.

G.4.2.1 The NID electronic submittal software provides tools for State and Federal data owners to efficiently collect, access, and manage NID data. The workflow starts by importing a State or Federal agency's local inventory of dams, which can be in a variety of database formats. Interactive graphical tools provided by the DSPMT are then utilized to check for data errors in numeric values and spelling errors or inconsistencies in text values. The NID inclusion rules are then applied. The data submittal is checked for differences between the candidate and the current NID, and is then electronically sent to USACE for review and incorporation into the NID.

G.4.2.2 By performing data submittal workflows at the state and agency level, those most familiar with the data and most qualified to make any changes, specifically the data owners, managers, and data providers, are kept in the loop by the program as it highlights areas in the data that potentially need attention, modification, or double-checking. By performing these workflows at the state and agency level, and by using the original data from the day-to-day dam inventory management tools, the data quality and accuracy of the submittal is significantly enhanced.

G.5 USACE DSPMT Implementation Specifics. Since the Dam Safety Program Managers at the district level should be most familiar with the details of the individual projects in their inventory, they shall have the primary burden of maintaining up-to-date information on the dams in the database.

G.5.1 DSPMT databases shall be fully updated quarterly prior to HQ quarterly review. As inspections are completed, the DSPMT shall be updated to include any modifications to NID information on the dam, and to include the results of the inspection and any impacts on the performance measures such as inspection date, identified deficiencies, estimated costs of remediation, priority ratings, etc.

G.5.2 The MSC shall be responsible for providing quality assurance and review functions on district submittal information on a periodic basis. Instructions for accomplishing these updates are described in the DSPMT User's Manual. If questions, data conflicts, or errors are noticed in district inventory information, they shall not be corrected or modified at the division level or HQ level. It shall be the district responsibility to resolve the question or implement the correction in the district database.

G.6 Dam Safety Scorecard for Routine Dam Safety. For several years now, we have been collectively building an unbiased dam safety database within the Dam Safety Program Management Tools (DSPMT). Progress of the program is being tracked using Dam Safety Program Performance Measures (DSPPM). Selected performance measures which represent key routine activities are utilized to export in the form of the Dam Safety Scorecard. The Dam Safety Score Card provides a numerical and graphical report of the implementation of routine dam safety activities on a per dam basis. The score card is not used to be an indicator of the dam's condition or to determine the dam safety action class (DSAC). It does, however, provide a uniform and consistent way of evaluating routine program implementation in the form of numbers, verbal ratings (Excellent, Fair to Good and Poor), and colors (Green, Yellow, and Red). The scorecard is generated by the Dam Safety Program Management Tools as an output on a per dam basis, or it can be rolled up for dams in a district, a division, or HQUSACE. The Dam Safety Scorecard will be reviewed approximately quarterly in forums such as the HQ Dam Safety Committee meetings and Civil Works DMRs.

G.6.1 The six sections of the scorecard are Staffing and Funding; Inspections and Evaluations; Project Instrumentation; Project Response Preparedness; Agency and Public Response Preparedness; and Interim Risk Reduction Measures. The subjects

and the numerical values assigned to each of the six sections are based on a consensus of solicited expert opinions. The weighted values were evaluated during a beta testing period, adjusted accordingly, and as data is collected, in time the scorecard index value will be a reasonable, recognizable, and accepted index of a routine dam safety program implementation.

G.6.2 The data used to populate the scorecard is retrieved from information that the districts provide in their DSPMT databases. The scores, verbal ratings and graphical output are automatically generated by the DSPMT. The scorecard allows managers to evaluate the overall program on a per-dam basis, perform trend and gap analyses, and convey program accomplishments to others.

G.6.3 Districts should include discussions of their scorecards in their dam safety committee meetings and for briefing their DSAC I and II dams at PRBS. It is envisioned that the scorecards can be useful when defending budget requests to highlight the need for funding items or activities that are not being accomplished due to inadequate funding.

G.7 Summary. With continued reductions in budgets and staffing, both Federal and non-Federal dam safety programs are in need of continuous efficiency and effectiveness improvements. In addition, there is an ever-increasing need for performance-based reporting internally and to FEMA, Congress, and State Legislatures. The DSPMT provides the tools necessary for evaluating dam safety programs, for reporting accomplishments, and for expressing program needs to others. As a working tool, it implements true one-time-only data entry, provides assistance to program managers in achieving continuous program improvement, is a self-evaluation tool and an internal and external reporting tool, and encourages results-oriented management practices. By using the DSPMT, the agency will be assured of a more consistent, error-checked submittal of inventory and performance measure information provided on a periodic or as-needed basis.

APPENDIX H

Dams Exempt from Portfolio Management Process

H.1 Purpose. To provide additional information and supplemental guidance on the identification and management of dams exempted from the portfolio management process as noted in paragraph 3.3.1 and Figure 3.1 of this regulation. These dams are referred to in paragraph 3.3.1 as *"dams found to have insignificant or no consequences should they fail."* The purpose in identifying and flagging such dams is to provide a mechanism to enable alternative, non-routine dam safety-related management of these structures.

H.2 References.

H.2.1 EP 1165-2-1, Digest of Water Resources Polices and Authorities, Chapter 7, Paragraph 7 (reference A.34).

H.2.2 ER 200-2-2, Procedures for Implementing NEPA (reference A.37).

H.2.3 ER 405-1-12, 27 Oct 80, Real Estate Handbook, Chapter 11, Disposal (reference A.38).

H.2.4 ER 1105-2-100, Planning Guidance Notebook, Appendix G, Section IV (reference A.42).

H.2.5 ER 1165-2-119, Modifications to Completed Projects (reference A.64).

H.3 Background. The portfolio of USACE dams managed in accordance with this regulation includes all structures that meet the definition of a dam and that would have unique and separate consequences should they fail. The portfolio thus includes as separate dams to be managed for safety, main dams, appurtenant saddle dams, ring dikes within reservoir pools initially intended to protect an area that would otherwise be flooded by the reservoir pool, debris dams both within the reservoir pool area or immediately upstream and other structures as yet identified. For the purposes of this document, all such structures are referred to as dams all of which have been assigned a DSAC class based on their risk. This policy is focused upon the subset of these dams found to have insignificant or no consequences should they fail. Thus, these dams do not warrant the same actions and attention as the larger set of remaining dams subject to routine application of the portfolio process.

H.4 Policy. Dams identified as meeting the requirements of paragraph H.4 below are exempt from the dam safety portfolio management process as described in Chapter 3 of this regulation. Subject to confirmation that exemption is justified, such dams are retained in the USACE inventory but will be managed in a non-routine manner tailored to their site-specific characteristics and circumstances. In essence, the posture taken by USACE with respect to these dams is that there is essentially no concern with their

possible failure, and thus, expenditure of scarce dam safety resources thereon is to be minimized. Non-routine management will generally take place as described in following paragraphs.

H.4.1 Dams that no longer serve an authorized purpose, nor any other Federal, state, local or tribe purpose and that pose a safety hazard to agency staff or the public if left to remain in their present state will be flagged for decommissioning. Decommissioning will be pursued in an expedited manner as authorities and funding permit – see paragraph H.6 below for further guidance. Routine operation, maintenance, and inspection will cease. Until decommissioned, the dams will undergo a 'routine inspection' at five year intervals to verify their status and justify continued non-routine management.

H.4.2 Dams as described in H.4.1 that pose insignificant hazard to agency staff and the public if left to remain in their present state will be flagged for decommissioning and routine operation, maintenance, and inspection will cease. Decommissioning will be pursued as authorities and funding permit – see paragraph H.6 below for further guidance. Until either the status of the dam changes (decommissioned, becomes a hazard to agency staff and the public if left in present state, fails, or deteriorates to a non-dam status), such dams will undergo 'routine inspection' at five-year intervals to verify their status and justify continued non-routine management.

H.4.3 Dams that have potential to serve a USACE or other Federal purpose, or state, local or tribe purpose will be flagged as such and routine operation, maintenance, and inspections will cease. Efforts to remove such dams from the dam safety inventory will be pursued as authorities and funding permit - see paragraph H.6 below for further guidance. If such dams pose a hazard to agency staff or the public if left to remain their present state, expedited efforts will be pursued to accomplish the appropriate action. Until such time as the purpose to be served by the dams is changed and the project modified, and/or title is transferred, the dams will undergo a 'routine inspection' at five year intervals to verify their status and justify continued non-routine management.

H.5 Criteria for 'Insignificant or No Consequences'. The consequences of interest for this guidance are those described in this regulation which are life safety, economic impact and environmental consequences, with life safety of primary concern. Of concern is the consequences should the dam fail, e.g. there would be an uncontrolled release of the reservoir pool.

H.5.1 Life safety criteria. Dam classified as 'low hazard potential' and failure would not result in fatalities exceeding the Corps 'Tolerable Risk Guidelines for Life Safety.'

H.5.2 Economic criteria. Reservoir pool area or downstream damage and/or disruption of business activities would be considered in the nuisance category, requiring but a few days to a week of typical maintenance activity to resolve.

H.5.3. Environmental criteria. Stated simply, the concept is that for 'insignificant or no consequences' should the dam fail, that no environmental laws or regulation would be violated, nor would there be negative impact on aquatic and terrestrial species, cultural resources, or local community environmental values. This concept is consistent with 'Findings of No Significant Impact' – Reference A.37. Thus, loss of reservoir pool would not permanently impact endangered species as listed by Federal or state agencies in the vicinity of the reservoir, including the reservoir pool, or downstream, nor permanently diminish what might be classified as critical habitat for threatened species. Potential erosion of sediment from the pool area may be of concern, e.g. sediment containing toxic material released or sediment movement impacting downstream in-stream habitat.

H.6 Confirmation of Meeting Exemption Criteria. A memorandum is to be prepared that documents the basis for a recommendation for exemption of the dam from 'routine' dam safety management. The memorandum is to be signed by the district Dam Safety Officer with concurrence by the MSC Dam Safety Officer. The copy of the memorandum is to be furnished to the Corps Dam Safety Officer and the Director, Dam Safety Risk Management Center. Scope and content of the memorandum is to include:

H.6.1 Brief dam/project/feature description,

H.6.2 DSAC classification and basis thereof,

H.6.3 Life safety, economic, and environmental consequences of dam failure, including summary of data, analysis, and confidence in estimates,

H.6.4 Hazard to agency staff and public if dam is left to remain in present state,

H.6.5 Recommended action (Decommission, change purpose, transfer Title, other), and

H.6.6 Approximate cost estimate/savings, schedule, potential funding source, priority to implement recommended action.

H.7 Authorities and Actions.

H.7.1 Authorization Research. The beginning point for any recommended exemption actions to decommission, modify, transfer, or dispose is thorough research of the original authorization and any other subsequent project/feature-related authorization changes or modifications. The project/feature authorization is the critical factual information.

H.7.2 Decommission. Decommissioning involves demolition of the structure, removal of the material, and restoration of the site in accordance with Federal, state, and local laws and regulations; e.g. the structure would cease to exist and any remaining authorization would be dropped or become moot and the structure removed

from the dam safety inventory. There are likely to be appropriate scales of decommissioning that range from just breaching/disabling the function of the dam through to complete removal of the structure. Regardless, the site would be prepared in such a manner that any remaining physical components do not present a hazard to agency staff or the public or violate applicable laws and regulations. Authority to study a dam for de-commissioning is 'Modification to Completed Projects' (reference A.64). The level-of-detail required and approval level, up to and including Congress, is case-specific. The Chief of Engineers has discretionary authority to approve actions in certain circumstances that may apply. The test governing the Chief's discretionary authority is the degree of impact on authorized project purposes. A dam meeting the criteria of this guidance might well fall into the Chiefs discretionary authority because its removal would not materially affect the authorized purpose of the project as a whole.

H.7.3 Transfer or Dispose. Should a civil works structure no longer serve an authorized Federal purpose but be of potential value to local interests, the project/structure title and all associated responsibilities may be transferred to other institutions. The hierarchy of preferred transfers documented in Chapter 11 of the Real Estate Handbook (ER 405-1-12 - Disposing Excess Property (reference A.38)), ranges from transfer to another DoD agency through to transfer to an authorized local agency. The end-point of the hierarchy is that of disposal of the property via competitive sale. Necessary investigation and decision processing is outlined in the Handbook and associated GSA regulations. Studies and documentation to justify such transfer/sale would be expected to be similar to that required for 'Modifications to Completed Projects' as discussed in ER 1165-2-119 (reference A.64).

H.7.4. Use of O&M Authority. On a case-specific basis, existing O&M authorities and policies may be applicable to actions outlined in this guidance. As an example, the continued maintenance of a dam meeting the criteria of paragraph H.4 may require continued operation and maintenance to ensure its presence does not present a potential safety hazard to agency staff or the public, or violate Federal or state laws and regulations, thus consuming resources while serving no useful Federal purpose. Savings in resources might be possible by disabling or removing the structure, thus accomplishing cost-effective management of the property. Coincidentally, if action is undertaken in this manner, for all practical purposes, the structure would no longer exist and could thus be removed from the dam safety inventory.

H.7.5. Convert Property to Another Purpose. On a case-specific basis, application of Section 1135 of the Water Resources Development Act of 1986 entitled 'Project Modifications to Improve the Environment' (reference A.99) might be applicable. This is a small project authority that permits modification of USACE projects for such purposes. Such a purpose might be accomplished by breaching and/or some other minor site preparation that enhances habitat or would serve some other environmental purpose. Thus, the project purpose could change; responsibility and management handed over to another USACE entity, and coincidentally remove the structure from the dam safety inventory.

H.8 Funding. There are several possible funding sources to pay for ‘exemption’ studies and for subsequently implementing the ‘exemption’ actions.

H.8.1 For studies to validate flagging dams for ‘exemption’ (e.g. justify ‘’non-routing management), the primary and logical source is regular O&M funds.

H.8.2. For studies to develop the actions and implementation plans, depending on the scale of the action, O&M funds are also a logical source. For substantial studies that would be undertaken under ‘Modification to Completed Projects’ (reference A.64) authorities, funding guidance provided therein would be appropriate and likely require cost sharing.

H.8.3. For implementation of actions formulated and approved under H.8.2 funding could be from a variety of sources and may or may not require cost sharing. The appropriate funding source would be case-specific.

This Page Left Blank

APPENDIX I

Screening Portfolio Risk Assessment Process

I.1 SPRA Process. The SPRA process includes having an independent regional cadre comprised of various disciplines including geotechnical, geology, structural, hydrologic, economic, and mechanical visit the district with dams to be screened. In one day, the cadre has a district presentation on the dam and reviews existing reports to estimate the consequences and engineering ratings to be entered in the SPRA spreadsheet. A SPRA report is prepared to document the range of the load cases considered, the engineering ratings, and consequences estimated from the existing data.

I.2 SPRA Spreadsheet. The SPRA spreadsheet provides information in the form of annualized risk in terms of potential loss of life and economic damages as well a probability of failure. These items are used to determine the appropriate DSAC for each dam. The methodology used for determining the appropriate DSAC (DSAC dam binning) has evolved over time. The current procedure plots the annualized potential loss of life (for Flood Damage Reduction (FDR) structures) or annualized economic damages (for Navigation (NAV) structures) after being divided by the resulting failure probability for the dam as rated. This operation results in an “average” potential loss of life or economic damage for a single dam failure. These values are plotted on the x-axis as shown in Figures I.1.a and I.1.b. The y-axis plots the probability of failure for the dam as rated by the regional cadre divided by the probability for a baseline dam. The baseline dam probability of failure is for a dam meeting all current guidelines. For example all features were rated “Adequate”. The y-axis then represents how many more times likely the dam (as rated) is to fail than a baseline dam or a dam meeting all current guidance. Navigation structures with potential for loss of life are plotted on both charts and the appropriate DSAC rating used.

I.3 SPRA Methodology. SPRA methodology does calculate a probability of failure, but the methodology in the SPRA calculations includes modifiers of 1, 10, 100, and 1000 for engineering ratings of Adequate, Probably Adequate, Probably Inadequate, and Inadequate respectively. These modifiers are multiplied times the baseline probability of failure for each feature and therefore result in a probability of failure that is comparable only to results of other dams using the SPRA spreadsheet. SPRA results represent more of a “relative comparison” system and the data is not compatible with the tolerable risk guidelines. DSAC V determinations cannot be made based on SPRA data since it is not compatible with tolerable risk guidelines.

I.4 DSAC Binning. The DSAC binning chart has “bounding” lines based on an interpretation of the DSAC descriptions for DSAC I, II, III and IV. These “bounding” lines are not finite lines and cannot be described by simple bounding limits. The basic limits for these bounding lines are shown in Table I.1.a, but should not be considered as absolute values as there is considerable uncertainty in the SPRA estimates. This requires the dam values to be plotted on the chart to determine the initial estimate of the DSAC for the dam. Once plotted, the initial estimate is the beginning point that is reviewed for other factors to determine if the rating should be adjusted higher or lower

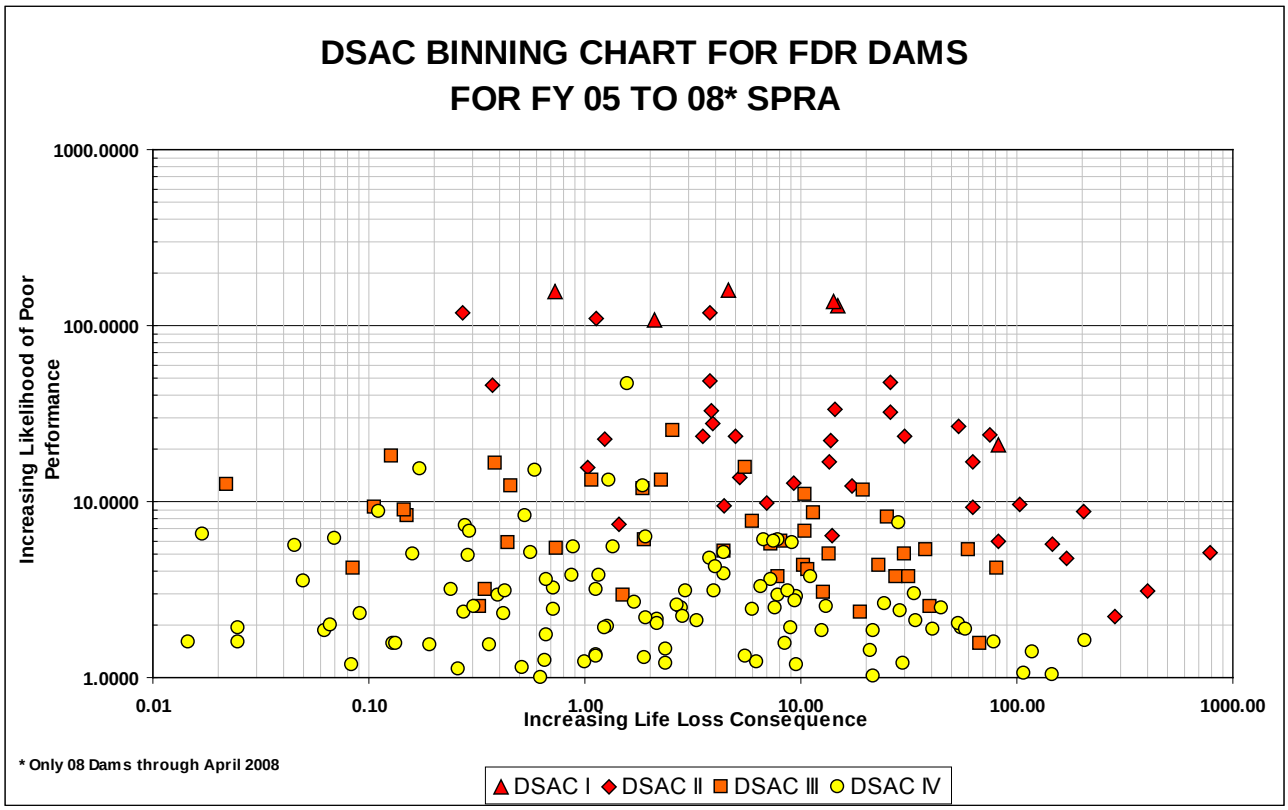

Figure I.1.a

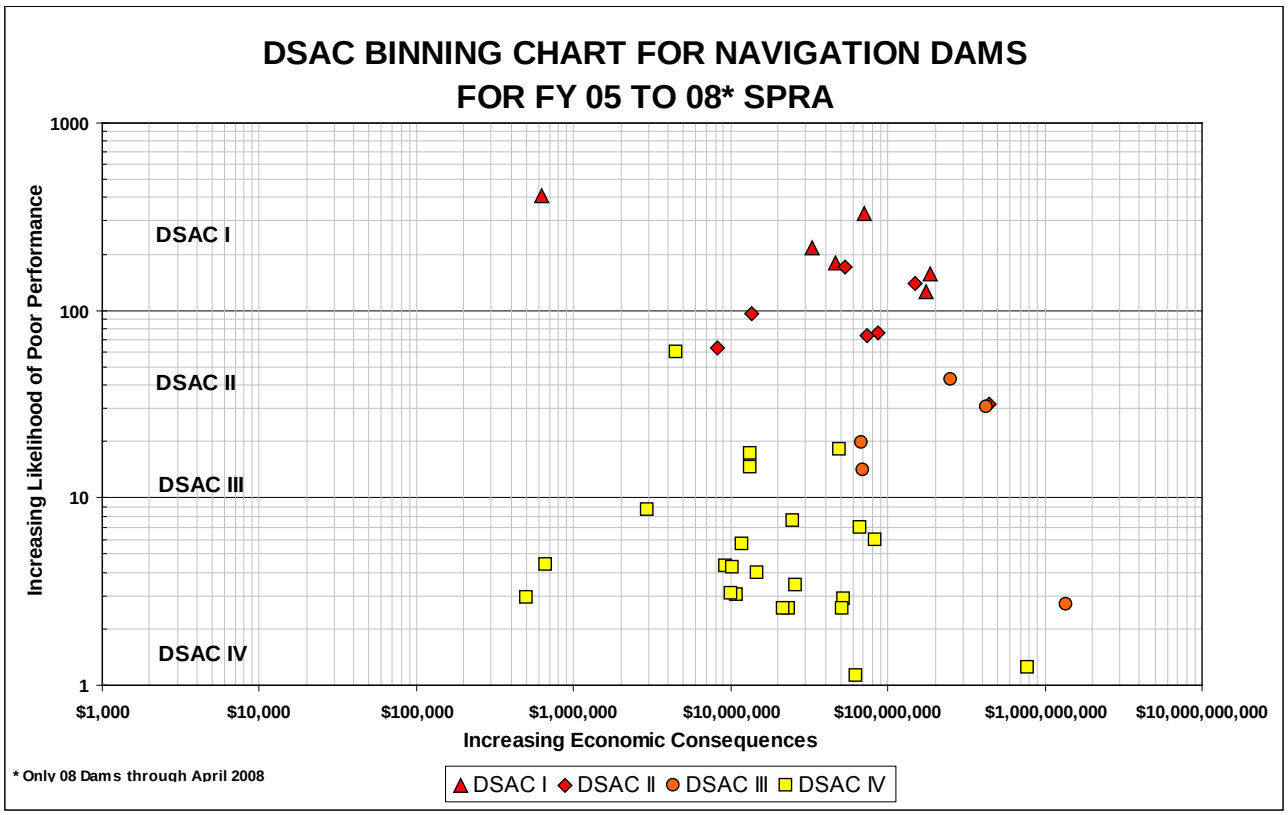

Figure I.1.b

Table I.1.a
Guidelines for determining
USACE Dam Safety Action Classification using SPRA

Dam Safety Action Class		SPRA Classification Criteria
I **URGENT AND COMPELLING** (Unsafe)		Life Risk Index > 40 and Performance Index > 100 or Economic Risk > $3B
II **URGENT** (Unsafe or Potentially Unsafe)		20 < Life Risk Index < 40 or $300M < Economic Risk < $3B or 20< Performance Index < 100
III **HIGH PRIORITY** (Conditionally Unsafe)		5 < Life Risk Index <20 or $50M < Economic Risk < $300M or 6 < Performance Index < 20
IV **PRIORITY** (Marginally Safe)		Life Risk Index < 5 or Economic Risk < $50M or Performance Index < 6
V **NORMAL** (Adequately Safe)		Cannot be determined using SPRA

as shown in Table I.1.b. The DSAC rating is then determined for dam with a brief justification for keeping or changing the initial DSAC for the dam.

I.5 Rating and Review of Rating. The initial DSAC rating is determined by the regional cadre following the district visit. The SPRA ratings, consequences, and DSAC determination go through two levels of review prior to being finalized.

I.5.1 The first level of review is completed by a group of quality control personnel including past regional cadre members and the Engineering Risk and Reliability Directorate (ERRDX) and the cadre lead responsible for the dam. The review consists of reviewing the district presentation, SPRA report, and SPRA spreadsheet. Based on the information presented, questions are asked about various SPRA items including engineering ratings, consequences, breach release severity parameters, justifications, and DSAC determination. These items are recorded and provided to the regional cadre to vet back with the entire cadre. The cadre considers the comments and either makes the recommended changes or documents why they are not changed. A follow-up discussion is held if the changes could potentially impact the agreed upon DSAC determination. From this effort a presentation summarizing the results of the screening are prepared for the next review.

Table I.1.b
Dam Safety Action Class Adjustment Guidelines

Dam Safety Action Class		Reasons to adjust Dam Safety Action Class	
I **URGENT AND COMPELLING** (Unsafe)		To Class II • External Peer Review does not support DSAC. • Studies and Investigations do not support suspected defect or failure mode. Extreme risk is not supported	
II **URGENT** (Unsafe or Potentially Unsafe)		To Class I • Progression toward failure is confirmed or supported by field observations (boils, excessive seepage, deformation, sink holes, etc)	Class III • Primary deficiency is in the extreme loading events. • History to indicate good performance at unusual loading range.
III **HIGH PRIORITY** (Conditionally Unsafe)		Class II • Field observations indicate signs of distress for unusual loading (Seepage & Piping) • Project has high component risk • Cadre belief that the dam has creditable failure modes that could initiate under unusual loading that is supported by a review of construction records and project documents. • Effectiveness of prior repairs are questionable • Site seismicity is believed to be significantly higher than original design basis.	Class IV • Deficiencies are at extreme loading events • Low component risk
IV **PRIORITY** (Marginally Safe)		To Class IV • Increasing piezometric pressure over time	
V **NORMAL** (Adequately Safe)		N/A	

I.5.2 The second level of review is completed by the Senior Oversight Group (SOG). The summary presentation is made by the cadre lead. SOG members have access to the district presentation, SPRA report, and the summary presentation prepared by the cadre lead. Based on the presentation questions, recommendations, and comments are made for the cadre lead to answer or address later. If the recommendations or comments may impact the proposed DSAC rating, the determination of the DSAC is withheld until addressed. If the recommendations would not change the DSAC rating, the SOG reviews the recommended rating and votes on the final DSAC determination.

I.5.3 Following the SOG meeting, any needed changes to SPRA reports and spreadsheets are made. The final DSAC recommendation is included in the SPRA report. Once finalized, the reports are finalized and distributed to the division DSPM.

APPENDIX J

Corps of Engineers Dam Safety Community of Practice Steering Committee (DSSC)

J.1 Authority and Responsibilities. The Steering Committee is empowered to develop and implement a strategic plan and a long-range plan for the USACE Dam Safety Program, including a mission statement, goals, objectives, and performance measures. The Steering Committee shall establish USACE Dam Safety Standards and monitor district compliance with these standards. The Steering Committee shall function in accordance with requirements of the Project Management Business Process (PMBP).

J.2 Objectives and Goals. The objective of the Steering Committee is to provide a formal USACE structure to develop policies, practices, and relationships to effectively facilitate dam safety practices and accomplishments. The Steering Committee maintains a consistent and accountable nationwide dam safety program. The Steering Committee works with other agencies to improve the USACE Dam Safety Program. The Steering Committee affirms accountability for dam safety to all elements within the command chain, monitors performance, and inculcates dam safety as a fundamental USACE mission. The goals of the Steering Committee are:

J.2.1 Participating in development of USACE-wide guidance when requested by the HQUSACE Dam Safety Officer (DSO),

J.2.2 Making recommendations to HQUSACE Dam Safety Officer for studies, investigations, and research designed to improve the safety of dams,

J.2.3 Rendering consulting service and advice on specific safety of dams issues and problems as requested by various elements of USACE or other agencies,

J.2.4 Maintaining a continuing evaluation of the state-of-the-art for the safety of dams,

J.2.5 Serving as a liaison for the dam safety process between HQUSACE and MSC/districts and disseminate pertinent information throughout USACE, and

J.2.6 Promoting dam safety engineering career development.

J.3 Scope of Steering Committee Activities. The Steering Committee will provide recommendations to the HQUSACE DSO on all topics in the areas of safety of dams such as roles and responsibilities, training, career development, automated systems and software, guide specifications, uniformity of project specifications, uniformity of process, research and development, and interface with other elements within USACE, other agencies, and professional organizations.

J.4 Composition. The steering committee members are full-time civilian employees of USACE. The Steering Committee shall seek to maintain a diversity of civil works dam safety experience as well as a diversity of the engineering disciplines. A current list of

members will be posted on the Corps of Engineers Technical Excellence Network (TEN). The steering committee officers shall be steering committee leader, alternate steering committee leader, and recording secretary. The Special Assistant for Dam Safety shall serve as the steering committee leader. The HQUSACE Dam Safety Program Manager shall serve as recording secretary. The Steering Committee shall elect an alternate steering committee leader. The Steering Committee shall be composed of seventeen (17) members as listed below.

J.4.1 HQUSACE Members. Four (4) HQUSACE individuals, who will be the Special Assistant for Dam Safety (CECW-CE), the Dam Safety Program Manager (CECW-CE), one member from Operations (CECW-CO), and one member from Program Integration Division (CECW-IP).

J.4.2 Major Subordinate Command (MSC) Members. Eight (8) individuals comprised of the Dam Safety Program Manager from each MSC.

J.4.3 Engineering Research and Development Center (ERDC) Member. One (1) ERDC individual appointed by the ERDC Director.

J.4.4 District Members. Four (4) district representatives, with experience in the safety of dams, shall be nominated by the Steering Committee as at-large members with final selection by the Corps DSO. At least one of the district representatives shall be from an operating element, one should be a DSPM, and one should be a DSO.

J.4.5 Alternate Members. In the event that a member of the Steering Committee cannot attend a Steering Committee meeting, the member may designate an alternate to serve in his capacity. The member shall provide the name of the alternate to the steering committee leader prior to the meeting.

J.5 General. The Steering Committee will carry out its objective in accordance with the following:

J.5.1 Oversight. The Steering Committee functions under the general direction of the USACE DSO.

J.5.2 Meetings. The steering committee leader will call meetings as required to carry out the Steering Committee's objective; normally meetings will be held semi-annually. Advance notice, agenda, and minutes of each meeting will be furnished to steering committee members and pertinent USACE commands.

J.5.3 Funding. HQUSACE, MSC, and ERDC members will be funded by their respective organizations for steering committee activities. District members' salary, travel and per diem expenses may be funded by HQUSACE for steering committee activities based on the availability of funds.

APPENDIX K

Observations on How Reclamation Uses Their Guidelines

K.1 Basis for Decision Making.

K.1.1 Decisions regarding the safety of the facility are made using two perspectives; the numerical risk estimate and the case made to justify the risk estimate. Reclamation has many levels of detail for the risk estimates it generates relative to the significance of the corresponding decision. Some evaluations are simplified and scripted, some are determined after several team evaluations and consultant reviews.

K.1.2 For any level of risk estimate, a technical report of findings is developed to justify the numbers that are generated. It also includes the primary factors that led to the risk estimate, a description of the uncertainties, and the strengths and weaknesses behind the numbers. These pieces of information are used to "make the case" to the advisory panel and the decision makers. This is a critical component that is intended to give the decision makers enough information to make an informed decision.

K.2 Risk Estimates Related to Tolerable Risks. Reclamation uses the tolerable risk guidelines as goals for achieving public protection, as shown in Figure K.1 (reference A.100). They are also thresholds, shown below, used to justify expending funds to reduce risks. They are not the sole piece of information used to judge the absolute safety of a structure, but they are the primary means to judge the relative safety of a structure. When considering these guidelines, Reclamation generally averages over the distribution of uncertainty to obtain the mean estimate of risk for an individual failure mode in comparison to the threshold values. Graphical depiction of this is shown in the f-N diagram in Figure K.2. Each point on the plot represents the mean risk estimate for an individual failure mode. The lines near the two axes represent the uncertainty associated with each estimate. Uncertainty is also considered in the decision process, and will be discussed in a later section. The primary focus of the dam safety program is life safety. As such, the thresholds are listed below in order of importance.

K.2.1 Expedited Public Protection.

K.2.1.1 Reclamation considers that there is justification for taking expedited action to reduce risk when the mean estimate of the annualized life loss for an individual failure mode exceeds 0.01 lives per year or the total risk of all failure modes for the project exceeds 0.01 lives per year. While there is a full range of possible risk reduction actions that can be taken, Reclamation focuses on those that can quickly reduce risk or improve understanding of the uncertainties associated with the risk. As confidence increases that the risk is in this range, actions concentrate more on reducing the risk than reducing the uncertainties. Every effort is made to take actions to reduce risks and complete any reassessment within 90 days of determining the need for expedited risk reduction action.

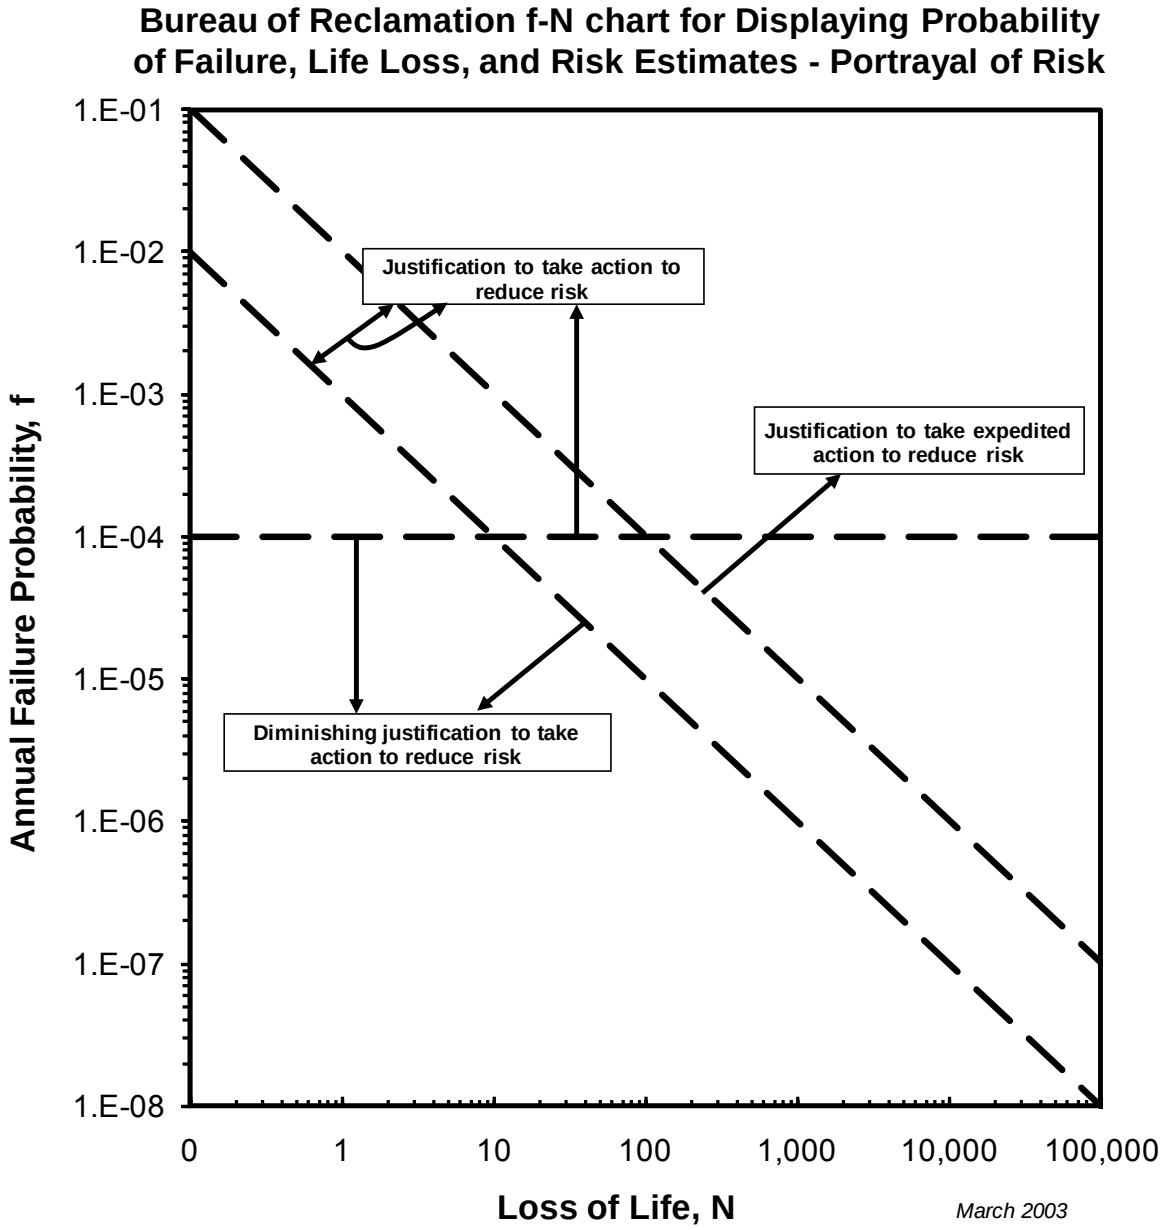

Figure K.1 - Reclamation's Public Protection Guidelines

K.2.1.2 The purpose of the "expedited guideline" is to reinforce the importance of reducing risks in an expedited fashion. In general, *identified risks* are addressed more rapidly the higher they plot in relation to the guidelines. In many occasions, risks that result in an expedited action are a result of an incident or observed change in structural behavior. In these cases, every effort is made to reduce risks on an interim basis while the magnitude of the problem is evaluated.

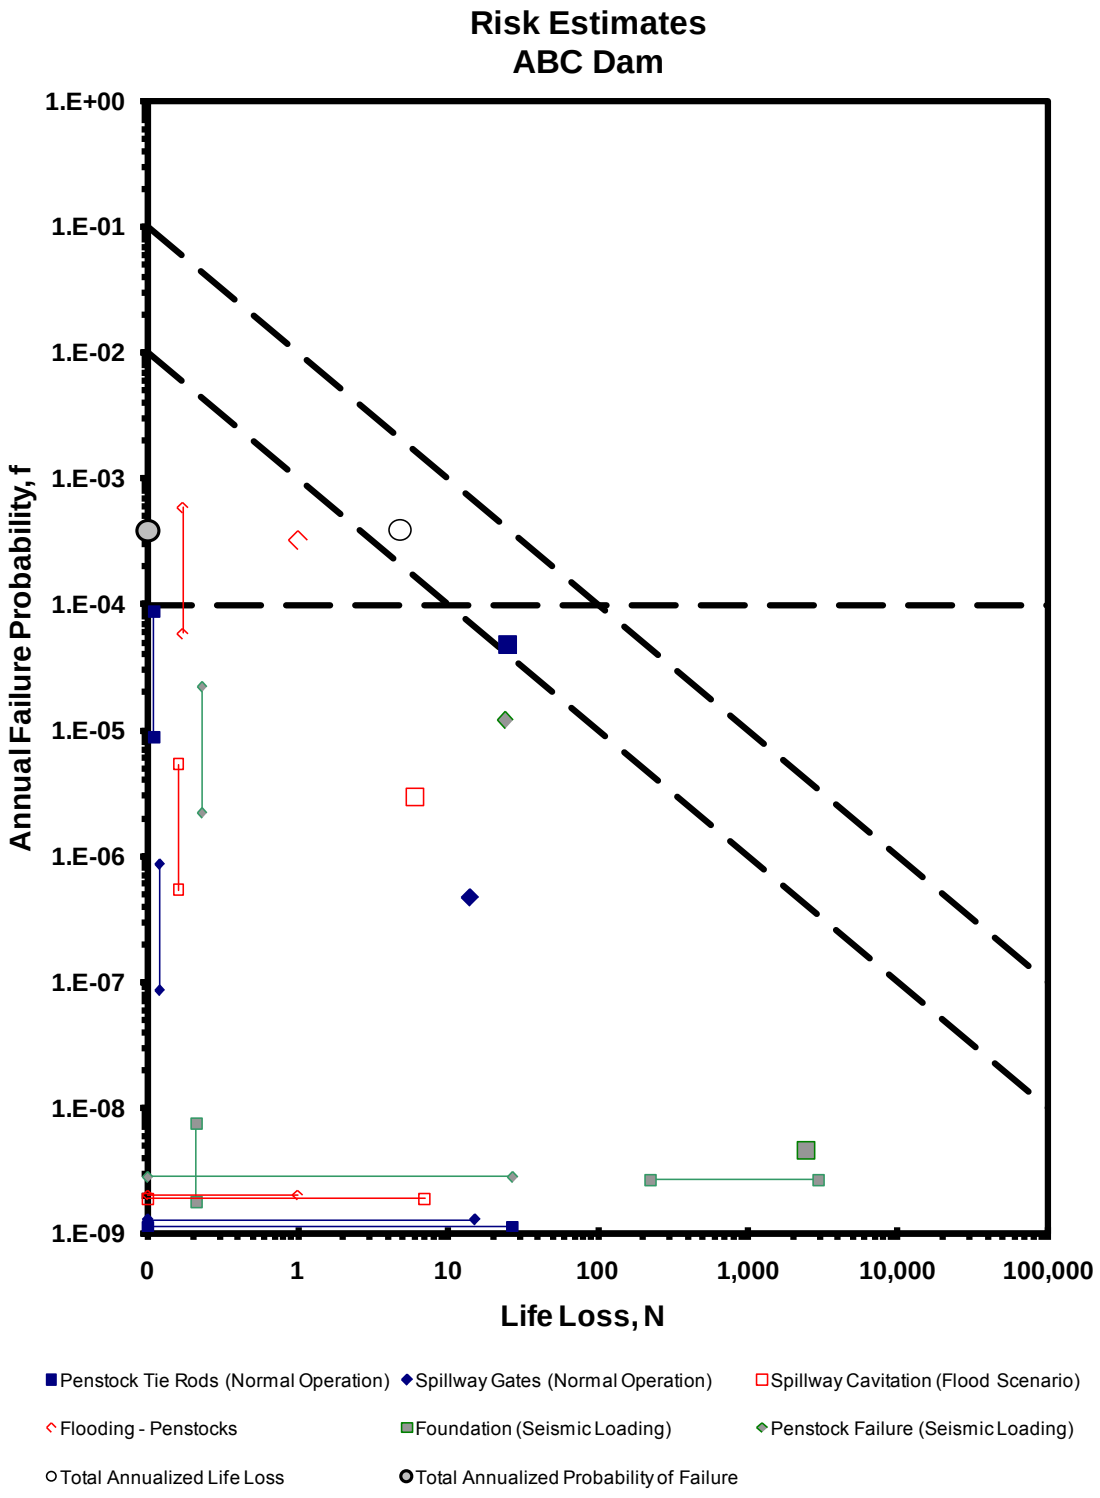

Figure K.2 - Example of an f-N Diagram for a Facility

K.2.2 Long-term Public Protection.

K.2.2.1 Reclamation considers that there is increasing justification for taking action to reduce risk when the mean estimate of the annualized life loss for an individual failure mode exceeds 0.001 lives per year or the total risk of all failure modes for the project exceeds 0.001 lives per year. When risk estimates exceed this value, there are a wide variety of possible actions which may be appropriate. The actions are scheduled into the dam safety program and coordinated with other needs at the facility and at other facilities. Actions to reduce risks are implemented on a schedule that is consistent with budgeting and appropriations processes. Typically, risk reduction should be accomplished within 7 years of a decision that identifies a need to reduce risk.

K.2.2.2 The purpose of the 'long-term' guidelines is to identify a threshold where actions are important, but not necessarily urgent. In this area, risks are managed in a more detailed and conscious manner while awaiting further evaluation or structural modifications. Interim actions are considered but not required. Decisions related to interim actions are constantly re-evaluated acknowledging that structures and conditions change over time and new information may influence the original decision.

K.2.3 Public Trust.

K.2.3.1 The justification to implement risk reduction actions increases as the mean estimate of the annual probability of failure for an individual failure mode exceeds 0.0001 per year or the total probability of failure for all failure modes for the project exceeds 0.0001 per year. Reasonable and prudent actions should be considered for implementation when the annual probability of failure estimate exceeds this value. A variety of possible actions may be appropriate.

K.2.3.2 The purpose of the public trust guidelines is to reinforce the idea that safety is important, even for facilities with low consequences.

K.2.4 Total Risk.

K.2.4.1 Figure K.3 illustrates the risk profile for one of Reclamation's five regions. Each point represents the total risk for an individual facility. In Reclamation, remediation decisions are made using the *mean estimate of risk for an individual failure mode*, whereas studies are prioritized based on the *sum of the mean risk estimates for an individual facility*.

K.2.4.2 Occasionally facilities with lower risk are worked on due to stakeholder requests or project requirements. Occasionally facilities with higher risk or probability of failure are delayed either intentionally or by circumstance. As Figure K.3 illustrates, most of the high-risk facilities in this particular region are currently being studied or modified.

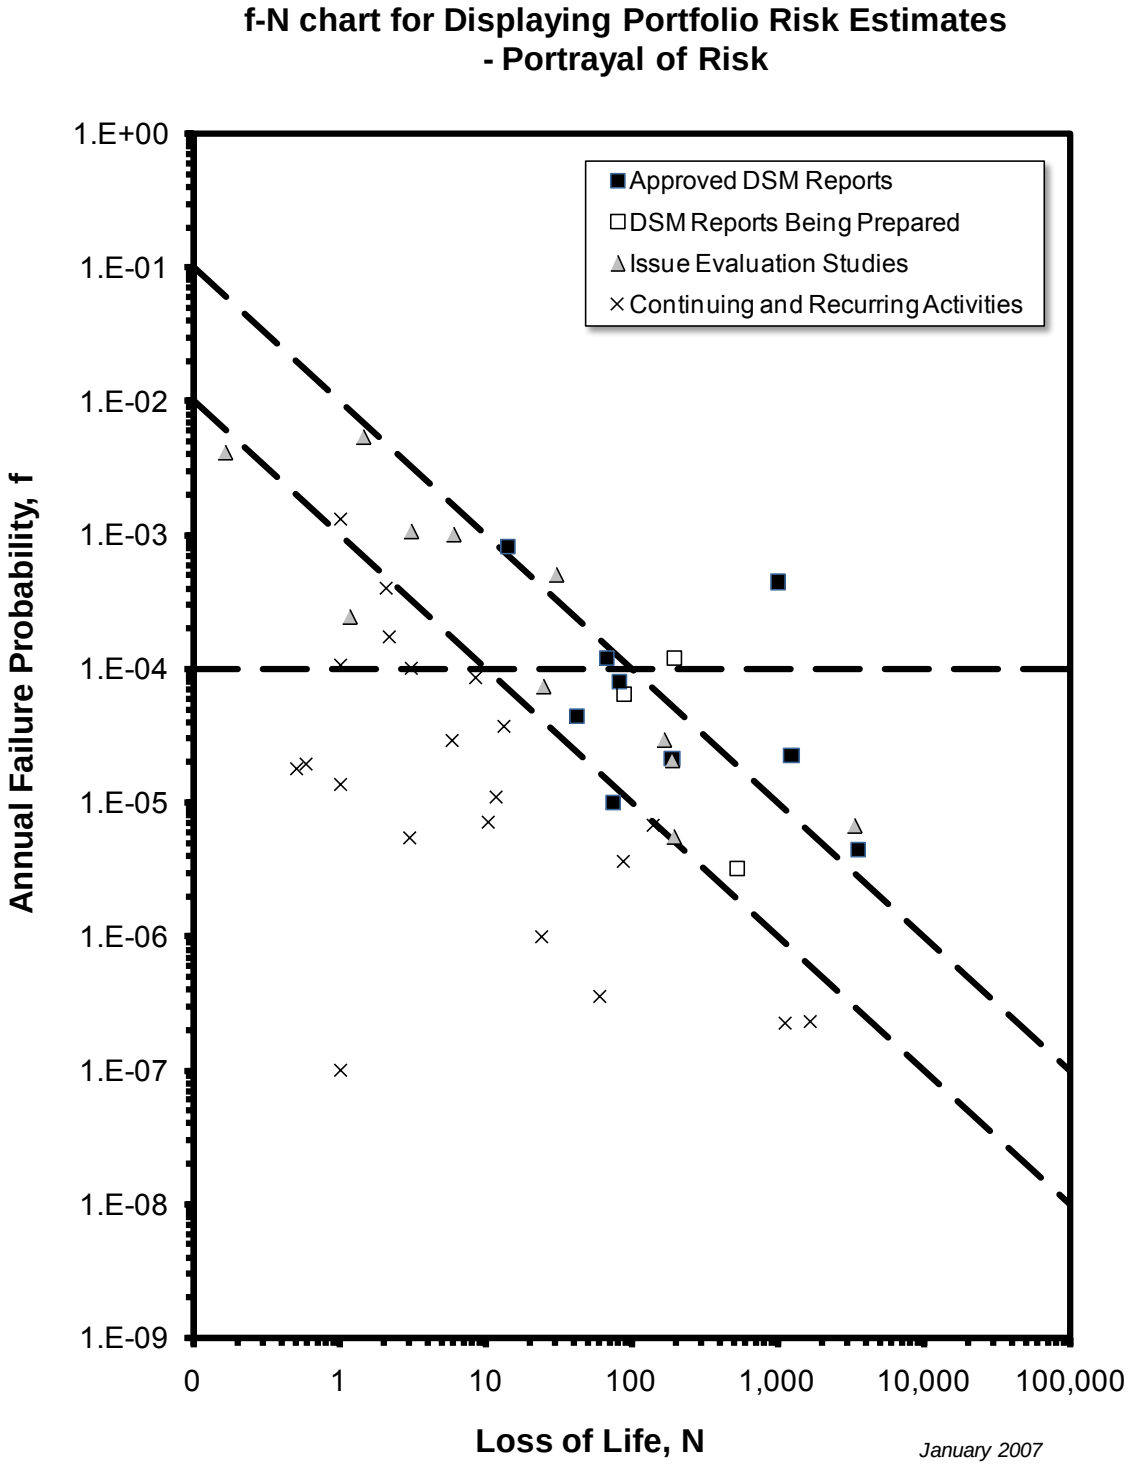

Figure K.3 - The Risk Profile for One Region in Reclamation

APPENDIX L

Calculation of the Cost to Save a Statistical Life (CSSL)

Two variants of CSSL are calculated – unadjusted CSSL(U) and adjusted CSSL(A).

The adjusted CSSL(A) is calculated as follows:

$$CSSL(A) = \frac{C_A - (E[R:e] - E[E:pr]) - ([O:e] - [O:pr])}{E[L:e] - E[L:pr]}$$

Where CSSL(A) = adjusted cost-to-save-a-statistical-life, with the proviso that a negative value is taken as zero

C_A = ANNUALIZED cost of implementing risk reduction measure, dollars per annum

E[R:e] = existing expected value of risk cost (failure probability times monetary losses to the owner) for existing dam, dollar per annum

E[R:pr] = expected value of risk cost post-risk reduction, dollars per annum

E[L:e] = expected value of life loss for existing dam, lives per annum

E[L:pr] = expected value of life loss post-risk reduction, lives per annum

O:e = existing operating costs per annum

O:pr = post-risk reduction operating costs per annum

The "unadjusted" CSSL is calculated as follows:

$$CSSL(U) = \frac{C_A}{E[L:e] - E[L:pr]}$$

Reference: ANCOLD 2003 (reference A.80)

APPENDIX M

Interim Risk Reduction Management Plan Development Sequence

M.1 General. IRRMP must be developed in an aggressive timeline to minimize the probability of failure once a potentially major dam safety deficiency is identified. IRRMPs are mandatory for DSAC I, II, and III Dams.

M.2 Development Sequence. The following table describes the sequence for IRRM development.

Table M.1 – Interim Risk Reduction Measures
Development Sequence

Item	Process	Notes
1	Designate dam as DSAC I, II, or III	One time screening or risk assessment
2	Alert MSC DSO, OPs Chief, EOC, and local PAO	
3	Use emergency contracting procedures to implement IRRM if necessary.	
4	District begins to pre-position contracts and materials and informs major stakeholders if appropriate.	
5	Obtain O&M funding from district to develop Interim Risk Reduction Measures Plan (IRRMP). Begin development of Communications Plan	District O&M funds are used for development & implementation of IRRMP.
6	District begins NEPA actions if necessary	
7	District completes IRRMP to include communications plan	
8	Public Coordination/Communication	Refine IRRM Communications Plan
9	DQC review of IRRMP done with Regional Technical Specialists	Includes Senior Oversight Group and concurrent RTS reviews throughout development
10	Seek approval of IRRMP from MSC DSO. Obtain O&M Funding for PED to implement the IRRMP	If requested include formal brief of IRRMP to MSC and HQ DSO

Item	Process	Notes
11	Approval of IRRMP by MSC DSO	Concurrence of approval by HQ DSO
12	Public Coordination/Communication	Begin coordination
13	NEPA actions completed for IRRM	
14	District implements non-structural IRRM and begins plans, specs, and detailed cost estimate for structural IRRM activities	Pool restrictions, exercises, etc.
15	District develops plans, specs and cost estimate for structural IRRMP activities	Completion
16	District issues contracts for structural IRRM	

M.3 Submission and Approval. IRRMPs for DSAC I dams shall be submitted to the MSC DSO within 60 days after being designated as a DSAC I, or within 90 days after being designated as a DSAC II, or within 120 days after being designated as a DSAC III. A formal IRRMP is not required for DSAC IV dams, and remedial actions may follow more routine processes.

APPENDIX N

Interim Risk Reduction Management Plan Review Checklist

N.1 Overall Project Description and Purposes. Make sure the description includes a brief summary of construction and operational history including remediation and past and current problems. A summary of instrumentation would be good as well (needs to be in appendix). This helps provide sufficient background for evaluating the validity of the potential failure modes and how they relate to the history of the dam.

N.2 Overview of Identified "Credible and Significant" Potential Failure Modes. Include an overview of all credible and significant potential failure modes. Identify if a quick PFMA based on SPRA results was completed or facilitated PFMA was completed. Both are acceptable for the initial IRRMP. If PFMA has not been done, have all identified potential failure modes from SPRA been included? If a facilitated PFMA has not been done, it should be identified as an IRRM and completed as soon as practical.

N.3 General Consequences Associated with Each Identified Potential Failure Mode. Estimates for each potential failure mode should be included. Consequences should include at least a qualitative estimate of consequence (SPRA results, etc.).

N.4 Structural and Nonstructural IRRM Alternatives. Alternatives considered to reduce the probability of failure and/or consequences associated with the failure modes (reservoir pool restrictions and modification of reservoir regulation plan must always be included as an option that is addressed).

N.4.1 Reservoir Restrictions. If a reservoir restriction or pool deviation has been ruled out, very specific reasons should be included as to why.

N.4.2 Non-Structural IRRM. Non-structural measures such as increased monitoring and surveillance, stockpiling materials, help to reduce probability of failure by early detection and ability to intervene should an incident occur. Non-structural measures can also be testing of EAP for better notification and evacuation, updated EAP inundation mapping, etc. that all reduce potential life loss.

N.4.3 Structural IRRM. These measures typically improve the system response which will reduce the probability of failure.

N.4.4 For each considered IRRM, a detailed explanation of how measure reduces system loading, uncertainty in the load, improves the system response, or reduces the estimated consequences.

N.5 Discussion of Probability of Failure and Consequences. A general discussion of how predicted reduction in risk (the probability of failure and associated consequences) impact on project purposes, environmental impacts, and economic impact to region associated with potential IRRM, both positive and negative is provided. This will help

reviewers discern if the cost of the IRRM is clearly justified based on its estimated risk reduction.

N.5.1 NOTE. Analysis does not reduce risk – just reduces the uncertainty associated with the risk estimate.

N.5.2 Has NEPA coordination been started and continued throughout the process?

N.6 Recommendations and Risk-Informed Justification for IRRM to be Implemented. Each justification should include an estimate of the risk reduction from the IRRM implementation. Address potential for reduction in probability of failure and consequences along with the estimated cost and impacts on other aspects of the project (possibly environmental, recreation, flood reduction, ability to execute). A table of this information by IRRM should be included as a summary.

N.7 Schedules and Costs for Implementation of IRRM Recommendations. Verify the IRRM's have been prioritized and consider the expediency of reducing overall risk. Prioritization shall consider the expediency of implementing the IRRM. Resources, funding, capability, execution time, and the time to complete the dam remediation shall all be considered when prioritizing IRRM's. For example, a warning system IRRM may take 2 years to design, coordinate, and construct while performing a table top exercise with the local emergency managers can be done in the next 2 months. Clearly one is more expedient than the other. IRRM's that can be implemented quickly should be given high priority particularly those that impact the ability to warn and help evacuate the public including increased monitoring and surveillance.

N.8 Estimate of Benefits and Costs for IRRM (DSAC I Dams). Include the proposed cost and schedules for conducting a risk-based assessment to estimate the benefits and costs for incremental evaluation of IRRM. This is primarily for DSAC I dams where significant and urgent risk reduction is necessary.

N.9 ATR Comments and Comment Resolutions. Review shall include multiple disciplines including water management, geotechnical, structural, hydraulics, and other disciplines as needed (environmental and counsel). Comments and resolution of comments need to be completed in a timely manner by all offices.

N.10 Updated EAP. The IRRMP should include updating the EAP to reflect site specific risks, and include emergency exercises for DSAC I, II, and III dams conducted in manners that are appropriate for the risk involved. Specifically it should include the local emergency managers for DSAC I, II, and III dams.

N.11 Communication Plan (Internal and External). Verify communication plan is in place and way of handling media, stockholders, and public is addressed. Check for schedule for media training based on DSAC rating, and discussion of how plan will be updated as the study progresses.

N.12 PFMA Report. Is an electronic link to the PFMA provided? Verify proper team skill sets were involved and that ALL credible and significant failure modes are addressed in the IRRMP.

N.13 MSC Internal Review Coordination. Coordination could include Environmental, Operations, Engineering, Water Management, Public Affairs, Programs, and Office of Counsel.

This Page Left Blank

APPENDIX O

Seepage Failure Mode Continuum

O.1 The Seepage Failure Mode Continuum. The Continuum (Figure O.1) was developed to illustrate the progressive nature for seepage\internal erosion failure of a dam. The failure continuum illustrates two relative and interdependent scales:

O.1.1 Stages of a seepage erosion/piping failure development, and

O.1.2 Corresponding risk reduction strategies that can be considered for implementation as the failure mode is progressing toward breach formation.

O.2 Stages. The stages of a seepage erosion/piping failure mode development as presented are generally consistent with the stages described by Foster and Fell (1999) (reference A.87), and the US Bureau of Reclamation (2000). The stages include initiation, continuation, progression, and breach formation. The literature describing these stages is somewhat ambiguous with regard to the transition between the continuation and progression phases. It is not uncommon for these terms to be used interchangeably depending on various nuances associated with a material transport (erosion and piping) failure of an embankment dam. However, the continuum developed in Figure O.1 illustrates these as two distinct and separate stages in the development of the failure mode as described further below.

O.2.1 Initiation. Initiation begins at the onset of a loading condition that leads to the development of a concentrated leak (e.g. raising the pool, development of a crack due to an earthquake, differential settlement, and hydraulic fracture). Initiation can also occur when seepage begins to exit a free (unfiltered) discharge face with sufficient gradient, quantity and velocity of flow so that soil particles begin to move. Initiation may occur in the embankment, in the foundation/abutment, or at the interface between the embankment and foundation materials.

O.2.2 Continuation. Following initiation is the continuation stage. During continuation, the pipe or erosion front moves up gradient toward the source of water and is not arrested due to the presence of a filter, cutoff, restriction or stoppage by material at the upstream end, caving because a roof does not form, or other intervention activity. The piping or erosion typically continues towards the source of water at an accelerating rate due to increasing gradients and flow quantities.

O.2.3 Progression. The progression phase occurs when the piping/erosion feature(s) widen and/or deepen as flows increase in the feature. Progression is enhanced when a roof continues to form and there are no other restraints to growth. The amount of flow continues to increase causing in most, if not all, cases the piping/erosion feature to grow rapidly. The progression phase follows the continuation phase and begins when there is a significant increase in the volume and velocity of flow in the erosion/pipe feature to cause it to enlarge. For example, the progression phase

would begin when a piping feature breaks through the upstream slope of the core (for a dam having highly permeable shells) or the upstream shell (for more homogeneous or low permeability shell materials) of an embankment, or through foundation materials and into the reservoir. The formation of the sinkhole through the upstream slope of the dam signifies the completion of the continuation phase and the start of the progression phase of failure mode development. In some instances where overlying foundation and/or embankment materials are very stiff or well compacted, the progression stage may not manifest itself in the form of sinkhole development until significant progression has occurred.

O.2.4 Breach Formation. As progression continues, flow through the erosion/piping feature and the corresponding erosion of material is not arrested. Typically, the dam crest will begin to settle due to sinkhole development, localized slope instability or unraveling of the downstream slope to the point where overtopping from the reservoir begins to occur. During breach formation, the materials in the dam are eroded, widening and deepening the opening in the dam until the full contents of the reservoir are lost.

O.3 Risk Reduction Strategies. The corresponding risk reduction strategies shown on the continuum diagram have been grouped into three overall categories that generally reflect the timeframe available for intervention: long-term, short-term, and heroic (i.e., crisis management).

O.3.1 Long-term. The timeframe for implementation of long-term risk reduction strategies would be in the range of 1 to 5 years. Corrective actions accomplished during this timeframe would not only stop a piping/erosion failure mode development, but in general would provide sufficient safeguards that would prevent any future failure mode initiation. Embankment dams on Karst foundations are a special consideration and long-term solutions that prevent future failure mode initiation may not be possible. In this case, long-term solutions such as cutoff walls that do not fully penetrate the formation with Karst may provide only a limited design life.

O.3.2 Short-term. The timeframe for the implementation of short-term risk reduction strategies would be in the range of 1 to 3 months. In some circumstances, depending on how far along are the continuation stage and the rate of failure mode development, short-term risk reduction strategies such as grouting or construction of filters/drains and cutoffs may occur over slightly longer periods of time. Corrective actions accomplished during this timeframe are generally aimed at preventing the failure mode from reaching the progression phase and failure of the dam. Short-term strategies usually involve some form of reservoir drawdown or modified reservoir operations under reduced storage levels.

O.3.3 Heroic. Heroic risk reduction (crisis management) strategies are typically those that must be implemented in the range of a few hours to a few days or weeks. Heroic actions are typically required when a piping/erosion failure mode has reached an

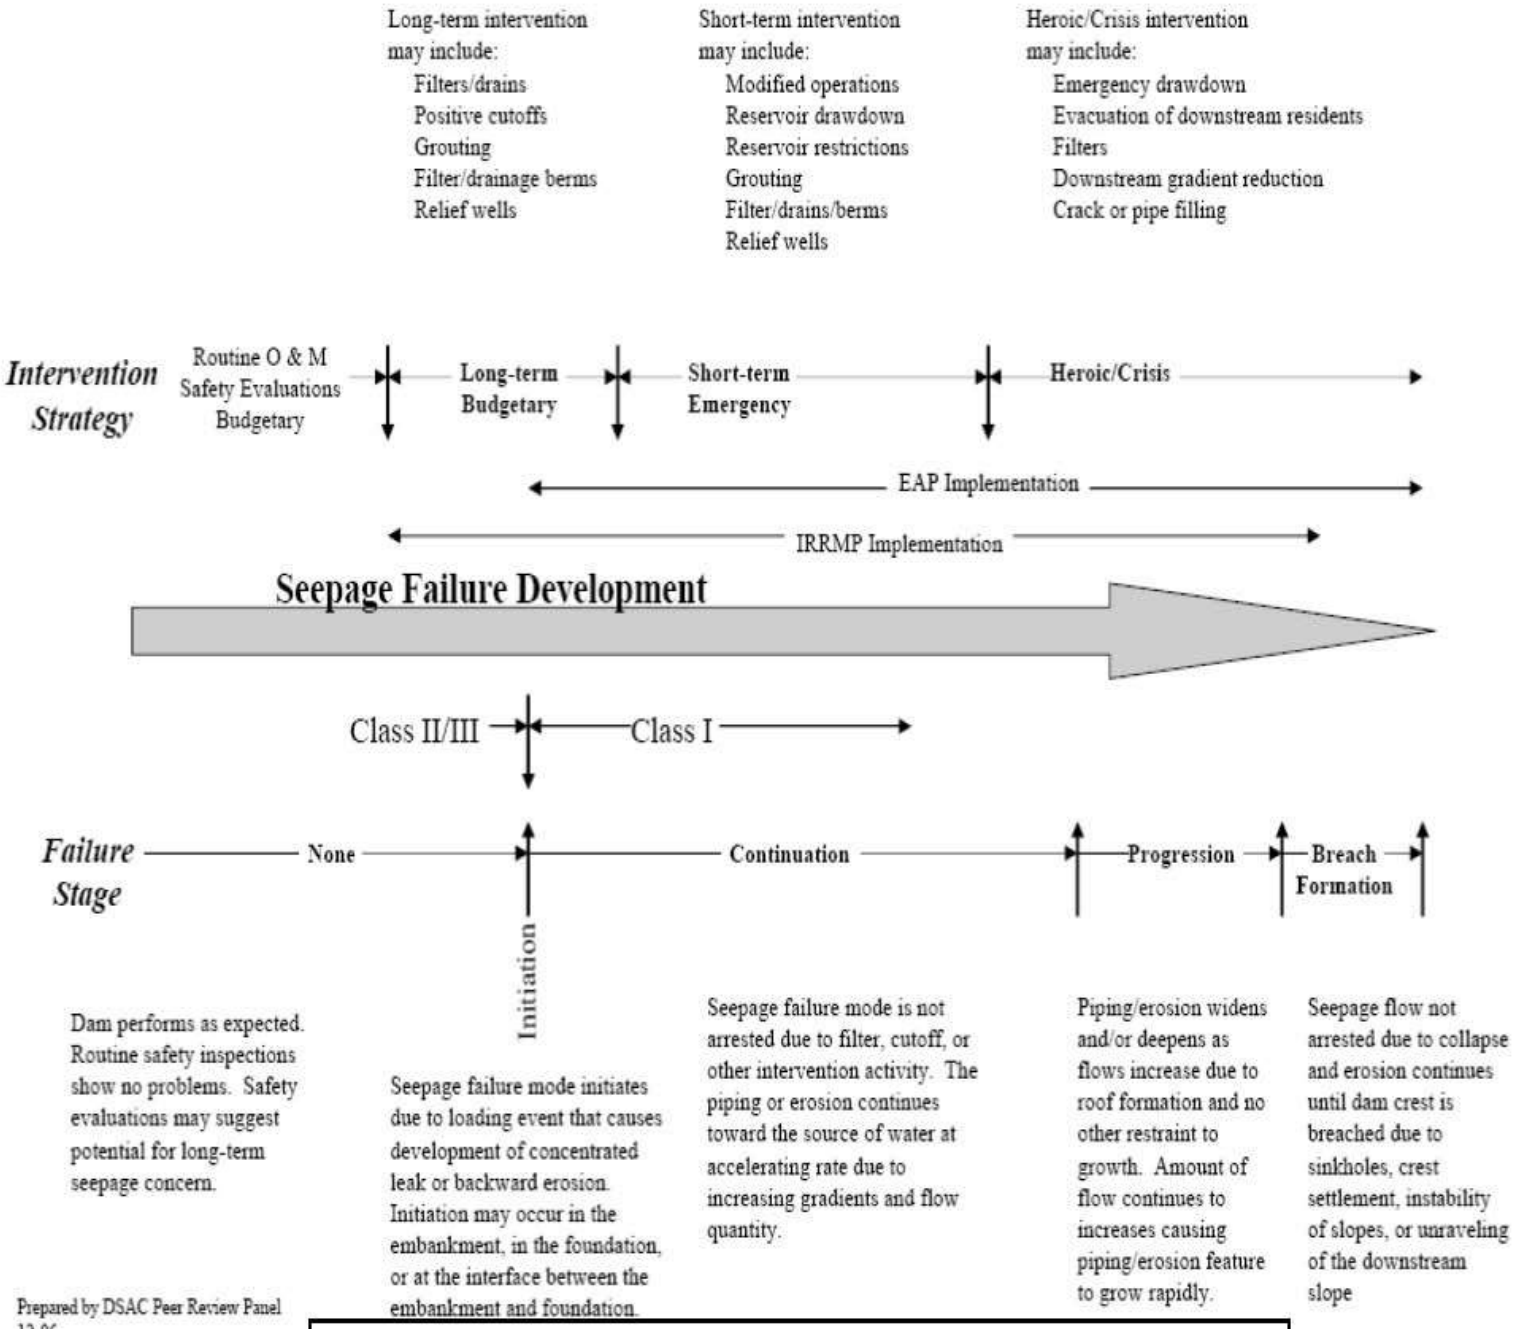

Figure O.1 – Seepage Failure Mode Development Continuum
DSAC Peer Review Panel. December 14. 2006

advanced continuation stage. The actions taken are aggressive and implementable in order to prevent entry to the progression stage or to arrest the progression stage in its earliest period of development and usually involves a rapid lowering of the reservoir level. Corrective actions accomplished during this timeframe would stop a piping/erosion failure mode development, and provide enough time for planning, design and construction of short- and long-term risk reduction measures leading to a permanent solution that will prevent any future failure mode initiation. It should be noted that each dam is unique and the actions taken at each site will need to be tailored to the attributes of the dam and the nature of the failure mode that is developing.

APPENDIX P

Format and Content for Issue Evaluation Study Documents

P.1 Issue Evaluation Study Summary of Findings (IESSF). This portion of the appendix describes the format and content of the IESSF.

P.1.1 Title Page. Include the following items on the title page:

P.1.1.1 Issue Evaluation Study Summary of Findings - Issue Evaluation Study

P.1.1.2 Dam Name

P.1.1.3 Location (river, city, state)

P.1.1.4 USACE District and USACE Division

P.1.1.5 Date

P.1.2 Approval Certification Sheet. Signature sheet in accordance with the approval requirements outlined in Table 8.2.

P.1.3 IESSF Section 1. Dam Safety Portfolio Risk Management Process. For Section 1 use the standard text (boiler plate) provided in Table P.1. Fill in the blanks at the end of the text.

P.1.4 IESSF Section 2. Summary History of Dam Safety-related Actions. Summarize, using text, diagrams, and photographs (as appropriate), the dam-safety-related issues and actions that might have arisen during design, construction, and operation continuing to the present. The information to be presented should include the following safety issues identified; remediation proposed and adopted; and a brief assessment of the degree of success of the remediation. A time-line diagram of major safety-related events and actions is a powerful way of presenting such history. Include the appropriate charts and diagrams.

P.1.5 IESSF Section 3. Guiding Principles and Key Concepts. For Section 3 use the standard text (boiler plate) provided in Table P.2.

P.1.6 IESSF Section 4. The following questions are to be answered in a narrative manner that succinctly communicates the essential dam safety issues, failure modes and risk assessment, and the recommended action(s). Tables, illustrations, and graphs are to be used as appropriate to summarize information and support the narrative.

P.1.6.1 Current Dam Safety Action Classification (DSAC). What is the existing DSAC classification, and what are the significant dam safety issues that have lead to this classification? (Include a summary listing of physical manifestations or PFM's.)

Table P.1 – Standard Text for IESSF Section 1
The overall Dam Safety Portfolio Risk Management Process is a series of hierarchical activities used to assess, classify, and manage the risks associated with the USACE inventory of dams. Dam Safety Action Classification (DSAC). The DSAC classification system provides consistent and systematic guidelines for appropriate dam safety actions, which are designed to address the dam safety issues and deficiencies of USACE dams and which are commensurate with the level of the dam failure risk. USACE dams are placed into a DSAC class based on their probability of failure or the individual dam safety risk estimate considered as a combination of probability of failure and potential life safety, economic, environmental, or other consequences. The intent is that the classification of a dam is dynamic over time, being revised as project characteristics are modified or more refined information becomes available affecting the loading, probability of failure, or consequences of failure. Portfolio Risk Management Process. The portfolio risk management process defines and documents the USACE risk assessment and risk management action decisions for each dam and facilitates risk communication. The actions and documents that reflect the process include normal operations and maintenance (O&M) activities and the documents generated through the portfolio risk management process to address dam safety issues. These documents are principally the Screening Portfolio Risk Assessment report, the Interim Risk Reduction Measures report, the Issue Evaluation Study report, and the Dam Safety Modification report. See ER 1110-2-1156 Chapter 3 for a detailed description of the process. Dam <*insert name*> is presently classified <*Insert dam's DSAC class*> and is poised at decision point <*Insert decision point ID*>. Prior dam safety actions for this dam are summarized in the following section.

P.1.6.2 Description of Potential Failure Mode(s) Judged to be Significant. List each significant PFM separately, (PFM-1, PFM-2, PFM-3, etc) and answer the following questions for each PFM:

P.1.6.2.1 Dam Safety Issue for PFM

P.1.6.2.1.1 What is the Dam Safety Issue?

P.1.6.2.1.2 What instigated the safety concern?

P.1.6.2.1.3 What physical evidence or project performance indicates that there is a problem or that a problem cannot be ruled out?

P.1.6.2.1.4 Why are these issues significant?

Table P.2 – Standard Text for IESSF Section 3
Assessments of the safety of USACE dams are conducted using a risk assessment approach which provides input to risk informed decision making. The approach combines the evaluation of dam safety against engineering guidelines, and evaluates the risk posed by USACE dams compared to tolerable risk guidelines. The former focuses on satisfying essential USACE guidelines for a wide range of engineering considerations (for an Issue Evaluation Study risk estimate this evaluation against engineering guidelines is very limited if done at all, and if done, is only done for those potential failure modes assessed in the IES). The latter involves identifying all credible and significant failure modes for a specific dam, quantifying their probabilities of occurrence and associated consequences, and evaluating their estimated risk of dam failure against the USACE tolerable risk guidelines. The tolerable risk guidelines address the probability of failure, risk to the public (life loss), economic risk and environmental risk. For a particular USACE dam, by combining the two evaluation approaches and the breadth of understanding gained from both, well-reasoned recommendations are made for reducing risks to tolerable levels and to meet essential USACE guidelines. Achieving and maintaining tolerably low risk levels for USACE dams requires structural measures in concert with an effective safety management regime, including staff training, operation and maintain, monitoring and surveillance, and emergency action planning. Since each USACE dam is part of a large portfolio of dams, risk management decisions viewed from a national perspective will be made centrally by HQUSACE. Therefore, the evaluation of dam safety for a particular dam must be made in a consistent manner such that the information obtained from these evaluations can be used to prioritize risk reduction actions across the portfolio of USACE dams. In addition, the Dam Safety Action Classification (DSAC) system is designed and used to maintain the appropriate degree of urgency for addressing safety issues at individual dams. It is recognized that both the engineering guidelines approach and the risk-informed approach are subject to limitations based on the available information, understanding about dam safety issues and failure modes, and limitations in the state-of-the-practice of dam safety engineering. Thus it is important that the degree of confidence in quantitative analyses be considered in both engineering analyses and risk assessments for each dam. Hence USACE does not consider tolerable risk guidelines as strict criteria, and it does not rely solely on these guidelines to demonstrate adequate dam safety, but rather USACE uses the entirety of the information available to support the recommendations made to take a particular risk management action. The IESSF presents a balanced and professional distillation of the risk assessment in support of the recommended risk informed decision.

P.1.6.2.2 Estimation of Risk Conditions for PFMA.

P.1.6.2.2.1 What is the estimated risk condition?

P.1.6.2.2.2 What are the major contributors of the risk condition? Provide a summary on the likelihood of the initiating event, the conditional probability of failure, and the exposure of people, property, and environment, given this failure, and the ultimate loses due to the failure. Discuss the nature of the flooding, the nature of the warning, the ease of evacuation, and size of the population at risk from a best case to a worst case evaluation.

P.1.6.2.2.3 What physical evidence or project performance metrics support that there is or could be a significant failure mode and what is the confidence in its existence?

P.1.6.2.2.4 What are the estimated probabilities of failure and consequences for the identified significant failure mode and the degree of confidence in these estimates?

P.1.6.2.2.5 Can the confidence in the risk estimates be increased and if so, how?

P.1.6.3 Evaluation of Risk Condition

P.1.6.3.1 Tolerable Risk Guidelines

P.1.6.3.1.1 What order of magnitude above or below the tolerable risk limit is the estimated risk, with respect to:

P.1.6.3.1.1.1 APF - total annual probability of failure and

P.1.6.3.1.1.2 ALL - annualized incremental societal risk.

P.1.6.3.1.2 What is the estimated individual risk (IR)?

P.1.6.3.1.3 Does the probability distribution of potential life loss exceed the societal (F-N) tolerable risk limit?

P.1.6.3.1.4 How does uncertainty impact the evaluation of the estimated risk in relation to the tolerable risk guidelines?

P.1.6.3.2 Recommended Dam Safety Action Classification (DSAC) – Do the results of the risk assessment justify a change in the DSAC classification? IESSF

P.1.6.3.3 Dam Safety Modification Study – Is a dam study modification study justified? If so, what is the rationale?

P.1.6.3.4 Interim Risk Reduction Measures.

P.1.6.3.4.1 Are changes in the interim risk reduction measures indicated by the risk assessment in support of the IES?

P.1.6.3.4.2 Are there minor dam safety issues or loss of service issues that should be addressed by operation and maintenance? If so, what is the rationale?

P.2 IES Report. This portion of the appendix describes the format and content of the IES Report.

P.2.1 Chapter 1 – Introduction. Overall project authority, purposes, location, and descriptions of pertinent project features.

P.2.2 Chapter 2 – Background. Discussion of past performance and key observations, Include summary of the dam features and components, foundation conditions, seepage control features, unique design considerations, and construction methods.

P.2.3 Chapter 3 – Current Assessment. Overview from the results of any past SPRA or PA findings and the reasons for the current DSAC rating. The current assessment shall include a summary of the objectives from the approved Issue Evaluation study plan. Include a description of the Phase 2 study efforts and investigations (if applicable).

P.2.4 Chapter 4 – Interim Risk Reduction Measures. Summary of the IRRMP implementation, and the benefits and impacts of the corresponding interim risk reduction measures.

P.2.5 Chapter 5 – Potential Failure Modes. Summary of the facilitated PFMA results with a listing of the significant and credible failure modes, the impacts if failure was to occur, and corresponding opportunities for risk reductions.

P.2.6 Chapter 6 – Hydrologic and Hydraulic Analysis. A discussion of the hydrologic loading events and frequency for the project as well as hydraulic modeling efforts.

P.2.7 Chapter 7 – Seismic Loading. A discussion of the seismic loading events and frequency for the project shall be included in this chapter. The overall seismic analysis process is provided in Appendices AB and AC.

P.2.8 Chapter 8 – Consequences. A detailed summary of the estimated life, economic, and environmental consequences. (e.g. impact on project purposes, loss of life, environmental and economic impact to region, etc.).

P.2.9 Chapter 9 – Risk Estimate.

P.2.9.1 Methodology. A description of the methodology and risk estimating tools, used to estimate the risk.

P.2.9.2 Sensitivity. Discussion of model and data uncertainty, and assumptions, including explicit presentation of how uncertainty influences the risk estimate using sensitivity analysis or other appropriate uncertainty analyses.

P.2.9.3 Summary of risk estimates. Discussion of the risk estimates based upon current tolerable risk guidelines. Plot the risk estimate results on the tolerable risk guideline charts. The summary shall provide a tabular summary of results that includes the Annual Probability of Failure, the estimated Life Loss (Mean Value), the Annualized Life Loss, and economic risk for each failure mode analyzed (see Chapter 5).

P.2.10 Chapter 10 – Conclusions and Recommendations. This section should include the findings and conclusions of the risk estimate, recommendations, and risk-informed justification for more detailed study. This section should also include a discussion on future data needs required to reduce unacceptable uncertainty at the next level of study.

P.2.11 Chapter 11 – Interim Risk Management Plan. A comprehensive discussion on the significant dam safety deficiencies identified by the risk analysis, the short and long term efficiency, effectiveness, and potential impacts of current and proposed IRRMs, the justification and urgency to take further action, the proposed scope of the efforts required to accomplish these actions, including the anticipated planning, design, and investigation tasks required to perform a DSM study.

P.2.12 Chapter 12 – Risk Communications Plan. A summary of efforts and actions the district intends or has implemented in accordance with chapters 7 and 10.

P.2.13 Supporting Documentation. Supporting documentation shall be included in the following Appendices:

P.2.13.1 Appendix A – References.

P.2.13.2 Appendix B – PFMA Documentation.

P.2.13.3 Appendix C – Initiating Events.

P.2.13.4 Appendix D – System Response.

P.2.13.5 Appendix E – Consequence Documentation.

P.2.13.6 Appendix F – Risk Engine Results.

P.2.13.7 Appendix G – Pertinent Project Data used in Risk Estimates.

P.2.13.8 Appendix H – Agency Technical Review.

P.2.13.9 Appendix I – IRRM Supporting Documentation.

This Page Left Blank

APPENDIX Q

Dam Safety Modification Investigations, Studies, and Reports

Q.1 Format of Dam Safety Modification Report. Each report shall include the requirements contained in the following paragraphs and the report format shall follow the order as presented below.

Q.2 Dam Safety Action Decision Summary (DSADS). The DSADS is intended to be an extractable, stand alone component of the DSM report. (Note: This is a different document from the Part 1, IES.) The DSADS is intended to meet the information needs of senior USACE officials in making dam safety decisions. It would be a public document with unrestricted distribution, but is not designed to be a public communications document per se. Detailed guidance for preparation of the DSADS is in Appendix R.

Q.3 Executive Summary. The Executive Summary will include project location, description, and DSAC; dam safety issues and significant potential failure modes; baseline risk estimate and relation to tolerable risk guidelines; alternatives considered; and recommendations with expected effects on risk. The Executive Summary should be brief, about 2 to 3 pages in length, summarizing the above items in such a way as to not include sensitive information so that the Executive Summary may be released publicly without being designated as “For Official Use Only.”

Q.4 Background.

Q.4.1 Project Authorization and Appropriate Funding Legislation. Provide pertinent information on the project authorization, including any modifications, and quote verbatim the requirements of local cooperation in the original authorization.

Q.4.2 Location and Description. Briefly describe the project, including type of dam or major structure and seismic zone and enclose a map to indicate its location.

Q.4.3 Project History. Provide a chronology of the expenditures for maintenance on the project since its completion, and a brief description of all previous major rehabilitations or dam safety modifications and their associated costs.

Q.4.4 Current Use of the Project and Projected Future Use. Provide a narrative description of the use currently being made of the project and the use projected during an appropriate period in the future (e.g., useful life without and, new useful life with, recommended modifications for dam safety). Indicate whether the project currently satisfies the authorized project purposes and what impact the proposed modifications for dam safety will have on the project’s capability to do so. Provide supporting data, as available from USACE or non-USACE sources.

Q.5 DSM Study Findings and Recommendations. This section presents a summary of the investigations, analysis, studies, and decision process for the recommended risk management plan.

Q.5.1 Identify Dam Safety Issues and Opportunities (Chapter 9, Section 9.5.2). Problems and opportunities statements will be framed in terms of the USACE dam safety program objectives, identified dam safety issues, and life safety tolerable risk and essential USACE engineering guidelines.

Q.5.2 Estimate Baseline Risk Condition (Chapter 9, Section 9.5.3). The baseline condition provides the basis from which alternative plans are formulated and impacts are assessed. All dam safety issues and credible potential failure modes will undergo a risk assessment to identify the significant potential failure modes and to estimate the baseline risk. All risk estimates must give due consideration for intervention. Risk estimates are to be made and presented for both with and without intervention scenarios. A risk assessment for each subsequent risk management alternative will be done to determine the estimated risk reduction.

Q.5.2.1 Provide a narrative description of the investigations and studies used to support the baseline risk estimate.

Q.5.2.2 Present any investigations and studies and explain how they improved the quality and reduce uncertainty of the baseline risk estimate and risk reduction estimates. This narrative should address the engineering assessment, related to each type of dam safety issue (failure mode); to characterize and quantify the existing conditions both deterministically and probabilistically. The narrative should address the uncertainty in all of the analyses performed. Present the loading and system response curves.

Q.5.2.3 Dam Break Analysis and Inundation Maps. Provide a narrative description of the dam break analysis used to estimate the flood characteristics and inundation area associated with a breach for each type of significant failure mode. This analysis is required to be done for a representative range of pool elevations. (Typically this done using selected reservoir elevations that represent break points that allow reasonable determination of consequences without extensive analysis.) The Modeling Mapping Consequence Production Center (MMC) has overall responsibility for developing dam failure, inundation mapping, and consequence models for USACE dams in support of the DSMS.

Q.5.2.4 Baseline Consequence Analysis. Provide a narrative description and tabular summary of the consequence analysis for the baseline condition developed to estimate the consequences associated with dam breach for the full range of loading and exposure conditions.

Q.5.2.4.1 Baseline Life Loss Consequences. This shall include the estimate of the population at risk; threatened population, and the potential loss of life.

Q.5.2.4.2 Baseline Economic Consequences. This shall include the estimated direct economic damages to property and infrastructure, cost of emergency response, loss in regional and national income and employment, and the discounted present value of project future economic benefits.

Q.5.2.4.3 Baseline Environmental and Other Consequences. This shall include the estimated environmental damages (i.e., acres of habitat destroyed, threatened or endangered species impacted.) and HTRW contamination from contaminates either within the reservoir or in the downstream inundation area. Other consequences that cannot be quantified shall be qualitatively described.

Q.5.3 Formulating alternative risk management plans (Chapter 9, Section 9-5.4.). A risk management alternative plan consists of a system of structural and/or nonstructural measures, strategies, or programs formulated to meet, fully or partially, the identified DSM study risk management objectives subject to the constraints. Provide a narrative description of the investigations and analysis included in the report supporting alternative formulation.

Q.5.3.1 At least one proposed risk management alternative must be shown to reduce the risk to the levels defined in the tolerable risk guidelines.

Q.5.3.2 Other alternatives to be considered include:

Q.5.3.2.1 Do nothing – continue project as is;

Q.5.3.2.2 Removal of dam;

Q.5.3.2.3 Replacement of dam;

Q.5.3.2.4 Plan formulated with full ALARP considerations;

Q.5.3.2.5 Only achieving tolerable risk limit for life safety; and

Q.5.3.2.6 Make Interim Risk Reduction Measures permanent.

Q.5.4 Evaluating Alternative Risk Management Plans (Chapter 9, Section 9.5.5). The evaluation of effects is a comparison of the with-risk reduction condition to the baseline condition for each risk management alternative.

Q.5.4.1 Present engineering analysis related to each dam safety issue (failure mode) addressed by each risk management alternative. Characterize and quantify the best estimate of the risk reduction for each alternative and the uncertainty around the best estimate of the risk reduction for each alternative. Develop and present system loading and system response curves for each alternative that relate the probability of failure to the full range of loading.

Q.5.4.1.1 Life Loss Consequences. Provide a narrative and tabulation of estimated Life Loss reduction for each of the alternatives. Characterize and quantify the best estimate of the life loss consequences, and the associated uncertainty, for each alternative.

Q.5.4.1.2 Economic Consequences. Provide a narrative and tabulation of economics consequences for each risk management alternatives. Characterize and quantify the best estimate of the economic consequences, and the associated uncertainty, for each alternative.

Q.5.4.1.3 Environmental Consequences. For each alternative provide a narrative and tabulation of estimated loss or impact on species and habitat for each of the alternatives. Characterize and quantify the best estimate of the environmental consequences, and the associated uncertainty, for each alternative.

Q.5.4.2 Alternative Cost Estimates. Provide a preliminary cost/economic analysis for each alternative included in the report.

Q.5.5 Comparing Alternative Risk Management Plans (Chapter 9, Section 9.5.5). In this step, plans (including the no permanent risk management action plan) are compared against each other, with emphasis on the outputs and effects that will have the most influence in the decision making process, e.g. annual probability of failure, life safety tolerable risk guidelines, ALARP considerations, and essential USACE guidelines.

Q.5.5.1 At a minimum for each alternative show the estimated probably of failure for the baseline condition and the with-risk reduction condition, show the estimated consequences - life loss, economic, present value of project future economic benefits that would be lost with a project failure, and environmental, present baseline condition and with-risk reduction condition estimated risk, show the reduction in total estimated risk and estimated risk for each failure mode, list the ALARP considerations to indicate the residual risk is tolerable, and the estimated cost for the alternative.

Q.5.5.2 Under the ALARP considerations present the disproportionality ratio, cost effectiveness of reducing statistical life loss, and the benefit cost ratio for each alternative. Present the evaluation to determine if each alternative meets essential USACE guidelines. See chapter 5 for details of the various risk guideline parameters to be used in evaluation of alternatives

Q.5.6 Selection of a Risk Management Plan (Chapter 9, Section 9.5.6). The primary evaluation factors of annual probability of failure, life safety tolerable risk guidelines, ALARP considerations, and essential USACE guidelines form the basis for plan selection.

Q.5.6.1 When available information is insufficient to justify the need for modification, recommendations will be made for additional special engineering

investigation(s), which would support a decision. In this case, the most probable plan shall be presented, pending the outcome of the proposed investigations.

Q.5.6.2 Present the justification for any aspect of the recommended plan that requires additional project authorization.

Q.5.6.3 Provide a narrative description of how the dam currently (no risk management measures implemented) deviates from current essential USACE guidelines.

Q.5.6.4 Provide a narrative on the cost to fully meet current standards based criteria. A discussion of the baseline risk, residual risk with the recommended plan, and residual risk for other alternatives that fully meet current standards based criteria (if different from the recommended plan) should be included in the report. Present the results of the economic cost analysis and the total project cost for the recommended plan. An M-CACES cost estimate is required for the recommended risk management plan. Cost estimates shall include a cost risk analysis showing the uncertainty per ER 1110-2-1302, (reference A.53).

Q.6 Cost Sharing Considerations.

Q.6.1 For risk assessment and decision document approval this dam safety regulation treats the dam safety assurance work (Section 1203 cost sharing) and major rehabilitation work for seepage and stability (regular cost sharing) the same way. Each dam safety issue shall be discussed and alternatives reviewed in light of all potential failure modes. For cost sharing purposes this section of the report shall tabularize the recommended risk management alternatives and discuss the proper cost sharing for each of the risk management alternatives in light of the section 1203 and regular cost sharing guidance – the cost sharing is failure mode dependent.

Q.6.2 Include a general explanation of the cost sharing requirements followed by a discussion of the circumstances of the particular project. Show the amount to be cost shared for each of the different cost sharing criteria. Explain the determination of cost allocation and cost sharing for the specific project. This will require documentation of pertinent agreements or contracts. The discussion shall include a tabulation of the costs to be paid by the Federal Government and the sponsor(s). Identify the sponsor(s) for the project and their contributions to initial project development, and sponsor(s) subsequently added to the project. Include the sponsor(s) views concerning cost sharing. Include copies of the existing contracts or agreements.

Q.7 Real Estate Plan(s). Present a summary of any real estate requirements. The Real Estate Plan shall be prepared at a level of detail commensurate with the scope of the project and included in the DSM report appendices. If no land acquisition or relocation requirements are identified, the appendix shall so document that finding.

Q.8. Environmental Compliance Documentation. Documentation of compliance with applicable environmental laws and regulations must be prepared. This may include items such as biological assessments required by the Endangered Species Act and the Fish and Wildlife Coordination Act Reports, in addition to NEPA documents. In accordance with ER 200-2-2, the NEPA document, either an EA or EIS, may either be a self-supporting document combined with and bound within the feasibility report or integrated into the text of the feasibility report. The EA/EIS should generally be integrated into the text of the report unless complex environmental impacts preclude this alternative. Additional information on environmental compliance documentation is in ER 1105-2-100, Appendix C. (reference A-42)

Q.9 Summary of Independent External Peer Review. When an Independent External Peer Review is completed on the project; a summary of the review report should be included in the report. (The detailed review report should be presented in an appendix.)

Q.10 Dam Safety Modification Report Appendices.

Q.10.1 Risk Assessment and Risk Management Alternative Formulation. Provide the detailed risk assessment for the dam and also of any reliability analysis conducted concerning the operating equipment on the structure. Provide the detailed analysis.

Q.10.2 Life Loss Consequences. Include all approaches, data sources, description of models, and model results for all life loss evaluations conducted to estimate the baseline condition life loss consequences of dam failure. This should also include the effect of each alternative on these consequences. Provide the results of the life loss analysis for the recommended plan with detailed backup data.

Q.10.3 Economic Evaluation and Economic Consequences. Include all approaches, data sources, description of models, and model results for all economic evaluations conducted to estimate the baseline condition economic consequences of dam failure. This should also include the effect of each alternative on these consequences. Provide the results of the economic cost analysis for the recommended plan with detailed backup data.

Q.10.4 M-CACES Estimate for Recommended Plan. A Micro Computer Aided Cost Engineering System (MCACES) baseline feasibility estimate (ER 1110-2-1302 (reference A.53)) in the Civil Works/HTRW Work Breakdown Structure will be prepared for the recommended plan. Cost estimates shall include a cost risk analysis showing the uncertainty following “Memorandum: Application of Cost Risk Analysis Methods to Develop Contingencies for Civil Works Total Project Costs, 3 July 2007.” The level of the cost detail will vary with the design information available to support the project scope, but shall be at least to the sub-feature level of detail. However, a higher level of detail approaching that of a feasibility report should be the goal in order to more accurately identify the baseline cost estimate. Although this baseline estimate is not subject to reauthorization if the Section 902 limit (WRDA 86) (reference A.99) is exceeded, the goal is to make every effort to adhere to the criteria of the 20% growth

limitation. Provide a Total Project Cost Summary (TPCS) and separate the costs to the sub-feature level. The TPCS shall be prepared following the current cost engineering policy. Include a summary and the full detail M-CACES estimate for the recommended plan.

Q.10.5 Environmental Documentation.

Q.10.5.1 NEPA and ESA. Include all NEPA and other environmental investigation and study results. Provide an assessment/description (for each alternative evaluated) of the impacts on the existing environment. Highlight any significant resources that are likely to be affected as well as any that are covered by a specific law (e.g., endangered species, clean air, clean water, cultural and historical, etc.). Compare the environment impacts of constructing the modification to those environmental impacts that would occur if we did nothing and let the dam fail.

Q.10.5.2 Pertinent Correspondence. For the recommended plan, provide the pertinent correspondence, a summarization of the studies conducted to evaluate the environmental effects of the plan, and the necessary National Environmental Protection Act (NEPA) documentation required in ER 200-2-2 (reference A.37) (e.g., EA, FONSI, EIS, or Supplement) and/or Section 404(1)(b) evaluation.

Q.10.5.3 Hazardous, Toxic, and Radioactive Waste. Include potential hazardous, toxic and radioactive waste concerns and conduct appropriate surveys. Identify the location of impacts and explain their significance, the likelihood of being able to mitigate such impacts, and associated cost. Indicate the concurrence or non-concurrence given by resource agencies that mitigation is possible and appropriate. Identify any environmental constraints that would render an alternative infeasible.

Q.10.6 PPA. When the project includes requirements of local cooperation, indicate the views or concurrence of local interests in the general plan of the proposed work, state whether these views were obtained by conference or public meeting, and provide a letter from local interests, which sets forth their views. Give the best available estimate of required local cooperation cost, a statement of the prospects for fulfillment of the required conditions, and the names, titles, and addresses of the principal officers and representatives responsible for fulfillment. Identify any differences in local cooperation requirements under existing agreements that should be changed and the basis therefore. Also indicate what will be done to obtain the desirable local cooperation. Include a copy of the draft PPA if required.

Q.10.7 PMP for Design Phase. Include the detailed Project Management Plan for the investigations in support of design, additional studies, design, and construction. Include a schedule of any additional engineering investigations and studies needed in the design phase and all DDR’s that will be prepared.

Q.10.8 Schedule of Fully Funded Project Costs by FY. Federal and non-Federal – Include a schedule for fully funding the project to achieve the intended risk reduction as

quickly and efficiently as possible. This is to include additional investigations and analysis, engineering and design (Pre-construction engineering and design), and construction cost. Provide a schedule of funding requirements by fiscal year to accomplish recommended modifications to the project based on current budgetary guidance. Indicate which requirements are recommended for funding under Construction, and which are recommended for funding under Operation and Maintenance, as part of continuing project operations; for example - routine instrument readings. If both authorized and unauthorized work are recommended and both items can stand on their own from an engineering and economic standpoint, a two-stage design and construction procedure may be required. The first stage would consist of work that is authorized. The second stage could involve those items of work that require additional congressional authorization.

Q.10.9 Authorizing Legislation. Present applicable legislation dealing with the initial construction and subsequent addition of project purposes. Specifically include documentation on cost sharing of added authorized purposes. Include a copy of the original and current authorizing legislation for the project.

Q.10.10 Existing Contracts with Sponsors, etc. Copies of existing contracts, agreements or letters of intent from project sponsor(s), cost sharing partners, and users. Provide a copy of any existing cost sharing and water supply contracts.

Q.10.11 Engineering Analyses and Determination of Compliance with Essential USACE Guidelines. Provide annexes with the engineering analysis of the geotechnical, structural, hydrologic and hydraulic investigations for site characterization, load determination, determination of probability of failure, etc. to determine the dam's ability to meet current design and performance criteria and develop component fragility and system response curves.

Q.10.11.1 Hydraulic or Hydrologic. Evaluate the ability to pass the spillway design flood in accordance with current policy.

Q.10.11.2 Seismic. Evaluate the ability to withstand seismic loads in accordance with current policy.

Q.10.11.3 Static stability. Evaluate the ability to withstand static pool loads in accordance with current policy. (e.g., seepage and piping, static stability)

Q.10.11.4 Erosion and Landslides. Evaluate the ability to withstand loads generated during operation of the dam in accordance with current policy. (e.g., spillway erosion, landslides)

Q.10.11.5 Spillway Gate Operations. Evaluate the ability to operate within the full range of design loads in accordance with current policy.

Q.10.11.6 Evaluate other conditions not meeting current design or construction criteria or seriously affecting project performance.

Q.10.11.7 Recommended Plan Drawings. Provide summary drawings for the recommended plan for use in review and presentation of the recommended plan.

Q.10.12 Real Estate Plan (including relocations). A Real Estate Plan shall be prepared at a level of detail commensurate with the scope of the project and the real estate requirements, if any, included in the modification report. If no land acquisition or relocation requirements are identified, the appendix shall so state. Provide the background details concerning the Real Estate requirements for the recommended plan.

Q.10.13 Independent External Peer Review. Section 2034 of WRDA 2007 (P.L. 110-114) requires an independent external peer review (IEPR) for all new projects and for all project modifications where an environmental impact statement (EIS) is required. The documentation of IEPR as required by EC 1165-2-209, Water Resources Policies and Authorities, Review of Decision Documents will be contained in this appendix.

Q.10.14 Agency Technical Review Documentation. When an agency technical review is completed on a study, the documentation of the review should be included in the report.

This Page Left Blank

APPENDIX R

Instructions for the "Dam Safety Action Decision Summary for a Dam Safety Modification Study"

R.1 Overview. The Dam Safety Action Decision Summary (DSADS) for a Dam Safety Modification Study is intended to be an extractable, stand-alone component of the DSM report that provides information to senior USACE officials to make dam safety decisions. The DSADS is a public document with unrestricted distribution but it is not designed as a public communications product. DSADS concisely summarizes the following the USACE dam safety program; the history and status of safety issues and actions for the subject dam; the risk management alternatives considered; the recommended actions and supporting facts; the outcomes from analysis and assessment; and the degree of confidence in the basis for the recommendations. The document will be ten to fifteen pages, well formed and will comprise text, tables, diagrams, and photos.

R.2 Document Content. The DSADS consists of:

R.2.1 Title page – Dam Safety Action Decision Summary. The title page shall include Dam Safety Modification Study, name of the dam, location, name of the USACE district and division, and date of the decision summary.

R.2.2 Section 1. Overview of USACE dam safety portfolio risk management process (*standardized text (boiler plate)*) (Table R.1), concluding with identifying the current stage of the dam in that process.

R.2.3 Section 2. Dam safety action summary for the dam.

R.2.4 Section 3. Principles and key concepts that guided the synthesis of the data, analyses and evaluations that provided the basis for action recommendations (*standardized text (boiler plate)*) (Table R.2).

R.2.5 Section 4. Succinct answers to the required standard set of questions posed in this guidance that encompass the scope of issues, investigations, alternatives, and consequences, and that substantiate the recommendations.

R.3 DSADS Instructions. The instructions for the DSADS content are presented in this attachment.

R.3.1 Title Page. Dam name, location (river, city, state), USACE district, USACE division.

R.3.2 Section 1 –"Dam Safety Portfolio Risk Management Process". For Section 1 use the standard text (boiler plate) provided in Table R.1. Fill in the blanks at the end of the text. Include a copy of Figure 3.1 and Table 3.1 in the DSADS at this point.

Table R.1 – Standard Text for DSADS Section 1
The overall Dam Safety Portfolio Risk Management Process is a series of hierarchical activities used to assess, classify, and manage the risks associated with the USACE inventory of dams. Dam Safety Action Classification (DSAC). The DSAC classification system provides consistent and systematic guidelines for appropriate dam safety actions, which are designed to address the dam safety issues and deficiencies of USACE dams and which are commensurate with the level of the dam failure risk. USACE dams are placed into a DSAC class based on their probability of failure or the individual dam safety risk estimate considered as a combination of probability of failure and potential life safety, economic, environmental, or other consequences. The intent is that the classification of a dam is dynamic over time, being revised as project characteristics are modified or more refined information becomes available affecting the loading, probability of failure, or consequences of failure. Portfolio Risk Management Process. The portfolio risk management process defines and documents the USACE risk assessment and risk management action decisions for each dam and facilitates risk communication. The actions and documents that reflect the process include normal operations and maintenance (O&M) activities and the documents generated through the portfolio risk management process to address dam safety issues. These documents are principally the Screening Portfolio Risk Assessment report, the Interim Risk Reduction Measures report, the Issue Evaluation Study report, and the Dam Safety Modification report. Portfolio Risk Management Process Graphic Depictions. Table 3.1 contains the definition of the USACE dam safety action classification system. Figure 3.1 is a flow chart of the USACE dam safety portfolio risk management process. Chapter 3 of the Safety of Dams regulation provides a detailed description of the process and discussion of the figures. Dam <*insert name*> is presently classified <*Insert dam's DSAC class*> and is poised at decision point <*Insert decision point ID*>. Prior dam safety actions for this dam are summarized in the following section.

R.3.3 Section 2 – Summary History of Dam Safety-Related Actions. Summarize, using text, diagrams, and photographs (as appropriate), the dam-safety-related issues and actions that might have arisen during design, construction, and operation continuing to the present. The information to be presented should include the following safety issues identified; remediation proposed and adopted; and a brief assessment of the degree of success of the remediation. A time-line diagram of major safety-related events and actions is a powerful way of presenting such history. Include the appropriate charts and diagrams.

R.3.4 Section 3 –"Guiding Principles and Key Concepts". For Section 3 use the standard text (boiler plate) provided in Table R.2.

Table R.2 – Standard Text for DSADS Section 3

Assessments of the safety of USACE dams are conducted using a risk assessment approach which provides input to risk informed decision making. The approach combines the evaluation of dam safety against engineering guidelines, and evaluates the risk posed by USACE dams compared to tolerable risk guidelines. The former focuses on satisfying essential USACE guidelines for a wide range of engineering considerations. The latter involves identifying all credible and significant failure modes for a specific dam, quantifying their probabilities of occurrence and associated consequences, and evaluating their estimated risk of dam failure against the USACE tolerable risk guidelines. The tolerable risk guidelines address the probability of failure, risk to the public, economic risk and environmental risk. For a particular USACE dam, by combining the two evaluation approaches and the breadth of understanding gained from both, well-reasoned recommendations are made for reducing risks to tolerable levels and to meet essential USACE guidelines. Achieving and maintaining tolerably low risk levels for USACE dams requires structural measures in concert with an effective safety management regime, including staff training, operation and maintain, monitoring and surveillance, and emergency action planning.

Since each USACE dam is part of a large portfolio of dams, risk management decisions viewed from a national perspective will be made centrally by HQUSACE. Therefore, the evaluation of dam safety for a particular dam must be made in a consistent manner such that the information obtained from these evaluations can be used to prioritize risk reduction actions across the portfolio of USACE dams. In addition, the Dam Safety Action Classification (DSAC) system is designed and used to maintain the appropriate degree of urgency for addressing safety issues at individual dams. To appropriately manage the prioritization and urgency of risk reduction for each individual dam across the entire portfolio, opportunities for staging risk reduction actions using logically separable construction packages are considered in the dam safety modification studies.

It is recognized that both the engineering guidelines approach and the risk-informed approach are subject to limitations based on the available information, understanding about dam safety issues and failure modes, and limitations in the state-of-the-practice of dam safety engineering. Thus it is important that the degree of confidence in quantitative analyses be considered in both engineering analyses and risk assessments for each dam. Hence USACE does not consider tolerable risk guidelines as strict criteria, and it does not rely solely on these guidelines to demonstrate adequate dam safety, but rather USACE uses the entirety of the information available to support the recommendations made to take a particular risk management action.

The DSADS presents a balanced and professional distillation of the risk assessment in support of the recommended risk informed decision.

R.3.5 Section 4. The following questions are to be answered in a narrative manner that succinctly communicates the essential dam safety issues, failure modes and risk assessment, alternatives formulated and analyzed, estimated risk reduction for each alternative, the recommended risk reduction action(s), and potential remaining dam safety issues. Tables, illustrations, and graphs are to be used as appropriate to summarize information and support the narrative. The questions are grouped consistent with the investigation structure presented in Chapter 9, paragraph 9.5.

R.3.5.1 Identification of the dam safety issues, risk reduction objectives, limitations and opportunities

R.3.5.1.1 What are the dam safety issues?

R.3.5.1.2 What instigated the safety concern?

R.3.5.1.3 What physical evidence or project performance indicates that there is a problem or that a problem cannot be ruled out?

R.3.5.1.4 Why are these issues significant?

R.3.5.1.5 What is the existing DSAC classification and what are the significant dam safety issues that have lead to this classification?

R.3.5.1.6 What are the dam safety risk reduction objectives?

R.3.5.1.7 What tolerable risk guidelines are being used for performance objectives – life safety, economic, and environmental?

R.3.5.1.8 What essential USACE guidelines are pertinent for this dam and why?

R.3.5.1.9 Is the ALARP principle to be applied and how?

R.3.5.1.10 What are the potential constraints on risk reduction actions that need to be addressed?

R.3.5.1.11 Are there physical site constraints and if so, what are they?

R.3.5.1.12 Are there resource constraints such as institutional, people, funding and if so, what are they?

R.3.5.1.13 Are there policy and legal constraints that must be considered, and if so, what are they?

R.3.5.2 Estimation of baseline risk conditions

R.3.5.2.1 What is the estimated baseline risk condition?

R.3.5.2.2 What are the major contributors of the baseline risk condition? And what is the likelihood of the initiating event; conditional probability of failure; exposure of people, property, and environment given this failure; and the ultimate losses due to the failure?

R.3.5.2.3 Was it necessary to consider future risk conditions (changes in consequences or deterioration in condition) and if so, what are they?

R.3.5.2.4 What physical evidence or project performance metrics support that there is or could be a significant failure mode and what is the confidence in its existence?

R.3.5.2.5 What are the estimated probabilities of failure and consequences for each significant failure mode and the degree of confidence in these estimates?

R.3.5.2.6 Can the confidence in the risk estimates be increased and if so, how?

R.3.5.2.7 Which essential USACE guidelines are not met?

R.3.5.2.8 Which tolerable risk guidelines are not met for baseline conditions, and what is the confidence in these assessments?

R.3.5.2.9 What is the risk estimates for with and without intervention scenarios? What are the interventions considered?

R.3.5.3 Formulation of alternative risk management plans

R.3.5.3.1 What risk reduction measures were considered in formulating the alternative plans?

R.3.5.3.2 How were the measures grouped to form the initial set of alternative plans?

R.3.5.3.3 What specifically are the alternative plans proposed for evaluation?

R.3.5.3.4 Does the set of alternatives formulated address all credible and significant dam safety issues?

R.3.5.3.5 How have staging of construction phases for remediation action been considered in the alternative plans?

R.3.5.3.6 Are there stakeholders or other interested parties promoting or objecting to one or more of the alternatives and why?

R.3.5.4 Evaluation of alternative risk management plans

R.3.5.4.1 What is the risk (hazard, probability of failure, and consequences) estimate for each failure mode for each alternative?

R.3.5.4.2 Which essential USACE guidelines remain unmet, if any, for each alternative risk reduction plan?

R.3.5.4.3 What are the costs, any changes in benefits, and tolerable risk evaluations, including benefit/cost, ALARP and disproportionality considerations, for each alternative plan and the degree of confidence in these?

R.3.5.4.4 How is the implementation of each alternative expected to affect the Interim Risk Reduction Measures that currently exist?

R.3.5.4.5 Are there any opportunities for increased project benefits (integrating remediation with enhancing other purposes) for each alternative plan and what are the incremental costs? Is additional congressional authorization required for these plans that increase benefits?

R.3.5.4.6 What would be the effect of staging implementation of selected components of the alternatives?

R.3.5.5 Comparison of alternative risk management plans

R.3.5.5.1 How much does each alternative plan reduce risk in comparison with the baseline risk, and what is the cost of the alternative?

R.3.5.5.2 How does each alterative plan compare in terms of meeting essential USACE guidelines?

R.3.5.5.3 What are the changes in relation to the tolerable risk evaluations, including ALARP (to include disproportionality) for each alternative plan?

R.3.5.5.4 What are the potential negative aspects of each alternative plan, such as reduction in benefits, increased cost to users, impact on the environment, and can they be mitigated?

R.3.5.6 Selection of the recommended risk management plan

R.3.5.6.1 What is the recommended risk management plan?

R.3.5.6.2 Are all dam safety issues (credible and significant failure modes) addressed by the recommended plan and if not, which are not addressed and what is the rationale?

R.3.5.6.3 Does the recommended risk management plan achieve the desired objectives including tolerable risk guidelines, ALARP, cost effectiveness, and essential USACE guidelines.

R.3.5.6.4 What is the expected DSAC class after implementation of the recommended risk management plan?

R.3.5.6.5 What would be the effect of delaying implementation of the recommended plan?

R.3.5.6.6 What are the consequences of not implementing, or delaying implementation of the recommended risk management plan?

R.3.5.6.7 Is there consensus on the recommended plan by principal stakeholders and other interested parties and who are they?

R.3.5.6.8 Are there opposing views and what are they and how were differences addressed?

R.3.5.7 Cost Sharing

R.3.5.7.1 What are the cost sharing requirements?

R.3.5.7.2 If there are no cost sharing requirements, what would the cost sharing requirements be under modern day legislation and policies?

This Page Left Blank

APPENDIX S

Dam Safety Modification Report Issue Checklist

S.1 Sensitive Policy Areas. Areas which require vertical team coordination with MSC/HQUSACE to Washington: _____

_____

_____

_____

S.2 General Project Information.

S.2.1 Project Name. (State, County, River Basin/Waterbody under Study)

S.2.2 Project Description. (Need project description with general details, such as a fact sheet attached--if project is the same as authorization attach a summary, if different provide a description of what differs from original authorization, the authorizing language, and dimensions to give perspective of the change in scope and scale. If there was an authorizing report, what level approved it—i.e., OMB, ASA(CW), HQUSACE (include date of approval). If no prior reports, give a more detailed description.)

S.2.3 Cost Sharing. (Describe the cost sharing for the project to be constructed. Describe whether the cost sharing follows general law or if there is other special cost sharing for the project)

S.3 General Questions.

S.3.1 Has a NEPA document been completed?

Response: YES _____ NO _____*

Remarks:

* A response where there is a "*", requires coordination through vertical team and complete description of issues under "Remarks", before decision to approve project/report can be delegated.

S.3.2 Will the NEPA Documentation be more than 5 years old at the time of PCA signing or construction initiation?

Response: YES _____* NO _____

Remarks:

S.3.3 Will the ESA Findings be more than 3 years old at the time of PCA signing or construction initiation? [Note: Findings refers to USACE documentation and/or US Fish and Wildlife Service's opinions and recommendations]

Response: YES _____* NO _____

Remarks:

S.3.4 Is ESA coordination complete?

Response: YES _____ NO _____*

Remarks:

S.3.5 If an EIS/EA was completed for the project, has the Record of Decision/Finding of No Significant Impact been signed?

Response: YES _____ NO _____*

Remarks:

S.3.6 Is the proposed project consistent with the ROD/FONSI?

Response: YES _____ NO _____*

Remarks:

S.3.7 Has there been any changes in Federal environmental laws or Administration or USACE policy since original project authorization that make updating necessary? [e.g., change to the Clean Air Act status for the project area…going from attainment to non-attainment]

Response: YES _____* NO _____

Remarks:

S.3.8 Is there a mitigation plan?

Response: a. Fish and Wildlife: YES _____* NO _____
b. Flood Damage: YES _____* NO _____
c. Cultural and Historic Preservation: YES _____* NO _____
d. Recreation: YES _____* NO _____

Remarks: [If yes, identify and describe what is being mitigated and cost shared. Describe the authority for the cost sharing.]

S.3.9 Are the mitigation plan(s) that are now being proposed the same as the authorized plan?

Response: a. Fish and Wildlife: YES _____ NO _____*
b. Flood Damage: YES _____ NO _____*
c. Cultural and Historic Preservation: YES _____ NO _____*
d. Recreation: YES _____ NO _____*

Remarks:

S.3.10 Is there an incremental analysis/cost effectiveness analysis of the fish and wildlife mitigation features based on an approved method and using an accepted model?

Response: YES _____ NO _____*

Remarks:

S.3.11 Does the project involve HTRW clean-up?

Response: YES _____* NO _____

Remarks:

S.3.12 Does the work involve CERCLA covered materials?

Response: YES _____* NO _____

Remarks:

S.3.13 Are the project purposes now being proposed different than the authorized project? [Note: different than specifically noted in authorization or noted in Chief's report and is it measured by project outputs]

Response: YES _____* NO _____

Remarks:

S.3.14 Are there any proposed scope changes to the authorized project? [Reference: ER 1105-2-100 (reference A.42)]

Response: YES _____* NO _____

Remarks: [Describe the authority that would enable the project to proceed without additional Congressional modification]

S.3.15 Is Non-Federal work-in-kind included in the project? [Note: Credit to a non-Federal sponsor for work-in-kind must be based upon having an existing authority. Need to identify the authority and if not a general authority such as Sec 215, provide a copy of the authority.]

Response: YES _____* NO _____

Remarks:

S.3.16 Does project have work-in-kind authority? [Note: If there is no existing authority, as determined in conjunction with District Counsel, the only other vehicle is to propose work-in-kind and rationale in the decision document and submit to HQUSACE for specific Congressional authorization.]

Response: YES _____ NO _____*

Remarks:

S.3.17 Are there multiple credit authorities (e.g., Sec. 104 & 215) including LERRDS, Work-In-Kind and Ability to Pay? [Note: See App. B of ER 1165-2-131 (reference A.65)]. Describe the authority for work-in-kind and if authority exists, the PM should submit a completed App. B through the vertical team.]

Response: YES _____* NO _____

Remarks:

S.3.18 Is an Ability to Pay cost sharing reduction included in the proposed project? [If yes, fully describe the proposal, citing how this authority is applicable. Include a table showing the cost sharing by project purpose and expected Ability to Pay reductions.]

Response: YES _____* NO _____

Remarks:

S.3.19 Is the recommended plan different from the NED plan? [Note: if this answer is yes, then a series of questions arise that will need to be addressed in the Remarks section…is plan less costly than NED plan, is the plan more costly with the same cost sharing the same as NED plan (exception), is plan more costly with all costs exceeding the cost of the NED plan at 100% non-Federal cost, or has ASA(CW) already grant exception]

Response: YES _____* NO _____

Remarks:

S.3.20 Was a standard accepted USACE methodology/model used to calculate NED benefits?

Response: YES _____ NO _____*

Remarks:

S.3.21 Are there non-standard benefit categories? [Reference ER 1105-2-100 (reference A.42)].

Response: YES _____ NO _____*

Remarks:

S.3.22 Is there a flood damage reduction component in the project?

Response: YES _____ NO _____
(If Yes, answer following question)

S.3.23 Are reallocation studies likely to change the existing allocated storage in lake projects?

Response: YES _____* NO _____

Remarks:

S.4 CONCURRENCE

_____ Date:_____
Project Manager

_____ Date:_____
District Counsel

_____ Date:_____
District Dam Safety Officer

_____ Date:_____
MSC Dam Safety Officer

_____ Date:_____

APPENDIX T

Post-Authorization Decision Document Checklist

T.1 Basic Information.

T.1.1 Name of Authorized Project: _____

T.1.2 Name of Separable Element: _____

T.1.3 PWI Number: _____

T.1.4 Authorizing Document: _____

T.1.5 Law/Section/Date of Project Authorization: _____
(Note: attach copy to checklist)

T.1.6 Laws/Sections/Dates of Any Post-Authorization Modification: _____

T.1.7 Non-Federal Sponsor(s): _____

T.1.8 Project/Separable Element Purpose(s): _____

T.1.9 Congressional Interests (Senator(s), Representative(s) and District(s)): _____

_____

T.2 Project Documents.

T.2.1 Type of Decision Document: _____

T.2.2 Approval Authority of Decision Document: _____

T.2.3 Project Management Plan Approval Date: _____

T.2.4 Agency Technical Review (ATR) Approval Date: _____

T.2.5 Independent External Peer Review (IEPR) Completion Date: _____

T.2.6 Mitigation Authorized: ___ Yes ___ No Cost of Mitigation _____

Describe Type of Mitigation and Whether Included in Project Report: _____

_____
(Note: Project report is the one that supports the authorization for the mitigation. Need to make sure that mitigation is authorized as part of the project cost)

T.2.7 Current M-CACES Estimate: $ _____

Date Prepared and Price Level: _____

T.2.8 Date of Latest Economic Analysis: _____

T.3 Cost Sharing Summary.

Purposes	Non-Fed Cash	Non-Fed LERRD	Non-Fed Const. Credit	Non-Fed Total Share	Federal Share (%)	Total Project Cost
Totals						

T.3.1 Projected Credit for Section 215 Work and Date Section 215 Agreement Signed: _____

T.3.2 Projected Credit for Section 104 or Other Authorized Creditable Work and Date Work Approved by ASA(CW) or Agreement Addressing Work Signed: _____

_____

T.3.3 Annual Non-Fed OMRR&R Costs (1 Oct FY_____ Price Levels): _____

T.4 Funding History. Appropriations History for Project/Separable Element (include Wedge Funding)

Fiscal Year	Budget Amount	Appropriated Amount

_____	_____	_____
_____	_____	_____
_____	_____	_____

T.5 Certification For Delegated Decision Documents. You must answer "Yes" to all of the following questions to approve the decision document under delegated authority.

T.5.1 Project Plan.

T.5.1.1 Has the project study issue checklist been completed and all issues resolved?

___Yes ___No

T.5.1.2 Does the non-Federal sponsor concur in the project plan as submitted?

___Yes ___No

T.5.1.3 Has project plan as submitted been reviewed and concurred with by the non-Federal sponsor's counsel?

___ Yes ___ No

T.5.2 Authority –

T.5.2.1 Has the Dam Safety Officer at each level approved the project report?

___Yes ___No

T.5.2.2 Is authority adequate to complete the project as proposed?

___ Yes ___ No

T.5.3 Policy/Legal/Technical Compliance

T.5.3.1 Has the District Counsel reviewed and approved the decision document for legal sufficiency?

____Yes (Certification included in decision document package submittal) _____ No

T.5.3.2 Have all aspects of ATR and IEPR have been completed with no unresolved issues remaining?

_____Yes _____No

T.5.3.3 Has the District Dam Safety Officer documented policy/legal/technical compliance of the decision document?

_____Yes _____No

T.5.3.4 Has the MSC Dam Safety Officer certified the policy/legal/technical compliance of the decision document?

_____Yes _____No

T.6 Authentication.

_____Date: _____
Project Manager

_____Date: _____
District Counsel

_____Date: _____
District Dam Safety Officer

_____Date: _____
District Support Team Leader

_____Date: _____
MSC Counsel

_____Date: _____
MSC Dam Safety Officer

APPENDIX U

Dam Safety Communication

U.1 Sample Frequently Asked Questions and Answers.

U.1.1 Question. Am I safe?

Answer. While we cannot completely eliminate risk, we can reduce risk. Our safety classification of this project does not mean the dam is in imminent danger of failing. It means we have identified dam safety issues that don't meet industry dam safety standards and the risk to public safety is unacceptable. The objective of our Dam Safety Program is to maintain public safety and to make sure our dams are safe and risks are minimized. Interim Risk Reduction Measures are in place to maintain public safety, until we complete engineering evaluations and develop a plan of action for permanent repairs. Routine inspections and operation of the lake and dam will continue and emergency action plans have been developed in coordination with local emergency management officials. Currently, there is no evidence to suggest an emergency situation exists, or is about to occur. USACE is responsible to take actions for suspected high risk conditions, until we have adequate information to confirm risks are acceptable.

U.1.2 Question. What is risk?

Answer. Risk is the measure of the likelihood, chance, or degree of belief that a particular outcome or consequence will occur along with the outcome of the failure including immediate, short and long-term direct and indirect losses and effects. Losses may include human casualties, water supply, recreation, and hydropower benefits. Effects may include downstream damages and/or adverse environmental impacts.

U.1.3 Question. What does failure mean?

Answer. In the context of dam safety, failure is generally confined to issues of structural integrity, and in some contexts to the special case of uncontrolled release of a reservoir through collapse of the dam or some part of it.

U.1.4 Question. Why do the DSAC categories emphasize the "unsafe" term? What does unsafe mean?

Answer. DSAC classifications are based upon confirmed and unconfirmed dam safety issues, the probability of failure and life or economic consequences. USACE will only designate a dam normal or safe when there are no unconfirmed dam safety issues.

U.1.5 Question. Is this (are these) dam(s) at risk of failing?

Answer. (For DSAC I projects) Our screening and classification of _____Dam identified this project as urgent and compelling. A dam with this classification is critically near failure or extremely high risk under normal operations. Critically near failure means we have confirmed failure is taking place and it is almost certain to fail under normal operations any time within a few years without intervention. Extremely high risk means that the dam poses a combination of life or economic consequences with a high probability of failure. Modification studies for DSAC I dams are funded immediately. We are taking the following interim risk reduction measures _____.

Answer. (For DSAC II projects) Our screening and classification of _____Dam identified this project as urgent. A dam with this classification is considered to have failure initiation foreseen or very high risk. Foreseen failure initiation means the dam has confirmed and/or unconfirmed safety issues and failure could begin during normal operations or from a hydrologic or seismic event. Very high risk means that the dam poses a combination of life or economic consequences with a high probability of failure. We are taking the following interim risk reduction measures _____.

Answer. (For DSAC III projects) Our screening and classification of _____Dam identified this project as a high priority. A dam with this classification is considered significantly inadequate or moderate to high risk. Significantly inadequate means the dam has confirmed and/or unconfirmed safety issues. Moderate to high risk means that the dam poses a combination of life or economic consequences with moderate to high probability of failure. We are taking the following interim risk reduction measures _____.

In all cases, interim risk reduction measures are taken to reduce the risk to public safety.

U.1.6 Question. May we have copies of your risk analysis and inspection reports?

Answer. You should contact the respective district headquarters for that information. Requests for inspection reports will be evaluated on a case-by-case basis because of information that may expose a vulnerability that could be an operational security concern. In many cases, the Corps has posted information on District websites that can be accessed by the public.

U.1.7 Question. If there are Classification I dams, are there other classifications? What are they and how are they defined?

Answer. The five Dam Safety Action Classes are:

DSAC I – URGENT AND COMPELLING (Unsafe)

DSAC II – URGENT (Unsafe or Potentially Unsafe)

DSAC III – HIGH PRIORITY (Conditionally Unsafe)

DSAC IV – PRIORITY (Marginally Safe)

DSAC V – NORMAL (Safe)

U.1.8 Question. What are interim risk reduction measures?

Answer. Interim risk reduction measures are a short-term approach to reduce dam safety risks while long-term solutions are pursued. They are an important step in returning the project to a stable and safe condition. In establishing IRRM, the prevention of loss of life is the first and foremost objective, followed by prevention of catastrophic economic or environmental losses.

U.1.9 Question. Is there funding available to complete the IRRM on these projects?

Answer. Development of IRRM Plans, and the accompanying actions should not be delayed, “contingent upon funding”. IRRM planning and implementation is a high USACE priority. In some cases, funds have been allocated from existing funding sources to initiate and implement IRRM. Some IRRM actions may require supplemental budgeting. We have been successful in obtaining critical IRRM funding via the American Recovery and Reinvestment Act and emergency authorities.

U.1.10 Question. What is the Corps doing to make sure the dam in my area gets fixed?

Answer. Funding for dam safety studies at DSAC I and II dams has been prioritized Corps wide, to allow us to advance work on the highest risk dams first. Studies are required to identify permanent repair options. The Corps of Engineers has updated our criteria on how to conduct dam safety evaluations. Projects that pose significant public safety risks are our top priority.

Routine Operations and Maintenance funds will be used for DSAC III projects, unless new information changes the risk classification.

The Corps has also set up a new organization, called our Risk Management Center, and has assigned our best engineering experts to work on dam and levee projects.

U.1.11 Question. Is there funding available to make permanent construction repairs?

Answer. Funding for DSAC I and II projects already in construction receive high budgeting DSAC ratings are being used to set national construction repair priorities. Projects classified as DSAC III and IV will not receive funding until the higher

risk DSAC I and II projects are addressed. Districts may elect to make partial repairs for DSAC III and IV projects with O&M funds.

USACE will continue to request funding for DSAC I and II projects, and transition to fund future studies and repairs for DSAC III projects as the repairs on the DSAC I and II dams are completed.

U.1.12 Question. Why is my dam now at high risk, when it has been here for many years?

Answer. In 2005 we began evaluating the risks at Corps operated dams. This was in response to recommendations a Peer Review of the USACE Dam Safety program conducted in 2001 by the Association of State Dam Safety Officials (ASDSO). ASDSO recommended that USACE develop risk reduction, risk assessment, and risk management procedures for implementing a nationwide evaluation process that prioritizes the funding and allocation of dam safety resources USACE-wide. USACE began an approach to consistently take appropriate actions to address our dam safety issues.

Following the first three years of risk-informed screening in 2005, 2006 and 2007, USACE categorized dams into Dam Safety Action Classes (DSAC) based on their individual dam safety risk considered as probability of failure and potential failure consequences.

As a result, our understanding of the conditions at our dams has changed. In some cases we have new observations at our dams that are symptoms of potentially serious problems. In other cases we have learned that the original design and construction methods do not meet our safety standards. External independent peer reviews have confirmed that we are doing the right things to help reduce risk and increase public safety. Lessons learned from our high risk dams, such as Wolf Creek, have heightened USACE's commitment to address risks attributed to our aging infrastructure, and take all actions necessary to prevent failure of a USACE dams.

U.1.13 Question. How long has the USACE known these dams were unsafe?

Answer. The dams validated as critically near failure is not new information. What is new is how we assess our dams and are incorporating risk concepts into dam safety management, routine activities and programming decisions.

U.1.14 Question. What will we do with the findings?

Answer. USACE will use DSAC information to set dam safety remediation priorities in its annual budget requests and to implement IRRM. The overall objective is to reduce the risks to public safety.

U.1.15 Question. How did USACE determine which dams are highest risk?

Answer. USACE developed a risk-informed screening tool to compare the condition of each dam with the risk associated with a new dam. Cadres of USACE professional personnel were trained in the use of the tool and evaluated each dam screened using information provided by the operating district. A group of senior engineers from across USACE reviewed the screening information and established the DSAC for each dam.

U.1.16 Question. What criteria did USACE use?

Answer. The criteria used in the screening are the current state-of-the art criteria for the design and construction of large dams. Tolerable risk guidelines from other agencies, including the Bureau of Reclamation, have been referenced to ensure consistency with public safety standards.

U.1.17 Question. What does “critically near failure” mean?

Answer. Critically near failure means a condition exists at the dam that if not properly addressed, the likelihood of the dam failing in the near future is high. While we can’t physically “see” this occurrence, we know it is happening through various scientific instruments embedded within the dam and foundation. While there are no cracks visible in the dam, instrumentation indicates settlement of the dam is occurring on a small scale. Instrumentation which monitors the water pressure in and beneath the embankment also indicates a rise in pressure over time above what would be expected or considered to be safe. These types of instrumentation readings along with increasing wet spots that have shown up on the downstream face of a dam are indications that the condition at this dam is worsening over time.

U.1.18 Question. If the dam fails, how do I find out if my home and business will be impacted?

Answer. The Corps has developed flood inundation maps as part of the emergency action plan (EAP) for each dam. Copies of these EAPs are provided to local Emergency Response agencies. The maps are not routinely posted for public use, because this information may expose a vulnerability that could be an operational security concern.

Information on high risk (DSAC I and II dams) will be shared with communities via public meetings. Property owners are encouraged to attend these meetings, to assess how their homes and businesses could be impacted.

Additionally, the local District office can provide site specific flood elevation information when contacted by individual home and business owners. In cases where public safety issues outweigh Security concerns, the local District may request a waiver from the Corps of Engineers HQ, and provide the maps to landowners.

U.1.19 Question. How do I prepare to make sure my family is safe?

Answer. Safety is a shared responsibility. The Corps has the responsibility to coordinate with local officials and communicate with the public on the condition of Corps operated dams. Private individuals are encouraged to become educated and aware of local conditions. Personal planning is encouraged, such as purchasing weather alert radios, keeping emergency supplies on hand, and determining personal evacuation routes.

U.1.20 Question. Should these dams be decommissioned?

Answer. Decommissioning of the dam is in the range of available options. However decommissioning a dam involves Congressional approval and to assure the safety of those living downstream of the high risk dam, immediate action is necessary.

U.1.21 Question. What is this classification system that we keep hearing about? How many more of these will you review?

Answer. There are two classification systems for dams:

1. The Potential Hazard Classification which is developed in accordance with FEMA Publication 333, Hazard Potential Classification System for Dams. This system ranks a dam as Low, Significant, or High Hazard Potential based on the damages that would occur if the dam failed. The hazard potential classification does not address the condition of the dam or its risk of failure.

2. The USACE Dam Safety Action Classification (DSAC) which is a classification of dams accomplished by a team of USACE dam safety professionals as a means to group dams that exhibited certain characteristics for potential safety concerns. From 2005-2007, USACE conducted an initial risk-informed screening of approximately 202 dams and the remaining dams operated by USACE will be screened in the next two years.

U.1.22 Question. Are External Peer Reviews Required?

Answer. HQUSACE is sponsoring External Peer Reviews by nationally known dam safety experts. These reviews are being conducted for the DSAC I Flood Damage Reduction dams. Additionally, USACE is complying with new requirements set by Congress in 2007 to conduct Independent External Peer Review (IEPR) on dam safety studies and designs.

U.1.23 Question. IRRM Plans are to include overview information on potential failure modes. What does this mean?

Answer. Potential Failure Mode Analyses (PFMA) is conducted as the first step in a risk analysis.

U.1.24 Question. Why does it take the Corps so long to fix a dam?

Answer. That is a good question. Given the multiple purposes of our dams and the long term benefits they provide we require through analysis of any modification to assure public safety and benefits are not comprised by modification to the dam.

Dam analysis and designs are complex technical efforts. Risk assessments must be performed to understand the extent of a problem and to evaluate options to fix the dams. In some cases a dam may have multiple deficiencies that require correction which increases the time required to start the fixes.

We also take great effort to comply with the National Environmental Protection Act and the Endangered Species Act which does require significant time to assure that all requirements are met.

Once construction starts most fixes will take two or more years to implement.

APPENDIX V

Periodic Inspection Program – Inspection and Evaluation Procedures

V.1 Periodic Inspection Program.

V.1.1 Initial Pre-Inspection Brochure. A technical brochure shall be prepared in advance of the first project inspection to familiarize inspection team members with general project features. This brochure shall include a technical summary of the structural, material, and foundation conditions, instrumentation data, including settlement monuments, location of instrumentation and description of reservoir operations procedures, if pertinent. The brochure shall also include appropriate pertinent project data, project layout and typical section drawings, Federal and non-Federal responsibilities for OMRR&R, summaries of sub-surface soil profiles and boring logs, brief construction history and construction description, and the checklist developed for conducting the inspection. Pre-inspection brochures shall be completed and distributed to inspection team members at least 30 days prior to the inspection date.

V.1.2 Pre-Inspection Packets. A technical pre-inspection packet shall be prepared in advance of all subsequent project inspections to familiarize inspection team members with general project features and history. Pre-inspection packets shall be completed and distributed to inspection team members at least 15 days prior to the inspection date. Packets may be tailored to each discipline to avoid excessive reproduction. To be efficient and generate a 95% complete draft of the PI Report to leave at the project site (see paragraph W-3), many paragraphs and Appendices of the PI Report may be completed with the information that would be contained in the Pre-Inspection Packet. The partially completed PI Report may be distributed to the inspection team members instead of the packet. This packet shall include:

V.1.2.1 A project access map, history of project deficiencies and remedial measures, technical summaries of the structural, material, and foundation conditions, and description of reservoir operations procedures, if pertinent.

V.1.2.2 A written evaluation and plots of all instrumentation data, including settlement monuments shall be prepared along with the location of the instruments.

V.1.2.3 Project data, layout and typical section drawings, Federal and non-Federal responsibilities for OMRR&R, sub-surface soil profiles plots, examples of typical boring logs, list of project documents and engineering data that identifies the status and location of the project documents, and the checklist developed for conducting the inspection.

V.1.2.4 Findings of annual inspections since the last periodic inspection and the status of recommended action items shall be reviewed and included in the packet.

V.1.2.5 A section discussing the need for updating the project design parameters (hydraulic, seismic, HSS, etc.) shall be prepared, if applicable.

V.1.2.6 A brief summary of past performance and problems and concentrate on the continuing conditions that affect or may affect the overall safety and operational capability of the structure. Include narrative on intermediate inspections.

V.1.2.7 A summary of the project's bridge inspections that may impact project safety or access during emergency conditions shall be included.

V.1.2.8 Status of seismic re-evaluations, per ER 1110-2-1806 (reference A.56) shall be included in the packet.

V.1.2.9 Status of Hydrologic re-evaluations shall be included in the packet.

V.1.3 Inspection Procedures. A systematic inspection plan, based on the most recent risk informed methodology assessment from a Portfolio Risk Assessment (SPRA/PRA), will be established for the inspection and operation of those features related to the safety and stability of the structure and to the operational adequacy of the project. Operational adequacy means the inspecting, testing, operating, and evaluation of those components of the project whose failure or failure to operate properly could impair the operational capability and/or usability of the structure. Where the operation of these components is vital to the safe operation of the project under emergency conditions, these components will be operated by emergency power at least annually and these operations recorded in a project log. Emergency generators shall be tested under load on more frequent intervals to maintain their integrity. In addition, standby emergency generating systems shall be reviewed and tested during the scheduled inspection to assure the inspection team that all critical project features, including communication systems, can be operated under emergency conditions or in the absence of the normal source of power. The testing of emergency power shall include the maximum power demand that could be expected in emergency situations. As much as possible the operation and/or inspection of all the features outlined in the inspection plan shall be conducted during the scheduled inspection. The inspection of the remaining features may be conducted any time prior to completion of the inspection report but no earlier than occurrence of the last major flood event for the project. However, if possible, the inspection of certain features such as stilling basin dewatering, tainter gate inspections, operability inspections, etc., shall be completed before the periodic inspection so that the team can review the findings during the periodic inspection. If appropriate, a video of the event could document pertinent results of the pre-inspection for showing at the regularly scheduled inspection.

V.1.4. Inspection Plan. The risk-informed systematic inspection plan shall assure adequate coverage of the project in the most expedient manner. The plan will cover technical skills required by members of the inspection team, items of equipment to be operated, areas that will be inspected and support equipment that will be required, including equipment to generate a 95% complete draft of the PI report. The plan and

Site Specific Checklist shall complement each other. The plan shall provide, as appropriate, the examination and the operation of, but not be limited to, the following features and conditions:

V.1.4.1 Hydraulic Steel Structures (HSS), as defined and required in ER 1110-2-8157 (reference A.52), which include flood and outlet control gates (including flood gates in levees or flood walls), navigation lock gates and valves, emergency closure gates, spillway tainter gates, stoplogs and bulkheads, and associated lifting beams; hoists and operating machinery (including safety devices such as limit switches and fail-safe interlocks)**;** flood control pumps and related equipment**;** and cathodic protection systems. When several of the same type of HSS exists at a project, at least one of each type of HSS must be inspected as part of each periodic inspection. A different HSS should be selected for each inspection. For HSS whose failure could result in loss of life, the critical components should be subjected to at least a thorough visual examination during each inspection.

V.1.4.2 Structures including piers, overflow and non-overflow monoliths, roadways, parapets, training walls, spray walls, dam outlet conduits and tunnels, intake towers, bridges to gate towers, and steel sheet pile features.

V.1.4.2.1 Structural features.

V.1.4.2.2 Concrete surfaces.

V.1.4.2.3 Structural cracking and deterioration of material.

V.1.4.2.4 Joints and joint materials, including relative movement at joints between structures or portions of structures.

V.1.4.3 Water passages.

V.1.4.4 Embankments including foundation drains, joint drains, face drains.

V.1.4.4.1 Embankment cracks, bulging, and sliding; condition of abutment and embankment junctions; and vertical and horizontal alignment of the embankment or structure crest, slope, or toe area.

V.1.4.4.2 Unusual movement or cracking at or beyond the embankment or slope toe.

V.1.4.4.3 Seepage through or under embankment or abutment slopes.

V.1.4.4.4 Sloughing, sinkholes, or erosion of embankment or abutment slopes.

V.1.4.4.5 Condition of riprap, armor or other slope protection.

V.1.4.4.6 Scour protection stone and below water surface erosion control features.

V.1.4.4.7 Conditions of relief wells, collector pipes, inspection manholes, or other features of seepage control systems (EM 1110-2-1914 (reference A.14) and ER 1110-2-1942 (reference A.50)).

V.1.4.4.8 Condition and location of any known embedded utilities, including gas, water, and sewer lines in the embankment, abutments, or toe of the dam.

V.1.4.4.9 Seepage, depressions, sinkholes, and soft, marshy areas downstream of the dam.

V.1.4.4.10 Tailrace area, for muddy flows.

V.1.4.5 Spillways, spillway buckets and stilling basins and outlet channels including submerged features as necessary.

V.1.4.6 Conditions of instrumentation, and most recent measurements prior to the inspection

V.1.4.7 Reservoir rim conditions. (This can be limited to areas impacting the operation or stability of the dam).

V.1.5 Checklist. A detailed site specific checklist of elements relative to the structural stability and operational adequacy of the project shall be developed for each structural component of the project in order to ensure adequate examination coverage for each feature. The facility's instrumentation shall be included in the checklist to ensure that data are regularly collected and analyzed and to ascertain whether the instruments are in proper operating condition.

V.1.6 Photographs. In order to more accurately portray conditions and changes in conditions of surfaces and structural details, high resolution digital color photographs are highly recommended. In addition to photographs, video is encouraged for use in monitoring areas of concern. This is especially useful for comparing movement, water leakages, wave action, etc.

V.1.7 Examination of Deteriorated Concrete Structures. If the inspection reveals the need for any type of in-depth evaluation to determine the cause of deterioration or malfunction and to make sound recommendations for remediation, the need for the investigation shall be stated in the periodic inspection report. Guidance on repair of concrete is given in EM 1110-2-2002 (Reference A.15).

V.1.8 Structures. Steel structures shall be visually inspected for structural and operational adequacy. The inspection shall be sufficient to identify major defects such as visible cracks. Those structures involved directly in the safety of the project shall receive special consideration. Fracture critical members, where failure would result in

probable loss of life, shall initially be inspected by additional means, such as ultrasonic or other nondestructive testing. HSS inspection reports shall be prepared in accordance with ER 1110-2-8157 (reference A.52) and shall be included in the Periodic Inspection Report. Reference EM 1110-2-6054 (reference A.32) for additional information on these structures.

V.1.9 Riprap. The quantity, size, and location of riprap, sand, gravel, clay, sand bags, geotextiles, and other related materials and available equipment required to place these materials under any weather conditions shall be stated. Material sources that have unsatisfactory performance records shall be identified, reported, and eliminated from further use.

V.2 Composition and Qualifications of the Inspection and District Quality Control Review Teams.

V.2.1 Inspection team and District Quality Control Review team personnel shall consist of individuals qualified by experience and training in the design, construction, inspection, and operation of the project, and of individuals with appropriate specialized knowledge in structural, mechanical, electrical, hydraulic, geotechnical (embankment design), geology, concrete materials, and construction procedures, as required. Team leaders shall be registered professional engineers or geologists with dam safety experience. A representative(s) of the sponsor and the state dam safety agency shall be invited to be part of this team. Also, if the dam includes hydropower, representatives of the Federal Energy Regulatory Commission (FERC) shall be invited to be part of this team. The inspection team qualifications and composition may vary with the complexity of the facility and with the level of inspection, but at a minimum will include the disciplines of geotechnical, structural, and hydraulic engineering and Operations are required at all inspections. All team members shall receive training in the inspection procedures and personal safety during the inspection, including the use of personal protective equipment. Training Aids for Dam Safety (TADS) modules are recommended as a minimum for each team member, as well as a thorough understanding of this regulation. Where appropriate, inspection personnel shall be trained for confined space entry. The Dam Safety Officer of each district is responsible for scheduling this training.

V.2.2 In order to complete the Periodic Inspection report in a timely manner and be responsive to Operations Division, it is strongly recommended that the district institute an expedited report preparation method. To do so, the inspection team should be supplemented by at least one skilled technician and one clerical person with sufficient office equipment (computers, scanners, copiers, digital cameras, phones/radios) to be able to generate a 95% complete draft of the PI report to leave at the project site with the Operations personnel. The remaining 5% of the report can be accomplished in the office.

V.3 Executive Summary and Content. The district shall submit an electronic Executive Summary of each Periodic Inspection Report to HQ-DamSafety@usace.army.mil within 90 days of the completion of the formal inspection. The Executive Summary shall also

be entered into the Dam Safety Program Management Tools (DSPMT) database at the district level. The electronic executive summary should be limited in length to two to four pages and shall contain the following information.

V.3.1 Brief description of the project that was inspected.

V.3.2 Statement concerning the current inspection and major findings.

V.3.3 Statement regarding the project's safety status for continued operation.

V.3.4 General periodic inspection schedule including the dates of the previous, current, and next scheduled inspections of the project.

V.3.5 Statement concerning any major uncorrected deficiencies from the previous inspection.

V.3.6 List of major deficiencies found during the inspection and recommendations to correct the deficiencies.

V.3.7 Summary of conclusions from the periodic inspection report.

V.4 Inspection Report Content. The periodic inspection report shall present the results of each project inspection. The title of this report shall indicate the name of the project, watercourse, NID identifier, project features, and inspection number and date, in that order. An example of an appropriate title is "Beech Fork Lake Project; Twelvepole Creek, WV09903; Dam, Outlet Works and Spillway; Periodic Inspection Report No. 1, September 1992". Report No. 1 (report of initial inspection) shall provide a general project description and present the results of the initial inspection. Reports of subsequent inspections shall be supplementary to the initial report and will be numbered sequentially with the initial report; i.e., Report No. 2 would describe inspection number 2, etc.

V.4.1 Initial Periodic Inspection Report. To the extent possible, major elements of this report are:

V.4.1.1 An executive summary of the major items found in the inspection, including a statement regarding the project's ability to continue acceptable and safe operation.

V.4.1.2 A general project description including statement on hazard potential classification, layouts and typical section for the purpose of familiarization with general features of the project, and Federal and non-Federal responsibilities for OMRR&R.

V.4.1.3 List of project documents and engineering data that identifies the status and location of the project documents.

V.4.1.4 Discussion of dam safety training, emergency action plan and updates, and exercises.

V.4.1.5 Results of examination for each feature, including a statement as to its ability to function as designed.

V.4.1.6 Evaluation and summaries of the observations and inspection of instrumentation (Chapter 14 of this regulation) and relief wells with comparison to design predictions and actual conditions that signal changes in the structure's performance.

V.4.1.7 Where appropriate, statements, or exhibits summarizing the duration and frequency of spillway and control gate operations, including heads or velocities, and number of lock filling and emptying operations.

V.4.1.8 Technical assessment of the causes of distress, of abnormal conditions, and evaluation of the behavior, movement, deformation, and loading of the structure and its individual components. If such assessment cannot be accomplished within the time allotted to complete the inspection report, a preliminary assessment shall be discussed with a plan scheduled to complete the assessment.

V.4.1.9 High resolution digital color photographs with an appropriate caption, including the date taken.

V.4.1.10 A discussion of the deficiencies, the proposed remedial measures, with sketches if appropriate, related maintenance operations and both the cost estimates and a proposed completion schedule.

V.4.1.11 A discussion of the overall structural and individual project components stability, safety, and operational adequacy compared to its intended purpose(s) for the conditions with and without the recommended remedial measures. The DSMPT priority code 1 thru 6 assigned to each recommendation should be updated in the deficiency spreadsheet module screen 4.5 of the Dam Safety Program Management Tool software so the assigned priority can be tracked over time.

V.4.1.12 Recommendations, except for the routine maintenance type that can be performed by project personnel, should include the priority level for the recommended action in accordance with the following Table V.1.

V.4.1.12.1 Ensure prioritization of WORK CATEGORY CODES 61130, 61230, 61330, and 61630 as these are the primary work categories to be designated for correction of dam safety deficiencies using O&M funds. Other routine dam safety and maintenance requirements in the WCC 61XXX and 60XXX series may also be prioritized in DSMPT. Ensure coordination of all budgetary requirements with the Operations Manager, Business Line Manager(s) for your district and the Risk Assessment team in or visiting with your district.

Table V.1 – O&M Dam Safety Work Item Funding Priority Levels and Description		
Priority Funding Level	DSPMT Code	Descriptions
CFY	1	Serious dam safety deficiency exists that needs remediation immediately. If not corrected, item has an unacceptable dam safety risk. May require operational restrictions placed on the project. Reprogramming funds is appropriate.
CFY + 1	2	Remediation should be initiated within 12 months. May require operational restrictions placed on the project. Reprogramming funds is appropriate.
CFY+2	3	Study and remediation (as applicable) should be initiated within 24 months. The funds are currently being budgeted.
CFY+ 3	4	Study and remediation (as applicable) should be initiated within next budget cycle or 36 months. Used for tracking and monitoring.
CFY+ 4	5	Study and remediation (as applicable) should be initiated within next budget cycle or 48 months. Used for tracking and monitoring.
CFY+5	6	Needs to be resolved within 5 years. This work will probably not get funded unless the deficiency worsens. Monitoring is appropriate.

Notes: Priority codes are determined by setting the Current Fiscal Year from 1 Oct to 30 Sept with a priority code value = 1. For successive years add the number of fiscal years to 1 to get priority code.

V.4.1.12.2 See the current Budget EC for full definitions of all WORK CATEGORY CODES and specific requirements for Dam Safety Program activities.

V.4.1.13 Views of the non-Federal sponsor on any of the above shall be included (if applicable).

V.4.1.14 Exhibits (or Appendices) shall include, as appropriate trip reports; plots of instrumentation data; completed inspection checklist; summaries of crack surveys; correspondence that documents the performance of the project; the results of special investigations; a summary table/spreadsheet for documenting deficiencies, repair/evaluation recommendations, estimated costs, schedules, responsible office, and current status; district Quality Control Review Comments and Resolutions; and the

status and location of the project documents required by this document and ER 1130-2-530 (reference A.55). For the initial inspection report, the Pre-Inspection Brochure shall also be an Exhibit (or Appendix).

V.4.1.15 A discussion of the need for updating the project design parameters (hydraulic, seismic, HSS, etc.), if applicable.

V.4.1.16 Copies of selected drawings and boring logs.

V.4.2 Subsequent Reports. Subsequent reports shall generally include the items stated in paragraph V.4.1 above and shall follow the requirements of paragraph V.5 below, however they shall also include:

V.4.2.1 Brief summary of intermediate inspections and past performance and problems, and concentrate on the new and continuing conditions that affect or may affect the overall safety and operational capability of the structure. This summary shall not be merely a reference to a previous report. Include technical summaries of the structural, material, and foundation conditions, and description of reservoir operations procedures, if pertinent.

V.4.2.2 A discussion on maintenance and remedial activities to include materials used, application techniques, and performance.

V.4.2.3 A discussion on recommended remedial measures not completed since the previous inspection report, as well as a proposed schedule to accomplish the remedial measures.

V.4.2.4 Copies of selected drawings; however, extensive reproduction of previously published drawings shall be avoided. As a minimum, a location and vicinity map which also shows project access shall be included, as well as a general plan that shows each feature discussed in the report. The names and stationing shall be consistent on the drawings, narrative, and photograph captions.

V.4.2.5 A summary of the project's bridge inspections that may impact project safety or access during emergency conditions shall be included. ER 1110-2-111 (reference A.40) provides guidance on bridge inspections.

V.5 Inspection Report Format. The following paragraphs describe the requirements for hard-copy reports. Reports may be submitted electronically, as approved by the respective MSC, and shall be prepared in the same format as stated herein; however, at least two hard copies shall be retained at the district and at least two hard copies submitted to the MSC.

V.5.1 Organization. Reports shall generally be organized as follows:

V.5.1.1 Table of Contents

V.5.1.2 Executive Summary in accordance with Paragraph V.3, along with a Certification of district Quality Control Review.

V.5.1.3 General Statement of Inspection Program.

V.5.1.4 Description of the Project.

V.5.1.5 Brief Project Summary and History.

V.5.1.5.1 Construction history and construction description.

V.5.1.5.2 Project characteristics.

V.5.1.5.3 Description of past major remedial measures.

V.5.1.5.4 Deficiencies corrected since last inspection.

V.5.1.5.5 Past deficiencies not yet corrected, and explanation for not correcting.

V.5.1.5.6 Non-Federal sponsor OMRR&R responsibilities (if applicable).

V.5.1.5.7 Emergency Preparedness—Status of Dam Safety training (ER 1130-2-530 (reference A.55)) and status of Emergency Action Plans and their updates.

V.5.1.6 Inspection Results.

V.5.1.7 Recommendations, including date of next inspection.

V.5.1.8 Exhibits (or Appendices)

V.5.1.8.1 Figures (including Construction Plates, and other drawings that describe the project).

V.5.1.8.2 History of Remedial Measures.

V.5.1.8.3 Photographs (from current and previous inspections).

V.5.1.8.4 Inspection Checklist.

V.5.1.8.5 Summary of Inspection Notes.

V.5.1.8.6 Summary of Intermediate Inspection Reports

V.5.1.8.7 Instrumentation Data and/or Plots. Data shall contain all figures since the last inspection and have sufficient background data to support the report discussion, conclusions and recommendations. Reproduce the plan of instrument locations in each

report. Where appropriate, cross-sections showing piezometric data shall show design uplift assumptions along with the current pressure line. Plots of piezometric elevation versus pool elevation and plots of relief well or drain flow versus pool elevation shall be included. In each case, upper limit correlation lines should be drawn (to help eliminate time lag effects) and when possible, extrapolations should be made to maximum possible pool elevations. A summary of analyses of all instrumentation should be set forth. Where possible, threshold values for key instruments should be established. Threshold values should also be entered into the project emergency operations plans.

V.5.1.8.8 Summary of Crack Surveys.

V.5.1.8.9 Project Documentation.

V.5.1.8.10 District Quality Control Review Comments and Resolutions.

V.5.2 Text. All sections and paragraphs shall be numbered and shall be on 8 1/2 by 11-inch paper with sufficient margin on the left side for binding. Reproduction shall be any available process with printing done head-to-head, if possible.

V.5.3 Drawings. Drawings or plates shall normally be 8 1/2 by 11-inch with sufficient margin on the left for binding. Foldouts normally shall not exceed 11 inches by 17 inches. Drawings and photos may be included in the text or placed entirely in the Exhibit (or Appendix.) However, any figure or drawing in the text shall support the written material. All drawings and figures will be dated for ease of reference.

V.5.4 Binding and Cover. Reports shall have flexible paper or card stock, hidden hinge covers with fasteners that facilitate removal and insertion of pages and drawings. Information to be on the cover will be sufficient to identify the project report as unique from other reports name of the project; periodic inspection number; name of the preparing agency, and the date of inspection, and date of the report.

V.6 Project Documentation. All engineering data relating to project structures inspected shall be collected and permanently retained in appropriate files at the project site for availability to the inspection team and readily accessible for emergency response. Periodic Inspection Reports shall indicate which items are not available, and describe attempts to locate such records or documents. Project engineering data shall also be retained at the district office. In the absence of storage space at the district office, the data shall be retained at the nearest field office. These documents and drawings shall be considered as permanent engineering data, subject to retirement or disposal only upon termination of operation of the project. These data shall consist of, but not be limited to, the items listed below.

V.6.1 All previous Periodic Inspection and Periodic Assessment Reports.

V.6.2 Records of inspections by project personnel and interim/special event inspections by district personnel.

V.6.3 Design Memoranda, Design Documentation Reports, or Dam Safety Deficiency Reports to include principle design assumptions, stability and stress analyses, slope stability, seepage and settlement analyses, consolidation, shear, permeability, compaction, classification tests or summaries thereof, and contract plans and specifications.

V.6.4 As built plans, elevation, and sections.

V.6.5 As built drawings of important project features, to include details such as instrumentation, internal drainage, transition zones, or relief wells, and reports of any special investigations.

V.6.6 Foundation data and geological features, including boring profiles, foundation mapping, foundation reports, and final logs of subsurface exploration.

V.6.7 Location of borrow areas and identification of embankment, filter, riprap, large stone sources.

V.6.8 Laboratory Reports including:

V.6.8.1 As built properties of foundation and embankment materials, such as shear strength, unit weight, and water content and classification. The number of control tests and undisturbed record sample tests shall be included.

V.6.8.2 Physical, chemical, and thermal properties of concrete and concrete-making materials.

V.6.8.3 Summary of concrete mixture proportions and control procedures.

V.6.9 Project Geotechnical and Concrete Materials Completion Report.

V.6.10 Construction history records, construction photographs, construction videos, construction anomalies (piping, settlement, etc.) including diversion schemes and construction sequences shown on appropriate drawings.

V.6.11. Details of the overall instrumentation program to include predicted performance and record of actual observations, and annual updated evaluations.

V.6.12 Operations and Maintenance Manual.

V.6.13 Water Control Manual.

V.6.14 Copy of PCA.

V.6.15 Dam Safety Information:

V.6.15.1 Project copy of "Federal Guidelines for Dam Safety" (reference A.71).

V.6.15.2 Emergency Action Plan.

V.6.15.3 Records of dam safety training for project personnel.

V.6.15.4 Surveillance plan of the project that includes any special/significant events and threshold reservoir levels that initiate observations and/or inspections and reporting procedures.

V.6.15.5 List of local contractors and construction materials available for use in emergency situations.

V.6.15.6 Site-specific security and rapid recovery plans.

V.6.16 Manufacturers’ data for purchased items.

This Page Left Blank

APPENDIX W

Periodic Assessments

W.1 Periodic Assessment Purpose.

W.1.1 USACE risk management process resulted in assignment of a DSAC for each project. In many cases, the data used for initial classification may have been preliminary or incomplete or information used in the Screening Portfolio Risk Analysis (SPRA) process. The Periodic Assessment (PA) applies a higher level of rigor to further identify and refine project risks.

W.1.2 The PA is a Periodic Inspection (PI) with a facilitated Potential Failure Mode Analysis (PFMA), updated project consequences and evaluation of significant project risk drivers by a risk cadre working in tandem with district personnel. The normal field inspection activities for both the PI and PA will be maintained every five years. The PFMA and risk assessment will be completed prior to the traditional field inspection. The PA will be performed once every ten years.

W.1.3 The primary purposes of the PA are to:

W.1.3.1 Verify\re-evaluate the DSAC classification of a project;

W.1.3.2 Justify and revise interim risk reduction measures if needed;

W.1.3.3 Evaluate\revise the project risk assessment;

W.1.3.4 Identify operations and maintenance, monitoring, emergency action plan, training and other recurrent needs;

W.1.3.5 Confirm essential USACE dam safety guidelines are met and determine if the current risk is tolerable; and

W.1.3.6 Identify and prioritize any issue evaluation study needs.

W.1.4 Specific steps included in the PA that differ from a PI are:

W.1.4.1 Compilation of existing historic documents from design, analysis, and construction photos and records for the PFMA session.

W.1.4.2 Compilation and evaluation of project performance, instrumentation readings, and any recent remediation or improvements for the PFMA session.

W.1.4.3 Cursory site visit by the PFMA team. (Risk cadre and select district personnel)

W.1.4.4 District participation of a facilitated PFMA. (Documented by the risk cadre)

W.1.4.5 Update of project consequences by a regional cadre production pool.

W.1.4.6 District integration of a risk assessment report prepared by the risk cadre.

W.1.5 Completed PA reports will also serve as a “blue print” for districts to tailor and target on-going intermediate field site inspections and monitoring of dam features where significant PFM and/or high risk critical O&M features (i.e., relief wells, gallery drains) have been identified.

W.2 Periodic Assessment Report. The Periodic Assessment report ties existing information, field inspections, and the risk assessment together and provides engineering recommendations to decision makers. The report format is closely aligned to the Issue Evaluation Study (IES) and will have fifteen chapters and associated appendices as follows:

W.2.1 Executive Summary

W.2.2 Summary of All Dam Safety Recommendations (old\new compiled together)[1]

W.2.3 Introduction and Description of Dam and Operations

W.2.4 Current DSAC Assessment[1]

W.2.5 Evaluation of Foundation Materials and Construction Methods

W.2.6 Observed Project Past Performance Evaluation

W.2.7 Engineer’s Inspection Report (PI field inspection)

W.2.8 H&H Analysis - Hydrologic Loading and Duration[2]

W.2.9 Seismic Loadings[2]

W.2.10 Consequences of Failure[2]

W.2.11 Potential Failure Mode Analysis[2]

W.2.12 Risk Assessment[2]

W.2.13 Future Performance Monitoring\Risk Management Practice[1]

Notes: [1] = New district report sections from traditional PI.
[2] = Prepared by regional risk cadre.

W.2.14 Compliance with USACE Engineering Criteria[1]

W.2.15 Conclusions and Recommendations[1]

W.2.16 Report Appendices:

W.2.16.1 O&M History of Remedial Measures

W.2.16.2 Instrumentation Review

W.2.16.3 EIR Photos

W.2.16.4 EIR Field Notes

W.2.16.5 Intermediate Inspections (AI, Bulkheads, Conduit, Bridge Inspections)

W.2.16.6 Conduit Inspection

W.2.16.7 Supporting H&H Data[2]

W.2.16.8 Supporting Consequence Data[2]

W.2.16.9 Potential Failure Modes Analysis Report[2]

W.2.16.10 Support Risk Assessment Data[2]

W.2.16.11 Quality Control (ATR) Documentation

Notes: [1] = New district report sections from traditional PI.
[2] = Prepared by regional risk cadre.

W.3 Overall Workflow for PA. Proper scheduling and sequencing of the PA activities will be critical due to the need to engage the regional cadre, the engineering staff, the site operations staff, and MSC personnel. The general PA procedure is summarized in the following subsections.

W.3.1 The Risk Management Center will identify dams for Periodic Assessment and assign a PFMA Facilitator.

W.3.2 The district team shall compile all available design documentation reports including As-Built Drawings, construction records and photographs, foundation completion reports, Design Memoranda, Seismic Studies, Special Investigations, Periodic Inspection Reports, Water Control Manual, EAP, etc. for the PFMA and risk assessment. This activity should ideally be completed in the 1st and 2nd quarter of the fiscal year.

W.3.3 The Facilitator and Regional Cadre will be required to review the project design, construction, and performance records, prior to PFMA session.

W.3.4 A site visit shall be completed prior to the Potential Failure Modes Analysis session. All team members shall attend the cursory site visit and PFMA session.

W.3.5 The assigned regional cadre team will take the results from the PFMA and develop Event Trees for each plausible failure mode of concern using DAMRAE. System response curves will be estimated using available information and toolboxes and entered into the risk engine as well.

W.3.6 The district Team will perform the traditional field inspection and finalize a draft PA report.

W.3.7 An ATR will be performed by an independent regional cadre.

W.3.8 The Risk Management Center will review the final PA risk assessment and finalize any changes required to the DSAC ratings and prioritize funding of studies for the budget.

W.4 PA District Versus Risk Cadre Responsibilities. The initial PA will involve a greater level of effort due to the data gathering and documentation requirements. Once completed, this information will be available for future risk assessments as will additional data and performance history data collected following the initial PA. In addition, the PFMA and risk assessment within the PA will serve as a living document for ongoing district judgments required to manage normal O&M tasks within the program such as instrumentation replacement priorities, adjustments to surveillance and monitoring programs, etc.

W.4.1 For the PA, additional effort will be required by the district. These tasks will include:

W.4.1.1 The district will select a team leader (coordinator) to collect and organize a variety of documents and other information to support the PFMA, risk assessment, and compliance to USACE engineering criteria verification. The district will organize and summarize this information in preparation for the PFMA.

W.4.1.2 Appropriate in-house experts from engineering and operations including field personnel will participate in the PFMA process, which will include a cursory site visit and follow-on PFMA session.

W.4.1.3 Engineering and operations will collaborate in follow-up data for system loading events and system response for the risk assessment.

W.4.1.4 District personnel shall prepare the PA report including incorporating chapters supplied by the regional cadre.

W.4.2 The risk cadre will perform the following activities for the PA.

W.4.2.1 The regional cadre facilitator will verify proper district and regional cadre participants are assigned to the PA team.

W.4.2.2 Prepare updated consequences.

W.4.2.3 Conduct site visit and PFMA session and fully document findings.

W.4.2.4 Complete risk analysis system response curves using the latest methodologies.

W.4.2.5 Risk facilitator will assemble risk assessment portion of report and submit to district POC.

W.4.2.6 Risk cadre will help educate district personnel with the PFMA and risk assessment process. The district is encouraged to use this process to educate their technical staff on how to complete the PFMA and risk assessment portions of the PA.

W.4.2.7 Communicate the draft results from the baseline risk estimation process with district personnel.

W.4.3 The following subsections provide more detail on the risk cadre activities outlined above.

W.5 Updated Consequences.

W.5.1 For the PA, the regional cadre H&H engineer will work with regional consequence production pool members and district personnel to generate models and data needed to complete updated consequences.

W.5.2 The rapid consequence estimate requires a very limited detail unsteady model to reproduce various with and without dam failure scenarios including sunny day, PMF and several interim load cases in between all for with and without dam failure condition. Using GIS tools, the unsteady model results will be used to generate flood inundation mapping downstream as well as travel time and other values. This data will be used to interface with appropriate downstream data such as HAZUS to calculate population at risk, economic damages, potential for loss of life, and other consequence data. In addition, loss of function from a dam breach will need to be estimated such as hydropower, recreation, flood control, etc.

W.5.3 All of this data will be aggregated to allow consequences to be estimated for the risk assessment.

W.6 Potential Failure Modes Analysis (PFMA) Session. A PFMA chapter will be prepared by the regional cadre. The report records the thought process behind the derivation and justification of significant PFMs to be carried forward or excluded from the PA. More detailed information on the overall Potential Failure Modes Analysis process in Appendix X.

W.7 PA Risk Assessment. This risk assessment effort include identifying significant PFMs and critical O&M features from the PFMA session and develop system response curves for each PFM using the latest risk methodologies (toolboxes). Once these tasks are complete, the facilitator will generate the risk engine using DAMRAE to develop component and total project risk and compare of the overall and component risks with tolerable risk guidelines. Preparation of the related risk assessment chapters will incorporate the risk assessment findings.

W.8 Quality Control. The draft PA report will be prepared by the district and submitted to the facilitator for an ATR review. The ATR of the draft PA will be completed by another regional cadre not involved in the risk assessment process.

W.9 Periodic Assessment Schedule. The overall duration for the Periodic Assessment will depend on the level of complexity of the project. In some cases significant preparation may be needed for some sites while other project may have much of the data needed for the PA already on hand from the SPRA process. Regardless, 30 days before the scheduled PFMA site visit, the collected data should be transferred to the assign risk facilitator. The site visit and Potential Failure Modes Analysis will be completed in 1 week for most dams. The risk assessment will be completed by the regional cadre 45 days after completion of the PFMA session. PFMA and risk assessment activities should ideally be completed prior traditional field inspection such that findings can be used for targeted and more comprehensive engineering inspection of the project features. A draft of the PA report should be left “at the door” at the conclusion of the field inspection. The draft PA report should be submitted to the independent regional cadre for ATR 30 days after completion of field activities. The regional cadre shall complete review of the PA in 30 days. After which the final PA report shall be submitted to MSC 30 days after ATR is complete.

W.10 Periodic Assessment Funding. The district will budget for the expense of the Periodic Assessment through normal O&M processes. The cost of the regional cadre and facilitator will be funded by the Risk Management Center.

W.11 Approval Process of Periodic Assessment Report. The Periodic Assessment Report would be submitted to the district Dam Safety Officer for approval and sent to the MSC Dam Safety Officer for concurrence. A copy of the report will be sent to Risk Management Center.

APPENDIX X

Potential Failure Mode Analysis (PFMA) for Dams

X.1 Purpose/Applicability. Guidance for determination of potential failure modes for use in risk assessments of dams.

X.2 PFMA Overview.

X.2.1 PFMA is a method of analysis where particular faults and initiating conditions are postulated and the analysis reveals the full range of effects of the fault or the initiating condition on the system. The methods of failure are indentified, described, and evaluated on their credibility and significances. Failure Modes are a way that failure can occur, described by the means by which element or component failures must occur to cause loss of the sub-system or system function. The failure mode encompasses the full sequence of events from initiation (cause) through to the realization of ultimate failure effect of interest to include physical, operational, and managerial systems. PFMA is the first step in conducting a risk assessment for an existing dam or a risk reduction action. A significant increase in Dam Safety awareness can be learned from this step. Thorough failure mode identifications and complete descriptions will lead to a more efficient risk assessment process. Interim risk reduction measures and study plans can be effectively developed based on the results of the PFMA.

X.2.2 A PFMA is normally a facilitated identification and examination of potential failure modes (PFM) for a dam by a diverse team of persons who are qualified by experience and/or education to evaluate the dam. It is based on a review of available data and information, first hand input from field and operational personnel, site inspections, completed engineering analyses, discussion of known issues/problems, a general understanding of dam characteristics, and an understanding of the consequences of failure.

X.3 Outcomes. The PFMA outcomes will include the following:

X.3.1 List and detailed description of each PFM with a list of the factors that make the failure mode more likely to occur and a list of the factors that make the failure mode less likely to occur.

X.3.2 Classify PFM as not credible, credible and significant.

X.3.3 Major findings and understandings

X.3.4 Initial event tree development for each PFM to be carried forward in the next step of the risk assessment.

X.3.5 Review and update routine dam safety activities.

X.3.6 Identify needed additional investigations, analysis, testing, data, etc. for each PFM with unresolved issues.

X.3.7 PFMA documentation.

X.3.8 Plan for the risk assessment effort.

X.3.9 Review and update IRRM plan.

X.4 PFMA Process Description. The following is a brief overview of the steps required to perform a PFMA.

X.4.1 Step 1. Dam Safety Risk Management Center designates the PFMA facilitator and the facilitator coordinates with the district to assign PFMA participants.

X.4.2 Step 2. Collect and summarize background information, (requires assignment in the district).

X.4.3 Step 3. Perform a site visit/review (all members of the PFMA team should participate in the site visit).

X.4.4 Step 4. Review background information on the dam (by PFMA team)

X.4.5 Step 5. Conduct the PFMA.

X.4.6 Step 6. Generate final PFMA report.

X.5 Subject Matter Expert Facilitator Requirements /Corps Qualifications.

X.5.1 The facilitator is critical to the success of the PFMA, and should have a broad background and experience in dam engineering and experience in performing a PFMA. The Dam Safety Risk Management Center and USACE Dam Safety Program Manager shall approve PFMA facilitators.

X.5.2 Typical requirements to be an approved PFMA facilitator are:

X.5.2.1 Be a licensed engineer or a licensed engineering geologist/geologist with a minimum of ten years of experience in the design, construction, or operations of dams.

X.5.2.2 Be experienced in dam safety and related risk assessments.

X.5.2.3 Participate in a PFMA for at least one for embankment dam and one concrete structure PFMA for projects operated/regulated by USACE or USBR.

X.5.2.4 Complete the USACE facilitator training course.

X.5.2.5 Shall have consolidated data and written the report from at least one the PFMA session.

X.5.2.6 Successfully facilitated at least two PFMA sessions observed by an experienced facilitator with associated formal feedback and endorsement.

X.5.2.7 Possess good communication and group leadership skills.

X.6 Development of Supporting Data for PFMA. Gathering supporting data prior to the PFMA session is a critical step. The search for records should not be limited to the district files, but should include research in other locations (e.g. National Archives, university libraries, etc).

X.7 Identifying and Describing Potential Failure Modes. The potential failure modes must be described fully from initiation to breach and uncontrolled reservoir release and\or significant loss of operation control. Loss of operational control includes loss of projects purposes or services such as navigation capability. The reasons for completely describing the potential failure modes are shown below.

X.7.1 To ensure the PFMA team has a common understanding of the failure mode.

X.7.2 To document PFM for future reference and use.

X.7.3 To facilitate subsequent development of an event tree.

X.8 Evaluating a Potential Failure Mode. After the detailed PFM descriptions have been completed, the PFM are evaluated by listing the factors that make the failure mode more and less likely to occur. These are based on the team's understanding of the facility and background material.

X.9 Performance Monitoring Enhancements, Data Collection Needs, Analyses, and Risk Reduction Measures. Following development of a potential failure mode, the team will have a thorough understanding of the available information and circumstances leading to its development. This is the time to capture the team's thoughts on what additional information or analyses would be useful in understanding the potential failure mode, and additional opportunities for monitoring and risk reduction. Whether these will actually be implemented depends largely on the follow-on study plan and risk assessment.

X.10 Major Findings and Understandings. The knowledge gained from the PFMA and a determination whether or not USACE essential guidelines are met should be documented in the form of "Major Findings and Understandings" in the PFMA report. Below are examples of a major finding and understanding.

X.10.1 Galleries. There are four galleries that penetrate the base of the dam as described above: Duck Creek, utility galleries on either side of the spillway, and the

diversion gallery at the outlet works. The galleries have not been inspected during recent Periodic Inspections. Hence, the condition of the joints and any cracks and/or seepage is unknown. It is recommended that the district include inspection of the galleries as part of the Periodic Inspection program. The results of the inspection are needed to resolve the potential failure mode of internal erosion of the embankment materials into the galleries.

X.10.2 Seepage Control. Foundation reports were prepared for the outlet works and spillway structures only. However, there is little to no documentation of foundation preparation in the embankment areas. Only a 5-foot deep inspection trench was excavated during construction, and no cutoff was provided for the deep pervious foundation. The primary seepage control feature is a series of relief wells near the downstream toe. Material compatibility is essential to resolving several potential failure modes associated with internal erosion. Based on a review of embankment design gradations, it appears that filter criteria is not met at some locations. It is recommended that the district review the conclusions of the *Hydraulic Fracturing Evaluation Report* dated September 1997, for material compatibility for both internal erosion through the embankment and from the embankment into the soil foundation. Best available gradation data for the various materials as well as the original design gradations should be used in conjunction with the filtering criteria provided in EM 1110-2-1901 *Seepage Analysis and Control*, Change 2 dated February 2005 (reference A.9).

X.10.3. High Consequences. The area downstream of the dam is the highly developed urban area of Made-up County that extends for miles to the bay downstream. Even if the probability of failure is determined to be low for the credible and significant potential failure modes, the incremental loss of life and economic damages for dam failure will likely generate considerable risk because of the relatively flat flood plain and high population density. Furthermore, regardless of the level of modifications or improvements to the project, there will probably always be some appreciable residual risk due to high consequences that must be managed through emergency preparedness, communication, and/or education.

X.11 Documentation. The results of the PFMA will be documented using the following outline.

X.11.1 Introduction and Background including a summary of the last risk assessment completed (SPRA, Periodic Assessment, Issue Evaluation, etc.)

X.11.2 Current Assessment Effort (include a list of participants in this section)

X.11.3 Description of Project

X.11.4 Major Findings and Understandings

X.11.5 Potential Failure Modes Identified.

X.11.6 Credible Potential Failure Modes

X.11.7 Significant Potential Failure Modes

X.11.8 Potential Failure Modes with Unresolved Issues

X.11.9 Not credible Failure Modes

X.11.10 Summary and Conclusions

This Page Left Blank

APPENDIX Y

Dam Safety Vegetation Management

Y.1 Purpose. The establishment, maintenance, and control of vegetation pose Engineering, as well as routine maintenance considerations. In accordance with ETL 1110-2-571 (reference A.67), this guidance establishes minimum requirements for maintenance/control of vegetation at USACE-owned dams, abutments, spillways, inlet/outlet channels, and other appurtenances.

Y.2 References.

Y.2.1 ETL 1110-2-571, “Guidelines for Landscape Planting and Vegetation Management at Levees, Floodwalls, Embankment Dams, and Appurtenant Structures” (reference A.67).

Y.2.2 Federal Emergency Management Agency, (2005), “Technical Manual for Dam Owners: Impacts of Plants”, FEMA Document 534, Washington, DC (reference A.75).

Y.3 Background. Maintaining the integrity of our dams and appurtenant facilities is a critical USACE responsibility. Vegetation is much more than an aesthetic consideration. Proper vegetation management is necessary to preserve the design functionality of critical project features. Requirements for mowing and eradication are documented in the project specific Operations and Maintenance Manual. Changes in vegetation management practices to promote project benefits such as recreation and environmental enhancement must be carefully evaluated from a dam safety perspective and coordinated with dam safety experts. Vegetation that adversely impacts engineered structures or inhibits inspection, monitoring, and emergency response actions is not allowed.

Y.3.1 Beneficial Vegetation. Beneficial vegetation, such as grass cover, can assist in preventing erosion, controlling dust, defining zones of use, and creating a pleasant environment. Uniform grass cover enhances visual inspection, allowing the detection of seeps, settlement, displacements, and other evidence of distress. Robust grass coverage along embankments and discharge channels can help deter the natural establishment of trees and other deep rooted species.

Y.3.2 Undesirable Vegetation. Woody vegetation and aquatic plants (e.g. cattails) can obscure large portions of the dam, preventing adequate visual inspection, creating potential seepage pathways, reducing discharge capability, and can threaten the stability and integrity of a structure.

Y.3.2.1 Structural instability can occur due to falling/decaying tree/woody vegetation and root system growth. Large, seemingly stable and innocuous trees can easily be blown over or uprooted in a storm/flood and cause a large hole left by the root system. This in turn can shorten the seepage path and initiate piping, or a breach in the dam.

Y.3.2.2 Root systems may undermine concrete slabs, causing erosion of foundation materials and subsidence or heave. Additionally, root systems can interfere with interior drainage systems. Trees and aquatic vegetation in channels can restrict flow volumes, or become a source of debris which blocks releases. Trees in channels can also initiate uneven flow patterns and cause erosion that may divert discharges out of bank. All of these can ultimately threaten public safety.

Y.4 Policy.

Y.4.1 The following areas shall remain free of trees and other woody vegetation such as shrubs and vines:

Y.4.1.1 The dam and dam toe area

Y.4.1.2 In or around seepage monitoring systems or critical areas for seepage observation

Y.4.1.3 Abutments and groins

Y.4.1.4 Emergency spillways and regulating outlet channels, including channel floors, side slopes and approaches

Y.4.1.5 Outlet works discharge channels

Y.4.2 All areas of dam projects must be inspected according to Chapter 11 of this regulation and ER 1130-2-530 (reference A.63). Inspections conducted either by project personnel, or engineering personnel must always consider the potential dangers from excessive or inadequate vegetation growth. Changes in surfaces, such as cracks, depressions, and movements must also be readily observable via controlled grass cover. Any evidence of seepage or erosion must be quickly identified, monitored evaluated and controlled to prevent flows that could become detrimental to the safety of the structure. Inspection of vegetation shall be part of each annual and formal periodic inspection for each project and shall be discussed in the respective reports.

Y.4.3 The governing criteria for maintenance of vegetation on the dams, or areas adjacent to, or immediately downstream of dams is to provide ready and adequate visual observation.

Y.4.4 Design and construction of landscape plantings, including irrigation systems, must be carefully devaluated and reviewed from a Dam Safety perspective, comply with ETL 1110-2-571 (reference A.67), and approved by dam safety experts.

Y.4.5 Trees, brush, and weeds in spillways and inlet and outlet channels shall be maintained so as not to obstruct flows, or cause any threat or potential threat to areas downstream of the dam. Specified spillway and outlet works design discharge capacities must be maintained. Tree and vegetation removal from spillway discharge

areas downstream of the crest or sill is required to avoid “head cutting” or causing flow concentrations.

Y.5 Implementation.

Y.5.1 Mowing/ clearing limits for each dam shall be identified by dam safety personnel within Engineering Division and documented on aerial photographs or plan drawings, as part of the project Operations and Maintenance Manual. The limits shall be site-specific and shall take into consideration the topography, phreatic surfaces within the structure and abutments, foundation characteristics and any historical problems with the structure.

Y.5.2 The horizontal limits of clearing shall not be less than the entrance width of the spillway. In the vertical direction, no encroachment by woody vegetation of any kind can be tolerated up to the elevation of the inflow design flood profile. Dam safety personnel within Engineering Division shall establish specific clearing limits for spillways based on project hydrological characteristics, and they shall be permanently and clearly marked in the field.

Y.5.3 Riprap in all areas shall be maintained free of vegetation. This includes embankment slopes, discharge channel slopes, and emergency rock stockpiles.

Y.6 Remediation Procedures.

Y.6.1 Undesirable woody vegetation identified by Dam Safety personnel shall be removed. Removal of woody vegetation will require engineering judgment to determine if the root system has engaged water bearing regions of the dam and\or site specific geologic areas of special interests such as jointed rock formation which contain water at the toe or dam abutments.

Y.6.2 Tree and woody vegetation growth on the upstream slope should be undercut to remove all stumps, root balls, and root systems. The undercut area must be thoroughly inspected to confirm that all major root systems (greater than about one-half inch in diameter) have been removed during the undercutting operation to prohibit regrowth. Suitable backfill shall be placed in the excavation and properly compacted to the dam remediation design limits. Backfill shall be similar to the in-situ embankment fill material and shall be compacted. Installing a slope protection system is recommended to reduce the potential for wave and surface runoff erosion.

Y.6.3 Engineering judgment will be required to identify the depth and extent of stump and root ball removal, laying back the undercut slope and selection of backfill based on dam design.

Y.6.4 Alternative methods, such as herbicide spraying, burning, or cutting trees flush to the ground surface and leaving roots in place may be considered, in consultation with

dam safety experts. However, burning atop riprap is prohibited as this can weaken and degrade the rock.

Y.6.5 The suggested dam remediation design and construction procedure suggested for complete removal of trees, stumps, root balls, and root systems consists of the following activities:

Y.6.5.1 Cut the tree approximately two (2) feet above ground leaving a well-defined stump that can be used in the root ball removal process;

Y.6.5.2 Remove the stump and root ball by pulling the stump, or by using a track-mounted backhoe to first loosen the root ball by pulling on the stump and then extracting the stump and root ball together;

Y.6.5.3 Remove the remaining root system and loose soil from the root ball cavity by excavating the sides of the cavity to slopes no steeper than 1:1 (horizontal to vertical) and the bottom of the cavity approximately horizontal;

Y.6.5.4 Backfill the excavation with compacted soil placed in relatively loose lifts not greater than about eight (8) inches in thickness. Compaction of backfilled soils in these tree stump and root ball excavations typically requires the use of manually operated compaction equipment or compaction equipment attached to a backhoe.

Y.6.5.5 Procedure for total removal of trees near the toe is more complicated. Treatment of mature tree penetrations in a downstream slope may involve installation of a subdrain and/or filter system in the tree penetration excavation and backfill with compacted soil placed in maximum loose lifts of eight inches.

Y.7 Establishment of Vegetation. All disturbed areas must be protected by seeding and mulching. Timing must be considered to allow seed to germinate and develop roots prior to winter or heavy precipitation seasons.

Y.8 Waivers. Waivers to allow additional vegetation or alternate remediation techniques must be submitted in writing to the district Dam Safety Officer. A multi-discipline team shall review the proposed change, assess potential dam safety impacts, and provide a written recommendation to either approve or decline by the Dam Safety Officer.

APPENDIX Z

Hazard Potential Classification

Z.1 Discussion. The current classification system used to evaluate the hydrologic hazard potential of dams was established in response to several dam failures in the early 1970's which resulted in significant loss of life and property damage. This classification system, while useful for the evaluation of hazard to life and property, is deficient in that it does not consider the indirect losses of critical lifelines due to a dam failure. These losses, such as the loss of water supply, loss of key transportation or medical facilities, loss of power generation capability, or loss of navigation and environmental damage can have a significant impact on the public after a major hydrologic or seismic event. Some attempt has been made in the past to consider lifeline and environmental losses as economic losses; however, a standard classification system has not been established. An additional deficiency in the existing classification system is in the potential loss of life posed by the significant and high classifications. The terms "few" under the significant category, and "high potential" under the high category are too vague and subject to interpretation. The following is an attempt to quantify the loss of life associated with each level of hazard potential.

Z.2 Classification System. Table Z.1 establishes a classification system, which groups losses into four general categories: loss of life, property, lifeline and environmental losses. This hazard potential classification is related to the functional integrity of the project, not the structural integrity of project features or components. Direct loss of life is quantified as either none, certain (one or more) or uncertain. Economic indirect losses are classified as either direct property, environmental or lifelines losses. Hazard potential ratings are based entirely upon the proximity of the project to population, which would be at risk due to project failure or operation, and the impact upon life, and property of the loss of essential services. A more detailed discussion on each of the four categories follows:

Z.2.1 Loss of Life. “Federal Guidelines for Dam Safety: Hazard Potential Classification System for Dams” (reference A.76) states that the difference between the significant and high hazard potential classification levels is that a high hazard potential dam includes the probable loss of human life, regardless of the magnitude of other losses. If no loss of life is probable as the result of dam failure or mis-operation, the dam would be classified as Low or Significant Hazard Potential. The probable loss of human life is defined to signify one or more lives lost. The term "probable" indicates that the scenario used to predict the loss of human life must be reasonable and realistic, not contrived. In the definition for High Hazard Potential, the probable loss of human life is further clarified to exclude the casual user of the downstream or upstream area in determining the potential for loss of human life. Potential public response to the emergency should not be used to reduce the calculated probable loss of human life.

Z.2.2 Property Losses. Property losses are classified as either direct economic losses due to flood damaged homes, businesses, and infrastructure; or indirect

economic losses due to the interruption of services provided by either the failed facility or by damaged property or infrastructure downstream. Examples of indirect losses include:

Z.2.2.1 Loss of power generation capability at the failed dam (or at an inundated powerhouse downstream).

Z.2.2.2 Loss of navigation due to evacuation of the navigation pool at a failed reservoir (or due to direct damage to a lock).

Z.2.2.3 Loss of water supply due to a reservoir emptied by a failed dam.

Z.2.3 Lifelines Losses. Disruption of essential lifeline services or access to these services during or following a catastrophic event can result in indirect threats to life. The loss of key transportation links such as bridges or highways would prevent access to medical facilities at a time critically injured people need access the most. Another example would be the loss or damage to medical facilities.

Z.2.4 Environmental Losses. Damage to the environment caused by project failure or operation can result in the need for mitigative measures, or can cause irreparable damage to the environment. Environmental damage estimates shall consider the damage, which would normally be caused by the flood event under which the project failure occurs. Only the incremental damage caused by the project failure shall be attributed to project failure or operation. Some other examples of environmental impacts are:

Z.2.4.1 Environmental damage caused by the release of a reservoir contaminated by toxic or hazardous mine waste.

Z.2.4.2 Environmental damage caused by sediment released by a reservoir.

Z.3 Classification Table. See Table Z.1 for guidance in classifying Civil Works projects as low, significant, or high hazard potential.

Table Z.1 – Hazard Potential Classification for Civil Works Projects

CATEGORY[1]	LOW	SIGNIFICANT	HIGH
Direct Loss of Life[2]	None expected	None expected	Certain (one or more) (extensive downstream residential, commercial, or industrial development)
Lifeline Losses[3]	No disruption of services - repairs are cosmetic or rapidly repairable damage	Disruption of essential or critical facilities and access	Not considered for this classification
Property Losses[4]	Private agricultural lands, equipment and isolated buildings	Major or extensive public and private facilities	Not considered for this classification
Environmental Losses[5]	Minimal incremental damage	Major or extensive mitigation required or impossible to mitigate	Not considered for this classification

Notes:

[1] Categories are based upon project performance and do not apply to individual structures within a project.

[2] Loss of life potential based upon inundation mapping of area downstream of the project. Analyses of loss of life potential shall take into account the extent of development and associated population at risk, time of flood wave travel and warning time.

[3] Indirect threats to life caused by the interruption of lifeline services due to project failure, or operation, i.e., direct loss of (or access to) critical medical facilities or loss of water or power supply, communications, power supply, etc.

[4] Direct economic impact of value of property damages to project facilities and downstream property and indirect economic impact due to loss of project services, i.e., impact on navigation industry of the loss of a dam and navigation pool, or impact upon a community of the loss of water or power supply.

[5] Environmental impact downstream caused by the incremental flood wave produced by the project failure, beyond which would normally be expected for the magnitude flood event under a without project conditions.

This Page Left Blank

APPENDIX AA

Management Control

AA.1 Function. The function covered by this checklist is Civil Works Dam Safety Program.

AA.2 Purpose. The purpose of this checklist is to assist the District Safety Officer in evaluating the key management controls listed below. It is *not* intended to cover *all* controls.

AA.3 Instructions. Answers must be based on the actual *testing* of key management controls (e.g., document analysis, direct observation, sampling, simulation, etc.). Answers, which indicate deficiencies, must be explained and corrective action indicated in supporting documentation. These management controls *must* be evaluated at least once every five years and may be evaluated as often as very project. Certification that this evaluation has been conducted must be accomplished on DA Form 11-2-R (Management Control Evaluation Certification Statement).

AA.4 Test Questions.

AA.4.1 Does the office at each dam have a copy of the Federal Guidelines for Dam Safety – FEMA 93?

AA.4.2 Does the office at each dam have a set of the Training Aids for Dam Safety – FEMA 609DVD?

AA.4.3 Does the office at each dam have a copy of the Safety of Dams Regulation – ER 1110-2-1156?

AA.4.4 Does the office at each dam have a copy of the current Emergency Action Plan for the dam?

AA.4.5 Does the office at each dam have a copy of the latest Periodic Inspection Report and the latest Periodic Assessment Report?

AA.4.6 Does the office at each dam have a copy of the “as-built” plans for the dam?

AA.4.7 Is the Dam Safety Officer appointed on orders by the Commander in accordance with Chapter 4, ER 1110-2-1156?

AA.4.8 Does the Dam Safety Program Manager meet the qualifications requirements established in ER 1110-2-1156?

AA.4.9 Are both the Dam Safety Officer and the Dam Safety Program Manager registered Professional Engineers (or Geologists) with a current State registration?

AA.4.10 Is the Dam Safety Committee officially established with a list of members by names and does the committee meet on a regular basis?

AA.4.11 Is the data for the Dam Safety Program Management Tools up-to-date for all dams in the district or MSC?

AA.4.12 Are the Periodic Inspections and Periodic Assessments scheduled on a 10 year cycle and is the schedule current?

AA.4.13 Are inspection and assessment reports completed within 90 days of the field inspections and is a draft report left at the dam on the day of the inspections?

AA.4.14 Are instruments used to monitor the dams in working order and are they read in accordance with the established schedule? Is the data for instrumentation reading processed in 90 days or less for all projects?

AA.4.15 Are emergency exercises held at each dam in accordance with the schedule in ER 1110-2-1156?

AA.4.16 Do all new field employees receive 6 hours of dam safety training within 6 months of being assigned to the dam? Are new contractor employees also trained within 6 months?

AA.4.17 Does each dam (if required) have a current Interim Risk Reduction Plan?

AA.4.18 Does each PDT for a dam safety study have an assigned “Lead Engineer”?

This Page Left Blank

APPENDIX AB

Seismic Safety Evaluation Process for Embankment Dams and Foundations

AB.1 Introduction.

AB.1.1 This Annex provides detailed guidance for evaluating the seismic safety of existing USACE embankment dams and foundations. The process ensures:

AB.1.1.1 That seismic evaluations/re-evaluations for embankment dams and foundations are accurately identified and conducted with minimum expenditure of project funds, manpower or delay and

AB.1.1.2 That embankment dams and/or foundations not requiring modifications are accurately identified and removed from further study at the earliest possible point in the evaluation process.

AB.1.2 This guidance is to be used in evaluating the seismic safety of existing USACE Civil Works embankment dams in accordance with the provisions of the Dam Safety Program as defined in the main text of this regulation.

AB.1.3 The seismic safety of many existing embankment dams must be evaluated or re-evaluated in accordance with the requirements in ER 1110-2-1806. Seismic safety evaluation of major civil works projects, particularly embankment dams, is typically a complex, multi-stage process. It generally requires progressively more detailed definition of certain project characteristics and analysis of project response to the design earthquake ground motions at each subsequent stage. This process can be expensive and manpower intensive, and may take many months to several years to complete.

AB.2 Seismic Safety Evaluation Process.

AB.2.1 Evaluation Process. Stages of the seismic safety evaluation process are designated as:

AB.2.1.1 Seismic Safety Review,

AB.2.1.2 Phase I Special Studies, and

AB.2.1.3 Phase II Special Studies

AB.2.1.4 A flow chart illustrating the process is shown at Figure AB.1.

AB.2.2 The evaluation process is structured to validate technical conclusions and policy compliance as an integral part of each stage of the process. This is accomplished during appropriately timed Policy Compliance & Criteria Reviews (PCCR). These

reviews eliminate the need for several report submission and approval cycles preceding the development of an official decision document. The evaluation process leads either to negative findings (i.e., that critical project features are likely to perform in an acceptable manner during and following the design earthquake) resulting in removal of the dam from further evaluation, or to the conclusion that modifications are required to the embankment dam and/or its foundation to ensure acceptable performance when subjected to the design earthquake. Negative conclusions at any stage beyond the initial screening at the Seismic Safety Review stage require validation during a PCCR. Negative conclusions at any stage of evaluation require only minimal formal documentation. Conclusions which indicate additional studies are required or that the project requires some form of remediation or modification must be validated during a PCCR. Additionally, the evaluation process and resultant conclusions must be documented for record prior to proceeding into the next phase. If studies through the Phase II level lead to the conclusion that some form of remediation is required, the results of the evaluation process, recommended remediation or modifications and justification are presented in the Dam Safety Modification Report (DSMR).

AB.2.3 The Dam Safety Modification Studies and Documentation are described in Chapter 9 of this regulation.

AB.2.4 Phase III/Detailed Design. Following official approval of the DSMR, Phase III work should precede in accordance with the approved schedule. This includes detailed design for the seismic modifications approved in the DSMR as well as preparation of the plans and specifications for those measures.

AB.3 Funding. The Seismic Safety Review should be a recurring review has part of the Periodic Assessment of the dam and is funded with project O&M funds. The Phase I Special Studies are included in the Initial Evaluation Study (IES). The Phase II Special Studies are included in the Dam Safety Modification Study (DSMS). Both the IES and the DSMS are funded with Construction funds.

AB.4 Seismic Safety Review.

AB.4.1 A Seismic Safety Review (SSR) is required when certain conditions exist as described in ER 1110-2-1806. The SSR should be considered as a part of each Periodic Assessment (PA).

AB.4.2 The purpose of the SSR is to review and document conclusions about the seismic safety of embankment dams and foundations for civil works projects in accordance with ER 1110-2-1806. This review will conclude whether or not a Phase I Special Study is required. The SSR is normally limited to office examination and screening of available data and the results of the most recent PI and/or PA. In this review, available information, such as geologic maps, boring logs, seismic zone maps, acceleration contour maps, existing field investigation reports, as-built project records, and previous seismic evaluation reports, should be used. If the initial screening indicates that the embankment dam and/or its foundation may require

remediation/modification for seismic adequacy, then limited, simple preliminary analyses using existing available data should be performed as part of the SSR. If these analyses indicate that there is potential for sudden, uncontrolled loss of reservoir pool or other form of unacceptable performance which causes loss of life as a result of the project being subjected to the design earthquake, then a Phase I Special Study should be recommended. Where specialized expertise is needed, subject matter experts, either USACE or external, should participate in the examination and analysis as early as practical in the evaluation process.

AB.4.3 The level of effort to accomplish the SSR should be the minimum required to resolve whether or not seismic safety issues exist which require a Phase I Special Study. (The level of effort and associated cost are estimated to be on the order of a few man-weeks of office effort with costs in the range of $25-50K.)

AB.4.4 Seismic Safety Issues. Issues that are relevant to the determination of seismic safety and the need for further investigations may include some or all of the following:

AB.4.4.1 Project Hazard Potential Classification, which reflects the criticality of the project in terms of threat to public safety in the event of failure. It is USACE policy that seismic safety of USACE embankment dams, where failure would result in loss of life, must be assured. For embankment dams and other features for which the consequences of failure are economic and no loss of life is expected, the decisions about further investigations or other actions should be justified on an economic basis.

AB.4.4.2 Adequacy of past seismic evaluations, if any; including the adequacy of procedures used in selection of design ground motions and the appropriateness and adequacy of methods of analysis used, in light of the present state-of-the-practice.

AB.4.4.3 Proximity to seismic source zones

AB.4.4.4 Changes in the state of knowledge of regional or local seismicity since the last review.

AB.4.4.5 Existence of soils that are potentially unstable due to buildup of excess residual pore pressures or degradation of strength from cyclic loading in either the embankment or foundation.

AB.4.4.6 Existence of slopes that may be seismically unstable, including embankment slopes, the abutments or the reservoir rims.

AB.4.4.7 Existence of project features that may become critical to safety after small deformations of the embankment dam (i.e., outlet works becoming nonoperational or thin filter zones within the embankment being disrupted).

AB.4.4.8 A Policy Compliance & Criteria Review (PCCR) should be held after 95% completion of the technical examination and analysis for the SSR, but prior to forwarding a recommendation to the District Dam Officer. The PCCR should include geotechnical representatives from the RMC and the MSC as well as District representatives including representatives from Engineering and Operations. A PCCR is not needed if the results of the SSR indicate that the dam is seismically adequate. The PCCR should summarize the examination and screening and should provide a recommendation with justification for the initiation of Phase I studies. Supporting documentation should be presented. If a Phase I study is recommended, then a scope of work, cost estimate and schedule for the Phase I study should be presented. If the SSR is done in conjunction with a periodic assessment, the results of the SSR should be incorporated into the Periodic Assessment Report. As a minimum, the District should document the SSR as well as the results and conclusions of the PCCR in a memorandum for record to project files. No formal report or documentation is required to be submitted to the MSC or HQUSACE for review and approval; the PCCR replaces the MSC and HQUSACE review and approval process for the SSR. An information copy of the memorandum for record must be provided to both the MSC and HQUSACE (CECW-CE).

AB.5 Phase I Special Study.

AB.5.1 A Phase I Special Study is necessary when the PCCR for the SSR concludes that potential deficiencies exist in an embankment dam or foundation which could lead to sudden, uncontrolled loss of reservoir pool or other form of unacceptable performance likely to cause loss of life if the project were subjected to the Maximum Credible Earthquake (MCE), as defined in ER 1110-2-1806, or a lesser event.

AB.5.2 The purpose of Phase I study is as shown below. The Phase I study should be part of an overall risk-informed IES for the dam.

AB.5.2.1 Develop site specific ground motions appropriate for seismic evaluation of all project features to be evaluated,

AB.5.2.2 Perform limited field investigations and laboratory studies, and,

AB.5.2.3 Perform preliminary analyses, based on the ground motions, field data and laboratory testing results, to determine the response of the dam to seismic loading and to identify potential problem areas which may need more detailed analyses.

AB.5.3 The type and level of study required in the Phase I study will be project dependent; however, the content of a Phase I study normally includes the following:

AB.5.3.1 Project Description. Provide a brief description of the project, including type of dam, major structures or other critical feature. Provide tabulated pertinent project data. Describe design and current project operations. Identify key operational pool

levels such as conservation pool, power pool, seasonal pool levels, spillway crest, flood pool and maximum pool. Other relevant pool information should include reservoir pool history elevation versus time, average yearly maximum pool, and the reservoir pool elevation versus frequency relationship based on historical data supplemented with flood routing analyses for less frequent flood events as required.

AB.5.3.2 Purpose and Scope. Describe the purpose and scope of the study and the deficiency(s) identified in the SSR. (Estimating the level of effort and cost to perform a Phase I study is difficult to address on other than a project specific basis but are likely to range from many man-months to a few man-years of effort and involve expenditures in the range of $300-800K. Phase I duration should be limited to the shortest possible time period consistent with project complexity, manpower, funding and quality considerations.)

AB.5.3.3 Site Characterization. Perform limited field and laboratory investigations to define the soil and rock stratigraphy and to further clarify location and extent of potential problem areas. These investigations should be sufficient to develop preliminary soil and rock cross sections of the dam and foundation in areas which have potentially unstable soils. These investigations may include Standard Penetration Tests (SPT), Cone Penetration Tests (CPT), shear wave velocity, permeability, Becker Penetration Tests (BPT), conventional undisturbed sampling, and trenching in areas of much lateral heterogeneity or anisotropy.

AB.5.3.4 Seismotectonic Evaluation. Develop a detailed evaluation of the geology, tectonics and seismic history of the area, and the proximity of the dam to active seismic zones. Provide fault study and related field investigations and laboratory testing where necessary.

AB.5.3.5 Seismicity and Ground Motions. Select the final design earthquake ground motions and develop the ground motion parameters to which the project could be subjected. For all critical projects or features, these input ground motions will be obtained from a deterministic analysis of historic seismicity and active fault systems or seismic source zones and their activity. Develop several accelerograms for site response computations. The accelerograms should contain energy, frequency and duration components appropriate for the source, the region and the feature being evaluated. Caution is advised to avoid undue conservatism in selection of ground motions for use in analyses. Selection of specific accelerograms or the manipulation of accelerograms to generate records with specific time histories not representative of the characteristic ground motion records within the region of the project should be strongly justified and well documented. Of particular concern is that accelerograms be developed with energy content and occurrence of the peak energy representative of the seismological setting of the feature(s) being evaluated. For effective stress analyses, where site permeability profiles and boundaries are accurately known and seismic generated residual excess pore water pressures will be simultaneously dissipated, input motion time histories should not be manipulated to shift the energy content to the end of shaking to minimize pore pressure dissipation and thereby maximize excess residual

pore pressures during modeling of post earthquake response unless justified from seismological investigations and by expert seismologists. Selection of ground motions should be made with input from qualified seismologists, geologists and geotechnical engineers.

AB.5.3.6 Seismic Evaluations and Analyses.

AB.5.3.6.1 Liquefaction Potential. Evaluate the potential for liquefaction or development of excess pore pressure in soils of the embankment and foundation using standard methods. This should consist of using an appropriate empirical method linking documented field performance with site characteristics using field investigations. Use a 1-D analysis, such as SHAKE, to model propagation of earthquake induced rock motions through the foundation and the embankment.

AB.5.3.6.2 Post Earthquake Stability. Evaluate post earthquake limit equilibrium slope stability for the reach(es) of the embankment where liquefaction of the embankment and/or foundation is indicated. Post-earthquake shear strengths for zones not indicated to liquefy should be estimated taking into account residual excess pore pressures. Post-earthquake shear strengths for zones which are indicated to liquefy should be selected based on residual strengths back calculated for well documented liquefaction induced failures. The further reduction in shear resistance below the residual level is not justified.

AB.5.3.7 Post Earthquake Deformed Shape. Assess the shape and amount of deformation in the embankment after sliding or slumping for the cross section where inadequate factors of safety are indicated by limit equilibrium slope stability analyses. Similar cautions noted for selection of strength and pore pressure values in evaluating limit equilibrium stability are to be observed in evaluating the post earthquake deformed shape of an embankment or other slope.

AB.5.3.8 Conclusions and Recommendations. Develop conclusions and recommendations on the need for a Phase II seismic evaluation or departure from requirements of ER 1110-2- 1806.

AB.5.3.9 Cost Estimate and Schedule. If Phase II studies are recommended, develop a detailed scope, cost estimate and schedule for the proposed Phase II studies.

AB.5.3.10 Phase I PCCR. Conduct a PCCR for the Phase I study.

AB.6 Phase II Special Study.

AB.6.1 A Phase II Special Study is necessary when the PCCR for the Phase I concludes that potential deficiencies exist in an embankment dam or foundation which could lead to sudden, uncontrolled loss of reservoir pool or other form of unacceptable performance likely to cause loss of life if the project were subjected to the design earthquake. The Phase II study should be detailed and sufficiently comprehensive such

that conclusions reached concerning the seismic adequacy of the dam in question are definitive and constitute the basis for selection, detailed design and construction of modifications or other form of remediation required to ensure seismic safety of the project.

AB.6.2 The purpose and scope of Phase II study are as follows:

AB.6.2.1 Perform comprehensive detailed analyses to evaluate performance of the critical project features when subjected to the ground motions identified in Phase I.

AB.6.2.2 Determine if the dam is seismically adequate or if remediation/modifications are required to ensure acceptable seismic performance.

AB.6.2.3 Establish remediation requirements.

AB.6.2.4 Evaluate various alternative remedial techniques and select the most appropriate alternative.

AB.6.2.5 Prepare cost estimates, scope, and schedule for design documentation, plans and specifications, and construction.

AB.6.3 Methods of Analysis. The recommended engineering approach to analysis of an embankment dam and foundation for seismic stability generally consists of assessing both post earthquake static limit equilibrium slope stability and deformation response of the dam using, as appropriate, detailed 2D and 3D numerical analyses. The steps involved in a Phase II seismic analyses for earth dams normally include:

AB.6.3.1 Use the recommended design earthquake ground motions and accelerograms developed in the Phase I study for site response computations. For all critical projects or features, these input ground motions will be obtained from a deterministic analysis. The selected accelerograms should be used in the application of an appropriate, validated dynamic finite element program used for modeling the deformation process in response to an imposed earthquake ground motion time history.

AB.6.3.2 Perform detailed field investigations which may include SPT, BPT, CPT, field vane shear tests, field permeability, ground water observation wells, conventional undisturbed sampling, geophysical evaluations, and laboratory testing, to develop a detailed understanding of site conditions, including stratigraphy, geometry, hydrology, material properties and their variability, and the areal extent of potential problem zones.

AB.6.3.3 Determine the preearthquake vertical effective shear stresses, and the initial static shear stresses on horizontal planes throughout the dam and its foundation.

AB.6.3.4 Determine the dynamic shear moduli of the soils in the dam and foundation.

AB.6.3.5 Using an appropriate dynamic finite element analysis procedure, determine the stresses induced in the embankment and foundation when subjected to the accelerograms selected for the design earthquake. Pore water pressure dissipation should be properly accounted for in determining pore pressure behavior during shaking and residual excess pore pressure level after shaking stops. Consider relevant soil properties and stratigraphy including permeabilities in soil layers adjacent to the liquefiable soil layer, which restricts pore pressure dissipation.

AB.6.3.6 Determine the liquefaction resistance of the embankment and foundation soils and the maximum potential residual excess pore water pressure that can be generated by the earthquake using corrected penetration data from in-situ tests such as SPT, CPT, BPT, and laboratory index tests.

AB.6.3.7 Map the areal extent of all suspect materials. Determine post earthquake shear strength of relevant soils. Prepare several generalized cross sections of the dam and foundation for final analysis to determine seismic response.

AB.6.3.8 Perform static limit equilibrium slope stability analyses of the generalized cross sections to assess post earthquake stability and to identify potential zones of the dam and foundation which may require remediation.

AB.6.3.9 Estimate the deformation response of the embankment dam and the post earthquake shape of the embankment by using an appropriate 2D and/or 3D finite element or other appropriate deformation analysis program.

AB.6.3.10 Remediation should be recommended when the embankment dam is

AB.6.3.10.1 found to have inadequate limit equilibrium slope stability factors of safety and/or

AB.6.3.10.2 projected to experience unacceptable deformations when subjected to the design earthquake and it is concluded that either situation would result in sudden, uncontrolled loss of the reservoir pool and loss of life.

AB.6.3.10.3 If remedial measures are recommended, establish the remediation requirements, evaluate various remediation alternatives, and select the most appropriate alternative.

AB.6.3.11 Perform additional post earthquake limit equilibrium slope stability and finite element analysis to determine preliminary remediation needs such as extent and location of remediation required, strength/resistance required and to determine the level of protection to be obtained by remediation.

AB.6.3.12 Evaluate various preliminary remediation alternatives and select the most appropriate alternatives for cost estimating purposes.

AB.6.3.13 Perform additional finite element deformation analyses to determine expected deformations in both remediated and non-remediated sections of the dam. Determine overall dam response and differential deformation.

AB.6.3.14 Develop detailed scope, cost, and schedule for PED phase (Preconstruction Engineering and Design) which includes preparation of design documentation and plans and specifications (P&S).

AB.6.3.15 Conduct a PCCR for the Phase II study.

AB.6.3.16 Prepare the Phase II study summary. This is the basis for a technical appendix to the DSMR. The suggested format and content for the Phase II summary is described in Paragraph AB.6.4 below.

AB.6.4 Phase II Study Documentation. A detailed summary of the entire evaluation process including the Phase II study must be included as a Technical Appendix to the IES Report. To facilitate the Phase II PCCR, a summary should be developed and presented at the PCCR in the general format and scope indicated as follows:

AB.6.4.1 Introduction

AB.6.4.1.1 Authorization

AB.6.4.1.2 Purpose

AB.6.4.1.3 Project Description

AB.6.4.1.4 Method of Analysis

AB.6.4.2 Static Stress Analyses

AB.6.4.2.1 General

AB.6.4.2.2 Development of Static Properties of the Dam

AB.6.4.2.3 Results of Static Stress Analyses

AB.6.4.3 Design Earthquake Motions

AB.6.4.3.1 General

AB.6.4.3.2 Design Earthquake and Ground Motions

AB.6.4.3.2.1 Response Spectra

AB.6.4.3.2.2 Time Histories

AB.6.4.4 Dynamic Response Analyses

AB.6.4.4.1 General

AB.6.4.4.2 Field and Laboratory Tests and Results

AB.6.4.4.3 Development of Dynamic Properties

AB.6.4.4.4 Dynamic Analyses

AB.6.4.4.5 Dynamic Response

Figure AB.1 – Seismic Analysis Process

APPENDIX AC

Seismic Safety Evaluation Process for Concrete Structures and Foundations

AC.1 Seismic Safety Review.

AC.1.1 General.

AC.1.1.1 Types and levels of programs for seismic evaluation of concrete dams needed at various times and for various purposes start with a Seismic Safety Review (SSR) and may be followed by special studies consisting of preliminary seismologic investigations coupled with simplified seismic evaluations (Phase I), full seismologic investigations and dynamic analysis of the project (Phase II), and preparation of design documents, plans and specifications (Phase III). Flexible guidelines, consistent with the policy in paragraph 5.b.of ER 1110-2-1806 are needed to permit experienced investigators to do the best practical and economical job for each specific situation.

AC.1.1.2 A review is required to identify specific problem areas and establish priorities for further study. Generally, Seismic Safety Reviews are based on evaluations of available pertinent data and surface inspections. Seldom do SSR level investigations include extensive exploratory or testing provisions.

AC.1.2 Project Description. Briefly describe the project, including type of dam or major structure and seismic zone. Enclose a location map and the tabulated pertinent project data. Describe design and current project operations.

AC.1.3 Geology/Seismicity. Describe site specific geology and provide current detailed seismicity of the site including faulting, seismic evaluation parameters used in the design and changes or experienced shaking at site based on a search of existing project files and current professional literature. Describe site specific ground motion data.

AC.1.4 Structural Investigations. Summarize structural design and results of recent analyses, if available. Describe those analyses used to conduct the evaluation.

AC.1.5 Evaluation. Provide diagnostic seismic evaluation of the structure and foundation based on the data presented. Evaluate post-seismic stability. Develop a basis for decision on the need for and justification of additional studies or departure from further studies of risk assessment based on probabilities of occurrence of earthquakes, operating pool elevations and structural failure.

AC.1.6 E&D Cost Estimate and Schedule. Provide scope of recommended studies and associated study costs and schedule.

AC.1.7 Conclusions and Recommendations. Provide conclusions and specific recommendations based on existing data evaluations. Schedule and conduct PCCR.

AC.2 Phase I – Special Study Content.

AC.2.1 Project Authorization. Reference the Project Guidance Memo (PGM) from the Policy Compliance & Criteria Review (PCCR) of the SSR for the project.

AC.2.2 Project Description. Briefly describe the project, including type of structures. Provide tabulated pertinent project data. Describe design and current project operations.

AC.2.3 Purpose and Scope. Describe the purpose of the study, scope, and deficiency identified in the SSR.

AC.2.4 Seismologic Investigations. Provide detailed seismologic study results, including fault study investigations, related field investigations, and laboratory studies.

AC.2.5 Seismicity. Develop design earthquakes in relation to active fault systems and their activity.

AC.2.6 Seismic Evaluation. Provide seismic evaluation of features subjected to design earthquakes. Provide basis for selection of parameters, method of analysis, and rationale for the decision on seismic assessment of the project.

AC.2.7 Conclusions and Recommendations. Develop conclusions and recommendations for terminating the study or proceeding to a Phase II seismic evaluation in accordance with the requirements of ER 1110-2-1806.

AC.2.8 Cost Estimate and Schedule. Provide scope, cost estimate, and schedule of recommended Phase II studies. Conduct the PCCR.

AC.3 Phase II – Special Study Guidelines for Dynamic Analysis of Concrete Structures.

AC.3.1 Design Earthquakes and Ground Motions. Design earthquakes and ground motions for the seismic evaluations of concrete dams and appurtenant structures shall be determined in accordance with ER 1110-2-1806, paragraphs 5.h., 6 and 8.f. The study scope shall be consistent with the PGM for the Phase I PCCR.

AC.3.2 Dynamic Analyses of Existing Structures and Proposed Remedial Alternatives.

AC.3.2.1 Review the candidate earthquake, location, and ground motions for most severe conditions to concrete structures.

AC.3.2.2 Select design response spectra.

AC.3.2.3 Select appropriate acceleration-time history records compatible with the design response spectra.

AC.3.2.4 Select dynamic properties for the concrete and foundation.

AC.3.2.5 Analyze and evaluate any cracking.

AC.3.2.6 Follow guidance in the current technical guidance and EM appropriate for that concrete structure.

AC.3.3 Conclusions and Recommendations. Discuss remedial alternatives in the DSMR and selection of remediation plan to be developed in Phase III Plans and Specifications. Provide a summary of the Phase II studies in the DSMR

AC.4 Phase II – Special Study Content.

AC.4.1 Introduction.

AC.4.1.1 Authorization

AC.4.1.2 Purpose

AC.4.1.3 Project Description

AC.4.1.4 Method of Analysis

AC.4.2 Static Finite Element Analysis.

AC.4.2.1 General

AC.4.2.2 Development of Static Properties

AC.4.2.3 Results of Static FEM Analyses

AC.4.3 Design Earthquake Motions

AC.4.3.1 General

AC.4.3.2 Design Earthquake and Ground Motions

AC.4.3.3 Response Spectra

AC.4.3.4 Time Histories

AC.4.4 Dynamic Finite Element Analyses

AC.4.4.1 General

AC.4.4.2 Field and Laboratory Tests & Results

AC.4.4.3 Development of Dynamic Properties

AC.4.4.4 Dynamic Analyses

AC.4.4.5 Dynamic Response

AC.4.4.6 Evaluate Cracking in Concrete Structures

AC.4.4.7 Fracture Mechanics Analysis

AC.4.4.8 Non-Linear Analyses of Concrete Structures

AC.4.5 Seismic Stability Assessment

AC.4.5.1 Evaluation of Dynamic Strengths

AC.4.5.1.1 Laboratory Data

AC.4.5.1.2 Field Data

AC.4.5.2 Dynamic Structural Response

AC.4.5.3 Soil Structure

AC.4.5.4 Interaction of backfill, structure and piles

AC.4.5.5 Earthquake Induced Cracking Analyses

AC.4.6 Post Earthquake Stability Analyses

AC.4.6.1 General

AC.4.6.2 Evaluate Cracking in Concrete structures

AC.4.6.3 Evaluate Structural Stability

AC.4.6.4 Post Earthquake Stability

AC.4.7 Remediation

AC.4.7.1 General

AC.4.7.2 Alternatives

AC.4.7.3 Cost

AC.4.8 Summary

AC.4.9 Conclusions and Recommendations

AC.4.10 References

AC.4.11 Attachments

WTP ..... Willingness-to-pay-to-prevent-a-statistical-fatality

Terms

Abutment – That part of the valley side against which the dam is constructed. An artificial abutment is sometimes constructed as a concrete gravity section to take the thrust of an arch dam where there is no suitable natural abutment. The left and right abutments of dams are defined with the observer viewing the dam looking in the downstream direction, unless otherwise indicated.

Acceptable Risk – A risk, for the purposes of life or work, everyone who might be impacted is prepared to accept assuming no changes in risk control mechanisms. Such risk is regarded as insignificant and adequately controlled. Action to further reduce such risk is usually not required.

Acre-foot – A unit of volumetric measure that would cover 1 acre to a depth of 1 foot. It is equal to 43,560 cubic feet. This is approximately 325,851.4 U.S. gallons.

Adequately Safe Dam – A dam is adequately safe when the dam meets all essential USACE engineering guidelines and the residual risk is considered tolerable.

Adit – A nearly horizontal underground excavation in an abutment having an opening in only one end, such as an opening in the face of a dam for access to galleries or operating chambers.

Adverse Consequences – The outcome of the failure of a dam or its appurtenances, including immediate, short and long-term, direct and indirect losses and effects. Loss may include human casualties, project benefits, monetary and economic damages, and environmental impact (Adapted from USACE).

Agency Technical Review (ATR) – An independent in-depth review designed to ensure the proper application of clearly established criteria, regulations, laws, codes, principles and professional practices. The ATR team reviews the various work products and assures that all the parts fit together in a coherent whole.

ATR Team – For dam safety studies, the ATR team shall include members from and be coordinated with the Dam Safety Risk Management Center (DSRMC) as well as recognized experts in the field of risk assessment outside of the DSRMC. The ATR team findings will be vetted with the MSC DSO, Dam Safety Risk Management Center, and HQUSACE.

Annual Inspections – Inspections conducted annually by the Operating Project staff with technical experts from Engineering or Operations (Reference ER 1130-2-500 (reference A.62)). The goal is to monitor the performance of the dam and note any evidence of changes in performance or needed dam safety related maintenance. Findings shall be documented and reviewed in support of Periodic Inspections (PI's) and Periodic Assessments (PA's).

Annual Probability of Failure (APF) – For dams the total estimated annual probability of failure from all failure modes associated with all loading or initiating event types that result in an unintentional release of the reservoir.

Annualized Life Lost (ALL) – As used in the f-N plot, the expected value (average) of potential life loss of the probability distribution of potential life loss from dam failure.

Appurtenant structure – Ancillary features of a dam such as inlet and outlet works, spillways, tunnels, or power plants.

As-Low-As-Reasonably-Practicable (ALARP) – That principle which states that risks, lower than the limit of tolerability, are tolerable only if risk reduction is impracticable or if its cost is grossly disproportional (depending on the level of risk) to the improvement gained.

Axis of dam – The vertical plane or curved surface, chosen by a designer, which appears as a line, in plan, or in cross-section, from which the horizontal dimensions of the dam are referenced.

Baffle block – A block, usually of concrete, constructed in a channel or stilling basin to dissipate the energy of water flowing at high velocity.

Baseline – The condition, data, or other representations of the topic of interest that will be used for comparison of 1) changes that may occur without intervention or as a result of a remediation alternative remediation and 2) changes and impacts estimated to result from intervention or remediation alternative. It is comprised of the existing conditions and such future projected conditions as chosen to be relevant for the comparison.

Baseline Component Risk Estimates – An Estimate of risk contributed by an individual credible failure mode that associated with the dam for given load combinations.

Baseline Consequence Analysis – Analysis of existing and future without remediation project consequences.

Baseline Risk Estimate – The baseline risk estimate is the risk estimate at a point in time.

Base thickness – Also referred to as base width. The maximum thickness or width of the dam measured horizontally between upstream and downstream faces and normal to the axis of the dam, but excluding projections for outlets, or other appurtenant structures.

Batter – Angle of inclination from the vertical.

Bedrock – The consolidated body of natural solid mineral matter which underlies the overburden soils.

Berm – A nearly horizontal step in the sloping profile of an embankment dam. Also a step in a rock or earth cut.

Borrow Area – The area from which natural materials, such as rock, gravel or soil, used for construction purposes is excavated.

Breach – An opening through a dam that allows the uncontrolled draining of a reservoir. A controlled breach is a constructed opening. An uncontrolled breach is an unintentional opening caused by discharge from the reservoir. A breach is generally associated with the partial or total failure of the dam.

Broadly Acceptable Risk – "Risks falling into this region are generally regarded as insignificant and adequately controlled. The levels of risk characterizing this region are comparable to those that people regard as insignificant or trivial in their daily lives. They are typical of the risk from activities that are inherently not very hazardous or from hazardous activities that can be, and are, readily controlled to produce very low risks" (HSE, 2001) (reference A.105). By the nature of the hazard that dams pose it is inappropriate to attempt to manage them as a broadly acceptable risk and therefore the concept of the broadly acceptable risk level or limit does not apply to dams.

Catastrophe – A sudden and great disaster causing misfortune, destruction, or irreplaceable loss extensive enough to cripple activities in an area.

Channel – A general term for any natural or artificial facility for conveying water.

Cofferdam – A temporary structure enclosing all or part of the construction area so that construction can proceed in the dry. A diversion cofferdam diverts a river into a pipe, channel, or tunnel.

Compaction – Mechanical action, which increases the density by reducing the voids in a material.

Component Risks – Estimates of risk contributed by the physical components of a dam undergoing failure mode analysis for a remediation alternative.

Concept of Disproportionality – Entails the use of two measures associated with the 'statistical life' concept. The first is the cost effectiveness measure called, "cost-to-save-a-statistical-life" (CSSL). The second measure is the "willingness-to-pay-to-prevent-a-statistical fatality" (WPSF) or as sometimes used in the United States "the value to save a life" (VSL). The characterization of the sacrifice is based in part on the ratio of the CSSL estimate for a risk reduction measure to the WPSF value as an approximate efficiency measure.

Conditional Load Response Probabilities – Response probabilities (of failure) corresponding to the conditional load type and scenario under investigation.

Conditionally Unsafe – Assertion that the existence or occurrence of one thing or event (e.g., initiation of dam failure) depends on the existence or occurrence of another thing or event (e.g., extreme flood or extreme seismic event).

Conditional System Response Probability Estimates – System response probabilities that are conditional on the specific loading condition analyzed (over the range of loading conditions to be studied).

Conduit – A closed channel to convey water through, around, or under a dam.

Confirmed (Unconfirmed) – Through investigation or other means, Dam Safety issue is firmly established as of concern or not. Unconfirmed – not confirmed.

Confirmed Dam Safety Issues – Manifested or obvious issues are those impacting the safe operation of a dam. Examples of confirmed issues can be described as performance concerns - lack of spillway or seismic capacity, or deficiencies that are demonstrated by signs of seepage and boils, obvious flaws or defects, component distress or malfunction, unusual settlement, unsatisfactory instrument readings, etc. that can be specifically linked to one or more potential failure modes.

Conservation Pool – The permanent pool that lies just below the flood storage pool in a reservoir.

Construction Joint – The interface between two successive placings or pours of concrete where bond, and not permanent separation, is intended.

Contact Grouting – Filling, with cement grout, any voids existing at the contact of two zones of different materials, e.g., between a concrete tunnel lining and the surrounding rock.

Contractor Quality Control (CQC) – The construction contractor's system to manage, control, and document his own, his supplier's, and his subcontractor's activities to comply with contract requirements.

Core – A zone of low permeability material in an embankment dam. The core is sometimes referred to as central core, inclined core, puddle clay core, rolled clay core, or impervious zone.

Core Wall – A wall built of relatively impervious material, usually of concrete or asphaltic concrete, in the body of an embankment dam to prevent seepage.

Cost-to-Save-a-Statistical-Life (CSSL) – CSSL is the ratio of the cost of a proposed risk reduction measure divided by the consequent estimate of 'Statistical Lives Saved'.

Credible Baseline Risk Estimate – Occurs when the conditional load response probabilities and consequences used to estimate the total project risk are supported by sufficient data, analysis, and performance history. The need for additional information, studies, and investigations to determine or resolve uncertainty should be determined after parametric studies are completed and insight is gained as to improvement in the confidence of the risk estimate by more accurately predicting conditional load response

probabilities or life loss estimates. Typically, risk estimates for confirmed issues can be established with existing data and performance history because the physical manifestations are visual and measurable. Unconfirmed issues may require the collection of additional data if the concerns are less obvious or cannot be linked to a specific failure mode or observation.

Credible Failure Mode – A physically plausible failure mode.

Crest of dam – See top of dam.

Critically near failure – Failure sequence has been initiated and continues under normal loading. Without intervention (e.g., interim risk reduction measures or remediation), dam is expected to fail.

Cross section – An elevation view of a dam formed by passing a plane through the dam perpendicular to the axis.

Cutoff trench – A foundation excavation later to be filled with impervious material so as to limit seepage beneath a dam.

Cutoff wall – A wall of impervious material usually of concrete, asphaltic concrete, or steel sheet piling constructed in the foundation and abutments to reduce seepage beneath and adjacent to the dam.

Dam – An artificial barrier, including appurtenant works, constructed for the purpose of storage, control, or diversion of water, and which (1) is twenty-five feet or more in height from the natural bed of the stream or watercourse measured at the downstream toe of the barrier or from the lowest elevation of the outside limit of the barrier if it is not across a stream channel or watercourse, to the maximum water storage elevation or (2) has an impounding capacity at maximum water storage elevation of fifty acre-feet or more. Any such barrier which is under six feet in height regardless of storage capacity, or which has a storage capacity at maximum water storage elevation not in excess of fifteen acre-feet regardless of height is not considered a dam. This lower size limitation should be waived if there is a potentially significant downstream hazard.

This definition applies whether the dam has a permanent reservoir or is a detention dam for temporary storage of floodwaters. The impounding capacity at maximum water storage elevation includes storage of floodwaters above the normal full storage elevation. Various types of dams include the following:

a. *Afterbay dam.* See regulating dam.

b. *Ambursen dam*. A buttress dam in which the upstream part is a relatively thin flat slab usually made of reinforced concrete.

c. *Arch dam. A c*oncrete or masonry dam, which is curved upstream so as to transmit the major part of the water load to the abutments.

d. *Buttress dam.* A dam consisting of a watertight part supported at intervals on the downstream side by a series of buttresses. A buttress dam can take many forms, such as a flat slab or a massive head buttress.

e. *Cofferdam.* A temporary structure enclosing all or part of the construction area so that construction can proceed in the dry. A diversion cofferdam diverts a stream into a pipe, channel, tunnel, or other watercourse.

f. *Crib dam.* A gravity dam built up of boxes, crossed timbers, or gabions filled with earth or rock.

g. *Diversion dam.* A dam built to divert water from a waterway or stream into a different watercourse.

h. *Double curvature arch dam.* An arch dam, which is curved vertically as well as horizontally.

i. *Earth dam.* An embankment dam in which more than 50 percent of the total volume is formed of compacted earth material generally smaller than 3-inch size.

j. *Embankment dam.* Any dam constructed of excavated natural materials or of industrial waste materials.

k. *Gravity dam.* A dam constructed of concrete and/or masonry, which relies on its weight and internal strength for stability.

l. *Hollow gravity dam.* A dam constructed of concrete and/or masonry on the outside but having a hollow interior and relying on its weight for stability.

m. *Hydraulic fill dam.* An earth dam constructed of materials, often dredged, which are conveyed and placed by suspension in flowing water.

n. *Industrial waste dam.* An embankment dam, usually built in stages, to create storage for the disposal of waste products from an industrial process. The waste products are conveyed as fine material suspended in water to the reservoir impounded by the embankment. The embankment may be built of conventional materials but sometimes incorporates suitable waste products.

o. *Masonry dam.* Any dam constructed mainly of stone, brick, or concrete blocks jointed with mortar. A dam having only a masonry facing should not be referred to as a masonry dam.

p. *Mine tailings dam.* An industrial waste dam in which the waste materials come from mining operations or mineral processing.

q. *Multiple arch dam.* A buttress dam composed of a series of arches for the upstream face.

r. *Overflow dam.* A dam designed to be overtopped.

s. *Regulating dam.* A dam impounding a reservoir from which water is released to regulate the flow downstream.

t. *Rockfill dam.* An embankment dam in which more than 50 percent of the total volume is composed of compacted or dumped cobbles, boulders, rock fragments, or quarried rock generally larger than 3-inch size.

u. *Roller-compacted concrete dam.* A concrete gravity dam constructed by the use of a dry mix concrete transported by conventional construction equipment and compacted by rolling, usually with vibratory rollers.

v. *Rubble dam.* A stone masonry dam in which the stones are unshaped or uncoursed.

w. *Saddle dam (or dike).* A subsidiary dam of any type constructed across a saddle or low point on the perimeter of a reservoir.

x. *Tailings dam.* See mine tailings dam.

Dam failure – Failure characterized by the sudden, rapid, and uncontrolled release of impounded water. It is recognized that there are lesser degrees of failure and that any malfunction or abnormality outside the design assumptions and parameters that adversely affect a dam's primary function of impounding water is properly considered a failure. These lesser degrees of failure can lead to loss of services and progressively lead to or heighten the risk of a catastrophic failure.

Dam Safety – Dam safety is the art and science of ensuring the integrity and viability of dams such that they do not present unacceptable risks to the public, property, and the environment. It requires the collective application of engineering principles and experience, and a philosophy of risk management that recognizes that a dam is a structure whose safe functioning is not explicitly determined by its original design and construction. It also includes all actions taken to identify or predict deficiencies and consequences related to failure, and to document, publicize, and reduce, eliminate, or remediate to the extent reasonably possible any unacceptable risks.

Dam Safety Action Classification (DSAC) System – The Dam Safety Action Classification system is intended to provide consistent and systematic guidelines for appropriate actions to address the dam safety issues and deficiencies of USACE dams.

USACE dams are placed into a Dam Safety Action Classification (DSAC) class based on their individual dam safety risk considered as a combination of probability of failure and potential life safety, economic, environmental, or other consequences. The DSAC table presents different levels and urgencies of actions that are commensurate with the different classes of the safety status of USACE dams. These actions range from immediate recognition of an urgent and compelling situation requiring extraordinary and immediate action for unsafe dams through normal operations and dam safety activities for safe dams.

Dam Safety Committee – The Dam Safety Committee includes the Dam Safety Officer (DSO) and the Dam Safety Program Manager (DSPM) plus additional members as required. The members should include various technical engineering disciplines from within the district. Other disciplines and areas of expertise may be represented, as required by the DSO or Commander. There is a standing Dam Safety Committee at each level of the decentralized USACE program (districts, divisions, and HQ), who convening regularly to discuss dam safety project and program matters, and advice the Commander on critical dam safety related decisions.

Dam Safety Community of Practice Steering Committee (DSSC) – A committee charged with facilitating and promoting dam safety as a fundamental USACE mission in all levels of the organization, promoting dam safety career development, disseminating pertinent information throughout USACE, and reviewing and evaluating policy, technical criteria and practices, administrative procedures, and regulatory functions to support the USACE dam safety program. The DSSC reviews experience and qualifications of dam safety staffing at all levels within the USACE to assess competency, serves as a resource for sharing information and project specific Lessons Learned, and makes recommendations for future research and development in areas related to dam safety. The team shall meet as required, and shall provide advice and information to the Special Assistant for Dam and Levee Safety.

Dam Safety Deficiency – A material defect or load capacity limit that threatens a dam failure.

Dam Safety Issue – Any confirmed or not yet confirmed condition at a dam that could result in intolerable life safety, economic, and environmental risks.

Dam Safety Modification Risk Assessment – The risk assessment addresses the life safety, economic, and environmental risks associated with the identified potential failure modes and the risk reduction that can be achieved with risk reduction measures, including potential staged implementation options.

Dam Safety Modification Study – The safety case that presents the investigation, documentation, and justification of modifications for dam safety at completed Corps of Engineers projects. The report presents the formulation and evaluation for a full range of risk reduction alternatives with preliminary level cost estimates. A detailed risk assessment is required to look at incremental risk reduction alternatives that together

meet the tolerable risk guidelines and cost effectiveness of additional risk reduction below the minimum safety criteria. However, the level of detail should only be what is needed to justify the modification decision. Related NEPA (reference A.109) and ESA studies will be conducted during the Modification Study, in support of the recommended risk reduction measures. The resultant Dam Safety Modification Decision Document will present a comparison of alternatives and the recommended risk management plan to include actions, components, risk reduction by increments, implementation plan, detailed cost estimate, NEPA, and ESA determinations.

Dam Safety Officer – A registered professional civil engineer with management abilities who is competent in the areas related to the design, construction, operation, inspection or evaluation of dams. They must understand adverse dam incidents and the potential causes and consequences of dam failure. The DSO is the highest-ranking Registered Professional Engineer in each level of the Corps of Engineers responsible for implementing the dam safety program of that organization. The Commander shall ensure the DSO meets the technical qualifications and experience. The DSO is the Chair of the Dam Safety Committee.

Dam safety preparedness – The quality or state of being prepared to deal with emergency conditions which endanger the structural integrity of the dam and/or downstream property and human life.

Dam Safety Portfolio Risk Management – The management process shown generally on Figure 2.3 and for USACE in detail on Figure 3.1. It is a risk-informed USACE-wide portfolio perspective process applied to all features of all dams on a continuing basis.

Dam Safety Program – The purposes of a dam safety program are to protect life, property, and the environment by ensuring that all dams are designed, constructed, operated, and maintained as safely and effectively as is reasonably possible. Accomplishing these purposes require commitments to continually inspect, evaluate, and document the design, construction, operations, maintenance, rehabilitation, and emergency preparedness of each dam and the associated public. It also requires the archiving of documents on the inspections and history of dams and the training of personnel who inspect, evaluate, operate, and maintain them. Programs must instill an awareness of dams and the potential hazard that they may present in the owners, the users, the public, and the local and national decision-makers. On both local and national scales, program purposes also include periodic reporting on the degree of program implementation. Key to accomplishing these purposes is to attract, train, and retain a staff proficient in the art and science of dam design.

Dam Safety Program Management Tools – A shared software database, developed and maintained by USACE on behalf of FEMA, used for managing and monitoring Dam Safety Programs. It is used by multiple Federal and State agencies, to track program accomplishments, including entering data for the National Inventory of Dams and preparing the Federal Dam Safety Biennial Report to Congress.

Dam Safety Program Manager (DSPM) – The DSPM is a Dam Safety official at the HQUSACE, MSC, and district level responsible for the overall daily management of the Dam Safety program. These managers normally support and report to the Dam Safety Officer at their respective level.

Dam Safety Senior Oversight Group (SOG) – Designated USACE Dam Safety senior headquarters and field staff team that performs an oversight function for the Dam Safety program. The SOG meets periodically to advise the Dam Safety Officer on key issues related to the program, such as determining Dam Safety Action Classifications. The SOG generally consists of the following members: Special Assistant for Dam and Levee Safety (Chair); USACE CoP leaders (for Geotechnical, Structural and H&H technical disciplines); Regional representatives determined by Special Assistant for Dam and Levee Safety; USACE Business Line & Program Representatives to include USACE DSPM, Flood Damage Reduction, Navigation, Programs, and Dam Safety Risk Management Center Director; and any other Representatives determined by the Special Assistant for Dam and Levee Safety. The Senior Oversight Group is established to vet the findings of the Regional Risk Cadres and confirm dam safety work priorities based on portfolio risk findings.

Design Structural Capacity – The maximum loading condition that the project was planned to withstand, although the project may fail at a lesser loading condition

Design water level – The maximum water elevation including the flood surcharge that a dam is designed to withstand.

Design wind – The most severe wind that is reasonably possible at a particular reservoir for generating wind setup and run-up. The determination will generally include the results of meteorological studies, which combine wind velocity, duration, direction, and seasonal distribution characteristics in a realistic manner.

Diaphragm wall (membrane) – A sheet, thin zone, or facing made of an impervious material such as concrete, steel, wood, or plastic. Also see core wall.

Dike – See Dam, w. *saddle dam.*

Direct Economic Losses – Direct economic losses are the damage to property located downstream from the dam due to the failure. Items in this category include those commonly computed for the National Economic Development (NED) account in any USACE flood risk management study. These include damage to private and public buildings, contents of buildings, vehicles, public infrastructure such as roads and bridges, public utility infrastructure, agricultural crops, agricultural capital, and erosion losses to land.

Disproportionality Ratio – See definition for 'Concept of Disproportionality'.

Diversion channel, canal, or tunnel – A waterway used to divert water from its natural course. The term is generally applied to a temporary arrangement, e.g., to by-pass

water around a dam site during construction. “Channel” is normally used instead of “canal” when the waterway is short.

Drain, blanket – A layer of pervious material placed to facilitate drainage of the foundation and/or embankment.

Drain, chimney – A vertical or inclined layer of pervious material in an embankment to facilitate and control drainage of the embankment fill.

Drain, toe – A system of pipe and/or pervious material along the downstream toe of a dam used to collect seepage from the foundation and embankment and convey it to a free outlet.

Drainage area – The area, which drains to a particular point on a river or stream.
Drainage curtain – Also called drainage wells or relief wells. A line of vertical wells or boreholes placed to facilitate drainage of the foundation and abutments and to reduce water pressure.

Drawdown – The difference between a water level and a lower water level in a reservoir within a particular time. Used as a verb, it is the lowering of the water surface.
DSAC Class I (Urgent and Compelling) – Dams where progression toward failure is confirmed to be taking place under normal operations and the dam is almost certain to fail under normal operations within a time frame from immediately to within a few years without intervention; or, the combination of life or economic consequences with probability of failure is extremely high.

DSAC Class II (Urgent) – Dams where failure could begin during normal operations or be initiated as the consequence of an event. The likelihood of failure from one of these occurrences, prior to remediation, is too high to assure public safety; or, the combination of life or economic consequences with probability of failure is very high.

DSAC Class III (High Priority) – Dams that have issues where the dam is significantly inadequate or the combination of life, economic, or environmental consequences with probability of failure is moderate to high.

DSAC Class IV (Priority) – Dams are inadequate with low risk such that the combination of life, economic, or environmental consequences with a probability of failure is low and the dam may not meet all essential USACE engineering guidelines.

DSAC Class V (Normal) – Dams considered adequately safe, meeting all essential agency guidelines and the residual risk is considered tolerable.

Earthquake – A sudden motion or trembling in the earth caused by the abrupt release of accumulated stress along a fault.

Earthquake, Maximum Credible (MCE) – The most severe earthquake that can be expected to occur at a given site on the basis of geologic and seismological evidence.

Earthquake, Maximum Design (MDE) – A postulated seismic event, specified in terms of specific bedrock motion parameters at a given site, which is used to evaluate the seismic resistance of man-made structures or other features at the site.

Earthquake, Operating Basis (OBE) – The earthquake(s) for which the structure is designed to resist and remain operational. It reflects the level of earthquake protection desired for operational or economic reasons and may be determined on a probabilistic basis considering the regional and local geology and seismology.

Earthquake, Safety Evaluation (SEE) – The earthquake, expressed in terms of magnitude and closest distance from the dam site or in terms of the characteristics of the time history of free-field ground motions, for which the safety of the dam and critical structures associated with the dam are to be evaluated. In many cases, this earthquake will be the maximum credible earthquake to which the dam will be exposed. However, in other cases where the possible sources of ground motion are not easily apparent, it may be a motion with prescribed characteristics selected on the basis of a probabilistic assessment of the ground motions that may occur in the vicinity of the dam. To be considered safe, it should be demonstrated that the dam can withstand this level of earthquake shaking without release of water from the reservoir.

Earthquake, synthetic – Earthquake time history records developed from mathematical models that use white noise, filtered white noise, and stationary and non-stationary filtered white noise, or theoretical seismic source models of failure in the fault zone. (White noise is random energy containing all frequency components in equal proportions. Stationary white noise is random energy with statistical characteristics that do not vary with time).

Economic Consequences – Direct and indirect losses of the failure of a dam and other economic impacts on the regional or national economy. Part of the direct losses is the damage to property located downstream from the dam due to the failure. Items in this category include those commonly computed for the National Economic Development (NED) account in any USACE flood risk management study.

Economic Damages – These include damage to private and public buildings, contents of buildings, vehicles, public infrastructure such as roads and bridges, public utility infrastructure, agricultural crops, agricultural capital, and erosion losses to land.

Economic Regret – Condition when the costs of making a “wrong” decision are deemed to be high. The basic concept of regret is the difference between the outcome of the "best alternative for a future, uncertain state" and outcome of each alternative evaluated

for that state. So it is really the potential costs, if you choose an alternative as the best given some future scenario, and a different future actually happens. All regret values are determined by comparing each alternative to the best (e.g. maximum net benefits) for a scenario. So you end up with a regret matrix with scenarios as column headings and alternatives as row headings. There is nothing in the notion about regret about it being "too high." The minimax principle is usually applied to regret to identify the plan or plans that are robust across multiple future scenarios.

Efficiency – Efficiency is the need for society to distribute and use available resources so as to achieve the greatest benefit. For dam safety investments, this means ensuring that resources and expenditure directed to safety improvements are cost-effective and that an appropriate balance between the monetary and non-monetary benefits and the monetary and non-monetary costs is achieved.

Embankment – A raised structure of earth, rocks, or gravel, usually intended to retain water or carry a roadway.

Emergency – An emergency, in terms of dam operation, is a condition, which develops unexpectedly, endangers the structural integrity of the dam and/or downstream property and human life, and requires immediate action.

Emergency Action Plan (EAP) – An action plan that provides detailed instructions for agencies and individuals for responding to emergencies such as a potential dam failure. Plans typically include threat recognition, emergency action message formulation, message dissemination to authorities and the public, provisions for search and rescue, and early stages of recovery.

Emergency Exercise – Drill – A drill is the lowest level exercise that involves an actual exercise. It tests, develops, or maintains skills in a single emergency response procedure. An example of a drill is an in-house exercise performed to verify the validity of telephone numbers and other means of communication along with the response of the entity responsible for the dam. A drill is considered a necessary part of ongoing training.

Emergency Exercise – Full Scale – The full scale exercise is the most complex level of exercise. It evaluates the operational capability of all facets of the emergency management system (both dam operator and state and local emergency management agencies) interactively in a stressful environment with the actual mobilization of personnel and resources. It includes deployment to and movement in the field of personnel and equipment to demonstrate coordination and response capability. The participants actively "play out" their roles in a dynamic environment that provides the highest degree of realism possible for the simulated event. Actual evacuation of critical residents may be exercised if previously announced to the public.

Emergency Exercise – Functional – The functional exercise is the highest level exercise that does not involve the full activation of the entity responsible for dam operation and

state and local emergency management agency field personnel and facilities or test evacuation of residents downstream of the dam. It involves the various levels of the entity responsible for dam operation and state and local emergency management personnel that would be involved in an actual emergency. The functional exercise takes place in a stress-induced environment with time constraints and involves the simulation of a dam failure and other specified events. The participants "act out" their actual roles. The exercise is designed to evaluate both the internal capabilities and responses of the entity responsible for dam operation and the workability of the information in the EAP used by the emergency management officials to carry out their responsibilities. The functional exercise also is designed to evaluate the coordination activities between the entity responsible for dam operation and emergency management personnel.

Emergency Exercise – Orientation Seminar – This exercise is a seminar that involves bringing together those with a role or interest in an EAP, *i.e*., entity responsible for dam operation and state and local emergency management agencies, to discuss the EAP and initial plans for an annual drill or more in-depth comprehensive exercise. The seminar does not involve an actual exercise of the EAP. Instead, it is a meeting that enables each participant to become familiar with the EAP and the roles, responsibilities, and procedures of those involved. An orientation seminar can also be used to discuss and describe technical matters with involved, non-technical personnel.

Emergency Exercise – Tabletop – The tabletop exercise involves a meeting of the entity responsible for dam operation and the state and local emergency management officials in a conference room environment. The format is usually informal with minimum stress involved. The exercise begins with the description of a simulated event and proceeds with discussions by the participants to evaluate the EAP and response procedures and to resolve concerns regarding coordination and responsibilities.

Endangered Species Act (ESA) – The Endangered Species Act of 1973 (7 U.S.C. § 136, 16 U.S.C. § 1531 et seq.) or ESA is the most wide-ranging of the dozens of United States environmental laws passed in the 1970s. As stated in section 2 of the act, it was designed to protect critically imperiled species from extinction as a "consequence of economic growth and development untendered by adequate concern and conservation." See ER 1105-2-100 Appendix C (reference A.42) for detailed discussion.

Energy dissipater – A device constructed in a waterway to reduce the kinetic energy of fast flowing water.

Environmental and other Non-monetary Consequences – Direct and indirect consequences that cannot be measured in monetary terms. These stem from the impacts of the dam failure flood and loss of pool on environmental, cultural, and historic resources. In most cases, the assessment of the impacts of dam failure will be the reporting of area and type of habitat impacted, habitat of threatened and endangered species impacted, number and type of h

Environmental Impact Statement (EIS) – An environmental impact statement, in the United States, is a document that must be filed when the federal government takes a "major Federal action significantly affecting the quality of the human environment." The law requiring this is the National Environmental Policy Act. See ER 200-2-2 (reference A.37) and ER 1105-2-100, Appendix C (reference A.42), for details on preparation of EIS.

Epicenter – The point on the earth's surface located vertically above the point of origin of an earthquake.

Equity in Risk Management – Equity, in the risk management context, is the right of individuals and society to be protected, and the right that the interests of all are treated with fairness, placing all members of society on a (more) equal footing in terms of levels of risk faced. The equity objective is addressed by requiring that all risks higher than a limit value be brought down to below the limit, except in exceptional circumstances.
Essential Agency Guidelines – The state-of-practice for design, construction, operation, and maintenance of USACE dams as documented in current USACE regulations. The requirements specified in these USACE regulations must be met for a dam to achieve DSAC V (Adequately Safe) classification status. These regulations include: Engineer Circulars, Engineer Regulations, Engineer Manuals, Engineer Pamphlets and Engineer Technical Letters; and Engineering and Construction Bulletins, and other official HQUSACE dam safety-related Policy Letters and guidance. Current state-of-practice guidance is summarized in Appendix E.

Event Tree(s) – An event tree serves as a model of the physical dam system in which each node represents an identifiable behavior of the dam or its physical components and each event should be something that happens in space or time (Hartford and Baecher, 2004). An event tree begins with a single initiating branch on the left hand side and progress toward more detailed events to the right hand side. Starting with an initiating event branch (e.g. a severe flood, an earthquake or other natural or human caused hazards), each node is divided at various nodes to generate all possible subsequent events. Each node is an origin of possible subsequent events and each branch is a possible event that is a logical consequence of the one before it, and a necessary precursor of the one that follows. As the number of events increases, structure fans outs like the branches of a tree until each event tree chain comes to a terminal branch. Terminal branches are the system outcome or system effect of an initiating event which leads to adverse consequences or failure of the system completely or partially. The tree may be extended to represent the economic damages and life loss consequences associated with the terminal branches.

Exposure Assessment – Exposure occurs when a susceptible asset comes in contact with a hazard. An exposure assessment, then, is the determination or estimation (which may be qualitative or quantitative) of the magnitude, frequency, or duration, and route of exposure.

Failure Mode – A way that failure can occur, described by the means by which element or component failures must occur to cause loss of the sub-system or system function of a dam that could result in failure.

Fault – A fracture or fracture zone in the earth crust along which there has been displacement of the two sides relative to one another.

Fault, active – A fault which, because of its present tectonic setting, can undergo movement from time to time in the immediate geologic future.

Fault, capable – An active fault that is judged capable of producing macro earthquakes and exhibits one or more of the following characteristics:

a. Movement at or near the ground surface at least once within the past 35,000 years.

b. Macroseismicity (3.5 magnitude Richter or greater) instrumentally determined with records of sufficient precision to demonstrate a direct relationship with the fault.

c. A structural relationship to a capable fault such that movement on one fault could be reasonably expected to cause movement on the other.

d. Established patterns of microseismicity, which define a fault, with historic macroseismicity that can reasonably, be associated with the fault.

Fetch – The straight-line distance across a body of water subject to wind forces. The fetch is one of the factors used in calculating wave heights in a reservoir.

Filter (filter zone) – One or more layers of granular material graded (either naturally or by selection) so as to allow seepage through or within the layers while preventing the migration of material from adjacent zones.

Flashboards – Structural members of timber, concrete, or steel placed in channels or on the crest of a spillway to raise the reservoir water level but that may be quickly removed in the event of a flood.

Flip bucket – An energy dissipater located at the downstream end of a spillway and shaped so that water flowing at a high velocity is deflected upwards in a trajectory away from the foundation of the spillway.

Flood – A general and temporary condition of partial or complete inundation of two or more acres of normally dry land area or of two or more properties from: (1) overflow of inland or tidal waters; (2) unusual and rapid accumulation or runoff of surface waters from any source; (3) mudflow; or (4) collapse or subsidence of land along the shore of a lake or similar body of water as a result of erosion or undermining caused by waves or currents of water exceeding anticipated cyclical levels that result in a flood as defined

above. The four terms below are used to further define flooding and efforts to prevent flooding.

a. *Flood Level.* The size of a flood may be expressed in terms of probability, of exceedance per year such as one percent chance flood or expressed as a fraction of the probable maximum flood or other reference flood.

b. *Flood Control.* The Flood Control Act of 1936 declared that flood control was a national priority since floods constituted a menace to the national welfare. This act authorized the construction of levees, floodwalls, channel improvements, and reservoirs to control flooding.

c. *Flood Damage Reduction.* The term flood damage reduction was adopted in recognition that the structures built for flood control only reduced the level of flooding and did not totally control all floods. Projects developed for flood damage reduction also include non-structural elements.

d. *Flood Risk Management.* This term recognizes that there are different levels of risks in flood control works and in flood damage reduction activities. Since all flood management structures and other features have a risk of failure, the current practice is to seek to reduce the risk to a tolerable level that the public is willing to accept.

Flood routing – A process of determining progressively over time the amplitude of a floodwave as it moves past a dam or downstream to successive points along a river or stream.

Flood, antecedent – A flood or series of floods assumed to occur prior to the occurrence of an inflow design flood.

Flood, base safety standard (BSS) – The inflow design flood where there is no significant increase in adverse consequences from dam failure compared to non-failure adverse consequences.

Flood, Safety Evaluation (SEF) – The largest flood for which the safety of a dam and appurtenant structure is to be evaluated.

Flood, Inflow Design (IDF) – The flood used in the design of a dam and its appurtenant works particularly for sizing the spillway and outlet works, and for determining maximum temporary storage and height of dam requirements.
Flood, Probable Maximum (PMF) – The most severe flood that is considered reasonably possible at a site as a result of meteorological and hydrologic conditions.

Floodplain – An area adjoining a body of water or natural stream that has been or may be covered by floodwater.

F-N chart (plot) – This chart is a plot of the annual probability of exceedance (greater than or equal to) of potential life loss (F) vs. incremental potential loss of life (N) due to failure compared to the no failure condition. Thus, the F-N chart displays the entire estimated probability distribution of life loss for a reservoir encompassing all failure modes and all population exposure scenarios for a particular reservoir. See figure 5.4.b.

Freeboard – Vertical distance between the design water level and the top of dam.

Full pool – The reservoir level that would be attained when the reservoir is fully utilized for all project purposes, including flood control.

Gallery – A passageway in the body of a dam used for inspection, foundation grouting, and/or drainage.

Gantry crane – A fixed or traveling bent-supported crane for handling heavy equipment.

Gate – A movable, watertight barrier for the control of water in a waterway. Types of gate include the following:

a. *Bascule gate.* See flap gate.

b. *Bulkhead gate.* A gate used either for temporary closure of a channel or conduit before dewatering it for inspection or maintenance or for closure against flowing water when the head difference is small, e.g., for diversion tunnel closure.

c. *Crest gate (spillway gate).* A gate on the crest of a spillway to control the discharge or reservoir water level.

d. *Drum gate.* A type of spillway gate consisting of a long hollow drum. The drum may be held in its raised position by the water pressure in a flotation chamber beneath the dam.

e. *Emergency gate.* A standby or auxiliary gate used when the normal means of water control is not available. Sometimes referred to as guard gate.

f. *Fixed wheel gate (fixed roller gate or fixed axle gate).* A gate having wheels or rollers mounted on the end posts of the gate. The wheels bear against rails fixed in side grooves or gate guides.

g. *Flap gate.* A gate hinged along one edge, usually either the top or bottom edge. Examples of bottom-hinged flap gates are tilting gates and fish belly gates so called from their shape in cross section.

h. *Flood gate.* A gate to control flood release from a reservoir.

i. *Outlet gate.* A gate controlling the flow of water through a reservoir outlet.

j. *Radial gate (tainter gate).* A gate with a curved upstream plate and radial arms hinged to piers or other supporting structure.

k. *Regulating gate (regulating valve).* A gate or valve that operates under full pressure flow conditions to regulate the rate of discharge.

l. *Roller drum gate.* See drum gate.

m. *Roller gate (stoney gate).* A gate for large openings that bears on a train of rollers in each gate guide.

n. *Skimmer gate.* A gate at the spillway crest whose prime purpose is to control the release of debris and logs with a limited amount of water. It is usually a bottom hinged flap or Bascule gate.

o. *Slide gate (sluice gate).* A gate that can be opened or closed by sliding in supporting guides.

Gate chamber – Also called valve chamber. A room from which a gate or valve can be operated, or sometimes in which the gate is located.

Geotextiles – Any fabric or textile (natural or synthetic) when used as an engineering material in conjunction with soil, foundations, or rock. Geotextiles have the following uses: drainage, filtration, separation of materials, reinforcement, moisture barriers, and erosion protection.

Groin – The area along the contact (or intersection) of the face of a dam with the abutments.

Grout – A fluidized material that is injected into soil, rock, concrete, or other construction material to seal openings and to lower the permeability and/or provide additional structural strength. There are four major types of grouting materials: chemical, cement, clay, and bitumen.

Grout curtain – One or more zones, usually thin, in the foundation into which grout is injected to reduce seepage under or around a dam.

Grout blanket – An area of the foundation systematically grouted to a uniform shallow depth.

Grout cap – A concrete pad constructed to facilitate subsequent pressure grouting of the grout curtain.

Hazard – Hazard is anything that is a potential source of harm to a valued asset (human, animal, natural, economic, social).

Hazard Characterization – Hazard Characterization is the qualitative and/or quantitative evaluation of the nature of the adverse effects associated with the identified hazard(s), which may be present in the situation of interest.

Hazard Identification – Hazard Identification identifies all biological, chemical, social, economic, and physical agents or natural/anthropogenic events capable of causing adverse effects on people, property, economy, culture, social structure, or environment.

Hazard potential classification – The rating for a dam based on the potential consequences of failure. The rating is based on potential for loss of life and damage to property that failure of that dam could cause. Such classification is related to the amount of development downstream of a dam.

HAZUS – A database and software system sponsored by the Federal Emergency Management Agency (FEMA) for performing a range of hazard analysis, including flood loss and impacts, for a variety of levels of detail regional wherein analysis supported by national databases; and site specific wherein local data be substituted for data that would come from national databases.

Head, static – The vertical distance between two points in a fluid.

Head, velocity – The vertical distance that would statically result from the velocity of a moving fluid.

Headrace – A free-flow tunnel or open channel that conveys water to the upper end of a penstock; hence, the terms “headrace tunnel” and ‘headrace Canal.”

Heel – The junction of the upstream face of a gravity or arch dam with the ground surface. For an embankment dam the junction is referred to as the upstream toe of the dam.

Height, above ground – The maximum height from natural ground surface to the top of a dam.

Height, dam – The dam height is the vertical distance between the lowest point on the crest of the dam and the lowest point in the original streambed.

Height, hydraulic – The vertical difference between the maximum design water level and the lowest point in the original streambed.

Height, structural – The vertical distance between the lowest point of the excavated foundation to the top of the dam.

Incident – An event occurrence at a dam that could potentially result in a dam safety issue, such as a spillway flood, seismic event, gate operation failure, etc. that should be documented and trigger an investigation.

Inclinometer – An instrument, usually consisting of a metal or plastic tube inserted in a drill hole and a sensitized monitor either lowered into the tube or fixed within the tube. This measures at different points the tube's inclination to the vertical. By integration, the lateral position at different Levels of the tube may be found relative to a point, usually the top or bottom of the tube, assumed to be fixed. The system may be used to measure settlement during embankment construction (Bartholomew, Murray, and Goins 1987). A reference benchmark is used to establish the top of the inclinometer casing. The instrument probe is lowered to each slip joint in the casing, and the depth to each joint is read directly off the tape. Settlement measurements are made as each section of casing is added during embankment construction.

Incremental consequences – Incremental consequences are associated with a failure of the project to provide the planned level of public protection plus any additional risk created by the project due to dam failure. Incremental consequences = (Consequences associated with the estimated performance of the project including failure) - (Consequence associated with the estimated performance of the project hypothetically without failure).

Independent External Peer Review Team – A team of experts selected in accordance with Section 2034 and/ Section 2035 of the Water Resources Development Act of 2007 (Public Law 110-114) to review proposed Civil Works projects and projects under construction.

Independent Technical Review (ITR) – A comprehensive independent review of a technical product (design and construction documents). .The ITR was replaced by an ATR level of review in 2009.

Indirect Economic Impacts – Impacts associated with the destruction of property and the displacement of people due to the failure. The destruction due to the failure flood can have significant impacts on the local and regional economy as businesses at least temporarily close resulting in loss of employment and income. Similarly, economic activity linked to the services provided by the dam will also have consequences. All these indirect losses then have ripple or multiplier effects in the rest of the regional and national economy due to the resulting reduction in spending on goods and services in the region. These losses are the increment to flood losses above those that would have would have occurred had the dam not failed.

Individual incremental life safety tolerable risk guideline (ANCOLD) – For existing dams, the individual risk to the person or group, which is most at risk, should be less than a limit value of 1 in 10,000 per year, except in exceptional circumstances, following the ANCOLD (2003) (reference A.80) individual life safety risk guideline. For new dams or major augmentations , the individual risk to the person or group, which is most at risk,

should be less than a limit value of 1 in 100,000 per year, except in exceptional circumstances, following the ANCOLD (2003) (reference A.80) individual life safety risk guideline. In the case of existing dams and new dams or major augmentations, individual risks are to be lower than the limit values to an extent determined in accordance with the ALARP principle.

Individual Risk – The increment of risk imposed on a particular individual by the existence of a hazardous facility. This increment of risk is an addition to the background risk to life, which the person would live with on a daily basis if the facility did not exist. (ANCOLD October 2003) (Reference A.80).

Initial reservoir filling – A deliberate impoundment to meet project purposes (a continuing process as successively higher pools are attained for flood control projects).

Institute for Water Resources – The U.S. Army Engineer Institute for Water Resources (IWR) was formed to provide forward-looking analysis and research in developing planning methodologies to aid the Civil Works program. Since its beginnings in 1969, the Institute was envisioned to provide the Corps with long-range planning capabilities to assist in improving the civil works planning process. Today the Institute continues to provide the Civil Works program with a variety of products to enhance the U.S. Army Engineer Institute for Water Resources development planning. IWR is comprised of several semi-independent Centers, and a senior staff of planning and policy experts. See http://www.iwr.usace.army.mil.

Instrumentation – An arrangement of devices installed into or near dams (i.e., piezometers, inclinometers, strain gages, measurement points, etc.), which provide for measurements that can be used to evaluate the structural behavior and performance parameters of the structure.

Intake – Any structure in a reservoir, dam, or river through which water can be discharged. Placed at the beginning of an outlet-works waterway (power conduit, water supply conduit), the intake establishes the ultimate drawdown level of the reservoir by the position and size of its opening(s) to the outlet works. The intake may be vertical or inclined towers, drop inlets, or submerged, box-shaped structures.

Intangible Consequences – These are consequences that have no directly observable physical dimensions but exist in the minds, individually and collectively, of those affected. Such consequences are real and can support decisions. Intangible consequences identified in ANCOLD (2003) (reference A.80) include such things as: the grief and loss suffered by relatives and friends of those who die; the impact of multiple deaths on the psyche of the community in which they lived; the stress involved in arranging alternative accommodations and income; the sense of loss by those who enjoyed the natural landscape destroyed; and the fear of lost status and reputation of the dam owning organization and its technical staff (see discussion at paragraph 5.3.10.3 and ANCOLD (2003) (reference A-83). The affect of these intangible

consequences can be observed more tangibly in terms of increased mental health expenditures and increased suicides.

Interagency Committee on Dam Safety – The Interagency Committee on Dam Safety (ICODS) is comprised of a representative of each of the Department of Agriculture, the Department of Defense, the Department of Energy, the Department of the Interior, the Department of Labor, the Federal Emergency Management Agency, the Federal Energy Regulatory Commission, the Nuclear Regulatory Commission, the Tennessee Valley Authority, and the United States Section of the International Boundary Commission. ICODS encourages the establishment and maintenance of effective Federal programs, policies, and guidelines intended to enhance dam safety for the protection of human life and property through coordination and information exchange among Federal agencies concerning implementation of the Federal Guidelines for Dam Safety (reference A.71).

Interim Risk Reduction Measure (IRRM) – Dam Safety Risk Reduction Measures that are to be formulated and undertaken for dams that are not considered to be tolerably safe and are intended as interim until more permanent remediation measures are implemented. Increased monitoring and reservoir restrictions are examples of interim measures that can be taken at a project.

Interim Risk Reduction Measures Plans (IRRMP) – Plans prepared by the districts for all DSAC Class I, II, and III dams. The urgency of submittal corresponds to the DSAC Class. In general, the plans will describe the project and area, dam safety issues, failure modes and analysis, interim risk reduction plans, consequences with and without the plan, schedule, cost, coordination and review documentation, updated emergency action plan, and communications plan.

Intervention – An action taken during the sequence of any failure mechanism either when failure has been initiated or later to prevent or delay completion of failure progression.

Inundation map – A map showing areas that would be affected by flooding from releases from a dam's reservoir. The flooding may be from either controlled or uncontrolled releases or as a result of a dam failure.

Issue Evaluation Studies – Issue Evaluation studies for dams classified in DSAC Classes II, III, and IV are studies to better determine the nature of the dam safety issue and the degree of urgency for action within the context of the full USACE inventory of dams. The intent of an Issue Evaluation Study is to perform a more robust and detailed level of risk assessment, than used in the SPRA that will enable informed decisions about the need for further investigations, the DSAC classification, and interim risk reduction measures implementation. However the level of detail should only be what is needed to justify the decision to pursue or not to pursue a dam safety modification study.

Lead Engineer – A professional engineer, engineering geologist, or geologist, qualified through appropriate technical training and experience, assigned the responsibility to lead the technical team members of a product delivery team. The lead engineer is responsible for working closely with the Project Manager and insuring that all technical requirements are addressed in the Project Management Plan (PMP). The lead engineer insure that the necessary field investigations are completed during the study and design phases; that plans and specifications are reviewed; that the technical comments on the design are properly addressed; and that engineers on the PDT visit the project during the construction phase. When possible the same individual should function as the lead engineer from the start of the dam safety studies until the completion of the modifications to the dam. (This definition is specifically for the dam safety program.)

Length of dam – The length along the top of the dam. This also includes the spillway, power plant, navigation lock, fish pass, etc., where these form part of the length of the dam. If detached from the dam these structures should not be included.

Levee – An embankment whose primary purpose is to furnish flood protection from seasonal high water. Embankments that are subject to water loading for prolonged periods or permanently should be designed in accordance with earth dam criteria.

Life Loss Consequences – This shall include the determination of the population at risk, threaten population, and the estimated potential loss of life.

Life Loss Estimates – Estimate of potential life loss using approved life loss estimating methodology. May be for individual failure modes, or total for specified loading scenario.

Life Safety Tolerable Risk Guidelines – Three types of life safety tolerable risk guidelines will be used under the USACE tolerable risk guidelines. Individual incremental life safety risk using probability of life loss and Societal incremental life safety risk express in two different ways - Probability distribution of potential life loss (F-N chart); Annualized Life Loss (ALL).

Likelihood – Used as a qualitative description of probability and frequency. (ICOLD) A description of the occurrence chance of a particular event.

Limit Line for Life Safety – Tolerable Risk Limit is depicted in Figures 5.4 and 5.5 of Chapter 5, Tolerable Risk Guidelines. It defines the limit line separating unacceptable risk from tolerable risk on F-N diagram.

Limit of Tolerability – Limit of Tolerability as depicted on Figure 5.1 of Chapter 5. It defines the limit line separating Intolerable Residual Risk from Tolerable Residual Risk within the range of tolerability conceptually depicting the ALARP principle.

Liquefaction – A condition whereby soil undergoes continued deformation at a constant

low residual stress or with low residual resistance, due to the buildup and maintenance of high pore water pressures, which reduces the effective confining pressure to a very low value. Pore pressure buildup leading to liquefaction may be due either to static or cyclic stress applications and the possibility of its occurrence will depend on the void ratio or relative density of a cohesionless or slightly cohesive soil and the confining pressure.

Logboom – A chain of logs, drums, or pontoons secured end-to-end and floating on the surface of a reservoir so as to divert floating debris, trash, and logs.

Marginally safe – Safe with reservations, barely within the lowest standards or limits of safety.

Maximum flood control level – The highest elevation of the flood control storage.

Maximum pool – The highest pool elevation resulting from the inflow design flood.

Maximum wave – The highest wave in a wave group.

Minimum operating level – The lowest level to which the reservoir is drawn down under normal operating conditions.

National Dam Safety Review Board – The National Dam Safety Review Board provides the Director of FEMA with advice in setting national dam safety priorities and considers the effects of national policy issues affecting dam safety. Review Board members include FEMA, the Chair of the Board; representatives from four federal agencies that serve on the Interagency Committee on Dam Safety (ICODS); five state dam safety officials; and one member from the private sector.

National Environmental Policy Act (NEPA) – The National Environmental Policy Act (NEPA) (reference A.109) requires federal agencies to integrate environmental values into their decision making processes by considering the environmental impacts of their proposed actions and reasonable alternatives to those actions. To meet NEPA requirements federal agencies prepare a detailed statement known as an Environmental Impact Statement (EIS). EPA reviews and comments on EIS's prepared by other federal agencies, maintains a national filing system for all EIS's, and assures that its own actions comply with NEPA.

National Inventory of Dams – The National Inventory of Dams (NID) contains information on approximately 79,000 dams throughout the U.S. that are more than 25 feet high, hold more than 50 acre-feet of water, or are considered a significant hazard if they fail. The NID is maintained and published by the U.S. Army Corps of Engineers with information from all 50 states, Puerto Rico, and 16 Federal agencies. The NID is available on the web at https://rsgis.crrel.usace.army.mil/apex/f?p=397:12:854569765989113.

Non-Structural Risk Reduction – Risk reduction by measures that do not require structural modification or construction related to the dam and its appurtenant works.

Normal Operations – Loading on the dam resulting from day-to-day pool operations to achieve authorized purposes. (For the purposes of a screening analysis for dry dams, or where pool elevations fluctuate widely and no historical normal pool elevation has been established, the normal loading is usually correlated to a 1 to 10 year return period.)

Observation well – A hole used to observe the groundwater surface at atmospheric pressure within soil or rock.

Operation restrictions – Changes to operating pool levels and durations, or reduced lockages, power generation, water supply, or conservation operations.

Outlet – An opening through which water can be freely discharged from a reservoir to the river for a particular purpose.

Outlet works – A dam appurtenance that provides release of water (generally controlled) from a reservoir.

Parametric Studies – Parametric studies execute one application many times with different sets of input parameters. Such studies are in-effect, systematic, carefully controlled sensitivity studies.

Parapet wall – A solid wall built along the top of a dam (upstream or downstream edge) used for ornamentation, for safety of vehicles and pedestrians, or to prevent overtopping caused by wave run-up.

Peer Review – Peer review is a form of deliberation involving an exchange of judgments about the appropriateness of methods and the strength of the author's inferences. Peer review involves the review of a draft product for quality by specialists in the field who were not involved in producing the draft.

Peer Review Panel – A panel of peer experts, usually formed by a district, to review and to advise on particular difficult or controversial technical issues related to a dam safety study. The peer group may be from inside or outside USACE, or whatever combination of experts is judged to best fit the need.

Penstock – A pressurized pipeline or shaft between the reservoir and hydraulic machinery.

Performance Evaluation – Description of how the dam and appurtenant structures have performed over the years since construction.

Performance Uncertainty – Performance uncertainty refers to the situation in which more rigorous and detailed studies are needed to more accurately predict the system response probabilities within each applicable failure mode.

Periodic Assessments (PA) – The periodic assessment will consist of a periodic inspection, a potential failure modes analysis, and a risk assessment based on existing data and a minimum development of limited consequence data. The primary purposes of the Periodic Assessment are to: Confirm the DSAC classification of a project; Justify interim risk reduction measures; Provide initial input for quantitative risk reporting; Identify needed issue evaluation studies; Prioritize issue evaluation studies; Identify operations and maintenance, monitoring, emergency action plan, training and other recurrent needs; and Confirm essential USACE dam safety guidelines are met and determine if the current baseline risk is tolerable to confirm a DSAC class V.

Periodic Inspections (PI) – The recurrent engineering inspections conducted at dams and other civil works structures whose failure or partial failure could jeopardize the operational integrity of the project, endanger the lives and safety of the public or cause substantial property damage shall be periodically inspected and evaluated to ensure their structural stability, safety, and operational adequacy.

Phreatic surface – The free surface of water seeping at atmospheric pressure through soil or rock.

Piezometer – An instrument used for measuring fluid pressure (air or water) within soil, rock, or concrete.

Piping – The progressive development of internal erosion by seepage.

Plunge pool – A natural or artificially created pool that dissipates the energy of free falling water.

Population at Risk – The population downstream of a dam that would be subject to risk from flooding in the instance of a potential dam failure; usually documented in numbers of persons at risk.

Pore water pressure – The interstitial water pressure within a mass of soil, rock, or concrete.

Portfolio Risk Management Process – The management process shown generally on Figure 2.3 and in detail for USACE Figure 3.1. It is a risk-informed USACE-wide portfolio perspective process applied to all features of all dams on a continuing basis. Same definition as 'Dam Safety Portfolio Risk Management Process" above.

Potential Failure Mode (PFM) – The chain of events leading to dam failure or a portion there of that could lead to dam failure. The dam does not have to completely fail in the sense of a complete release of the impounded water.

Potential Failure Mode Analysis (PFMA) – A PFMA is an examination of "potential" failure modes for an existing dam by a team of persons who are qualified either by experience and\or education to evaluate dams. It is based on a review of existing data and information, first hand input from field and operational personnel, site inspection, completed engineering analyses, discussion of dam characteristics, failure causes and an understanding of the consequences of failure. The PFMA is intended to provide enhanced understanding and insight on the risk exposure associated with the dam or levee.

Probability – A measure, of the likelihood, chance, or degree of belief that a particular outcome or consequence will occur. A probability provides a quantitative description of the likelihood of occurrence of a particular event. This is expressed as a value between 0 and 1. (USACE)

Probability of Failure – The probability that a component of a dam or the dam will fail, given a specified load, leading to sudden, rapid, and uncontrolled release of impounded water.

Probability of Individual Life Loss – The probability of individual life loss, which is used in the evaluation of Individual incremental life safety risk, is not necessarily the same as the probability of failure that is used in the evaluation of Reclamation's APF guideline. The probability of life loss is based on the probability of failure and a consideration of exposure factors such as day-night differences in PAR and evaluation and the seasonal presence of people in campgrounds. The level of detail that is appropriate for characterizing exposure factors should be "decision driven", although it is noted that FEMA's HAZUS data base provides opportunity for some level of automation in capturing information on exposure factors. The distinction between probability of failure and probability of life loss is particularly important for navigation dams, but can also have a significant effect on the evaluation of life safety for other types of dams. It applies to societal risk as well as to individual risk.

Probable Maximum Precipitation (PMP) – Theoretically, the greatest depth of precipitation for a given duration that is physically possible over a given size storm area at a particular geographical location.

Pumped storage reservoir – A reservoir filled entirely or mainly with water pumped from outside its natural drainage area.

Quality (as related to construction) – Conformance to properly developed requirements.

Quality Assurance (QA) – The procedure by which the Government fulfills its responsibility to be certain the contractors' quality control is functioning and the specified end product is realized.

Quality Management – All control and assurance activities instituted to achieve the product quality established by the contract requirements

Rapid Consequence Analysis/Estimate – The rapid consequence estimate requires a very limited detail, unsteady-flow hydraulic model to reproduce various, with and without, dam failure scenarios. These failure scenarios would include sunny day, Probably Maximum Flood (PMF) and several intermediate load cases between these extremes for both the with and without dam failure condition.

Redundancy – The duplication of critical components of a system with the intention of increasing reliability of the system, usually in the case of a backup or fail-safe.

Regional Cadres – Teams of technical specialists and analysts (cadre) assembled to conduct project specific risk evaluations, such as PFMAs, based on expert knowledge of the geology, hydrology, structural integrity, soils, consequences, and other relevant factors.

Regulation Design Capacity – The maximum hydrologic loading condition (flood hydrograph) above which the project no longer has storage capacity to reduce flow that would provide flood damage reduction benefits. The regulation design capacity is typically the reservoir storage capacity (and attendant operation rules and policies) that are authorized for a flood damage reduction reservoir project. This will always be a hydrologic loading level less than the loading levels used as the structural design capacity.

Reliability – For gate and mechanical systems reliability is defined as the likelihood of successful performance of a given project element. It may be measured on an annualized basis or for some specified time period of interest or, for example, in the case of spillway gates, on a per demand basis. Mathematically, Reliability = 1 - Probability of unsatisfactory operation.

Remediation – Implementation of long-term structural and non-structural risk reduction measures to resolve Dam Safety issues.

Reservoir – A body of water impounded by a dam and in which water can be stored.

Reservoir regulation (or operating) procedure – Operating procedures that govern reservoir storage and releases.

Reservoir surface area – The area covered by a reservoir when filled to a specified level.

Residual Risk – The remaining level of risk at any time before, during and after a program of risk mitigation measures has been taken.

Resilience – The ability to avoid, minimize, withstand, and recover from the effects of adversity, whether natural or manmade, under all circumstances of use.

Riprap – A layer of large uncoursed stone, precast blocks, bags of cement, or other suitable material, generally placed on the upstream slopes of an embankment or along a watercourse as protection against wave action, erosion, or scour. Riprap is usually placed by dumping or other mechanical methods and in some cases is hand placed. It consists of pieces of relatively large size as distinguished from a gravel blanket. Also known as stone slope protection.

Risk – A measure of the probability and severity of undesirable consequences or outcome.

Risk Analysis – Risk analysis is a decision-making framework that comprises three tasks: risk assessment, risk management, and risk communication

Risk Analysis Framework – In 1995 and again in September 2007 the US Office of Management and Budget (OMB) published a memorandum (references A.82 and A.84) setting forth a set of principles (framework) to guide policymakers in assessing, managing, and communicating risk policies.

Risk assessment – Risk assessment is a broad term that encompasses a variety of analytic techniques that are used in different situations, depending upon the nature of the risk, the available data, and needs of decision makers. A risk assessment is a systematic, evidence based approach for quantifying and describing the nature, likelihood, and magnitude of risk associated with the current condition and the same values resulting from a changed condition due to some action. Risk assessment includes explicit acknowledgment of the uncertainties in the risk. As applied to dam safety, the process of identifying the likelihood and consequences of dam failure to provide the basis for informed decisions on a course of action.

Risk Characterization – Risk characterization is the qualitative or quantitative description of the nature, magnitude and likelihood of the adverse effects associated with a hazard with and without a risk management action. A risk characterization often includes: one or more estimates of risk; risk descriptions; evaluations of risk management options; economic and other evaluations; estimates of changes in risk attributable to the management options.

Risk Communication – Risk communication is the open, two-way exchange of information and opinion about hazards and risks leading to a better understanding of the risks and better risk management decisions.

Risk Engine – Software and computational algorithms either commercially available or under development by USACE that is used to construct an event tree for a plausible failure mode and automatically calculate the estimated risk.

Risk Estimate – The end result risk evaluation generated by application of a risk engine to the credible failure mode under study.

Risk Exposure – The population, infrastructure, and other assets and valued resources that would be adversely impact from a dam failure.

Risk-informed – Risk information will play a key role in decisions related to dam safety but will not be the only information to influence the final decisions.

Risk management – Risk management is the process of problem finding and initiating action to identify, evaluate, select, implement, monitor and modify actions taken to alter levels of risk, as compared to taking no action. The purpose of risk management is to choose and prioritize work required to reduce risk.

Risk Management Center (RMC) – An independent USACE Center assigned to the Institute for Water Resources, which is responsible for development and implementation of dam and levee safety policy, prioritization of national dam and levee safety projects and technical consistency of dam and levee safety products. The Center utilizes a combination of in-situ and virtual resources (district, contract, and Risk and Reliability Directory of Expertise, the Modeling, Mapping, and Consequence Production Center, and Policy and Procedures workgroups) to manage the program.

Risk Reduction Measure – Actions formulated and undertaken to reduce risk.

Risk to Tolerable Levels – In context, this refers to implementing dam safety risk reduction measures such that the resulting risk is 'tolerable' as shown graphically in figure 5.1. Generally is the outcome of application of the ALARP (As Low As Reasonably Possible) considerations.

Robustness – Robustness is the ability of a system to continue to operate correctly across a wide range of operational conditions, with minimal damage, alteration or loss of functionality, and to fail gracefully outside of that range. The wider the range of conditions included, the more robust the system.

Rock anchor – A steel rod or cable placed in a hole drilled in rock, held in position by grout, mechanical means, or both. In principle, the same as a rock bolt, but usually the rock anchor is more than 4 meters long.

Rock bolt – A steel rod placed in a hole drilled in rock, held in position by grout, mechanical means, or both. A rock bolt can be tensioned.

Run-up – The vertical distance above the setup that the rush of water reaches when a wave breaks on the dam embankment.

Safe (Unsafe) – Involving little or no chance of dam failure. Meets all required USACE guidelines and criteria.

Safety – Safety is thought of as the condition of being free from danger, risk, or injury. However, safety is not something that can be absolutely achieved or guaranteed. Instead safety is the condition to which risks are managed to acceptable levels. Therefore, safety is a subjective concept based on individual perceptions of risks and their tolerability

Safety Assurance Review Team – Section 2035, Safety assurance review team, Public Law 110-114, the Water Resource Development Act of 2007, requires a safety assurance review of the design and construction of work effecting public safety. This review team is formed at the time pre-construction engineering and design starts and stays with the project until the completion of construction.

Screening Portfolio Risk Analysis (SPRA) – This analysis screens projects based on available information, to expeditiously identify the highest risk dams requiring urgent and compelling action (Dam Safety Action Classification Classes I and II Dams) with low chance of missing any such dams Also, the SPRA is to provide information for preliminary classification of the remainder of the USACE dams into Dam Safety Action Classes III – IV. SPRA does not provide sufficient information to confirm whether a dam can be placed in Dam Safety Action Classification Class V. SPRA will be performed only once for every dam in the USACE inventory. Risk estimates that are computed from SPRA are a relative measure only to compare dams across the USACE portfolio. Decisions and actions relative to tolerable risk cannot be made solely from SPRA results.

Section 1203 – Dam Safety Assurance Cost Sharing – Section 1203, WRDA, 1986 (reference A.99) provides for special cost-sharing for modification of completed Corps of Engineers dam projects that are potential safety hazards in light of current engineering standards and criteria. The problems that meet the criteria of Section 1203 fall into three main categories: hydrologic, seismic, and change in state-of-the-art. (Modifications required on a project due to state-of-the-art changes, but not related to hydrologic or seismic deficiencies, shall be decided on a case-by-case basis by the ASA(CW). Costs incurred in modifications for dam safety assurance shall be recovered in accordance with provisions of the statute.

Seepage – The interstitial movement of water that may take place through a dam, its foundation, or its abutments.

Senior Oversight Group (SOG) – See Dam Safety Senior Oversight Group

Significant Failure Mode – Significant failure modes are a subset of credible failure modes (*i.e. physically possible*). The term “significant” should be judged in the context of the purpose of the risk assessment and the decisions that it will inform. Factors to consider include Dam Safety Action Classification, comparisons with tolerable risk guidelines, scoping the next level of study, portfolio roll-up of the risk estimates, the level of confidence in risk estimates, representation of uncertainty in estimates, and

prioritization for next phase of work. For example credible failure mode should be considered significant if the probability of failure and associated consequences approach closely or exceed a tolerable risk limit guideline.

Significant wave height – The average height of the one-third highest waves of a given wave group.

Sill – A submerged structure across a river to control the water level upstream. The crest of a spillway. A horizontal gate seating, made of wood, stone, concrete, or metal at the invert of any opening or gap in a structure; hence, the expressions “gate sill” and “stoplog sill.”

Slope – Inclination from the horizontal. Sometimes referred to as batter when measured from vertical.

Sluice – An opening for releasing water from below the static head elevation.

Societal incremental life safety tolerable risk guideline – For existing dams, the societal risk should be less than the limit line shown in the chart of societal risk guideline for existing dams, except in exceptional circumstances, following an adaptation of the ANCOLD (2003) (reference A.80) and NSW(2006) (Reference A.106) societal life safety risk guideline. For new dams or Section 216 major modifications (reference A.93), the societal risk should be less than the limit line shown in the chart for societal risk guideline for new dams and Section 216 major modifications (reference A-97), except in exceptional circumstances, following an adaptation of the ANCOLD (2003) (reference A.80) and NSW (2006) (Reference A.106) societal life safety risk guideline. Societal risks are to be lower than the limit lines to an extent determined in accordance with the ALARP principle.

Societal Risk – The risk of widespread or large scale detriment from the realization of a defined risk, the implication being that the consequence would be on such a scale as to provoke a socio/political response, and/or that the risk (that is, the likelihood combined with the consequence) provokes public discussion and is effectively regulated by society as a whole through its political processes and regulatory mechanisms. Such large risks are typically unevenly distributed, as are their attendant benefits. Thus the construction of a dam represents a risk to those close by and a benefit to those further off, or a process may harm some future generation more than the present one. The distribution and balancing of such major costs and benefits is a classic function of Government, subject to public discussion and discussion (HSE, 1995) (Reference A.103) and (ANCOLD October 2003) (Reference A.80).

Special Assistant for Dam and Levee Safety – Acts for the USACE DSO in the execution of daily program activities and serves as Chairman of the HQUSACE DSSC and the SOG. The Special Assistant shall be a registered professional civil engineer with management abilities, be competent in the areas related to the design, construction, or evaluation of dams and understand adverse dam incidents and the

potential causes and consequences of dam failure. The Special Assistant works for and reports directly to the USACE DSO and represents the USACE DSO in the development of the budget submission, working with the appropriate Business Line Managers and the DSRMC to ensure that dam safety priorities are addressed. The Special Assistant serves as the Department of Defense and/or USACE representative on various national teams as directed by the USACE DSO.
Spillway – A structure over or through which flow is discharged from a reservoir. If the rate of flow is controlled by mechanical means such as gates, it is considered a controlled spillway. If the geometry of the spillway is the only control, it is considered an uncontrolled spillway.

Spillway, auxiliary – Any secondary spillway, which is designed to be operated very infrequently and possibly in anticipation of some degree of structural damage or erosion to the spillway during operation.

Spillway, primary (or service) – A spillway designed to provide continuous or frequent releases from a reservoir without significant damage to either the dam or its appurtenant structures.

Spillway Design Flood (SDF) – See Flood, Inflow Design.

Spillway channel – An open channel or closed conduit conveying water from the spillway inlet downstream.

Spillway chute – A steeply sloping spillway channel that conveys discharges at supercritical velocities.

Spillway crest – The lowest level at which water can flow over or through the spillway.

Spillway, fuse plug – A form of auxiliary spillway consisting of a low embankment designed to be overtopped and washed away during an exceptionally large flood.

Spillway, shaft – A vertical or inclined shaft into which water spills and then is conveyed through, under, or around a dam by means of a conduit or tunnel. If the upper part of the shaft is splayed cut and terminates in a circular horizontal weir, it is termed a bellmouth or morning glory spillway.

Stakeholders – Elected, and agency officials, public and private individuals and groups that have a direct stake in the subject matter under consideration.

Stilling basin – A basin constructed to dissipate the energy of rapidly flowing water, e.g., from a spillway or outlet, and to protect the riverbed from erosion.

Stoplogs – Large logs, timbers, metal beams, or metal frames placed on top of each other with their ends held in guides on each side of a channel or conduit so as to

provide a cheaper or more easily handled means of temporary closure than a bulkhead gate.

Storage – The retention of water or delay of runoff either by planned operation, as in a reservoir, or by temporary filling of overflow areas, as in the progression of a flood wave through a natural stream channel. Definitions of specific types of storage in reservoirs are:

a. *Dead storage.* The storage that lies below the invert of the lowest outlet and that, therefore, cannot readily be withdrawn from the reservoir.

b. *Inactive storage.* The storage volume of a reservoir between the crest of the invert of the lowest outlet and the minimum operating level.

c. *Active storage.* The volume of the reservoir that is available for some use such as power generation, irrigation, flood control, or water supply. The bottom elevation is the minimum operating level.

d. *Live storage.* The sum of the active and the inactive storage.

e. *Reservoir capacity.* The sum of the dead and live storage of the reservoir.

f. *Flood surcharge.* The storage volume between the top of the active storage and the design water level.

Surcharge – Any storage above the full pool.

Tailrace – The tunnel, channel, or conduit that conveys the discharge from the turbine to the river; hence, the terms “tailrace tunnel” and “tailrace canal.”

Tailwater level – The level of water in the tailrace at the nearest free surface to the turbine or in the discharge channel immediately downstream of the dam.

Threshold Flood – The flood that fully utilizes the existing dam, i.e., the flood that just exceeds the design maximum water surface elevation at the dam.

Thrust block – A massive block of concrete built to withstand a thrust or pull.

Toe of dam – The junction of the face of a dam with the ground surface. For concrete dams, see heel.

Tolerable Risk – A risk within a range that society can live with so as to secure the benefits provided by the dam. It is a range of risk that we do not regard as negligible or as something we might ignore, but rather as something we need to keep under review and reduce it still further if and as we can (HSE, 1999) (Reference A.104). In addition to the tolerable risk limit the ALARP considerations will be applied to determine tolerable risk.

Tolerable Risk Guidelines – Tolerable risk guidelines are used in risk management to guide the process of examining and judging the significance of estimated risks obtained using risk assessment. The outcomes of risk assessment are inputs to the risk management decision process along with other considerations. Meeting or achieving the tolerable risk guidelines is the goal for all risk reduction measures including permanent and interim measures.

Tolerable Risk Limit – Tolerable risk limit, as depicted on Figure 5.1, defines the limit separating the unacceptable risk region from the range of tolerability.

Top of dam – The elevation of the uppermost surface of a dam, usually a road or walkway excluding any parapet wall, railing, etc.

Total Annual Probability of all Failure Modes – Total estimated annual probability of failure from all failure modes associated with all loading or initiating event types.

Trashrack – A device located at an intake to prevent floating or submerged debris from entering the intake.

Tunnel – A long underground excavation with two or more openings to the surface, usually having a uniform cross section used for access, conveying flows, etc.

Type I IEPR – An Independent External Peer Review conducted for feasibility, reevaluation, modification, and assessment reports with an EIS and managed by an outside eligible organization (OEO) that is described in Internal Revenue Code Section 501(c) (3); as exempt from Federal tax under section 501(a), of the Internal Revenue Code of 1986; as independent; as free from conflicts of interest; does not carry out or advocate for or against Federal water resources projects; and has experience in establishing and administering IEPR panels. These reviews are exempt from the Federal Advisory Committees Act (FACA). The scope of review will address all the underlying planning, engineering, including safety assurance, economics, and environmental analyses performed, not just one aspect of the project.

Type II IEPR – A Safety Assurance Review (SAR) of design and construction activities for flood damage reduction or coastal storm damage reduction projects or for other activities that affect public safety, and will also be conducted for reviewing the relevancy and effectiveness of the Corps inspection of completed works and safety programs in promoting safety and competent performance. They are not required to be managed by OEO's and may be managed by the Corps MSC or by an outside organization. While all aspects of the project may be included in the review, it will focus on the public safety aspects.

Unacceptable Level of Risk – The risk cannot be justified except under extraordinary circumstances.

Unacceptable Risk Region – The region within the risk range shown in figure 5.1 that is above the zone referred to as the 'Range of Tolerability'. In the 'Unacceptable Region' the risk is considered unacceptable and cannot be justified except in extraordinary circumstance HSE (2001) (reference A.105)

Uncertainty – Uncertainty is the result of imperfect knowledge concerning the present or future state of a system, event, situation, or (sub) population under consideration. The level of uncertainty governs the confidence in predictions, inferences, or conclusions.

Unsafe – Unacceptable chance of a dam failure.

Uplift – The uplift pressure in the pores of a material (interstitial pressure) or on the base of a structure.

Upstream blanket – An impervious blanket placed on the reservoir floor and abutments upstream of a dam. For an embankment dam, the blanket may be connected to the core.

Valve – A device fitted to a pipeline or orifice in which the closure member is either rotated or moved transversely or longitudinally in the waterway so as to control or stop the flow.

a. *Hollow jet valve.* A device for regulating high-pressure outlets. Essentially, it is half a needle valve in which the needle closure member moves upstream toward the inlet end of the valve to shut off flow. As there is no convergence at the outlet end, the flow emerges in the form of an annular cylinder, segmented by several splitter ribs for admitting air into the jet interior to prevent jet instability.

b. *Regulating sleeve valve.* A valve for regulating high-pressure outlets and ensuring energy dissipation. Inside the valve there is a fixed-cone, pointed upstream, which ensures dispersion of the jet. Outside the valve a cylindrical sleeve moves downstream to shut off flow by sealing on the periphery of the cone.

Variability – One of two components often thought of as comprising ‘uncertainty’. Epistemic or 'knowledge uncertainty' that is possible to reduce with additional data and study; and aleatory or 'natural variability' that reflects a process that is random but uncertainty in its magnitude and values may not be; reduced with additional data and study. Annual stream flow is an example of 'natural variability.'

Volume of dam – The total space occupied by the materials forming the dam structure computed between abutments and from top to bottom of dam. No deduction is made for small openings such as galleries, adits, tunnels, and operating chambers within the dam structure. Portions of powerplants, locks, spillway, etc., should be included only if they are necessary for the structural stability of the dam.

Watershed divide – The divide or boundary between catchment areas (or drainage areas).

Waterstop – A strip of metal, rubber, or other material used to prevent leakage through joints between adjacent sections of concrete.

Wave run-up – Vertical height above the stillwater level to which water from a specific wave will run up the face of a structure or embankment.

WEDGE Fund – A special line item in the Construction Remaining items entitled Dam Safety Assurance and Seepage Stability Correction Program. Funding is provided to a project for investigation (study and report) and the start of construction for a dam safety modification while waiting for the current budget cycle project funding to become available.

Weir – A notch of regular form through which water flows.

a. *Weir, broad-crested.* An overflow structure on which the nape is supported for an appreciable length in the direction of flow.

b. *Weir, measuring.* A device for measuring the rate of flow of water. It generally consists of a rectangular, trapezoidal, triangular, or other shaped notch, located in a

vertical, thin plate over which water flows. The height of water above the weir crest is used to determine the rate of flow.

c. *Weir, ogee.* A reverse curve, shaped like an elongated letter “S.” The downstream faces of overflow spillways are often made to this shape.

Willingness-to-Pay-to-Prevent-a-Statistical-Fatality – This is defined as the economic principle that attempts to place a value on a potential life lost by determining the willingness of society to pay to prevent a statistical fatality. Such values are determined from studies of court cases involving involuntary death, from Federal and other agency studies of establishing regulatory standards for public safety. See also definition for 'Concept of Disproportionality' for further insight.

Wind setup – The vertical rise in the stillwater level at the face of a structure or embankment caused by wind stresses on the surface of the water.

D.9. U.S. Bureau of Reclamation

conditions between borings requiring additional treatment and/or design modification.

9. It is time that the civil engineering profession in the area of dam design respond with action programs rather than reacting to disasters and analyzing why the situation occurred. This can only be achieved with adequate funding to provide for the proposed Phase I and following Phase II dam inspection and remedial works as outlined by the speakers from the Corps of Engineers. These funds must be generated so that the public safety can be adequately protected.

BUREAU OF RECLAMATION'S CRITERIA FOR THE DESIGN OF SPILLWAYS

By Erwin Thomas Scherich[1/]

Of the Bureau of Reclamation's 340 plus storage dams about 30 meet our definition of small dams - up to 50 feet in height above streambed and up to 1,000,000 cubic yards embankment volume. We also have designed over 136 diversion dams - nearly all meeting our definition of small dams. Of the small storage dams, storage capacities range from 100 acre-feet to 527,000 acre-feet. The dam impounding a 527,000 acre-foot reservoir is only 37 feet high. From a safety standpoint volume of storage, in most cases, should be of more concern than height of dam or volume of embankment, and we have no quarrel with the limitation of 1,000 acre-foot storage for the small dam category used by other agencies.

Our earliest storage dam, Minidoka, was completed in 1906. It is 48 feet high, has an embankment volume of 257,300 cubic yards, and creates a reservoir of 210,000 acre-foot capacity. I mention this early dam to focus attention on the fact that when design criteria are evaluated we must keep in mind that dams are not designed for a certain number of years of useful life. After a service of two, three, or many times the repayment period, dams are expected to continue to function in a safe manner. Dams and their appurtenant

1/ Civil Engineer, Spillways, Outlets, and Experimental Analysis Section, Hydraulic Structures Branch, Division of Design, Engineering and Research Center, Bureau of Reclamation, Denver, Colorado.

structures should be designed to give satisfactory and safe service for an indefinite period. Federal agencies continue to have responsibility for dams they design, or are placed under their supervision, after operation and maintenance have been transferred to the owners, perhaps an irrigation district. This accounts, at least in part, for a tendency toward conservatism in design.

Even with this tendency to be conservative in our design assumptions, we have 86 dams under study primarily to determine if they can safely handle newly prepared inflow design floods. Inadequate spillway capacity has proved to be a major cause for concern. I am convinced that the greatest single deficiency in dams throughout the world is inadequate spillway capacity.

In small as well as large dams the first and most important concern of the designer should be the capability, by temporary surcharge storage in conjunction with releases through spillways and outlet works, to safely handle the inflow design flood. The inflow design flood may be the maximum probable flood, a less than maximum probable flood, or even a definite frequency flood, for example, 100-year frequency.

The flood selected for the spillway design is obviously the key to the dam safety, and to a great extent, the structural cost, and in many cases, the project cost. The selection of the inflow design flood involves consideration of dam height, storage capacity of the reservoir behind the dam, type of development - present and projected - in the floodplain downstream from the dam, potential hazard to life

in case of failure, and importance of the value of water stored behind the dam. The following criteria are used by the Bureau of Reclamation for selection of the inflow design flood:

1. Where failure of the dam would endanger human life and/or would cause excessive property damage, a maximum probable flood is used to size surcharge space and spillway capacity.

2. Where failure of the dam would not endanger human life, and would not cause heavy property damage to present or to projected future development below the dam but would impair the usefulness of the project, a less than maximum probable flood may be used to size surcharge space and spillway capacity provided a minimum freeboard will result (depending on type and construction of dam) when the maximum probable flood is routed through the reservoir.

3. Where failure of the dam would not endanger human life, would not cause significant property damage, or seriously impair the usefulness of the project such as the supply of water to a municipality or other critical use or where repair or replacement would not involve major costs or delays in the supply of water, such as a diversion dam, a specific frequency flood (50- or 100-year frequency) may be used to size the surcharge space and the spillway.

Criterion No. 2 is currently (1974) being used for the design of

Palmetto Bend Dam in Texas, a dam of intermediate height - 64 feet above streambed - but large capacity and embankment volume - 170,500 acre-feet and 5,436,000 cubic yards. The less than maximum probable flood was used to establish the dam crest with a normal 8 feet of freeboard allowance for a gated spillway. The maximum probable flood results in a 3-foot encroachment on the freeboard - a 5-foot encroachment would have been considered the maximum for the existing conditions.

After having decided on the appropriate inflow design flood to use in establishing surcharge space and spillway capacity, the second step is to determine a freeboard allowance that will satisfy conditions that exist for the proposed dam. These conditions include computed wave heights based on fetch and wind velocity assumptions, provisions for settlement where poor foundation conditions exist, an arbitrary allowance for improper gate operation where applicable, and perhaps an arbitrary allowance for contingencies to provide an increased factor of safety.

The third step is to determine the combination of surcharge storage and spillway capacity which will result in the least total project cost. This is the least total cost for the level of safety established for conditions that exist for a particular dam and involves comparative cost estimates for various sizes and types of spillways and combinations with outlet works of various sizes and types. Ungated spillways should be favored because of greater reliability over gated spillways where the economic choice is not clearly indicated by the cost difference. It is acceptable Bureau of

Reclamation practice to use auxiliary spillways and flood outlets in combination with service spillways where site and operating conditions are favorable. It is also acceptable practice to store the volume of the inflow design flood provided flood outlet capacity is adequate to evacuate the volume of a 100-year frequency flood antecedent to or subsequent to the inflow design flood, and provided further that the flood outlet is considered to be highly reliable. Where no spillway is provided evacuation of surcharge space must be accomplished at the maximum rate possible for the outlet works. In some cases an emergency spillway may be added to increase the safety against overtopping. Outlet works reliability and requirements for use of auxiliary and emergency spillways are discussed further in later paragraphs.

The three steps that have been discussed establish the level of safety for the dam, assuming the spillways and outlet works function in a manner that will not endanger the integrity of the dam. The design criteria for these structures will now be considered.

The service spillway control structure must have the capacity assumed in the flood routings and must safely convey the flood releases to the stream beyond the toe of the dam. These criteria involve careful crest design and gating provisions where applicable; adequate chute capacity with allowance for freeboard; and adequate energy dissipation for the conditions that exist in the stream and at the downstream toe of the dam.

Where an auxiliary spillway is used in combination with the service spillway it is current practice in the Bureau to set the free overflow control level, or the reservoir level where auxiliary spillway gates are to be put into operation, at the maximum water surface elevation for a 100-year frequency flood or some other specific frequency flood routed through the service spillway. The auxiliary spillway thus will only have infrequent use and should be designed to minimum standards provided the following requirements are met:

1. The auxiliary spillway will discharge into a water course sufficiently separated from the dam abutment and discharging into the main stream a sufficient distance downstream from the toe of the dam that maximum releases will not endanger the dam integrity.

2. The control weir and spillway channel are separated from the dam and service spillway a sufficient distance or by adequate rock formation to insure that maximum releases will be contained in the auxiliary spillway channel and not endanger the service spillway.

3. The auxiliary channel is in adequate rock or is adequately protected by grass lining or other protective surfacing to withstand maximum flows to the degree that the reservoir control does not degrade to a level below the top of conservation storage and further to the extent that restoration of the channel to original grade and condition is feasible.

4. A permanent grade sill or overflow crest is provided to maintain a positive control level.

Where the volume of the inflow design flood is temporarily stored in the surcharge space of the reservoir, the outlet works must be highly reliable and of adequate capacity to evacuate a 100-year frequency flood antecedent to or subsequent to the inflow design flood. The time interval between peaks is established by hydrometeorological determination. The outlet works must also be operated at full capacity to evacuate the surcharge capacity as rapidly as possible.

Where an emergency spillway is used for additional safety, the control is usually set at the maximum water surface for the inflow design flood routed through the reservoir. The emergency type spillway is rarely used in Bureau designs. It would be appropriate where storage is provided for the entire flood volume and marginal evacuation facilities are provided or where a small service spillway can become clogged. We consider the auxiliary type, which by our definition is intended to function on a specific frequency basis, more desirable and may be more economic where flood volumes are relatively large with respect to reservoir storage capability.

Normally our policy is to locate spillways on the rock formation where such exists at reasonable depths. In some instances we have decided that the dam embankment may provide better foundation conditions than the natural ground at the site. In recent years we have located free overflow spillways for small and intermediate dam

heights on the embankment. These spillways have rather small capacity and are combined with high capacity flood outlet works. Two examples are Meeks Cabin Dam which is in operation, and Currant Creek Dam on which construction will begin this year. Meeks Cabin Dam is 74 feet high above streambed and has a storage capacity of 33,090 acre-feet. The flood release capacities are 1,070 cfs for the outlet works and 6,250 cfs for the spillway. Currant Creek Dam will be 132 feet high above streambed and has a storage capacity of 15,670 acre-feet. The flood release capacities are 5,540 cfs for the outlet works and 850 cfs for the spillway.

Of somewhat less importance than the foregoing considerations are the design details of the control structure; conveyance chute, conduit or tunnel; energy dissipator; and upstream and downstream channels. These features become of greater significance with increases in dam height. Individual spillway features should be designed to give the level of performance and safety that can be justified by the conditions that exist for a particular dam. Factors that should be considered include frequency of operation and type of flood used in establishing the dam crest elevation.

This means that the inflow design flood - maximum probable, less than maximum probable, or definite frequency - used in sizing surcharge space and spillway capacity should also be the design flood for the individual features. As in our practice for establishing dam freeboard, however, the maximum probable flood must be accounted for. For example, if the less than maximum probable flood is used for

sizing surcharge storage capacity and spillway capacity, and normal freeboard is provided to establish the crest of the dam, encroachment on freeboard is permitted up to a minimum established value for the maximum probable flood routed through the reservoir. All of the features of the spillway should be designed to normal standards for the less than maximum probable flood and to reduced but safe standards for the maximum probable flood. Likewise, performance standards should be higher for a spillway where reservoir operation studies indicate there will be frequent spills, than if the studies indicate the spillway will be rarely used.

The control structure may be a simple weir or may be of more complex design with automatic gates and precisely designed flow surfaces. Ordinarily, large discharge capacities and high heads will require much more refinement in the hydraulic design than small discharge and low heads. The designer has many types of spillway control structures to choose from.

Spillways are frequently classified according to the type of control (free overflow or gated) and according to type of conveyance (chute, tunnel, or conduit). In addition to these general classifications, the control structure may be one of the following:

1. Ogee crest - straight or curved
2. Broad crest or flat crest
3. Side channel or double side channel
4. Drop inlet, often called shaft or morninglory
5. Siphon

6. Straight drop inlet

Types of energy dissipators are as numerous and include the following:

1. Hydraulic jump stilling basin
2. Impact type dissipator
3. Deflector bucket
4. Submerged deflector bucket
5. Plunge pool
6. Baffled chute

The most appropriate combination depends upon topographic features of the site, the relationship of storage capacity to flood volume, geologic conditions, degree of protection desired, type of dam, height of dam, and many other factors peculiar to a particular site. The experienced designer has many highly developed options to choose from in providing a desired level of protection for a dam. In the Bureau of Reclamation we prefer to select protective measures which can be designed to reasonably assure a degree of risk which can be evaluated in terms of progressive structural damage without endangering human life or causing excessive property loss.

My discussion of spillway designs has intentionally included spillways for large dams and large reservoirs in order to avoid limitations as to applicability. For small dams of 40-foot hydraulic height and less than 1,000 acre-feet of normal storage capacity, the chances of a catastrophic failure will ordinarily be much less than for a large dam. However, I have observed some very questionable residential zoning immediately downstream from dams of this size.

Small dams can be designed to withstand a small amount of overtopping without rapid loss of water in storage. For example, compacted cohesive embankments provide considerable resistance to erosion. Where accurate predictions of release rates can be made, use of specific frequency floods (50 to 100 years) may frequently be justified for establishing surcharge storage space and spillway capacity. We would use a maximum probable flood for evaluation of overtopping risks.

Spillways for small dams usually are of simple design but should have adequate provisions for safe release of the routed inflow design flood to the stream below the dam. Two feet of freeboard for the dam may be adequate if the reservoir storage capacity is small. We consider an uncontrolled overflow crest superior to a gated flood outlet, but where a gated flood outlet is used, provisions can ordinarily be made for free overflow in the gate shaft at very little added expense. This overflow weir is usually located at the top of a divider wall in the gate shaft and at the top of active storage to prevent storage in the surcharge space when the gates are closed. The need for energy dissipation should always be investigated in order that the downstream toe of the dam or the end of the spillway is not subjected to damaging erosion conditions.

The design criteria that I have discussed apply to new construction. It is desirable that existing dams meet these criteria but a different set of economic factors may exist for an old dam than for a dam that is being planned. For example, the ability of the dam owner to finance expensive modifications may be severely limited or the

ratio of benefits to costs may not justify continued operation of the project. Faced with such conditions, the reasonable approach is to evaluate the probable results of continued unsafe operation.

The Bureau of Reclamation has established systematic evaluation procedures that are used for dams that do not meet acceptable standards for safe operation. Deficiencies are usually discovered by routing an updated inflow design flood through the reservoir. In areas of high seismic risk a seismic study is made in addition to the flood routing study.

Before corrective measures are recommended, freeboard allowances are reviewed taking into account the known condition of the dam and other factors that have become known during the operating life of the dam. Operating procedures are examined to determine if an acceptable level of safety can be produced by a limited reservation of storage space during periods of high flood risk. If it is finally determined that overtopping will occur for the inflow design flood, the failure mode and rate are estimated and time-stage relationship is computed for the flow through the breached dam. Downstream loss of life and property damage is then estimated. Finally a decision on the best course of action may be made on the basis of the following alternatives:

1. Modification of dam and spillway to a satisfactory level of safety and performance. (This alternative includes replacement of the dam and construction of additional upstream storage.)

2. Continue to operate the project with reduced storage or other operational adjustments which will assure safety.

3. Continue to operate the project without modification but with knowledge of effects of overtopping. Where human life is endangered or excessive property loss would result from overtopping the dam, this alternative is not considered to be acceptable.

4. Dewater reservoir, demolish dam, and restore site to acceptable environmental standards.

My discussion of spillway design criteria has been focused on those elements that are critical with respect to dam safety. Of greatest importance is the selection of the appropriate inflow design flood for the level of safety indicated by such factors as value of stored water and risks to property and human life in the flood plain below the dam. This desired level of safety can only be assured by adequate provisions for temporarily storing and/or releasing flood water. Flood releases must be conveyed over, under, or around the dam to the stream below in such a manner that the dam will not be damaged. To economically accomplish this the designer has at his disposal many highly developed types of spillways and flood outlets that can be used separately or in combination. For large and small dams alike the spillway should be considered equal in importance to the dam. No dam should be built without adequate provisions for safely handling a major flood.

RECLAMATION

Managing Water in the West

Design Standards No. 14

Appurtenant Structures for Dams (Spillway and Outlet Works) Design Standards

Chapter 1: Introduction
Draft: Phase 3 (Public and Stakeholders Review)

U.S. Department of Interior
Bureau of Reclamation

March 2010

MISSION STATEMENTS

The mission of the Department of the Interior is to protect and provide access to our Nation's natural and cultural heritage and honor our trust responsibilities to Indian tribes and our commitments to island communities.

The mission of the Bureau of Reclamation is to manage, develop, and protect water and related resources in an environmentally and economically sound manner in the interest of the American public.

Chapter 1: Introduction

DS-14(1)-2:[1] Draft: Phase 3 (Public and Stakeholders Review)
March 2010

Design Standard 14 is a new document. Chapter 1 of this Design Standard was developed to provide:

- An overview of how the Bureau of Reclamation analyzes/designs spillways and outlet works appurtenant for dams and/or dikes.
- An outline of the following chapters for this design standard that provides details for spillway and outlet works analyses/designs.
- A list of key technical references used for each major task involved with spillway and outlet works analyses/designs.

[1] DS-14(1)-2 refers to Design Standard No. 14, chapter 1, revision 2.

1.6.2-21 Preferred outlet works configuration: hydraulic control at downstream control structure, with guard/emergency gate/valve at/near centerline of dam/dike, and downstream pressurized pipe (between dam/dike centerline and control structure inside larger access conduit) 1-38

1.6.2-22 Acceptable outlet works configuration: hydraulic control at/near centerline of dam/dike with free flow conditions downstream of the regulating gate/valve 1-38

1.6.2-23 Least acceptable outlet works configuration: hydraulic control at downstream control structure (i.e., pressurized flow conditions upstream of the regulating gate/valve along most of the outlet works) 1-38

Chapter 1

Introduction

1.1 Purpose

The design standards present clear and concise technical requirements and processes to enable design professionals to prepare design documents and reports necessary to manage, develop, and protect water and related resources in an environmentally and economically sound manner in the interest of the American public. Compliance with these design standards assists in the development and improvement of Bureau of Reclamation (Reclamation) facilities in a way that protects the public's health, safety, and welfare; recognizes all stakeholder needs; and achieves the lasting value and functionality necessary for Reclamation facilities. The responsible designer(s) accomplishes this through processes that enable compliance with these design standards and all other applicable technical codes, as well as incorporation of the stakeholder's vision and values, that are then reflected in the construction project.

1.2 Application of Design Standards

All Reclamation design work, whether performed by the Technical Service Center (TSC), the regional offices, or an architectural/engineering (A&E) firm, will conform to the design standards.

Reclamation's use of its design standards requires designers to also integrate sound engineering judgment with applicable national standards, site-specific technical considerations, and project-specific considerations to ensure suitable designs and protect public safety.

The design standards are not intended to provide cookbook solutions to complex engineering problems. Strict adherence to a handbook procedure is not a substitute for sound engineering judgment. The designer should be aware of and use state-of-the-art procedures. Designers are responsible for using the most current edition of referenced codes and standards and to be aware that Reclamation design standards may include exceptions to requirements of these codes and standards.

1.3 Deviations and Proposed Revisions

Design activities must be performed in accordance with established Reclamation design criteria, Reclamation engineering, architectural, or technical standards, and approved national design standards. Exceptions to this requirement will be

pursued in accordance with provisions of Reclamation Manual Policy, *Performing Designs and Construction Activities*, FAC P03.

Reclamation designers should inform the TSC, via the Web site notification procedure, of any recommended updates or changes for the design standards to meet current design practices.

1.4 Scope

Design Standard No. 14 provides technical guidance concerning Reclamation's procedures/considerations for analyzing/designing two key appurtenant structures associated with dams and/or dikes. These appurtenant structures are spillways and outlet works. Chapter 1 provides an overview for the analysis/design of spillways and outlet works, while the following chapters provide detailed procedures/considerations that should be followed by Reclamation staff and others involved with analyzing/designing modifications to and/or new spillways and outlet works. It should be stressed that this design standard will not duplicate other existing technical references but, wherever possible, it will reference existing procedures/considerations that should be used for the analysis/design of spillways and outlet works.

1.5 Definitions

The following definitions are provided to clarify the terminology used in Design Standard No. 14. These definitions are consistent with other technical references used by Reclamation.

1.5.1 Spillway

A spillway is a hydraulic structure that passes normal (operational) and/or flood flows in a manner that protects the structural integrity of the dam and/or dikes (reservoir impoundment structures). Spillways are hydraulically sized to safely pass the Inflow Design Flood (IDF).[2] The IDF will be equal to, or less than, the Probable Maximum Flood (PMF).[3] For more details and guidance about floods, refer to Chapter 2, "Hydrologic Considerations."

---

[2] For significant and high hazard dams and/or dikes and their appurtenant structures, selection of the IDF will be based on a quantitative risk analysis. The IDF will be less than, or equal to, the PMF.

[3] The largest flood that may reasonably be expected to occur at a given maximum runoff condition resulting from the most severe combination of meteorological and hydrologic conditions that are considered reasonably possible for the drainage basin under study.

There are three types or classifications of spillways typically employed by Reclamation, which are based on frequency of use. They are explained in more detail below.

1.5.1.1 Service Spillway

A service spillway provides continuous or frequent regulated (controlled) or unregulated (uncontrolled) releases from a reservoir without significant damage to the dam, dike, or appurtenant structures due to releases up to and including the design discharge. Service spillways are illustrated in figures 1.5.1.1-1 and 1.5.1.1-2.

1.5.1.2 Auxiliary Spillway

An auxiliary spillway is infrequently used and may be a secondary spillway which is operated sparingly. During operation there could be some degree of structural damage or erosion to the auxiliary spillway due to releases up to and including the design discharge. Auxiliary spillways are illustrated in figures 1.5.1.2-3 and 1.5.1.2-4.

1.5.1.3 Emergency Spillway

An emergency spillway is designed to provide additional protection against overtopping of a dam and/or dike and is intended for use under extreme conditions such as misoperation or malfunction of the service spillway or other emergency conditions or during very large, remote floods (such as the PMF). As with auxiliary spillways, some degree of structural damage and/or erosion would be expected due to releases up to and including the design discharge. Emergency spillways are illustrated in figures 1.5.1.3-5 and 1.5.1.3-6.

1.5.2 Outlet Works

Outlet works consist of a combination of features (i.e., intake structure, conveyance features such as conduits, control structure, etc.) and operating equipment (electrical and mechanical) required for the safe operation and control of water released from a reservoir to meet downstream needs. The outlet works serves various purposes such as regulating streamflow and water quality; releasing floodwater; power generation; emergency evacuation; and providing irrigation, municipal, and/or industrial water. Features of outlet works are illustrated in figure 1.5.2-7.

1.6 Configurations

There are some common/typical and unique configurations (features) associated with spillways and outlet works. These features are further discussed in the following sections.

1.6.1 Spillway

Generally speaking, features common to most spillways are illustrated in figure 1.6.1-8 and include:

- Approach channel and safety/debris/log boom.
- Control structure, such as crest structure or grade sill, and gates, bulkheads, stoplogs, along with associated operating equipment.
- Conveyance features, such as chute floor and walls and/or conduit(s)/tunnel(s).
- Terminal structure, such as hydraulic jump stilling basin, flip bucket, plunge pool, etc.
- Downstream channel.

Another consideration of the spillway configuration relates to the type of hydraulic control. With some exceptions,[4] the two types are uncontrolled or free-flow spillways and controlled or gated spillways. The hydraulic control is usually based on whether the spillway crest structure has gates or not. Finally, with some exceptions, the spillway is typically referred to by the type of crest structure, such as:

- For uncontrolled spillways:
    - Ogee crest (figure 1.6.1-9) and grade control sill spillway (figures 1.5.1.2-4 and 1.5.1.3-6).
    - Bathtub (or double side-channel) (figure 1.6.1-10) and side-channel ogee crest spillway (figure 1.6.1-11).
    - Morning glory (or glory hole) spillway (figure1.6.1-12).
    - Labyrinth weir spillway (figure 1.6.1-13).

[4] There are exceptions, such as the morning glory spillway, that could experience hydraulic control shifts with increasing hydraulic head: crest or free flow control to throat or orifice control to pipe or pressure control.

- For controlled spillways:

    - Gated spillway (figures 1.6.1-14 through 1.6.1-16).
    - Fuseplug spillway (figure 1.6.1-17).
    - Fusegate spillway (figure 1.6.1-18).

Consideration should also be given to the location of the spillway, which should not be on or through an embankment dam/dike unless there is justification to deviate. The preferred locations would be on the dam abutments or through the reservoir rim.

For more detailed guidance, refer to Chapter 3, "General Spillway Design Considerations."

1.6.2 Outlet Works

Features common to most outlet works are illustrated in figure 1.6.2-19 and include:

- Intake structures, trashracks, gates/valves, and bulkheads (if appropriate).

- Conveyance features, such as conduit(s)/tunnel(s).

- Control structure, such as gate chamber, gates/valves, access shaft/adit/conduit, along with operating equipment.

- Terminal structure, such as hydraulic jump stilling basin, impact structure, plunge pool, etc.

- Downstream channel.

Considerations that should be used, unless there is justification to deviate, include:

- Two gates or valves in series should be installed and operated in Reclamation outlet works. The downstream gate or valve provides regulating capabilities, while the upstream gate or valve provides emergency closure capabilities under unbalanced head (flow) conditions, or routine closure capabilities under balanced head (nonflow) conditions.

- Although common throughout the water resource engineering industry, constructing an outlet works through/beneath an embankment dam and/or dike should be viewed as a second choice (i.e., avoid/limit contact/interface between the conduit and embankment). A preferred

alternative to minimize internal erosion potential is to construct a tunnel outlet works through the dam and/or dike abutment or through the reservoir rim.

Another aspect of outlet works configuration relates to the location of hydraulic control (i.e., the location of the regulating gate or valve). The four configurations [1][5] typically used by Reclamation are illustrated in figures 1.6.2-20 through 1.6.2-23 and include the following:[6,7]

- **Preferred configuration.** Hydraulic control at intake with free flow conditions downstream of the regulating gate or valve. Most often used for low head applications in embankment dams where pressurized flow is not required at the downstream end of the outlet works. When the outlet works is not being operated, there is access for inspection and maintenance through the entire length of the conduit (figure 1.6.2-20).

- **Preferred configuration.** Hydraulic control at downstream control structure, with guard/emergency gate/valve at/near centerline of dam/dike, and downstream pressurized pipe (between dam/dike centerline and control structure) inside larger access conduit. Applicable for power generation or pressurized downstream flow. During both operation and nonoperation of the outlet works, there is excellent access for inspection and maintenance through downstream conduit (figure 1.6.2-21).

- **Acceptable configuration.** Hydraulic control at/near the dam/dike centerline with free flow conditions downstream of the regulating gate or valve. When the outlet works is not being operated, there is access for inspection and maintenance through the downstream conduit (figure 1.6.2-22).

- **Least acceptable configuration.** Hydraulic control at the downstream end of the outlet works, which may be near the downstream toe or face of the dam/dike (i.e., pressure flow conditions upstream of the regulating gate or valve along most of the outlet works). Commonly used in concrete

---

[5] Numbers in brackets indicate a reference listed at the end of this chapter.

[6] Outlet works configurations are listed in order of increasing potential of pressurizing surrounding dam, dike, and/or foundation materials, which could lead to an incident or failure.

[7] Although the figures associated with following outlet works configurations illustrate an outlet works through/beneath an embankment dam/dike (which should be a second choice to a tunnel through the dam/dike abutment or reservoir rim), the focus is on the hydraulic control configuration, which would be applicable regardless of the location of the outlet works.

dams. Accessibility for inspection and maintenance is limited (underwater inspection) without bulkheading upstream intake structure or draining the reservoir (figure 1.6.2-23).

For more detailed guidance, refer to Chapter 4, "General Outlet Works and Diversion Design Considerations."

1.7 Design Procedures/Considerations

Details of analysis/design procedures/considerations will be provided in the following chapters of Design Standard No. 14. An overview is provided in the following text of this chapter. Analysis and/or design (including both new and modification) for a spillway and/or outlet works will typically follow a number of key procedural guidelines including:

- Design data collection guidelines [2].
- Feasibility design guidelines [3].
- Final design process [4].
- Cost estimating [5].
- Safety of Dams project management guidelines [6].

1.7.1 Spillway Design/Analysis

Tasks for analyzing/designing spillways are summarized in the following sections.

1.7.1.1 Location, Type, and Size

Selection of the location, type, and size of a spillway will be dependent on the evaluation of a number of factors including:

- Site conditions (geology/topography).
- Dam and/or dike type.
- Hydrologic considerations.
- Hydraulic considerations.
- Seismic considerations.

- Construction/constructability considerations.
- Project objectives.
- Robustness of design.
- Risks associated with Plausible Potential Failure Modes (PFMs), which must be tolerably below Reclamation's public protection guidelines [7].
- Operation and maintenance considerations.
- Economics.

These factors are further discussed in the following chapters of this design standard and some of the following sections. Two factors that should be highlighted, which are somewhat unique to Reclamation facilities, are the robustness of design and the risks associated with PFMs. Because many of the spillways are associated with significant and high hazard dams/dikes, it is important that any new or modified appurtenant structure designs protect the public to levels consistent with Reclamation's public protection guidelines [7] (i.e., maintain and/or reduce risks to acceptable levels). This could mean some redundant features/equipment and designing to stricter requirements than commonly called for by professional codes, standards, and/or guidelines.

For more detailed guidance associated with locating, along with selecting, a type and size of a spillway, refer to Chapter 3, "General Spillway Design Considerations."

1.7.1.2 Hydraulic Analysis/Design

The hydraulic analysis/design will be concurrent with the previous task of locating and selecting a type and size of spillway. The following chapters of this design standard explain the steps of hydraulic analysis/design, including:

- Develop/verify discharge curves.
- Prepare initial flood routings of frequency floods up to the PMF to verify the appropriateness of the spillway type and size, and to select the IDF.
- Refine spillway control (crest) structure layout and associated discharge curves based on results from previous steps.

- Prepare final flood routings to estimate maximum reservoir water surfaces (RWS) and discharge ranges for various floods and operational conditions (part of the final flood routings will include a freeboard assessment, which is sometimes referred to as a robustness study).

- Prepare initial water surface profiles to lay out the spillway conveyance features and terminal structure size and type.

- Refine spillway conveyance features and terminal structure based on results from previous step.

- Prepare final water surface profiles to finalize size and type of the spillway conveyance features and terminal structure.

For more detailed guidance associated with hydrologic and hydraulic analysis/design for a spillway, refer to Chapter 2, "Hydrologic Considerations," and Chapter 5, "Hydraulic Considerations."

- *Outlet Works Energy Dissipators: Best Practices for Design, Construction, Identification and Evaluation, Inspection, Maintenance, Renovation, and Repair* [53].

1.7.1.3 Foundation Analysis/Design

The foundation analysis/design will start when a tentative type and size of spillway is located and selected, and it parallels the structural analysis/design efforts. The following chapters of this design standard explain the steps of foundation analysis/design, including:

- Define site-specific foundation material and strength properties.

- Assist in identifying suitable sites based on site-specific foundation needs for a spillway.

- Define and analyze ground water conditions.

- Develop appropriate foundation designs which include:

    - Drainage features such as underdrains, slope drainage, and filters (NOTE: Identify and evaluate drainage features/systems that will be accessible for inspection using closed circuit television (CCTV) equipment).
    - Adequate support for the spillway, which could range from excavating to competent rock to driving piles or placing piers in a soil foundation.

- Accommodating loading conditions on the spillway that could include static (hydrostatic, rock/soil, ice and frost heave), hydrologic (floods), and seismic (hydrodynamic, dynamic soil/rock) loads.

For more detailed guidance associated with foundation analysis/design for a spillway, refer to Chapter 6, "Foundation Considerations."

Technical references associated with the foundation analysis/design of spillways include:

- *Design of Small Dams*, third edition [8].
- EM No. 13 – *Estimating Foundation Settlement by One-Dimensional Consolidation Tests* [21].
- REC-ERC-74-10 – *Rock Mechanics Properties of Typical Foundation Rock Types* [22].
- REC-ERC-82-17 – *Frost Action in Soil Foundations and Control of Surface Structure Heaving* [23].
- ACER TM No. 9 – *Guidelines for Controlling Seepage Along Conduits Through Embankments* [24].
- *Drainage for Dams and Associated Structures* [25].
- *Guidelines, Foundation and Geotechnical Studies for Existing Concrete Dams* [41].

1.7.1.4 Structural Analysis/Design

The structural analysis/design of the spillway typically follows the hydraulic analysis/design. The following chapters of this design standard explain the steps of structural analysis/design, including:

- Identify which features are considered "critical"[8] and "noncritical."[9] [26]

[8] A critical feature is one in which its failure or damage could lead to failure and/or damage of the dam/dike or other appurtenant structures, which, in turn, may lead to the uncontrolled release of part or the entire reservoir or leave the appurtenant structure inoperable, preventing releases needed to protect the dam/dike.

[9] A noncritical structure is one in which failure or damage would not lead to failure of and/or damage to the dam/dike, nor would it inhibit operations of the structure to protect the dam/dike.

- Identify and define loading conditions for both critical and noncritical features, which will typically fall into four categories, including:

  - Construction.
  - Operational (normal or static).
  - Flood (hydrologic).
  - Earthquake (seismic).[10]

- Identify, evaluate, and select material types and associated properties. Materials could include concrete (reinforced, conventional mass, roller compacted, and precast), steel, and plastic such as high-density polyethylene (HDPE).

- Apply appropriate structural analysis/design methods, which are based on the crawl, walk, and run philosophy (i.e., using the simplest approach that is technically adequate to prepare the analysis/design). These include:

  - **For analyses.** Pseudo-static, linear elastic finite element modeling (FEM), using response spectra, and nonlinear elastic FEM, using time histories, are employed to analyze a structure.
  - **For designs.** Design methods are typically based on Reclamation technical references, such as *Design of Small Dams* [8], and industry codes are used, such as the American Concrete Institute (ACI) manuals.

For more detailed guidance associated with structural analysis/design for a spillway, refer to Chapter 7, "Structural Considerations."

Technical references associated with the structural analysis/design of spillways include:

- *Design of Small Dams*, third edition [8].

- EM No. 14 – *Beggs Deformeter-Stress Analysis of Single-Barrel Conduits* [27].

- EM No. 14 Supplement – *Beggs Deformeter-Analysis of Additional Shapes* [28].

---

[10] For significant and high hazard dams and/or dikes and their appurtenant structures which have been identified as "critical," selection of the seismic design load will be based on a quantitative risk analysis. For noncritical structures, a minimum earthquake loading will be used which approximates a design basis earthquake (DBE) or about a 500-year event.

- EM No. 34 – *Control of Cracking in Mass Concrete Structures* [30].
- *Concrete Manual*, eighth edition [31].
- Current ACI 318 and ACI 350 building codes.
- EM 1110-2-2104 – *Strength Design for Reinforced Concrete Hydraulic Structures, U.S. Army Corps of Engineers* [32].
- ACI SP-3 – *Reinforced Concrete Design Handbook* (Working Stress Method), third edition [33].
- *Design Criteria for Retaining Walls* [34].
- *Roller-Compacted Concrete: Design and Construction Considerations for Hydraulic Structures* [35].

1.7.1.5 Mechanical/Electrical Design

The mechanical/electrical design takes place concurrently with the structural analysis/design. The following chapters of this design standard explain the steps of mechanical/electrical design, including:

- Select, size, and design gates/valves, if applicable.
- Select, size, and design trashracks, stoplogs, and/or bulkhead gates, if applicable.
- Select, size, and design gate/valve operators and generators, if applicable.
- Select, size, and design heating, ventilation, and cooling (HVAC) systems, if applicable.
- Select, size, and design hoists and/or cranes, if applicable.
- Design lighting and electrical control systems for gate/valve operations, HVAC systems, and supervisory control and data acquisition (SCADA) systems.
- Address life safety considerations as note in the National Fire Protection Association (NFPA) 100, *Life Safety Code Handbook*, 2009 edition.

For more detailed guidance associated with mechanical/electrical design for a spillway, refer to Chapter 7, “Mechanical/Electrical Considerations.”

Selection of type and size of a spillway gate and operating system will be dependent on the evaluation of a number of factors including:

- Site conditions.
- Spillway configuration.
- Access.
- Available power.
- Hydraulic considerations.
- Seismic considerations.
- Construction/constructability considerations.
- Ice loading.
- Navigation needs.
- Sediment and debris loading.
- Operation and maintenance considerations.
- Economics.

These factors are further discussed in the following chapters of this design standard and some of the following sections. Because many of the spillways are associated with significant and high hazard dams/dikes, and failure of gates/valves may result in uncontrolled release of large flows, some redundant features/equipment might be required. Therefore, it may be advisable to design to stricter requirements than commonly called for by professional codes, standards, and/or guidelines.

Technical references associated with the mechanical/electrical design of spillways include:

- American Institute of Steel Construction (AISC) *Manual of Steel Construction*, thirteenth edition - refer to American National Standards Institute (ANSI)/AISC 360-05, Specifications for Structural Steel Buildings).

- American Welding Society (AWS) AWS D1.1/D1.1M Structural Welding Code – Steel; AWS D1.6 Structural Welding Code - Stainless Steel.

1.7.1.6 Risk Analysis (Only for Significant and High Hazard Dams/Dikes)

Probabilistic (in the form of a quantitative risk analysis), rather than deterministic, considerations will be part of any analysis/design for significant and high hazard dams and/or dikes, along with associated appurtenant structures (such as spillways) or critical components of associated appurtenant structures. The steps will be integrated with the previous design/analysis and include:

- Identify and define credible PFMs for the existing, modified, and/or new spillway. Although each spillway may have some unique PFMs, common PFMs include:

  - Flood-induced overtopping of dam and/or dike.
  - Flood-induced spillway operations which exceed the original/maximum design discharge, leading to overtopping of the chute wall and/or terminal structure walls, pressurizing the conduit and/or tunnel, or sweepout of the terminal structure, and leading to erosional headcutting of the spillway foundation or erosion of the dam and/or dam foundation.
  - Flood-induced spillway operations which result in cavitation damage of the chute and/or conduit, leading to erosion of the foundation.

  - Flood-induced operations which result in stagnation pressure (hydraulic jacking) and/or structural collapse of the chute and/or terminal structure, leading to erosion of the foundation.
  - Seismic-induced structural collapse of the spillway crest structure or features (such as piers, walls, and/or gates).

- Based on Reclamation's public protection guidelines [7], estimate the sum of the baseline (existing) annual probability of failure (APF) for all credible PFMs, and annualized loss of life (ALL) for all credible PFMs for a given loading condition, associated with existing and/or new dams, dikes, and all appurtenant structures such as spillways and outlet works.

- If an existing spillway is to be modified, estimate the sum of the modified APF for all credible PMFs and the sum of ALL for all credible PMFs associated with a given loading condition.

- For the modified or new spillway, if estimated sum of APF for all credible PFMs, and the sum of ALL for all credible PFMs associated with a given loading condition are "tolerably"[11] below Reclamation guidelines (1E-4 or a 1 in 10,000 chance during a given year for APF; and 1E-3 or a 1 in 1,000 chance during a given year for ALL), designs may be acceptable; however, if not tolerably below Reclamation guidelines, additional design considerations/features will be necessary to lower the estimated APF and ALL for the modified or new spillway.

- To address the uncertainties associated with using quantitative risk analysis to select an IDF, a robustness study is done to evaluate plausible operational and hydrologic/hydraulic scenarios that could increase the maximum RWS above the IDF-induced RWS. Typical scenarios that are evaluated include:

    - Misoperation.
    - Change in hydrology.
    - Debris blockage.
    - Change in downstream consequences.
    - Wind-generated waves.

For more detailed guidance associated with risk analysis/design for a spillway, refer to Chapter 2, "Hydrologic Considerations" and Chapter 3, "General Spillway Design Considerations".

Technical references associated with the risk analysis/design of spillways include:

- *Guidelines for Achieving Public Protection in Dam Safety Decisionmaking* [7].

- REC-ERC-88-3 – *Overtopping Flow on Low Embankment Dams – Summary Report of Model Test* [15].

- DSO-07-07 – *Uplift and Crack Flow Resulting from High Velocity Discharges Over Offset Joints* [16].

- DSO-99-06 – *A Procedure for Estimating Loss of Life Caused by Dam Failure* [36].

---

[11] Tolerably below Reclamation guidelines will be unique to each condition/situation and will be mutually agreed to by the designer of record and Reclamation's Dam Safety Office, along with concurrence by Reclamation management. Consideration will include the level of uncertainty associated with estimates, and future conditions that could increase the estimates (such as changes in downstream consequences).

- *Risk Analysis Facilitator's Notebook* [42].

- *Dam Safety Risk Analysis Best Practices Training Manual* [43].

1.7.2 Outlet Works Design/Analysis

Tasks for analyzing/designing outlet works are summarized in the following sections.

1.7.2.1 Location, Type and Size

Similar to the spillway, selection of the location, type, and size of an outlet works will be dependent on the evaluation of a number of factors including:

- Site conditions (geology/topography).

- Dam and/or dike type.

- Hydrologic considerations.

- Hydraulic considerations.

- Seismic considerations.

- Construction/constructability considerations.

- Project objectives.

- Robustness of design.

- Risks associated with credible PFMs, which must be tolerably below Reclamation's public protection guidelines [7].

- Operation and maintenance considerations.

- Economics.

These factors are further discussed in the following chapters of this design standard and some of the following sections. Also, the two factors that were highlighted for the spillway are also highlighted for the outlet works, which are the robustness of design and the risks associated with PFMs. It is worth restating that because many of the outlet works are associated with significant and high hazard dams/dikes, it is important that any new or modified appurtenant structure designs protect the public to levels consistent with Reclamation's public protection guidelines [7]. This could mean some redundant features/equipment and designing to stricter requirements than commonly called for by professional codes, standards, and/or guidelines. Additionally, it should be restated that, as a starting point, an outlet works should include:

- Two gates or valves in series (one guard or emergency valve and one regulating gate/valve) that can be operated under unbalanced head conditions.

- Hydraulic control at or upstream of the projected centerline of the dam/dike with either a pressurized pipe inside a larger access conduit and/or tunnel or a free flow conduit and/or tunnel downstream of hydraulic control, particularly when associated with embankment dams/dikes.

- Stoplogs or bulkhead and slots provided near the intake structure.

- For embankment and/or rockfill dams/dikes, isolate the outlet works from the dam/dike (i.e., consider tunnel through the dam/dike abutments or reservoir rim, rather than a cut-and-cover outlet works through or beneath the dam/dike).

There will be cases where deviation from the above considerations will occur. However, there should be strong justification to not incorporate these considerations.

For more detailed guidance associated with locating, along with selecting, a type and size of an outlet works, refer to Chapter 4, "General Outlet Works and Diversion Design Considerations."

1.7.2.2 Hydraulic Analysis/Design

Similar to the spillway, the hydraulic analysis/design will be concurrent with the previous task of locating and selecting a type and size of outlet works. The following chapters of the design standard explain the following steps of hydraulic analysis/design:

- Develop/verify discharge curves.
- Evaluate intake structure and conveyance features (such as conduit) sizes, along with gate/valve types/sizes based on:
    - **Diversion.** If outlet works will be used for diversion during construction, initial flood routings of diversion floods (sometimes referred to as construction floods) should be done to size conveyance features and temporary cofferdams.
    - **Normal operations.** Evaluate conveyance features size and gate/valve type/size for passing operational flows.
    - **Emergency evacuation.** Evaluate ability of outlet works to lower the reservoir in a timely fashion pursuant to guidelines noted in *Criteria and Guidelines for Evacuating Storage Reservoirs and Sizing Low-Level Outlet Works* [45].
    - **Floods.** Although not typical, some outlet works are used in passing floods. If this is the case, flood routing steps similar to those noted for the spillway should be employed.
- Refine discharge curves based on results from previous steps and finalize intake structure and conveyance features sizes, along with gate/valve types/sizes.
- Depending on type/configuration of the outlet works, initial water surface profiles to layout conveyance features (such as chute/conduit) and terminal structure size and type.
- Final water surface profiles to finalize size and type of outlet works conveyance features and terminal structure.

For more detailed guidance associated with hydraulic analysis/design for an outlet works, refer to Chapter 2, “Hydrologic Considerations,” and Chapter 5, “Hydraulic Considerations.”

Technical references associated with the hydraulic analysis/design of outlet works include:

- *Outlet Works Energy Dissipators: Best Practices for Design, Construction, Identification and Evaluation, Inspection, Maintenance, Renovation, and Repair* [53].

1.7.2.3 Foundation Analysis/Design

The foundation analysis/design will start when locating and selecting a type and size of outlet works and parallels the structural analysis/design efforts. The following chapters of this design standard explain the steps of foundation analysis/design, including:

- Define site-specific foundation material and strength of properties.
- Assist in identifying suitable sites based on site-specific foundation needs for an outlet works.
- Define and analyze ground water conditions.
- Develop appropriate foundation designs which include:
    - Drainage features, which in many cases are the key foundation design feature. (NOTE: Identify and evaluate drainage features/systems that will be accessible for inspection using CCTV equipment).
    - Adequate support for the outlet, which could range from excavating to competent rock to driving piles, placing piers in a soil foundation, or supporting excavated tunnels with rock bolts, shotcrete, etc.
- Accommodating loading conditions loads on the outlet works that could include static (hydrostatic, rock/soil, ice, and frost heave), hydrologic (floods), and seismic (hydrodynamic, dynamic soil/rock) loads, etc.

For more detailed guidance associated with foundation analysis/design for an outlet works, refer to Chapter 6, “Foundation Considerations.”

Technical references associated with the foundation analysis/design of outlet works include:

- *Conduits through Embankment Dams: Best Practices for Design, Construction, Problems Identification and Evaluation, Inspection, Maintenance, Renovation, and Repair* [1].
- *Design of Small Dams*, third edition [8].
- EM No. 13 – *Estimating Foundation Settlement by One-Dimensional Consolidation Tests* [21].

- ACER TM No. 9 – *Guidelines for Controlling Seepage Along Conduits Through Embankments* [24].

- *Drainage for Dams and Associated Structures* [25].

1.7.2.4 Structural Analysis/Design

Similar to the spillway, the structural analysis/design of the outlet works typically follows the hydraulic analysis/design. The following chapters of this design standard explain the steps of structural analysis/design, including:

- Identify which features are considered "critical"[7] and "noncritical"[8] [26].

- Identify and define loading conditions for both critical and noncritical features, which will typically fall into four categories, including:

  - Construction.
  - Operational (normal or static).
  - Flood (hydrologic).
  - Earthquake (seismic).

- Identify, evaluate, and select material types and associated properties. Materials could include concrete (reinforced, conventional mass, roller compacted, and precast), steel, and plastic such as HDPE.

- Apply appropriate structural analysis/design methods which are based on the crawl, walk, and run philosophy (i.e., using the simplest approach that is technically adequate to prepare the analysis/design). These include:

  - **For analyses.** Pseudo-static, linear elastic FEM using response spectra and nonlinear elastic FEM using time histories.

  - **For designs.** Design methods are typically based on Reclamation technical references such as *Design of Small Dams* [8], and industry codes are used such as the ACI manuals.

For more detailed guidance associated with structural analysis/design for an outlet works, refer to Chapter 7, "Structural Considerations."

Technical references associated with the structural analysis/design of outlet works include:

- *Conduits through Embankment Dams: Best Practices for Design, Construction, Problems Identification and Evaluation, Inspection, Maintenance, Renovation, and Repair* [1].
- *Design of Small Dams*, third edition [8].
- EM No. 14 – *Beggs Deformeter-Stress Analysis of Single-Barrel Conduits* [27].
- EM No. 14 Supplement – *Beggs Deformeter-Analysis of Additional Shapes* [28].
- EM No. 27 – *Moments and Reactions for Rectangular Plates* [29].
- EM No. 34 – *Control of Cracking in Mass Concrete Structures* [30].
- *Concrete Manual*, eighth edition [31].
- Current ACI 318 and ACI 350 building codes.
- EM 1110-2-2104 – *Strength Design for Reinforced-Concrete Design of Hydraulic Structures* [32].
- ACI SP-3 – *Reinforced Concrete Design Handbook (Working Stress Method),* third edition [33].
- *Design Criteria for Retaining Walls* [34].
- *Roller-Compacted Concrete: Design and Construction Considerations for Hydraulic Structures* [35].

1.7.2.5 Mechanical/Electrical Design.

The mechanical/electrical design takes place concurrently with the structural analysis/design. The following chapters of this design standard explain the steps of mechanical/electrical design, including:

- Select, size, and design gates/valves.
- Select, size, and design bulkhead gates, if applicable.
- Select, size, and design trashracks.

- Select, size, and design steel pipe.
- Select, size, and design gate/valve operators and generators.
- Select, size and design HVAC systems.
- Select, size, and design hoists and/or cranes, if applicable.
- Design lighting and electrical control systems for gate/valve operations, HVAC systems, and SCADA systems.
- Address life safety considerations as noted in NFPA 100, *Life Safety Code Handbook*, 2009 edition.

For more detailed guidance associated with mechanical/electrical design for an outlet works, refer to Chapter 7, "Mechanical/Electrical Considerations."

Selection of type and size of an outlet gate or valve and operating system will be dependent on the evaluation of a number of factors including:

- Site conditions.
- Outlet works configuration.
- Access.
- Available power.
- Hydraulic considerations.
- Seismic considerations.
- Construction/constructability considerations.
- Ice loading.
- Sedimentation and debris loading.
- Operation and maintenance considerations.
- Economics.

These factors are further discussed in the following chapters of this design standard and in some of the following sections. Because reliable operation of outlet works may be critical in maintaining the safety of dams, some redundant

features/equipment might be required, and it may be advisable to design to stricter requirements than commonly called for by professional codes, standards, and/or guidelines. Of special note, gate and/or valve controls should be located outside of flooded area, should a failure occur, to ensure that emergency/guard gates and/or valves can be operated.

Technical references associated with the mechanical/electrical design of outlet works include:

- AISC *Manual of Steel Construction*, thirteenth edition (refer to ANSC/AISC 360-05, Specifications for Structural Steel Buildings).

- AWS D1.1/D1.1M Structural Welding Code – Steel; AWS D1.6 Structural Welding Code - Stainless Steel.

- *Hydraulic Downpull Forces on Large Gates*, Research Report No. 4 [49].

1.7.2.6 Risk Analysis (Only for Significant and High Hazard Dams/Dikes)

Similar to the spillway, probabilistic (in the form of a quantitative risk analysis), rather than deterministic, considerations will be part of any analysis/design for significant and high hazard dams and/or dikes, along with appurtenant structures such as outlet works. The steps will be integrated with the previous design/analysis and include:

- Identify and define credible PFMs for the existing, modified, and/or new outlet works. Although each outlet works may have some unique credible PFMs, common PFMs have included:

    - Flood-induced overtopping of dam and/or dike (if outlet works are used to help pass floods).

    - Flood-induced outlet works operations which exceed the original/maximum design discharge, leading to overtopping of the chute wall and/or terminal structure walls, or sweepout of the terminal structure, and leading to erosional headcutting of the outlet works foundation or erosion of the dam and/or dam foundation, overstressing the conduits and/or tunnels, introducing pressurized seepage through cracks/joints in the conduit and/or tunnels into surrounding embankment or foundation materials.

    - Operational- and/or flood-induced cavitation damage typically downstream of gates/valves in the chute and/or conduit, leading to erosion of the foundation.

  - Stagnation pressure (hydraulic jacking) and/or structural collapse of the chute and/or terminal structure, leading to erosion of the foundation.

- Based on Reclamation's public protection guidelines [7], estimate the sum of the baseline (existing) APF for all credible PFMs and ALL for all credible PFM for a given loading condition, associated with existing and/or new dams, dikes, and appurtenant structures such as spillways and outlet works.

- If an existing spillway is to be modified, estimate the sum of the modified APF for all credible PMFs and the sum of ALL for all credible PMF associated with a given loading condition.

- For the modified or new spillway, if estimated sum of APF for all credible PFMs, and the sum of ALL for all credible PFMs associated with a given loading condition are "tolerably" below Reclamation guidelines (1E-4 or a 1 in 10,000 chance during a given year for APF; and 1E-3 or a 1 in 1,000 chance during a given year for ALL), designs may be acceptable; however, if not tolerably below Reclamation guidelines, additional design considerations/features will be necessary to lower the estimated APF and ALL for the modified or new outlet works.

For more detailed guidance associated with risk analysis/design for an outlet works, refer to Chapter 2, "Hydrologic Considerations" and Chapter 4, "General Outlet Works and Diversion Design Considerations."

RECLAMATION

Managing Water in the West

Guidelines for Evaluating Hydrologic Hazards

U.S. Department of the Interior
Bureau of Reclamation

June 2006

MISSION STATEMENTS

The mission of the Department of the Interior is to protect and provide access to our Nation's natural and cultural heritage and honor our trust responsibilities to Indian tribes and our commitments to island communities.

The mission of the Bureau of Reclamation is to manage, develop, and protect water and related resources in an environmentally and economically sound manner in the interest of the American public.

Guidelines for Evaluating Hydrologic Hazards

Executive Summary

The purpose of this document is to establish guidelines for generating hydrologic hazard information for use in evaluating hydrologic risk at dams. This information is intended to be used for risk analysis and prioritization of further work at Bureau of Reclamation (Reclamation) dams and other U.S. Department of the Interior facilities. Hydrologic hazard information consists of a flood frequency analysis and frequency flood hydrographs for a full range of Annual Exceedance Probabilities (AEP) necessary for decision making.

Reclamation has developed an approach toward developing hydrologic hazard curves for use in evaluating dam safety issues. The procedure relies on extracting information from existing studies to the fullest extent possible. The procedures and analysis techniques defined in these guidelines allow for the possibility, and even plausibility, that peak discharge and volume estimates may exceed the probable maximum flood (PMF). This is a function of the uncertainty and inconsistency among and between analysis techniques. Therefore, in these cases, the PMF is believed to represent the upper limit to hydrologic risk.

The procedure for developing hydrologic hazard curves considers the dam safety decision criteria, potential dam failure mode and dam characteristics, available hydrologic data, possible analysis techniques, resources available for analysis, and tolerable level of uncertainty. Dam safety decision criteria determine the probabilistic range of floods needed to address hydrologic issues. The potential dam failure mode and dam characteristics impact the type of hydrologic information needed to assess the problem. The specific elements selected to be incorporated in an analysis of hydrologic hazards should consider the tolerable level of uncertainty. To reduce the uncertainty in the estimates, additional data collection and use of more sophisticated solution techniques may be required.

Reclamation currently uses a combination of seven hydrologic methods to develop hydrologic hazard curves. These general techniques include:

- Flood frequency analysis with historical/paleoflood data
- Hydrograph scaling and volumes
- The GRADEX Method
- The Australian Rainfall-Runoff Method
- Stochastic event-based precipitation runoff modeling with stochastic event flood model
- Stochastic rainfall-runoff modeling with CASC2D
- The PMF

It is believed that increasing the level of effort and sophistication of analysis technique increases the level of confidence associated with the results.

The amount of effort expended on analyzing a hydrologic hazard depends on the nature of the problem and the potential cost of the solution. A staged approach toward evaluating a hydrologic safety issue is recommended. Initially, very little effort is expended to determine the

magnitude of the hydrologic hazard. Reclamation attempts to make use of all the available studies for the site of interest. Often, the PMF and initial flood frequency studies are the only hydrologic studies available before the start of a probabilistic investigation. When other hydrologic studies have been performed, available data will be used to decrease uncertainty in results as well as provide an overall assessment of hydrologic risk.

Dam safety evaluations usually begin by characterizing hydrologic risk for the Comprehensive Facility Review (CFR) process. If detailed studies have been conducted for the site of interest, they are summarized, consolidated, and presented to the risk assessment team. About two-thirds of Reclamation's dams can safely accommodate the PMF; when the PMF is selected as the inflow design flood, no additional work may be required unless other hydraulic issues need evaluation. Additional hydrologic work begins with a flood frequency analysis developed for peak flows and volumes and hydrograph scaling. It is believed that this type of information is sufficient to address hydrologic issues and make dam safety decisions at about 80 percent of the remaining dams. For the sites that still have potential safety problems, more sophisticated solution techniques than the initial flood frequency analysis and hydrograph scaling may be required.

When planning more detailed studies, the goal is to achieve a balance between the amount of hydrologic analysis needed to address the issues and the level of effort required to conduct the study. As the studies get more detailed, the results should become more precise and contain less uncertainty.

When multiple methods are used, alternative hazard curves are developed by weighting results from the individual analyses. A team of hydrologists evaluates the alternatives and selects the one most representative for the site for use in the risk assessment. Selection of the final hydrologic hazard curve depends on the experience of the hydrologists and the assumptions that went into each analysis.

Three case studies, Los Banos, Fresno, and A.R. Bowman Dams, are presented in these guidelines to illustrate the variety of methods available. These sites were chosen to demonstrate the use of flood frequency analysis and hydrograph scaling to characterize the flood hazard and more detailed followup studies, where available. The A.R. Bowman example shows how multiple studies were combined into a single flood hazard curve for use in risk assessment.

1. Introduction

The purpose of these guidelines is to develop hydrologic hazard curves and flood hydrographs for use in evaluating and prioritizing the need for dam safety modifications at Reclamation and other U.S. Department of the Interior (Interior) facilities. Hydrologic hazard curves are defined as graphs of peak flow and volume (for specified durations) versus Annual Exceedance Probability (AEP). The range of AEPs that is displayed on these graphs is to be sufficient to support the decision making needs of the organization. The intent of these guidelines is to provide a procedure for developing hydrologic hazard information that will allow decision makers to determine appropriate courses of action to assure the safety of the dam while minimizing study costs. Hydrologic hazard information is intended to support Reclamation's risk-based Dam Safety Program.

These guidelines are based on the Dam Safety Research Report DSO-04-08, *Hydrologic Hazard Curve Estimating Procedures* (Swain et al., 2004). The research project used information developed at the Logan, Utah Workshop held in 1999 to provide a framework for Reclamation to assess flood hazards. The workshop produced the report, *A Framework for Characterizing Extreme Floods for Dam Safety Risk Assessment* (Bureau of Reclamation, 1999). Hydrologic research has led to advances in flood estimation procedures that allow improvements to the framework. These guidelines describe current approaches used by Reclamation to determine flood loadings for its dams. New techniques for developing hydrologic hazard information can be added to these guidelines as they are developed by the hydrology community.

2. Background

2.1 General

Reclamation's Dam Safety Program mission is "To ensure that Reclamation dams do not present unacceptable risks to people, property, and the environment" (Bureau of Reclamation, 1993). As the owner of over 350 high- or significant-hazard storage dams in the western U.S., Reclamation is committed to providing the public and the environment with adequate protection from the risks that are inherent in collecting and storing large volumes of water. Traditional design and analysis methods have focused on selecting a level of protection based on spillway evaluation flood loadings, which were usually based on the probable maximum flood (PMF) (Bureau of Reclamation, 1999).

Since 1995, Reclamation has used a risk assessment process to determine an appropriate level of public protection by evaluating a full range of loading conditions and possible dam failure consequences. This is in contrast to the traditional approach of using upper bound events without regard to their likelihood of occurrence and without assessment of their incremental consequences. As a water resources management agency, Reclamation strives to provide decisionmakers with risk-based information founded upon current or emerging water resources management and public safety practices (Bureau of Reclamation, 1999).

Risk assessment methods provide techniques to organize and plan the data collection and technical studies necessary to evaluate dam safety issues at a site. The risk assessment process allows the risk assessment team to consider the possible adverse outcomes to a given loading condition and compute the risk associated with each possible outcome. The process involves identifying all of the possible loading conditions, dam responses, exposure conditions, and consequences. The overall risk from the dam is the accumulation of the risks associated with each of these factors (Bureau of Reclamation, 1999).

When evaluating hydrologic hazards, a systematic means of developing flood hazard relationships is needed for risk-based assessments to determine hydrologic adequacy for Reclamation dams. The nature of the potential failure mode and characteristics of the dam and reservoir dictate the type of hydrologic information needed. For some sites, only a peak-discharge frequency analysis may be required, while at other sites, flood volumes and hydrographs may be required. The goal of any hydrologic analysis is to provide the hydrologic information needed to make dam safety decisions at the least possible cost.

2.2 Public Protection Guidelines

Guidance for providing adequate and consistent levels of public protection in the evaluation and modification of existing dams and the design of new structures are described in the *Guidelines for Achieving Public Protection in Dam Safety Decisionmaking*, (Bureau of Reclamation, 2003a). The reader may refer to the guidelines for a complete description of the assessment measures used by Reclamation in making dam safety decisions.

Determining an appropriate level of public protection involves assessing the existing risks, determining the need for risk reduction, and, where needed, evaluating specific alternatives to reduce risk. Because the total needs for the agency's financial and human resources generally exceed the available resources, the Public Protection Guidelines were prepared to assist Reclamation staff in presenting public safety information to decisionmakers for prioritizing among projects and allocating limited resources.

Reclamation's Public Protection Guidelines consist of two assessment measures of risk that are considered in the decision process for a dam: (1) the probability of dam failure and (2) the life loss consequences resulting from unintentional reservoir release. The annual probability of failure guideline considers the accumulation of risks from Reclamation's total inventory of dams. The life loss guideline deals with agency public trust responsibilities.

Dam Safety Program Processes

Hydrologic hazard information is generally required during four stages of the dam safety program process. These four stages include the Comprehensive Facility Review (CFR), Issue Evaluation (IE), Corrective Action Study (CAS), and Final Design (FD). Most projects do not progress through each stage of the process because the process is intended to address dam safety deficiencies, and many projects either have no deficiencies or the safety issues can be resolved without a need for structural modifications. The remainder of this section of the guidelines will

briefly describe the four stages of the dam safety program process that require hydrologic hazard information. For more detailed information about the dam safety process, the reader should review the references cited.

The CFR provides a mechanism for early detection of developing and/or existing dam safety issues. The CFR is performed every 6 years and consists of a state-of-the-art review of the dam and its performance, previous studies/analyses (including hydrology), construction practices, downstream consequences, risk, and dam safety decisions (Bureau of Reclamation, 1998). The CFR is used to identify risks at individual dams and to prioritize further work. Once hydrologic hazard information is developed for the CFR, the Dam Safety Office determines whether or not additional hydrologic studies are required to make decisions during subsequent stages of the process.

The IE stage is used to confirm problems identified previously. Data collection and/or analysis activities are focused on addressing specific dam safety issues and updating risk estimates. At the conclusion of the IE, the decision makers determine whether or not actions are required to reduce risk at the dam (Bureau of Reclamation, 2003b).

A CAS formulates and evaluates risk reduction alternatives. Data is collected and analyzed to the extent necessary to develop the details of identified alternatives, to estimate project costs, and to provide sufficient information to allow decision makers to select and justify the proper course of action. The baseline risk analysis is updated to show the risk reduction potential of each of the developed alternatives (Bureau of Reclamation, 2003b).

During the FD stage, the conceptual design is transformed into the final design. Additional data collection and analysis are used to improve the design, reduce and refine project costs, and finalize design drawings and specifications (Bureau of Reclamation, 2003b).

3. Process

The elements selected for incorporation in an analysis of hydrologic hazards must consider the potential dam failure mode and dam characteristics, available hydrologic data, possible analysis techniques, resources available for analysis, and tolerable level of uncertainty. The potential dam failure mode and dam characteristics impact the type of hydrologic information needed to assess the problem. Some problems may require only a peak-discharge frequency curve, while others may need complete hydrographs. The available data, possible analysis techniques, resources available, and needs of the decision makers influence the selection of elements to be included in developing hydrologic hazard curves.

The process that follows provides a systematic approach for estimating hydrologic hazard curves that can be used for dam safety decisionmaking. It recognizes that additional studies do not always lead to better decisions. Therefore, the process relies on using existing data and previous analyses as much as possible to produce hydrologic information suitable for dam safety decisionmaking at the least possible cost.

3.1 Data Sources

Developing hydrologic hazard curves for risk assessment uses the length of record and type of data to determine the extrapolation limits for flood frequency analysis. Extrapolation beyond the data is often necessary to provide information needed for dam safety risk assessments. The sources of information used for flood hazard analyses include streamflow and precipitation records and paleoflood data.

Streamflow records consist of data collected at established gaging stations and indirect measurements of streamflow at other sites. Streamflow data can include estimates of peak discharge as well as average or mean discharge for various time periods. Most streamflow measurements on U.S. streams began after 1900, with only a few records dating back that far. Most often, streamflow records at a single site range in length from about 20 to 60 years. In some cases these records can be extended to about 150 years using historical information, which include human observations and recordings prior to the development of systematic streamflow measurement.

Precipitation and weather data used in hydrologic models can include rainfall, snowfall, snow water equivalent, temperature, solar radiation, and wind speed and direction. These data are available from various sources and vary greatly in record length and quality throughout the United States. Some of these types of data (i.e., snowfall, snow water equivalent, solar radiation, and wind) are limited to record lengths of less than about 30 years; rainfall and temperature data are available for some stations for up to 150 years, but in most cases are limited to less than 100 years.

Paleoflood hydrology is the study of past or ancient flood events which occurred before the time of human observation or direct measurement by modern hydrological procedures (Baker, 1987). Unlike historical data, paleoflood data do not involve direct human observation of the flood events. Instead, the paleoflood investigator studies geomorphic and stratigraphic records (various indicators) of past floods, as well as the evidence of past floods and streamflow derived from historical, archeological, dendrochronologic, or other sources. The advantage of paleoflood data is that it is often possible to develop records that are 10 to 100 times longer than conventional or historical records from other data sources in the western United States. Paleoflood data generally include records of the largest floods, or commonly, the limits on the stages of the largest floods over long time periods.

3.2 Flood Frequency Extrapolation

The type of data and the record length used in the analysis form the primary basis for establishing a range on credible extrapolation of flood estimates. The objective of flood frequency analysis and extrapolation is to provide reliable flood estimates for a full range of AEPs necessary for dam safety decisionmaking. In order to develop reliable flood estimates, flood frequency relationships should include an estimate of the uncertainty around the median values. The data used in the analysis provide the only basis for verification of the analysis or modeling results, and as such, extensions beyond the data cannot be verified. The greatest gains to be made in providing credible estimates of extreme floods can be achieved by combining regional data from multiple sources. Thus, analysis approaches that pool data and information

from regional precipitation, regional streamflow, and regional paleoflood sources should provide the highest assurance of credible characterization of low AEP floods. The information that follows was developed in a workshop sponsored by Reclamation and documented in Bureau of Reclamation, 1999.

For Reclamation dam safety risk assessments, flood estimates are needed for AEPs of 1 in 10,000 and possibly ranging down to as low as 1 in 100,000,000. Developing credible estimates at these low AEPs generally requires combining data from multiple sources and a regional approach. Table 3-1 lists the different types of data that can be used as a basis for flood frequency estimates and the typical and optimal ranges of credible extrapolation for AEP (Bureau of Reclamation, 1999). In general, the optimal ranges are based on the best combination(s) of data envisioned in the western U.S. in the foreseeable future. Typical ranges are based on the combination(s) of data that are commonly available and analyzed for most sites.

Table 3-1.—Data types and extrapolation ranges for flood frequency analysis (Bureau of Reclamation, 1999)

Type of data used for flood frequency analysis	Range of credible extrapolation for annual exceedance probability	
	Typical	Optimal
At-site streamflow data	1 in 100	1 in 200
Regional streamflow data	1 in 500	1 in 1,000
At-site streamflow and at-site paleoflood data	1 in 4,000	1 in 10,000
Regional precipitation data	1 in 2,000	1 in 10,000
Regional streamflow and regional paleoflood data	1 in 15,000	1 in 40,000
Combinations of regional data sets and extrapolation	1 in 40,000	1 in 100,000

Many factors can affect the equivalent independent record length for the optimal case. For example, gaged streamflow records in the western United States only rarely exceed 100 years, and extrapolation beyond twice the length of record, or to about 1 in 200 AEP, is generally not recommended (Interagency Advisory Committee on Water Data [IACWD], 1982). Likewise, for regional streamflow data the optimal range of credible extrapolation is established at up to 1 in 1,000 AEP by considering the number of stations in the region, lengths of record, and degree of independence of these data (Hosking and Wallis, 1997). For paleoflood data, only in the Holocene epoch (or the past 10,000 years) is climate judged to be sufficiently like that of the present climate for these types of records to have meaning in estimating extreme floods for dam safety risk assessment. This climatic constraint indicates that an optimal range for extrapolation from paleoflood data, when combined with at-site gaged data, for a single stream should be up to about 1 in 10,000 AEP. For regional precipitation data, a similar range is imposed because of the difficulty in collecting sufficient station-years of clearly independent precipitation records in the orographically complex regions of the western United States. Combined data sets of regional gaged and regional paleoflood data can be extended to smaller AEPs, perhaps to about 1 in

40,000, in regions with abundant paleoflood data. Analysis approaches that combine all types of data are judged to be capable of providing credible estimates for an AEP range up to about 1 in 100,000 under optimal conditions.

In many situations, credible extrapolation ranges may be less than optimal. Typical ranges would need to reflect the practical constraints on the equivalent independent record length that apply for a particular location. For example, many at-site streamflow record lengths are shorter than 100 years. If in a typical situation the record length is only 50 years, then the range of credible extrapolation might be up to an AEP of about 1 in 100. Similarly, many paleoflood records do not extend to 10,000 years, and extensive regional paleoflood data sets do not currently exist. Using a record length of about 4,000 years, a typical range of credible extrapolation might be up to an AEP of 1 in 15,000 based on regional streamflow and regional paleoflood data.

The information presented in table 3-1 is intended as a guide; each situation is different and should be assessed individually. The ranges of extrapolation should be determined by evaluating the lengths of records, number of stations in a hydrologically homogeneous region, degree of correlation between stations, and other data characteristics that may affect the accuracy of the data.

Ideally, one would like to construct the flood frequency distribution for all floods that could conceivably occur. However, the amount of data and flood experience for any site or region constrain the range of the floods to which AEPs can be assigned based solely on data. In general, the scientific range to which the flood frequency relationship can be credibly extended, based upon any characteristics of the data and the record length, will fall short of the PMF for a site. However, there is a need in dam safety risk assessment to determine the probability of occurrence of very large floods with very small AEPs. The lack of an ideal data set does not absolve the hydrologist from extending the flood frequency relationship to cover the full range of AEPs needed for risk assessment. Therefore, a systematic approach is provided for estimating hydrologic hazard curves that can be used for dam safety decisionmaking.

Floods can be categorized, according to the Australian Rainfall and Runoff: A Guide to Flood Estimation (Nathan and Weinmann, 2001), as large, rare, and extreme. These flood categories are shown in figure 3-1. Large floods generally encompass events for which direct observations and measurements are available. Rare floods represent events located in the region between direct observations and the credible range of extrapolation from the data. Extreme floods generally have very small AEPs, which are beyond the credible range of extrapolation but are still needed for dam safety risk assessments. Occasionally, Reclamation has an interest in floods with an AEP as low as 1 in 10^8.

Extreme floods border on the unknowable. Uncertainty is very large and unquantifiable. Since data cannot support flood estimates in this AEP range, hydrologists and engineers must rely on our knowledge and understanding of hydrologic processes to estimate extreme floods. Oftentimes, these floods may result from unforeseen and unusual combinations of hydrologic parameters generally not represented in the flood history at a particular location. One potential upper bound to the largest flood at a particular site of interest is the PMF.

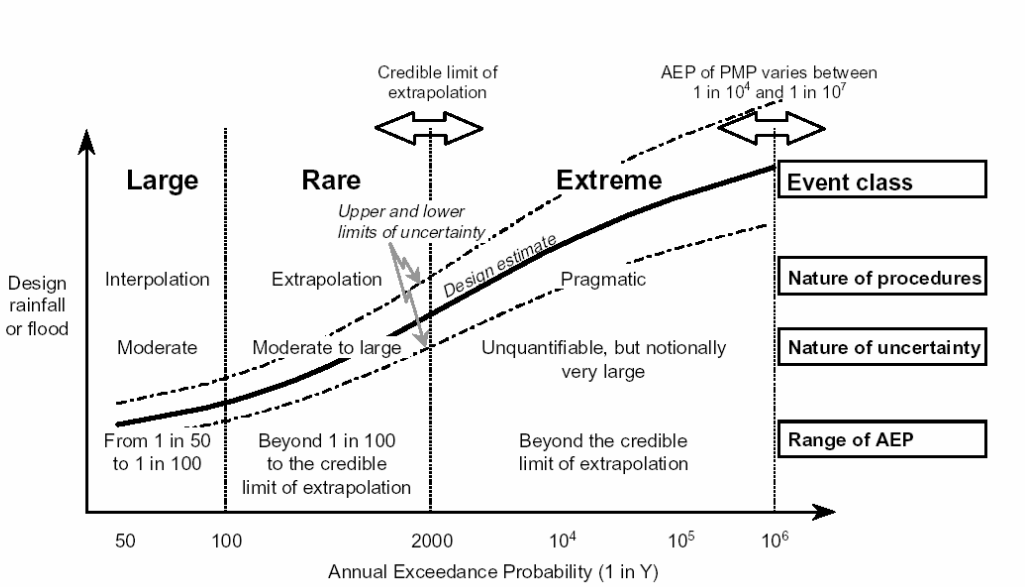

Figure 3-1.—Characteristics of notional floods (Nathan and Weinmann, 2001).

Reclamation uses the PMF as the upper limit of flood potential at a site for storm durations defined by the probable maximum precipitation (PMP). If peak flows or volumes calculated using probability or statistically based hydrology methods exceed those of the PMF, then the PMF is used in evaluating the hydrologic risk and as a theoretical and practical upper limit to statistical extrapolations. The PMF is defined as "the maximum runoff condition resulting from the most severe combination of hydrologic and meteorological conditions that are considered reasonably possible for the drainage basin under study" (Cudworth, 1989). If the PMF has been properly developed, it represents the upper limit to runoff that can physically occur at a particular site. Various storm types, sequences, and durations are taken together with the most severe hydrologic parameters in its development. Extrapolation of statistical analyses can become unbounded for flood distributions that exhibit positive skewness; therefore, Reclamation uses the PMF to limit extrapolation to flood discharges that are physically possible.

Oftentimes, reliable flood frequency estimates are needed for very low AEPs for use in dam safety decisionmaking. Considerable judgment may be required to extrapolate out to the low AEPs required for risk assessment. Even though the flood frequency estimates become less reliable as they are extended beyond the optimal ranges, a systematic way of doing this provides a useful decision making tool.

3.3 Flood Peak and Volume Relationships

Hydrologic hazard relationships display peak flow and flood volumes for various durations versus AEP. Figure 3-2 is a hypothetical example of the type of relationship needed to address hydrologic dam safety issues. Floods with AEPs as low as 1 in 10^8 are desired to encompass the full range of events needed for dam safety risk assessment. The next section of this report describes the available approaches for developing the flood peak and volume relationship. Some of the approaches will also produce flood hydrographs, which can be routed through the reservoir.

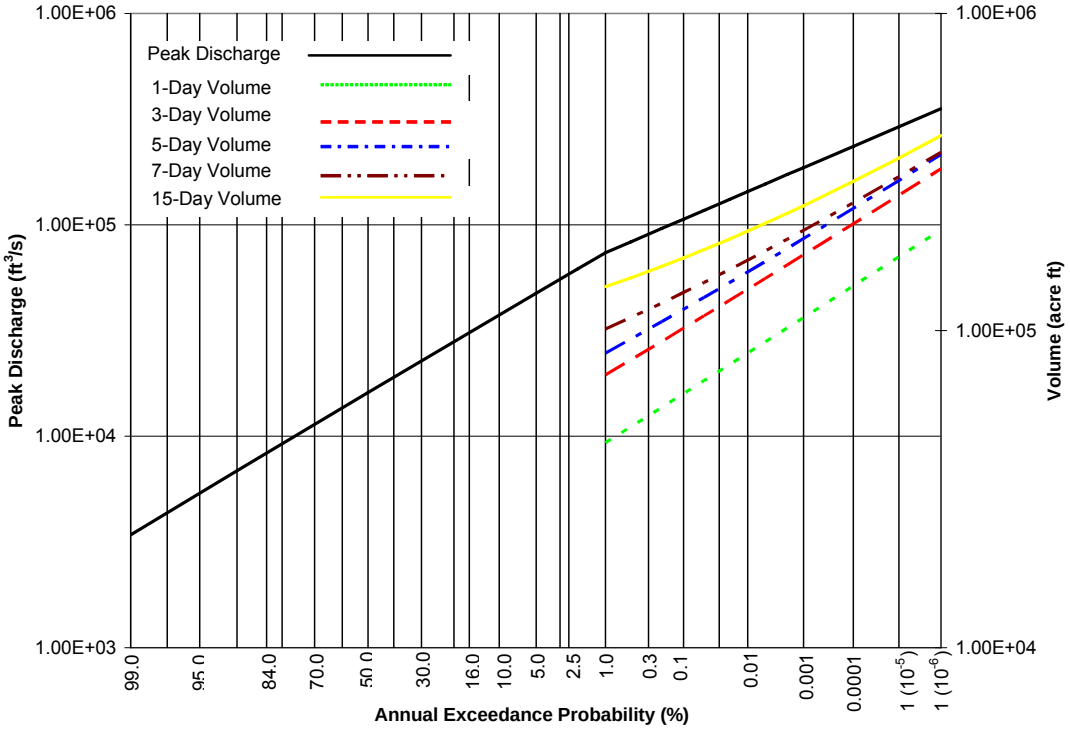

Figure 3-2.—Example hydrologic hazard curve.

4. Analysis Techniques

The main probabilistic and engineering hydrology methods that are currently being used, applied, and under investigation by the Flood Hydrology Group are summarized in this section of the report. There are seven general techniques:

- Flood frequency analysis with historical/paleoflood data
- Hydrograph scaling and volumes
- The GRADEX Method
- The Australian Rainfall-Runoff Method
- Stochastic event-based precipitation runoff modeling with the stochastic event flood model (SEFM)
- Stochastic rainfall-runoff modeling with CASC2D

- The PMF

Other models and approaches are briefly noted by reference in each section. General sources of models and approaches for estimating extreme floods are listed in Maidment (1993), Singh (1995), and Bureau of Reclamation (1999). Methods to calculate extreme floods and associated probabilities have recently been revised and published in the United Kingdom (Institute of Hydrology, 1999) and Australia (Nathan and Weinmann, 2001).

4.1 Flood Frequency Analysis with Historical/Paleoflood Data

There are three main techniques that Reclamation currently uses to develop a peak-flow frequency curve and integrate streamflow (gage) data, historical data, and paleoflood data. The first is a mixed-population graphical approach (England et al., 2001). The two other techniques are statistical models that use gage, historical, and paleoflood data. The Expected Moments Algorithm (EMA) (England, 1999) uses moments to estimate the parameters of a log-Pearson Type III (LP-III) distribution and is consistent with Bulletin 17B (IACWD, 1982). A Bayesian maximum likelihood approach is used by FLDFRQ3 (O'Connell, 1999) to estimate a peak-flow frequency curve with historical and paleoflood data and uncertainties. All three techniques have been used for estimating flood peaks at various Reclamation dams.

4.1.1 Historical and Paleoflood Data

Many different kinds of historical and paleoflood data can be used for flood frequency analysis. Historical flood data are typically extreme floods that have occurred and were described in some qualitative or quantitative fashion before establishing a stream gaging station. The typical information that is available for historical floods is the date of occurrence and the height of the water surface (Thomson et al., 1964). In many cases, people physically mark, on a relatively permanent surface, the approximate high-water mark of a flood (Thomson et al., 1964; Leese, 1973; Natural Environment Research Council, 1975; Sutcliffe, 1987; Fanok and Wohl, 1997).

Paleoflood hydrology is the study of past or ancient floods that occurred before the time of human observation or direct measurement by modern hydrologic procedures (Baker, 1987). The basic types of paleoflood indicators that are useful for flood frequency analysis are paleostage indicators and botanical evidence (Wohl and Enzel, 1995; Baker, 2000). Recent investigations, techniques, and analyses for collecting and using paleoflood data are discussed in House et al. (2002). Fluvial geomorphic evidence includes erosional and/or depositional features that are used to infer paleostages or non-inundation levels. The fluvial geomorphic evidence used in paleoflood and flood frequency studies that represents paleostage indicators includes: silt lines, scour lines, slackwater deposits, boulder and gravel bars, and modified geomorphic surfaces (Costa, 1978; Baker, 1987; Kochel and Ritter, 1987; Jarrett and Costa, 1988; Salas et al., 1994; Jarrett and England, 2002; Levish, 2002). Botanical evidence consists of vegetation that records evidence of a flood (or several floods) or indicates stability of a geomorphic surface for some time period. Botanical evidence of floods includes: corrosion scars, adventitious sprouts, tree age, and tree-ring anomalies (Hupp, 1987).

The historical and paleoflood data can generally be represented with four major data classes (Stedinger et al., 1988): floods of known magnitude, floods of unknown magnitude that are less than some level, floods of unknown magnitude that exceed some level, and floods with magnitudes described by a range. Historical and paleoflood data generally are described in terms of exceedance or non-exceedance of a discharge threshold (Q_o). To correctly interpret the data, one needs to understand the mechanisms by which historical and paleoflood records document the magnitudes of floods that either did, or did not, occur (Stedinger et al., 1993). In many situations, one knows the magnitude of each flood. Annual (gage) peak discharge estimates, historical floods, and paleofloods whose magnitudes are known are described by "floods of known magnitude" class. For example, the solid bars depicted in figure 4-1 describe known floods in the gage and historical period.

The most common situation for using historical and paleoflood data in flood frequency analysis is that a peak discharge Q is known to be smaller than some threshold Q_o, but the magnitude of Q is unknown. The shaded region in figure 4-1 represents these unknown floods that are below a threshold Q_o. The total record length (n) is the sum of the systematic (s) and historical/ paleoflood (h) record lengths (n=s+h). We define the number of observations that exceed the threshold in the systematic record (s) as e, which is equal to 1 in figure 4-1. The number of known observations in the historical period (h) is designated e' (equal to 3 in figure 4-1); it is also known that the values are greater than Q_o. We define k as a random variable equal to the number of observations greater than Q_o in the entire record n, where k = e + e'. The number of observed floods is denoted g, where g = s + k - e.

In some cases, one may know that no floods exceeded the discharge threshold, or k=0. Data in this case have been termed a "non-exceedance bound" (Levish et al., 1994; Levish, 2002), where one has knowledge that no flood has exceeded a designated threshold or geomorphic surface in some time period. An example of a non-exceedance bound is knowledge that a river has not inundated "Main Street," a bridge deck spanning a river, or a geomorphic surface in some time period. Knowledge that k = 0 is valuable information that can be used in flood frequency analysis.

Historical and paleoflood information may be described in terms of a flood that exceeded a threshold, with no upper bound. In some cases, one knows only that a flood was larger than some level and does not know the magnitude of the flood. One knows the number of floods that exceeded the discharge threshold. Stedinger and Cohn (1986) have termed this category as "binomial censoring," in which the exact magnitude of a value is unknown except that it exceeded a lower threshold (see also Russell, 1982). This situation is common for some types of botanical investigations where one can, at present, determine only the minimum stage for plant damage (Hupp, 1988).

There are many situations in which one does not know the exact magnitude of a flood, but that it lies within a range or interval. Interval censoring is used when the exact magnitude of a flood is unknown, but is known to be between some upper and lower amount (Stedinger et al., 1988; Cohn et al., 1997). This class can be used to describe floods with measurement uncertainty. In some cases, the upper threshold, Q_u, can vary for each observation, depending on the data source.

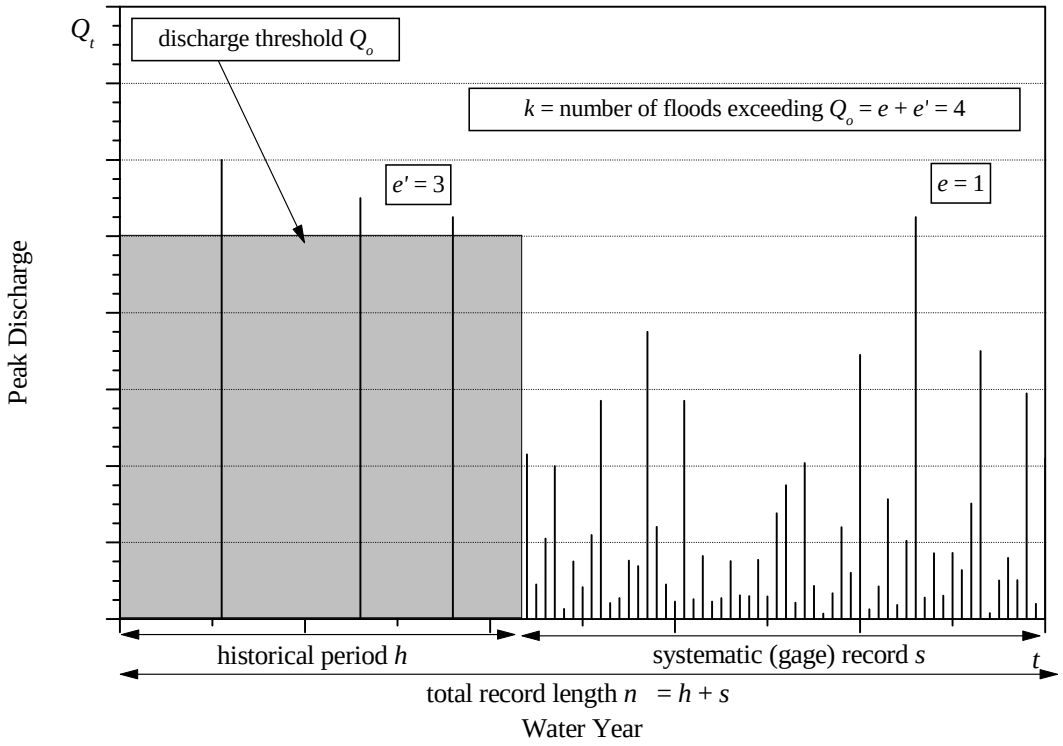

Figure 4-1.—Example of peak discharge time series with historical period and discharge threshold Q_o. The shaded area represents floods of unknown magnitude less than Q_o.

4.1.2 Mixed-Population Graphical Approach

A mixed-population graphical peak-discharge frequency approach has been developed by Reclamation (England et al., 2001). The graphical approach is an at-site frequency method and the frequency curve is constructed in two distinct parts: (1) standard hydrologic statistical methods are used to define a frequency curve for return periods less than and including the 100-year return period (e.g., IACWD, 1982; Ries and Crouse, 2002) and (2) graphical methods are used for estimates greater than the 100-year return period. Peak discharge estimates from gaging stations are used to define the first part of the curve and at-site paleoflood data are used to define the second part of the curve. The first part is estimated assuming an LP-III distribution. One of three at-site techniques and associated computer programs is typically used to estimate the parameters of the LP-III distribution, calculate quantiles, and estimate confidence intervals: (1) the Bulletin 17B Method (IACWD, 1982) and FREQY (Carson, 1989); (2) expected moments methods (Cohn et al., 1997) and EMA (England, 1999); or (3) Bayesian maximum likelihood and FLDFRQ3 (O'Connell, 1999). Historical information is included in the at-site frequency analysis when it is available. Historical data can be used to adjust a so-called "high outlier" using FREQY, EMA, or FLDFRQ3. Low outliers can be adjusted using IACWD (1982) methods. The second portion of the frequency curve is estimated assuming a 2-parameter log-Normal (LN-2) distribution. It is defined between the 100-year and the available paleoflood data return periods, and extrapolated beyond the paleoflood data using this LN-2 distribution. Two points are typically used to estimate this portion of the flood-frequency curve: (1) the LP-III

model 100-year peak discharge estimate and (2) the midpoint in time and discharge of the paleoflood data. Logarithms (base 10) of the peak flows and standard Normal variates of return periods are used to estimate the LN-2 parameters using least squares (England, 2000). The LN-2 distribution was found to reasonably represent daily standardized precipitation in the western United States (Lane, 1997).

The mixed-population graphical approach is used to estimate flood hazard curves. The approach has been developed so that one can estimate an extreme flood frequency curve at any location in the western United States with a minimal amount of effort using existing streamflow data and some site-specific paleoflood data. There are two main assumptions of this graphical approach for estimating extreme flood probabilities: the upper portion of the frequency curve is appropriately defined by the 100-year peak discharge and paleoflood data and the extrapolation of this portion of the curve using a LN-2 model is appropriate. An example peak-flow frequency curve using the graphical approach is shown in figure 4-2. The approach has been reviewed by Kuczera (2000). Kuczera pointed out the major weaknesses were the use of an envelope curve, lack of confidence intervals, and extrapolation. Kuczera recommended that regional growth curves be used to compliment the use of envelope curves.

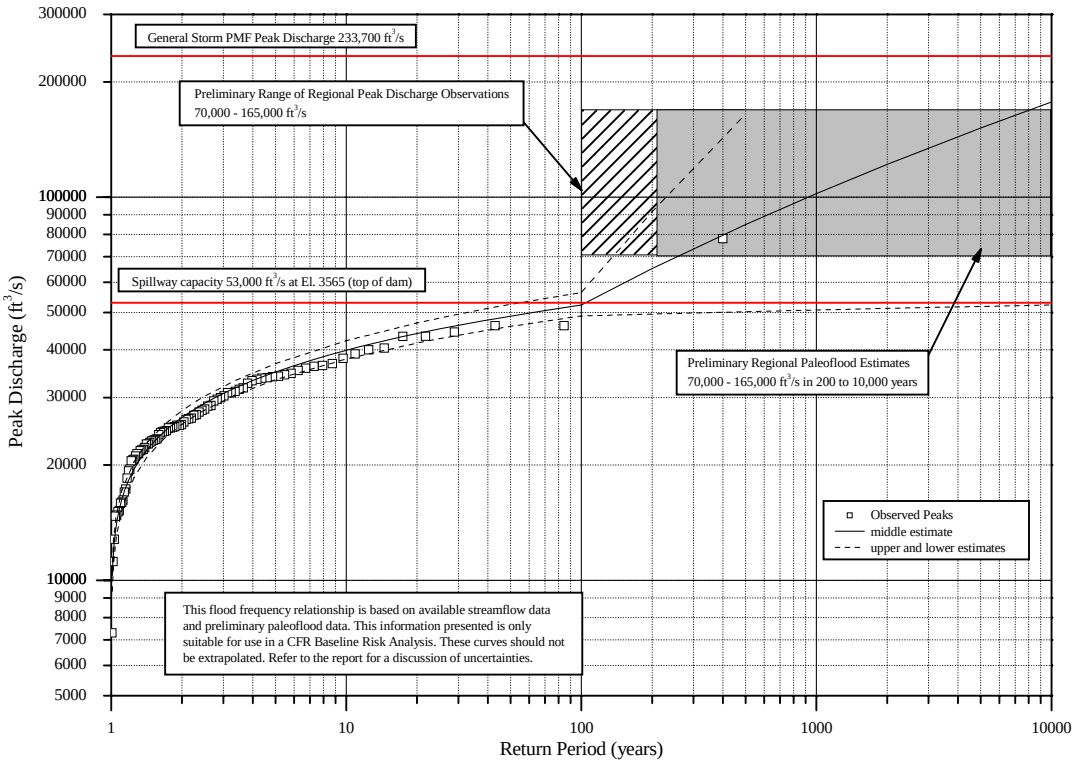

Figure 4-2.—Example application of mixed-population graphical flood frequency curve using peak discharges on the South Fork Flathead River near Hungry Horse, Montana.

4.1.3 Expected Moments Algorithm

The EMA (Lane, 1995; Lane and Cohn, 1996; Cohn et al., 1997, 2001) is a new moments-based parameter estimation procedure that was designed to incorporate many different types of systematic, historical, and paleoflood data into flood frequency analysis. EMA assumes the

LP-III distribution is the true distribution for floods. EMA was designed to handle the four different classes of historical and paleoflood data beyond the applicability of the Bulletin 17B historical weighting procedure (IAWCD, 1982). As noted by Cohn et al. (1997, 2001) and England (1998), EMA is philosophically consistent with, and is an improvement to, the Bulletin 17B method of moments procedure when one has historical or paleoflood information. EMA is specifically designed to use historical and paleoflood data, in addition to annual peak flows from gaging stations, in a manner similar to Maximum Likelihood Estimators (Lane and Cohn, 1996). It is a more logical and efficient way to use historical and paleoflood data than the current Bulletin 17B historical method, and it is a natural extension to the moments-based framework of Bulletin 17B.

The five basic steps of EMA are:

(1) Estimate an initial set of the three sample statistics $\left(\hat{\mu}, \hat{\sigma}^2, \hat{\gamma}\right)$, from the floods with known magnitudes. These floods are typically observations from the gaging station record and possibly some historical or paleofloods. At this step, floods with unknown magnitudes and magnitudes described by a range are not included.

(2) Based on the initial sample statistics from step (1), estimate a set of the LP-III distribution parameters $\left(\hat{\tau}, \hat{\alpha}, \hat{\beta}\right)$.

(3) From the set of LP-III parameters from step (2), estimate a new set of sample moments based on the complete data set: known-magnitude floods, floods less than some threshold(s), unknown magnitude floods that exceed some threshold(s), and floods described by a range.

(4) From this new set of moments, estimate a new set of LP-III parameters.

(5) Compare the parameters from step (4) to those computed from step (2). Repeat steps (3) and (4) until the parameter estimates converge. The main equations used by EMA are listed in Cohn et al. (1997), England (1999), and England et al. (2003).

EMA has been rigorously peer reviewed in the literature (Cohn et al., 1997, 2001; England et al., 2003a, 2003b) and provides a suitable flood frequency model. EMA has been applied at many sites for peak-flow frequency (England et al., 2003b). The National Research Council applied EMA for 3-day annual maximum mean floodflows on the American River (NRC, 1999). An example peak-flow frequency curve with EMA is shown in figure 4-3. There are several limitations with the current version of EMA: (1) the program assumes that the distribution is LP-III, (2) software has not been fully developed to implement the confidence interval technique of Cohn et al. (2001), and (3) low outlier and regional skew methods with EMA have been recently developed (Griffis et al., 2003), but not tested with actual data.

4.1.4 FLDFRQ3

FLDFRQ3 (O'Connell, 1999; O'Connell et al. 2002) uses a Bayesian maximum likelihood procedure to estimate parameters of various distributions. The Bayesian approach includes

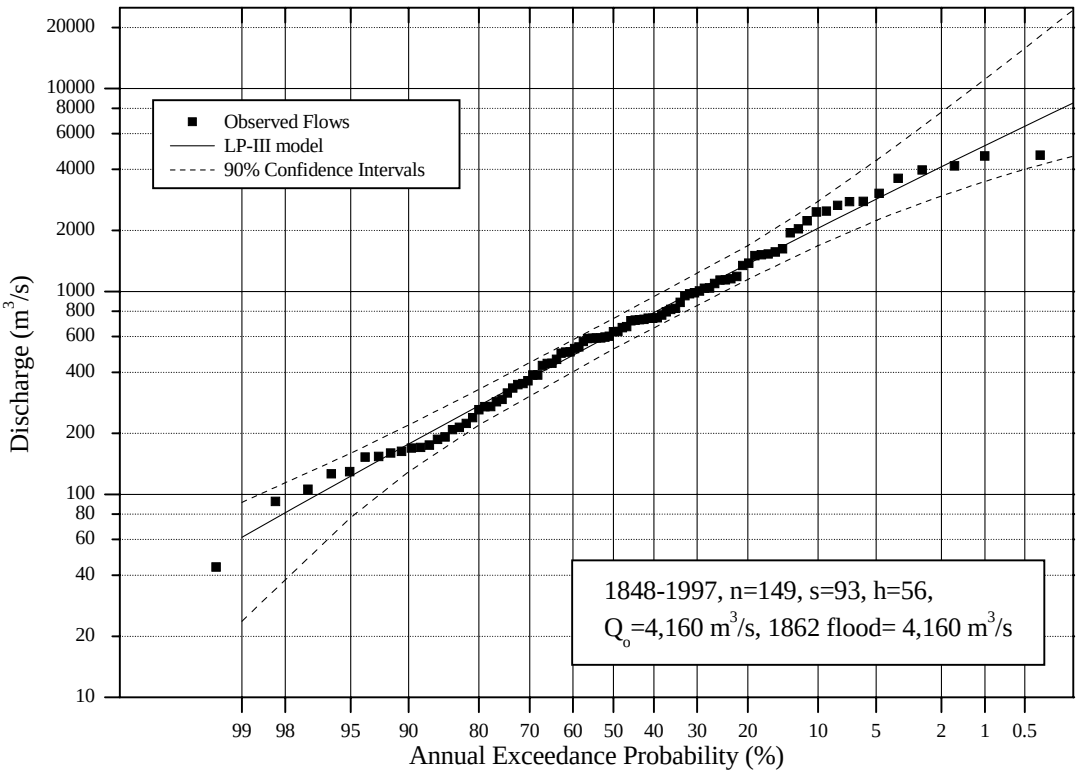

Figure 4-3.—Example application of EMA for American River annual maximum 3-day mean discharge frequency analysis.

measurement uncertainty in the parameter estimation procedure. This approach uses a "global" parameter integration grid in order to identify ranges of probability distributions that are consistent with the data (O'Connell, 1999). Two measurement error sources are included: peak discharge measurement errors and errors in paleohydrologic bound ages. Bayesian methods (Tarantola, 1987) and likelihood functions modified from Stedinger and Cohn (1986) are used to incorporate data and parameter uncertainties. Two options can be used to find the "global" maximum likelihood estimate in FLDFRQ3 (O'Connell, 1999): simulated annealing and the downhill simplex method. In FLDFRQ3, one is able to choose among five main three-parameter probability distributions to assume a peak discharge parent distribution. These distributions are the Generalized Extreme Value, Generalized Logistic, Generalized Normal, Generalized Pareto, and Pearson Type III (P-III) (Hosking and Wallis, 1997). These distributions include two logarithmic transform options for P-III models to include the LP-III. O'Connell (1999) provides details of the numerical approach used for estimating distribution parameters and uncertainty using grid integration.

There are generally three main steps in running FLDFRQ3 (O'Connell, 1999): input and data check, parameter estimation for a particular distribution, and generating parameter uncertainties for a particular model (e.g., LP-III) using grid integration. The data are grouped into two broad classes: data with normal uncertainties, such as peak discharge, and values in a range with potentially variable probability density and skew within the range, such as paleohydrologic bound discharges and ages and discrete paleofloods. After entering and checking data, the parameter estimates are obtained from the data and assumed model. The user then checks the appropriateness of the model and estimated parameters. There can be several steps here to

determine the "best models" (there can be more than one) that fit the data and the model parameters. Finally, the user estimates the parameter uncertainty given the chosen model and parameter combination. O'Connell et al. (2002) demonstrate how to combine results of several models and their parameter uncertainties using a likelihood criterion.

FLDFRQ3 has been rigorously peer reviewed in the literature (O'Connell et al., 2002) and contains suitable flood frequency models for all levels of analysis. It has been used at many sites for peak-flow frequency, such as Folsom Dam (Bureau of Reclamation, 2002), Seminoe and Glendo Dams (Levish et al., 2003), and Pathfinder Dam (England, 2003). An example peak-discharge frequency curve using FLDFRQ3 is shown in figure 4-4.

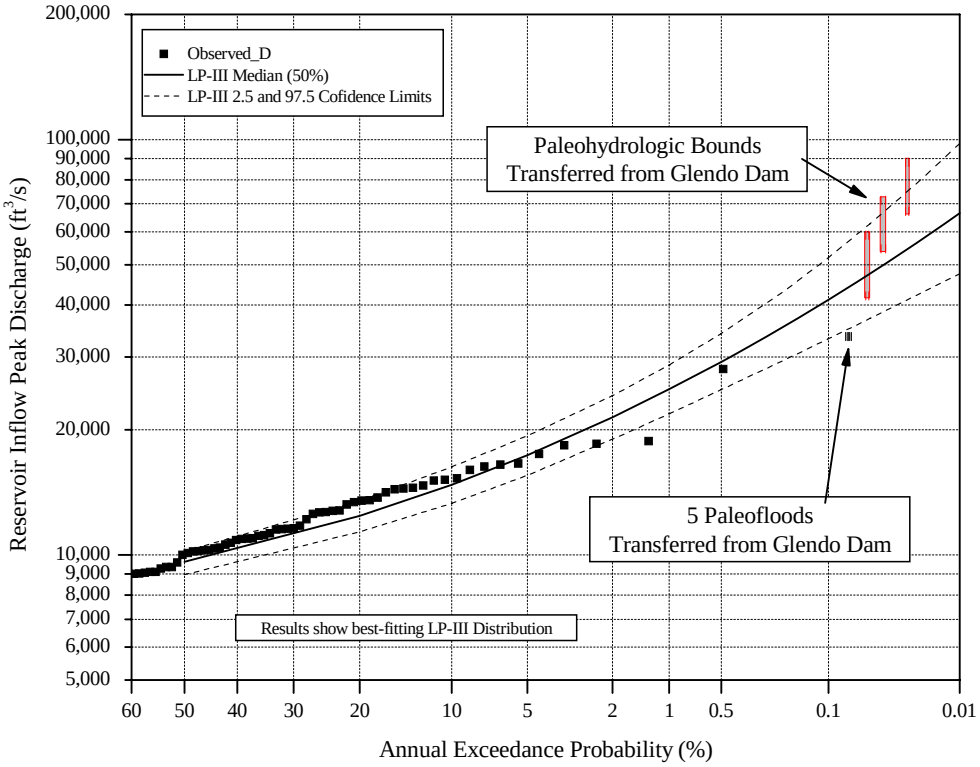

Figure 4-4—Annual peak-discharge frequency inflows to Pathfinder Dam, Wyoming, from best-fitting LP-III distribution using FLDFRQ3 (England, April 2003).

4.2 Hydrograph Scaling and Volumes

Practical tools have been developed for estimating probabilistic hydrographs that can be used in risk analyses for dam safety. These tools are presented in England (2003a) and are summarized below. The key feature of the approach is to use peak-discharge frequency curves that include paleoflood data as a basis to develop hydrographs and volume frequency curves. The methods are relatively flexible and can be tailored to different types of investigations. The methods need to be adjusted depending on the available data at the site and region of interest. For example, if a peak-discharge frequency curve developed using the graphical approach is available, one could use less detailed methods to develop hydrographs because the data might not warrant sophisticated techniques. In contrast, if detailed, high-quality peak discharge and paleoflood

data are available, one could use more refined methods such as the SEFM (MGS Engineering Consultants, Inc. [MGS], 2001) discussed below.

Probabilistic hydrographs can be constructed based on streamflow estimates from gaging stations, historical data, and paleoflood data. Four components are used: (1) a peak discharge-probability relationship, (2) an extreme storm duration probability relationship, (3) relationships between peak discharge and maximum mean daily flow volumes, and (4) observed hourly flow hydrographs that have regulation effects removed. The key idea is calibration or scaling of hydrographs to match peak discharge for a given probability. The approach relies completely on the specification of a peak-flow frequency curve that describes the probabilities of interest, based on paleoflood data.

There are four major assumptions for developing the hydrographs: (1) the probability of peak discharge represents a probability of the composite hydrograph, (2) unit hydrograph assumptions apply to the basin, (3) direct runoff volumes can be estimated from daily flow hydrographs, and (4) the recorded streamflow observations, historical information, and paleoflood data in the river basin of interest provide an adequate sample so one can extrapolate peak discharge probabilities, peak-volume relationships, and hydrographs for extreme floods. Maximum mean discharge ($\overline{Q}_d$) for n-day periods is related to peak discharge (Q_p) by a power function:

$$\log \overline{Q}_d = a + b \log Q_p \qquad (1)$$

The assumed known variable is peak discharge (Q_p), with an associated exceedance probability estimate from the frequency curve. The quality of the regression relationship expressed in equation (1) depends principally on the data from the site of interest and the flow duration (n). Mixed-population flood data (e.g., from thunderstorms, snowmelt, or rain-on-snow) can lead to difficulties in obtaining statistically significant relationships. Good regression fits are typically found for shorter duration (1- to 7-day) flow volumes; the relationships become progressively worse for longer durations. The maximum n-day hydrograph ordinates are linearly scaled, based on the selected n-day volume.

An alternate approach to using streamflow data is to use hydrographs from rainfall-runoff models as a basis for scaling. In these cases, there are typically no flood hydrograph data at the site of interest. A design flood hydrograph, a PMF hydrograph, or other suitable hydrograph for the basin is obtained. The hydrograph can then be scaled in some linear fashion to match peak flows from a peak-flow frequency curve. The analyst needs to be careful to ensure that flood volumes do not exceed physical limits when applying this scaling procedure.

Probabilistic hydrographs, developed from scaling streamflow observations or from rainfall-runoff models, are combined with recommendations for initial reservoir levels for hydrograph routing. Reservoir routing issues and selection of varying initial levels are discussed in England (2003a). One can then determine a maximum reservoir level by routing the given hydrograph and initial reservoir level. Initial reservoir levels can sometimes have a large effect on maximum reservoir level estimates for extreme floods. Maximum reservoir elevation probability estimates depend on the inflow hydrograph peak, volume, shape, and probability estimate. The initial reservoir level can also be a major factor. The selection of an appropriate initial reservoir level is of considerable importance in determination of spillway adequacy (Nathan and Weinmann,

1999, p. 57). For estimating maximum reservoir levels for design floods such as the PMF, Reclamation uses a fixed initial reservoir level. This initial reservoir level is usually set at the top of active conservation or bottom of the flood control pool. This assumption has been criticized as being unduly conservative. Newton (1983, p. 914) notes that current practice for most agencies is to assume conservatively high initial pool levels for routing PMFs. Instead of using a fixed initial reservoir level for routing hydrographs, variable initial reservoir levels are needed for risk analysis. Initial reservoir levels and associated exceedance probabilities should be estimated from daily reservoir elevation estimates for the period of record at the site of interest.

4.3 GRADEX Method

Much of this description of the GRADEX Method is paraphrased from the Ph.D. dissertation, "Methodology for Estimating the Upper Tail of Flood-Peak Frequency Distributions Using Hydrometeorological Information," by Mauro Da Chunha Naghettini, completed in partial fulfillment of the requirements for the Ph.D. degree at the University of Colorado, Department of Civil, Environmental, and Architectural Engineering, 1994. Naghettini, Potter, and Illangasekare later described the same method in the Water Resources Research publication in 1996. Some additional comments related to Reclamation dam safety needs are inserted when appropriate.

In its 1988 report, the National Research Council Committee on Estimating the Probabilities of Extreme Floods identified principles for improving the estimation of floods with AEPs on the order of 10^{-3} or smaller. These principles are: "(1) 'substitution of space for time'; (2) introduction of more 'structure' into the models; and (3) focus on extremes or 'tails' as opposed to or even to the exclusion of central characteristics" (NRC, 1988). The methodology proposed in Naghettini's Ph.D. dissertation (1994) presents techniques for the estimation of extreme flood peaks and volumes that make strong use of these principles. The main objective is to develop a peak-flow frequency curve for the extremely rare probabilities. To do so, the method involves a peak to volume relationship and the derivation of a frequency curve of extreme flood volumes based on extreme regional rainfall statistics. The method is useful to current Reclamation dam safety needs in that it provides a means to produce frequency curves for rare flood volumes and also some apparatus to define peak flows for the extreme flood volumes. It can also be used to create hydrographs based on the flood volumes and peaks, if needed.

The method relies on extrapolating a conventionally estimated probability distribution of flood volumes. To strengthen this step, the GRADEX Method, originally developed by Guillot and Duband (1967), is incorporated. The GRADEX Method has been used extensively in France since about 1967 for various improvements and hydrologic safety investigations and spillway renovations at numerous hydroelectric dams and facilities. The French Committee on Large Dams has prepared the publication, *Small Dams* (undated), which outlines the very basic steps that can be used to perform such calculations in France. The main GRADEX Method is based on two assumptions:

(1) That, asymptotically, the upper tail of the flood volume distribution is exponential with the same scale parameter as that which describes the upper tail of the

distribution of rainfall volumes for the basin. Figure 4-5 graphically displays this assumption.

(2) That any increase in total precipitation during a severe rain event, falling on already saturated ground, will produce a corresponding increase in volume of the resulting flood.

The estimation of the rainfall scale parameter has been enhanced in this application from the original French methodology by incorporating the work of Smith (1989), who developed a regional model for estimating the upper tail of a frequency distribution based on extreme order statistics. Figure 4-5 depicts the GRADEX Method.

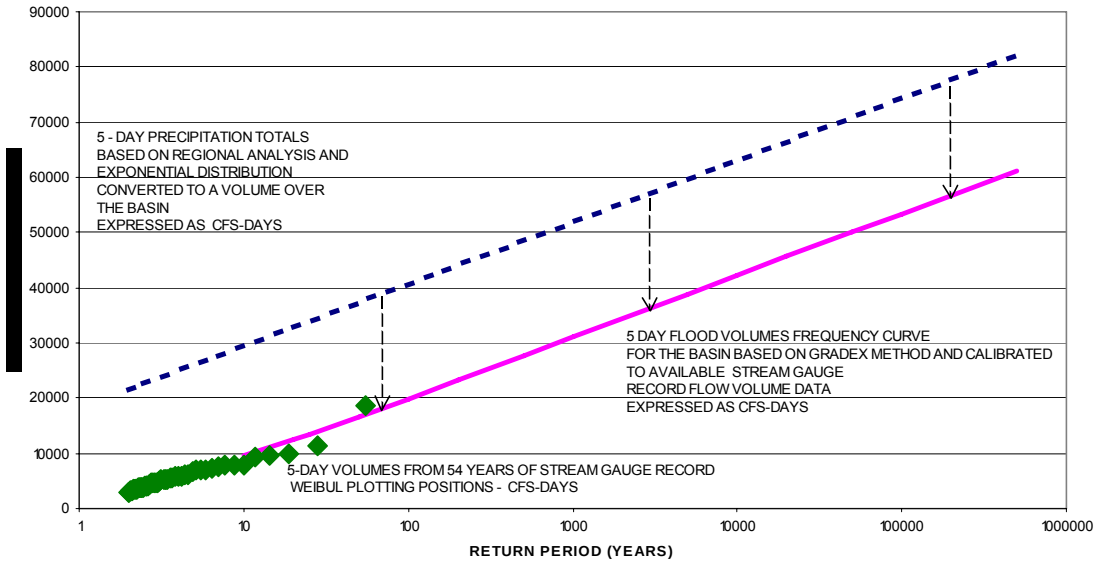

Figure 4-5.—GRADEX Method of volume frequency curve calculation.

The location where the extrapolated flood volume curve takes over from a more conventional analysis of stream gage volume data, such as using LP-III, is not fixed, but must be assumed. In the literature from France, this return period ranges from about 10 years, for very impermeable basins, to 50 years for very permeable basins.

The first assumption of the GRADEX Method given above refers to the upper tail of the rainfall volume distribution, which is assumed to be a generalized Pareto density function of the form:

$$g_p(p|s,K) = 1/a\ [1- ((Kp)/a)]^{1/K - 1} \quad \text{if } K \neq 0 \qquad (2)$$

This will reduce to a simple exponential density function of the form:

$$g_p(p|s,K) = (1/a)\exp(-p/a) \quad \text{if } K = 0 \qquad (3)$$

Where the positive constants K and *a* are the location and scale parameters, respectively. The scale parameter a is a function of various physical components of the available rain gage data

sets such as elevation and mean annual precipitation (MAP). If K > 0 then the distribution of rainfall for all sites has an upper bound; if K < 0 it is unbounded. If K = 0 the upper tail of the distribution is exponential with a scale parameter *a*. The parameter estimates are found by fitting a distribution that asymptotically exhibits an exponential upper tail (e.g., Exponential, Gumbel, Gamma, or log-Normal) to rainfall maxima. Combining the two GRADEX assumptions causes the upper tail of the flood volume distribution to also be exponential with the same scale parameter *a* (the GRADEX parameter) as the one estimated for the upper tail of the distribution of rainfall volumes, except for a necessary conversion to units of volume instead of precipitation depth.

The first step in the GRADEX Method involves selecting a critical duration. This begins with an examination of the time series of unregulated daily flows for a stream gage record deemed to be hydrologically similar to the basin being studied or a record of reservoir daily inflows. What is required is a series of independent flood events (hydrographs) that have occurred over the entire length of the unregulated streamflow record. These flood events should be rain-generated, as opposed to floods derived from snowmelt. Also, the rain-generated flood events should all be of the same storm type. For these reasons, the stream gage record analysis should be limited to a "season" when the rain floods of the same type are most likely to occur based on historic experience. Once the season is selected, the daily streamflows for each year within that season are examined. A threshold discharge, Q threshold, is set. The number of daily flows above this threshold value is observed. Multi-day events with several days of flow above the threshold are observed. The number of and the duration of each of these multi-day events are then calculated. It is desired to obtain a set of independent flood events with nearly the same number of events as the number of years in the length of record. If the number of events calculated is too large or small, then the threshold Q value is raised or lowered until approximately the number of events equals the number of years in the stream gage record. The average duration for the entire set of events is then calculated. This average duration, generally raised to the next highest number of days, will become the critical duration d used for the rest of the study. Once the critical duration *d* is determined, the average flow discharge of all of these events can be calculated. A second flow value, termed the reference discharge, is also determined such that 90 percent of the selected flood events will have average *d*-day flow values less than this discharge value. An approximate return period is also placed on this reference discharge value by the inverse of the Gringorten plotting position formula.

$$\text{Reference return period} = 1/\left((i - 0.44)/(N + 0.12)\right) \tag{4}$$

Where N is the total number of years of record and *i* is the rank of the selected reference discharge. This part of the analysis can require much hydrologic judgment. Often, a set of daily flows will show a pattern that is above the selected threshold Q for 1, 2, or 3 or more days, then drop just below the threshold for 1, 2, or 3 days, and then continue for a few more days above the threshold. Decisions have to be made as to whether this should all be considered one flood event or separated into two or more events. Rainfall records from the area may help with this decision, but, generally, it is left to the analyst to make the decision. Independence of the events is generally assumed if the time from the end of the first event to the beginning of the next event is longer than the critical duration that is calculated for this set of events.

In hydrology, this process is often referred to as a marked point process. Much literature is available dealing with statistical assumptions related to events derived by the marked point process. By its nature, the set of floods derived by this process may include several events in any one year, and no events for several years. This is what is desired because the data will be used to help calibrate the GRADEX-derived flood volume information from rainfall totals for the critical duration. It is often the case that several large rainfall events can occur in any one year. Cautions that are given for the selection of the critical duration are: (1) that selection of too short a duration might result in non-exponential, probably heavier-than-exponential, upper tails for the rainfall volumes and (2) adoption of too long a duration might result in poor peak-volume relationships. Since the goal of the application of the GRADEX Method to Reclamation dam safety investigations is to create a good volume relationship, it is advised to raise the computed critical duration value to the next higher full day.

In conventional applications of the GRADEX Method, the parameter *a* can be estimated by fitting an exponentially tailed distribution to seasonal or annual rainfall maxima. The simplest estimation procedure of the GRADEX parameter is to fit a Gumbel distribution to a series of annual maximum rainfall events for a duration *d* that is equal to the watershed critical duration, or some other measure based on time of concentration calculations. However, the most frequently used estimation procedure is to fit an exponentially tailed distribution to seasonal (sometimes monthly) rainfall maxima and then combine the seasonal (monthly) distributions to obtain the annual distribution. What can be shown is that the annual frequency curve, which would no longer be a strictly exponential curve, will tend to have the same shape or slope (GRADEX) as that of the month that produces the largest rainfall amounts, especially at the extreme upper end. A slightly more conservative approach is to use smaller durations of seasonal maxima rainfall totals for even smaller durations, even 24 or 48 hours.

Estimation of the GRADEX parameter of flood volumes requires that different units for expressing the rainfall be used. If the drainage area and critical duration *d* are expressed as mi^2 and days, respectively, and the GRADEX parameters are to be expressed in English units, then:

$$\text{Flood Volume GRADEX} = [(26.89 * DA)/d] * \text{Rainfall GRADEX} \quad (5)$$

Similar expressions exist for computations done in metric units.

Usually, following the French examples, the extrapolation of the flood volume distribution according to the GRADEX parameter starts at the 10-year flood for small and relatively impervious basins, or at the 20-year flood for larger basins, or possibly the 50-year flood for watersheds showing very little topographical relief or high infiltration capacity.

The current application of the GRADEX Method applies a new methodology to estimate the slope of the rainfall durations for a critical duration d within a specified season. This new approach combines deterministic constraints with contemporary statistical techniques, extracting the maximum information from the available data. The regional rainfall frequency model described in this section is based on the premise that meteorological processes affecting large rainfall events may be different from those affecting smaller rainfall events. The model is an adaptation of a regional flood frequency model developed by Smith (1989) and is based on results from extreme value theory. In this model, the parameters *a* and *K* in the Pareto or

exponential distribution functions (equations 2 or 3) are determined based on a regional analysis of the largest *d*-day rainfall totals for several daily rainfall stations that are shown to be or believed to be homogeneous and to represent the meteorological conditions of the basin under study. The parameter *a* is further allowed to be a function of the basin mean annual precipitation and the basin mean elevation.

$$a = S_i = \exp(c + b_1 W_{i1} + b2 W_{i2}) \quad (6)$$

Where W_{i1} and W_{i2} are the natural logarithms of the set of rain gage elevations and mean annual precipitation values for each gage site i, respectively. The constants b_1, b_2, and c are determined as part of the parameter estimation process. This is an improvement over the French general cases where only one rain gage or set of regional information reduced to one point for any basin may be used. Further, no consideration of elevation or mean annual precipitation is given in the standard GRADEX analysis.

The mathematical process to estimate the parameters K, c, b_1, and b_2 from the data set of rainfall totals proceeds as a maximum likelihood parameter estimation process. A log-likelihood function is then formed.

$$L_n(K, b_1, b_2, c) = \sum \sum \ln[g_p(Zg / K, b_1, b_2, c)] + C \quad (7)$$

Zg is the set of random variables of *d*-day rainfall totals above the threshold precipitation value at each gage site. The double sum is for all of precipitation values above the threshold value at each site and then summed over all sites.

Partial derivatives of the log-likelihood function with respect to the four parameters to be estimated (K, b_1, b_2, and c) are derived. In taking the partial derivatives, the additional constant C in the log-likelihood function is eliminated. These partial derivative functions are then set equal to zero, and a series of four non-linear equations with four unknowns (if $K \neq 0$) or three non-linear equations with three unknowns (if K = 0 is assumed) are formed. As part of the parameter estimation process, statistical tests are performed to see if the three-parameter exponential distribution form is equally valid for the data set as is the four-parameter Pareto distribution. In almost all cases, this is true. The assumption that the extreme rainfall totals can follow an exponential distribution is validated, and the rest of the GRADEX Method follows. The three parameters are then used to form the single scale parameter a (equation 5) for a single parameter exponential distribution form. In cases where the statistical test does not prove the validity of the three-parameter exponential distribution form, the rainfall total data sets need to be further investigated as to homogeneity.

Software to solve the complex sets of non-linear equations was adopted from the MINPACK software package originally developed in 1980 at the Argonne National Laboratory. This software is now free and in the public domain. Only the most extreme rainfall totals for the critical durations *d* at each daily rainfall stations are used as data. Once the equations are solved, the scale parameter *a* is estimated. Readers who are interested in the complete theoretical and mathematical background are referred to Naghettini (1994, chapter 4). The remainder of this discussion deals with the hydrological and meteorological details of this method.

The method requires that all stations selected have a common period of record that is as long as possible. Daily rainfall totals for all official rainfall gage stations in the United States are available on compact disks from Hydrosphere Corp. (2002). Several stations near the basin being studied need to be selected and their periods of record noted. These rain gage records should represent climate and meteorological conditions similar to conditions in the basin being studied. Stations too far from the study area or too high or low in elevation should not be used. The same continuous period of record should be available for each rain gage selected. It is also advisable to avoid selecting too many stations in any one area, which would then overly weight the climate and rainfall records in that localized area compared to the rest of the surrounding areas for the basin being studied.

The method relies on data from the rainfall gage records that cover the same continuous period of time for each gage. If large gaps in the gage record are found (even though the beginning and ending dates may cover the continuous period needed), the record should be discarded. Recorded rainfall data is subject to many errors, omissions, and other anomalies. Within each rain gage record, missing days, days with accumulated rainfall from several previous days, and days with only a trace of precipitation or other notations are noted. Analyzing the daily rainfall totals involves summing the total rainfalls for the number of days previously defined as the critical duration d for this basin based on analysis of the appropriate stream gage records. The process is complicated by the need to eliminate all the days with missing data or with special notes, such as when the recorded value was already an accumulated value. Any multi-day total rainfall that includes such data is then set to zero and eliminated from further consideration. Trace values are set to zero for the day that they were reported and then they are allowed in the summation process. Any extremely large daily rainfall totals need to be further checked against official hardcopy records, and the correct daily values for these dates are inserted in the analysis if changes are needed. In the process, independence of the rainfall total events also needs to be ensured. The start dates of any two multi-day events must be more than the critical duration *d* apart.

The method requires selection of a number of multi-day total rain events at each gage equal to the number of common years of record for all selected gages. A threshold *d*-day total rainfall for each gage is selected such that exactly the same number of independent *d*-day rain totals is above this value as are in the continuous period of record covered by all the rain gages in the analysis. Further, a reference total precipitation value for each rain gage is also selected such that 90 percent of the previously selected events are below this reference precipitation value. The threshold and reference precipitation values are used later in the statistical analysis. Only the top 10 percent of the *d*-day rainfall totals are used in the regional analysis. This amounts to a form of top-end fitting for the precipitation totals.

To further facilitate the computations, the rainfall multi-day totals are reduced by subtraction of the reference precipitation amount for each rain gage. This step is necessary to eliminate very large numbers in the calculations that follow. This is a form of “indexing” and is common in many regional flood methodologies.

The upper order statistical method calculates the slope (or GRADEX parameter) of the best-fit decaying exponential distribution of the top 10 percent of the *d*-day total indexed precipitation amounts for each selected rain gage site. The selected station elevations and mean annual

precipitations help weight the slope parameter. Knowing the basin's mean elevation and MAP, a GRADEX parameter fit specifically to the drainage basin being studied can be calculated. The result is the slope of the decaying exponential distribution of the most extreme precipitation amounts that the selected precipitation data suggest can occur over the drainage basin. The distribution of *d*-day total index precipitation values can then be used with knowledge of the contributing drainage area for the basin to create associated *d*-day volumes as shown in equation 5, above. This distribution of *d*-day volumes now has a slope, but it must also be fit to the actual reservoir *d*-day inflow volumes at the lower return periods. This is done through a statistical procedure. The fitted curve will match the experienced stream gage *d*-day volumes near the computed reference Q value previously computed. The resulting curve can be extended to very high return periods based on the second basic assumption of the method, that all large flood volumes will occur from rain falling on already thoroughly saturated conditions in the contributing areas of the basin, and any increase in a *d*-day rainfall will result in a corresponding increase in *d*-day inflow volume to the reservoir.

Since the GRADEX parameter *a* is calculated using a maximum likelihood estimate, it is further possible to place a confidence bound on this parameter. Note that for one-parameter distributions such as the exponential, the natural logarithm ratio between the estimated likelihood function and a true likelihood function for the one parameter can be proportional to a chi-square distribution with one degree of freedom. This process is displayed on the Web page, <http://www.weibull.com.LifeDataWeb/likelihood_ratio_confidence *bounds*exp.htm>. By a trial and error process, the upper and lower confidence bounds associated with the *a* parameter estimate can be determined for some set confidence level.

Once the slope and location of the flood volume curve for the *d*-day durations have been established, the question of what is the probability that a particular volume of flooding will be equaled or exceeded in any year can be answered. The more common question is what is the volume of flooding that will be exceeded on average only once in a stated return period, T_c = number of years. To answer that question, the calculated exponential distribution and associated confidence bounds, need to be inversed. The inverse of the distribution has the form:

$$\hat{x}(T_c) = \hat{\beta}_1 + \hat{a}\ln\left(T_c + \hat{\beta}_2\right) \tag{8}$$

Where:

$\hat{x}(T_c)$ is the *d*-day flow value for any required return period, in ft^3/s-days, T_c is the return period (in years) for which a *d*-day flow estimate is required, $\hat{a}$ is the previously estimated GRADEX slope factors converted to volume units, and $\hat{\beta}_1$ and $\hat{\beta}_2$ are constants that can be estimated from a system of simultaneous equations that are formed knowing the mean of the sample of *d*-day flood discharges and the reference *d*-day discharge with an approximate return period. Both of these discharge values and the reference discharge return periods are previously computed from the daily inflow record for the location of the study. The $\hat{x}(T_c)$ value can then be further converted to more common volume units such as acre-feet for a specified number of days.

The original goal of the method, as presented in Naghettini (1994), was to produce a peak-flow frequency curve. In this procedure, a known set of peak flows associated with *d*-day volumes can be determined from the stream or reservoir inflows, assuming peak flows have been recorded. This set of paired data for the period of the streamflow record can be further extended by the use of various rainfall-runoff models. Calibrated rainfall-runoff models can be created for some of the largest events in the stream gage record if appropriate rainfall data are also available.

In the original presentation of the method, it is suggested that several large storms, all of the same type and from meteorologically similar areas, could be transposed into the basin. For each of these large storms, the calibrated rainfall-runoff models can then be rerun with the transposed storm precipitation data and a new peak flow and hydrograph can be generated. Additional sensitivity analysis runs can be made by varying certain parameters in the rainfall-runoff model that affect the peak, such as the lag time or other parameters related to unit hydrograph development. The peaks and *d*-day volumes from all of the additional transposed storms can then be added to the original set of peak and volume data. Regressions on this extended set of peaks and volumes can provide the necessary information to help determine a peak flow for a selected volume at some rare return period that has been calculated by the GRADEX Method. In both the French and American literature for the GRADEX Method, it is suggested that the regression between volume and peak data should not be linear. The French literature states that the ratio of peaks to a *d*-day volume will increase with increasing return periods. A regression procedure known as LOWESS (Locally Weighted Regression and Smoothing of Scatter Plots) (Cleveland, 1979) can be used to perform the non-linear curve fitting required for this procedure.

Reclamation's practice with the method has not involved multiple storm transpositions. For each application, some attempt has been made to create a calibrated rainfall-runoff model using HEC-HMS (U.S. Army Corps of Engineers, 2002). The largest one or two floods from the stream gage record and the best available rainfall data are used to create the calibrated runoff model. The model is calibrated to match as nearly as possible the peak and the entire volume of flooding, which may be longer than the *d*-day critical duration determined earlier. Once the calibrated rainfall-runoff model is completed, the historic rainfall information, with both temporal and spatial distribution, is increased by a constant ratio at each time period. The resulting peak and *d*-day volume of the hydrograph is recorded. Additional runs are made and the lag times are reduced by 10 or 20 percent to account for the fact that the historic flood may not have resulted from such intense rainfall as the desired higher return period floods might produce. With more intense rainfalls, it may be that the basin lag times should be reduced to allow for quicker formation of the flood peaks. The extended peak and *d*-day volume set is then fit with the LOWESS procedure. Using this non-linear regression, peak flows associated with the various volumes for different return periods by the GRADEX Method can be estimated. This method will also allow for production of the entire hydrograph with exactly the required *d*-day volume estimated by the GRADEX Method. Examples of the results of this computation can be seen in the Fresno Dam example at the end of this report.

In the publication, *Small Dams*, (French Committee on Large Dams, undated), an empirical equation is given that will produce an entire hydrograph with a specified peak, time to peak, and the desired time step. One of the parameters in that equation can be varied by trial and error until the desired volume of the hydrograph over any period of time, such as *d*-days, is achieved. This

represents another strictly empirical method to derive a hydrograph once a peak and volume for the desired return period are known.

Some other concerns have become apparent in the application of the GRADEX Method to some dams in the Reclamation inventory. The first concern is with the possible additional volume of flooding that may result from snowmelt that may not be explicitly considered in the GRADEX Method. The available literature indicates that a separate snowmelt volume analysis should be undertaken. For each year of stream gage record, the maximum snowmelt volume for some time period larger than *d*-days should be estimated. A separate LP-III (or any other distribution) analysis of the snowmelt volumes can be constructed and extrapolated to rare return periods. This frequency curve of snowmelt flood volumes can be used with a combined probability analysis of the rain flood GRADEX *d*-day volumes. The resulting frequency curve will display the probability of getting a flood volume composed of both snowmelt and rain flood volumes. What becomes apparent for the large return periods is that the GRADEX rain flood curve will dominate the combined probability volumes. The combined probability curve is almost identical to the GRADEX curve at the large return periods. For a large return period, the probability of getting a flood with X acre-feet composed of Y acre-feet of snowmelt, plus Z acre-feet of rain generated flood volume (X = Y + Z), is nearly identical to getting the rain flood alone with X acre-feet of volume. An example of this type of combined probability analysis is given in the Fresno Dam example later in this report. It is recommended that in all future applications of the GRADEX Method to Reclamation dams some attempt be made to create a separate snowmelt flood volume frequency curve and a combined probability analysis with the GRADEX rain-flood curve be made to ensure that the rain floods dominate at the rare return periods.

A second concern is with drainage area size. The GRADEX Method is based on assumed basin average rainfall. Because of this, there is a clear question as to its applicability to large basins. The original French literature limits the size of the drainage basins where the GRADEX Method can be applied to about 10^4 square kilometers, or about 3,800 square miles. It is noted that few storms with greater aerial coverage exist in the rain gage data. The application of the method to such larger drainage sizes would not produce defendable results. To approach this problem, the suggestion is that the larger basin be broken into smaller parts along logical lines, such as at major tributary confluences, such that each part is no larger than 3,000 square miles. The GRADEX Method could be applied to each separate part, and a combined probability analysis could then be performed with the resulting curves for each part. The resulting frequency curve would show the volume of flooding that could occur resulting from contributions from each separate part of the basin. This approach has not yet been tried for any Reclamation dams.

For the full application of the method for a detailed hydrologic study, additional effort should be made to determine a homogeneous set of rain gages for use in the GRADEX Method. Naghettini (1994) provides some useful suggestions and examples along these lines. Due to time and money constraints, this has not been done in any Reclamation studies to date.

4.4 Australian Rainfall-Runoff Method

The Australian Institution of Engineers developed and published an approach for estimating large to extreme floods in 1999 and revised the method in 2001 (Nathan and Weinmann, 2001). The focus of this work is on estimating floods with very low probabilities of occurrence. The

floods developed using this technique usually have AEPs ranging between 1 in 50 and 1 in 10 million. Uncertainties involved in estimating floods increase with increasing sizes of floods. The following discussion describes Reclamation's experience with estimating rare and extreme floods using the Australian approach.

Three categories of floods are considered – large, rare, and extreme. Large floods typically have probabilities of occurrence ranging from 1 in 50 to 1 in 100. Rare floods include floods with AEPs extending from 1 in 100 to the credible limit of extrapolation, generally around 1 in 2,000. Extreme floods involve estimating floods for the AEPs beyond the limit of credible extrapolation. For risk analysis purposes, rare and extreme floods are of most interest.

Rare floods include events between the largest observed flood and the credible limit of extrapolation. The creditable limit of extrapolation depends on the type and amount of data used for flood frequency analysis. Generally, regional flood and precipitation data, and the inclusion of paleoflood data, allow extrapolation out to around 1 in 2,000 or 1 in 5,000. It is important to note that floods in this category contain considerable uncertainty because estimates are outside the range of observations.

Extreme floods extend beyond the credible limit of extrapolation from the data to AEPs out to 1 in 10 million. Estimating these floods requires prescriptive measures, which do not allow the hydrologist to quantify the uncertainty of the estimates even though it is known to be very large. Extreme floods determined by these methods are intended to be consistent and as reasonable as possible given the state of current knowledge.

4.4.1 Approach

The procedures involved in the Australian Rainfall-Runoff Method are based on flood frequency analysis and rainfall-runoff modeling. Any of the flood frequency analysis techniques previously discussed in previous sections of this report are applicable to the Australian Rainfall-Runoff Method. The unique concept in this approach is the use of "AEP-neutral" parameters in the rainfall-runoff modeling process. This involves selecting model parameters such that the AEP of the 1 in Y rainfall amount produces a flood with a 1 in Y AEP.

Reclamation has used an event-based deterministic rainfall-runoff model to convert a 1 in Y AEP design rainfall into a 1 in Y AEP flood. A single set of hydrometeorological parameters and watershed characteristics are used to produce a flood event. No soil moisture or surface storage recovery is provided. Therefore, the deterministic model always produces the same output.

The major inputs to the deterministic rainfall-runoff model are: (1) precipitation (rainfall and snowfall), (2) losses (infiltration/interception), (3) physical watershed characteristics for runoff and routing simulations (drainage areas, watershed and channel slopes, lag times, antecedent moisture, etc.), (4) precipitation-runoff transformation function, and (5) runoff conveyance and routing mechanisms. Model output includes runoff hydrographs at user-specified locations, maximum peak discharges, and total runoff volumes.

Deterministic event-based precipitation-runoff modeling applies design rainfall distributions and volumes to watersheds for which runoff response is characterized by unit hydrographs and

generalized loss-rate functions. Calculations proceed from upstream to downstream in the watershed. Subbasin hydrographs are routed and combined at the points of interest.
A design storm (rainfall and basin snow cover) is the primary model input. Typically, a time series of basin-average rainfall for a preselected duration and frequency is input to the model. A 1-hour to 72-hour duration storm event is typically simulated. Appropriate duration storm events should be derived from local and regional rainfall records. In the process of developing extreme floods, the Australian Rainfall-Runoff Method assigns an AEP to the PMP, and is solely a function of drainage area size. Reclamation assigns an AEP to the PMP on an as-needed basis and does not endorse the drainage area relationship used by the Australians. Reclamation considers the proximity to moisture sources, areal coverage of the storm, and other factors in assigning an AEP to the PMP.

Excess precipitation is estimated by subtracting losses typically due to infiltration and interception. A variety of infiltration models are available and range from constant uniform loss rates to approximate theory-based functions (Green and Ampt, Philips equation). Antecedent storm assumptions can have a severe impact on basin infiltration estimates. Since the deterministic rainfall-runoff model is based on a single event, soil moisture storage and recovery during and between storms is not considered.

The amount of watershed information required is a function of the type of precipitation-runoff model used. Two classes of models are currently used—lumped and distributed parameter models. Lumped parameter models consider the system as being spatially averaged. In contrast, a distributed system considers hydrologic processes at various points in space and defines model variables as functions of the space dimensions. Some lumped parameter models that are widely in use are HEC-1 (HEC, 1990), FHAR (Bureau of Reclamation, 1990), and RORB (Laurenson and Mein, 1995). Some distributed models that can handle single events include DR3M (Dawdy et. al, 1978), PRMS (Leavesley et. al, 1983), HEC-HMS, and WMS. Additional surface water models are discussed in DeVries and Hromadka (1993).

Transformation of rainfall excess to a direct runoff hydrograph is completed via a convolution integral using (1) unit hydrograph techniques or (2) kinematic wave routing for overland flow. The unit hydrograph has been used extensively for flood runoff estimation. Kinematic wave and distributed modeling approaches may be more appropriate for modeling non-linear systems. A good discussion about rainfall-runoff processes and floods, including practical issues comparing design floods and actual storms, is presented in Pilgrim and Cordery (1993). Beard (1990) presents a methodology for simulating floods of a given probability from hypothetical design storms derived from point rainfall.

Streamflow routing may be classified as either lumped/hydrologic (linear reservoirs, level-pool, Muskingum, etc.) or distributed/hydraulic (diffusive wave, kinematic wave, etc.). In lumped flow routing, streamflows are computed as a function of time at one location; however, in distributed flow routing, streamflows are computed as a function of time at several locations along the stream. Most precipitation-runoff models have adequate routing mechanisms. A detailed discussion of routing options is presented in Chow et al. (1988).

For risk-based dam safety studies, it is necessary to adopt an AEP-neutral approach, where the objective is to derive a 1 in Y AEP flood with an AEP equivalent to its 1 in Y rainfall. The

factors that influence the transfer between rainfall and runoff can be characterized by probability distributions. Thus, ideally, the design hydrograph should be determined by considering the joint probabilities of all the input factors. Stochastic methods are ideally suited to the AEP-neutral objective because they accommodate the observed variability of the inputs while still preserving the interdependencies between parameters. However, for the least important parameters, it may be appropriate to adopt a single representative value instead of the full distribution. Since the relationship between rainfall and runoff is non-linear, it is important to note that adoption of a single representative value for the major inputs will introduce bias into the rainfall-runoff transformation. Therefore, more important model inputs may require use of a joint probability approach.

The simplest approach to deriving AEP-neutral inputs is to use the correlation relationship between the two variables. For example, if it is necessary to derive a temporal relationship to use with the design rainfall magnitude, an appropriate relationship may be derived from the correlation between the largest observed storms and their temporal characteristics during the largest storms on record. When applying relationships based on a limited historical sample to large flood events, the inputs should be conditioned by physical reasoning. For instance, large snowmelt events may require large snowpacks and high temperatures, but the meteorological conditions required to sustain an extreme rainfall event may preclude the joint occurrence of extreme wind speeds. The concurrent wind speeds used in the transformation of snow into runoff must be bounded by a reasonable upper limit.

The selection loss parameters are required inputs common to all event-based rainfall-runoff models. With loss rates, there is evidence to suggest that loss rates are independent of flood magnitude for design floods up to 1 in 100 AEP, though, for more extreme events, it is possible that the loss rates depend on both the AEP and the duration of the design rainfall. When considering snowmelt design floods, it may be necessary to vary loss rates with snowpack extent (Nathan and Bowles, 1997).

The most appropriate approach required to achieve AEP-neutrality depends on the complexity of the system being modelled, the nature of the available data, and the requirements of the flood model. In many cases, it may be expedient to adopt model input parameters derived using regional data, and it will be necessary to supplement empirical evidence by physical reasoning. Calibration of the design flood estimates to flood frequency quantiles will help reduce the uncertainty in extreme flood estimates.

4.4.2 Calibration

Calibration of a flood event model for application to design flood estimation is traditionally restricted to the selection of model parameters to achieve a fit between observed and estimated hydrographs. Attention is focused on collecting streamflow and rainfall data corresponding to the largest events on record. Considerable effort is required to ensure that the temporal and spatial distribution of the rainfall data is representative of the actual event. The ability of a model to reproduce historic events certainly gives some confidence to the validity of subsequent flood estimates. However, the available historic information for floods is usually much smaller than the extreme floods of interest. In most watersheds, the AEPs of the calibration floods are likely to range between 1 in 10 and 1 in 25. While it would be expected that floods of this

magnitude would activate some floodplain storage, the non-linear nature of the out-of-bank flood response is such that the streamflow routing characteristics of larger events may be considerably different. Therefore, while calibration of the model provides valuable information on the flood routing parameters for small floods, caution is needed when using the model to estimate extreme floods of much larger magnitude.

Calibration of rainfall-runoff model results to flood frequency quantiles can provide important information on flood response characteristics for extreme flood events. With this approach, rainfall data are prepared for a specified AEP and then used with a given set of model parameters and input assumptions to derive a flood hydrograph. The peak (or volume) of the flood hydrograph can then be compared to the corresponding quantile obtained from flood frequency analyses. The model inputs associated with the greatest uncertainty can be varied within appropriate limits to ensure agreement between the selected flood quantile. It is recommended that model calibration be undertaken for a range of exceedance probabilities to ensure a consistent variation of parameters with flood magnitude. The approach is suited to ungaged watersheds using regional flood frequency methods as well as sites with limited information. The approach is considered to be particularly useful when combined with flood frequency information that uses paleoflood data.

4.4.3 Strengths and Limitations

Event-based deterministic rainfall-runoff modeling has a long track record in the engineering and hydrologic community and is a proven technique for generating design hydrographs. Reclamation uses deterministic precipitation-runoff modeling. From a technical standpoint, the approach is flexible and requires less effort than most of the more complex approaches. Model choice should be a function of the hydrometeorological and physical data available. For example, a distributed model could be applied in cases where detailed information was available; however, a simplified lumped-parameter model would be appropriate in less data-rich locations. Output from either model would be similar.

Limitations to this method arise from the need to calibrate model results to known historical flood events or to flood frequency analyses so that the AEP of the storm is the same as the resulting flood. Calibration can be difficult if the model is sensitive to many input parameters. A lack of good meteorological data can prove troublesome in developing design storms with appropriate temporal and special characteristics. Rainfall-runoff modeling in data-sparse locations may require a high level of regional data gathering and analyses to obtain the necessary hydrometeorological inputs.

4.5 Stochastic Event-Based Precipitation Runoff Modeling with the SEFM

The SEFM has been developed by MGS Engineering Consultants, Inc., in conjunction with Reclamation personnel. The SEFM was developed for analysis of extreme floods resulting from 72-hour general storms and to provide magnitude-frequency estimates for flood peak discharge, runoff volume, and maximum reservoir levels for use in hydrologic risk assessments at dams

(Schaefer and Barker, 2002). The SEFM is fully described in MGS Engineering Consultants, Inc. (March 2001) and summarized in Schaefer and Barker (2002).

The basic concept of the SEFM is to employ a deterministic flood computation model and treat the input parameters as variables instead of fixed values. Monte Carlo sampling procedures are used to allow the hydrometeorological input parameters to vary in accordance with those observed in nature, while preserving the natural dependencies that exist between some climatic and hydrologic parameters. Example outputs from the SEFM are shown in figures 4-6, 4-7, and 4-8 (MGS, March 2001).

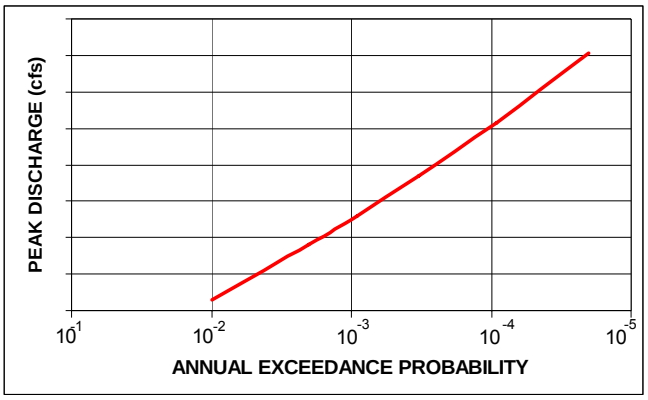

Figure 4-6.—Example of magnitude-frequency curve for peak discharge.

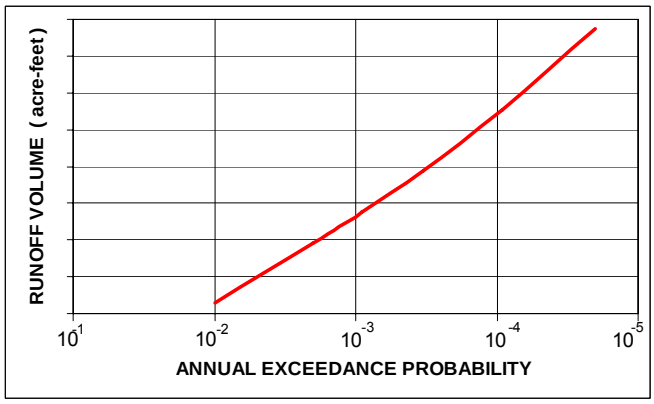

Figure 4-7.—Example of magnitude-frequency curve for runoff volume.

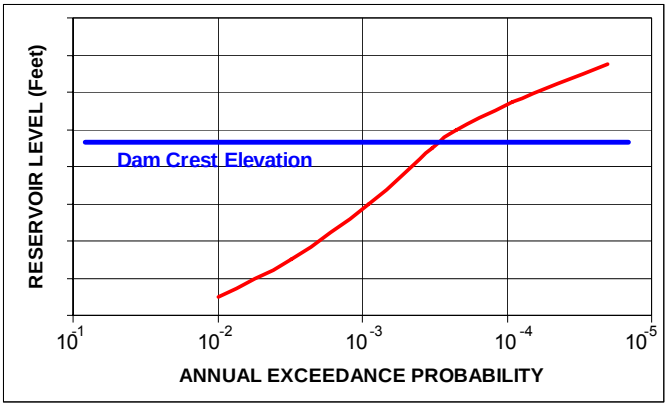

Figure 4-8.—Example of magnitude-frequency curve for maximum reservoir level.

A general flowchart for stochastic modeling with the SEFM is shown in figure 4-9. Thousands of computer simulations are conducted where each simulation contains a set of input parameters that were selected based on the historical record and, collectively, the simulations preserve the dependencies between parameters. The simulated floods constitute elements of an annual maxima flood series that can be analyzed by standard flood-frequency methods. The resultant flood magnitude-frequency estimates reflect the likelihood of occurrence of the various combinations of hydrometeorological factors that affect flood magnitude. The use of the stochastic approach allows the development of separate magnitude-frequency curves for flood peak discharge, flood runoff volume, and maximum reservoir level. Frequency information about maximum reservoir levels is particularly important for use in hydrologic risk assessments because it accounts for flood peak discharge, runoff volume, hydrograph shape, initial reservoir level, and reservoir operations. The precipitation estimates used in the SEFM are typically developed using regional precipitation frequency analysis with L-Moments (Hosking and Wallis, 1997). This approach uses a space-time substitution principle and assumes that there is sufficient precipitation data in a region to combine for subsequent model extrapolation to the probabilities of interest.

The general storm SEFM is composed of seven software components: data entry, input data pre-processor, multiple sample parameter test workbook, HEC-1 template file, stochastic inputs generator, HEC-1 rainfall-runoff flood computation model, and an output data post-processor. The flowchart shown below (figure 4-10) depicts the sequence of actions required for conducting the computer simulations using the software components. Each of these components is described in the SEFM Technical Support Manual (MGS, March 2001). The software (MGS, April 2001) helps the user input data, run the model, and visualize results.

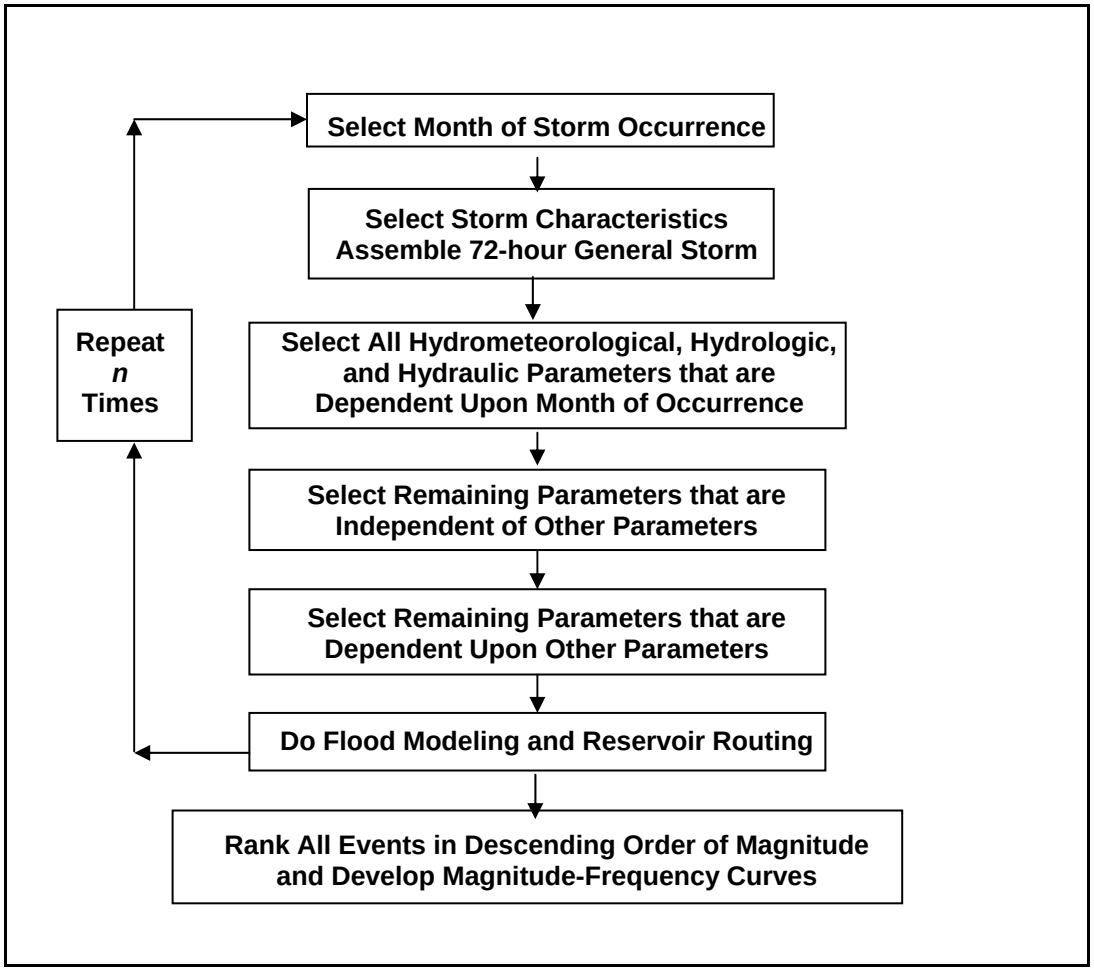

Figure 4-9.—General flowchart for the SEFM simulations (after MGS, 2001).

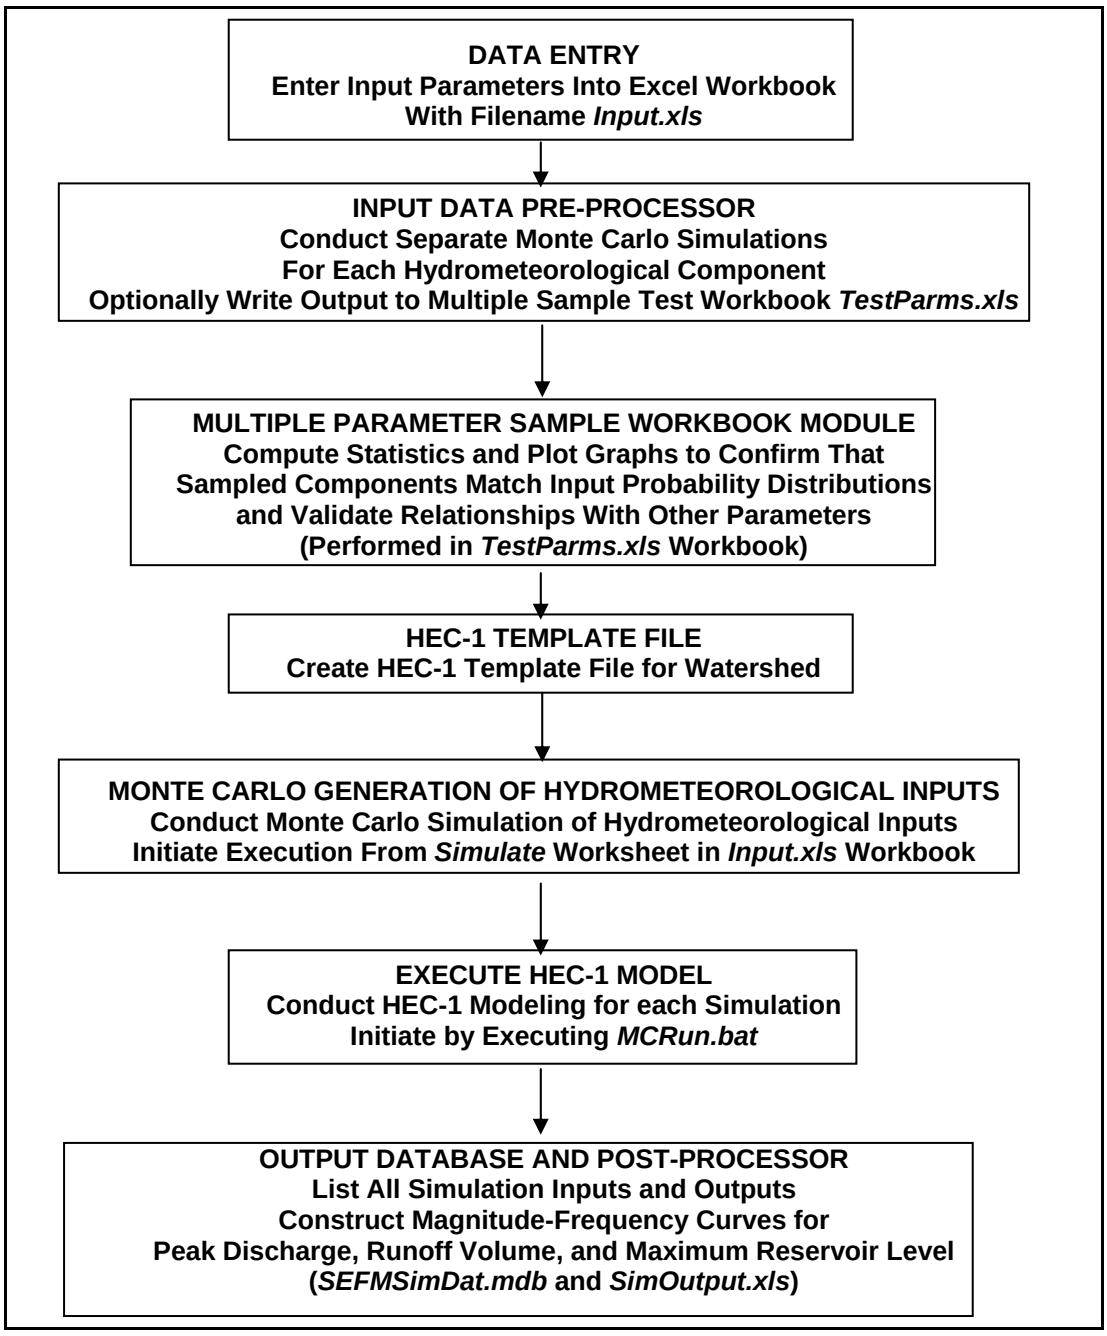

Figure 4-10.—General flowchart for the sequence of actions required for conducting the computer simulations using the SEFM.

The input processor to the SEFM is an Excel workbook. The workbook includes different spreadsheet screens for input (figure 4-11), for model execution, and for output (figure 4-12). The improvements are contained in software version 1.8 of the SEFM.

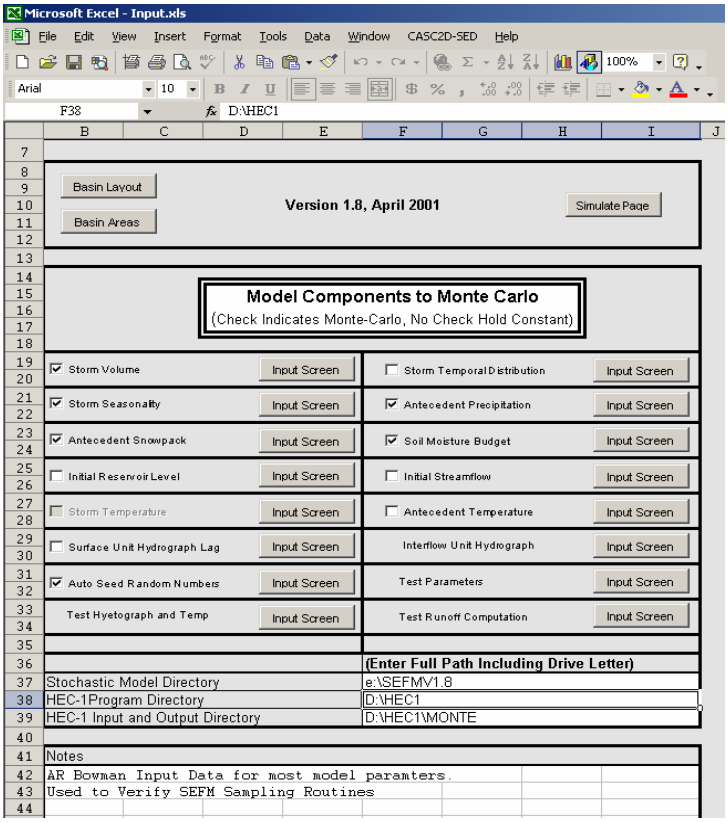

Figure 4-11.—The SEFM input screen.

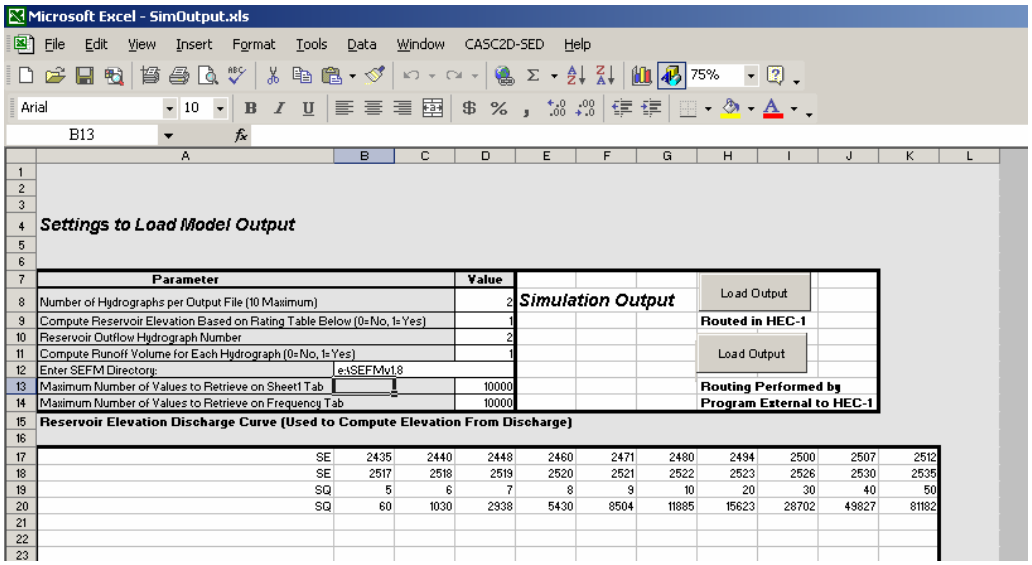

Figure 4-12.—The SEFM output simulation options.

The basic concept behind the SEFM was first used to explore PMF variability and extreme flood probability issues at Bumping Lake Dam for Reclamation (Barker et al., 1996; 1997). The prototype of the SEFM was developed for application to the A.R. Bowman watershed (Schaefer and Barker, 1997; 1998). The SEFM was subsequently generalized for use by Reclamation on other projects and applied at Keechelus and Cle Elum Dams (Bullard and Schaefer, 1999). A sensitivity analysis has been performed for A.R. Bowman Dam (MGS, January 2001) to determine the dominant features that affect model results. A brief review of the model (Singh, 1999) indicated that the model is a sound package for extreme flood modeling, and there could be some eventual improvements.

There are some current limitations to the SEFM and the applicability to certain Reclamation sites. The SEFM is currently configured for simulation of 72-hour general storms. There is no computational limit to the size of the watershed to which it can be applied. However, implicit in the development of the model is the condition that some hydrometeorological parameters are highly correlated spatially. As the watershed size increases, the requirement for high spatial correlation of multi-month precipitation and snowpack becomes more difficult to satisfy. This consideration suggests that the stochastic model is applicable to watersheds up to a nominal size of about 500 mi^2. For larger watersheds, the spatial variability of some hydrometeorological parameters may warrant that site-specific modules be developed to address the site-specific characteristics of the watershed under study (Schaefer and Barker, 2002, p. 732). Currently, the model does not handle thunderstorm events. Additional routines would need to be added to simulate any storms with durations that differ from 72 hours. These limitations may be relaxed as improvements are made to the model.

4.6 Stochastic Rainfall-Runoff Modeling With CASC2D

CASC2D is a fully unsteady, physically based, distributed-parameter, raster (square-grid), two-dimensional, infiltration-excess (Hortonian) hydrologic model for simulating the runoff response of a watershed subject to an input rainfall field for a particular storm event (Julien and Saghafian, 1991; Julien et al., 1995; Ogden and Julien, 2002). Major components of the model include rainfall interception, infiltration, surface and channel runoff routing using the diffusive wave method, soil erosion, and sediment transport. CASC2D is appropriate for simulating extreme floods and physically based extrapolations of frequency relationships combined with a derived distribution approach. The main differences between CASC2D and the SEFM are that CASC2D is a fully distributed model and uses hydraulic principles for runoff generation and routing precipitation excess. The SEFM is essentially a lumped model and uses the unit hydrograph as the basis for runoff and routing precipitation excess. Other differences are the infiltration models and routing mechanisms for river channels. CASC2D is also a somewhat experimental model that has not been used in extreme flood applications for dam safety, or for many applications outside academic research.

The idea and basis to use CASC2D for extreme flood modeling and prediction is centered on two concepts: (1) a derived distribution approach (e.g., Eagleson, 1972) can be used to estimate the extreme flood peak and volume probability distributions and (2) physically-based methods for flood runoff and routing provide a suitable and improved physical basis for the extrapolations of derived flood probability distributions. Ramirez (2000) summarizes the theory behind the

derived distribution approach. In the disciplines of science and engineering, relationships that predict the value of a dependent variable in terms of one or many basic (independent) variables are commonly developed. Physical systems are naturally complex. The functional form of the relationship between independent and dependent quantities or the values of the independent variables (or both) is not usually known with certainty. Techniques based on probabilistic assumptions can be used to account for this uncertainty. When the uncertainty derives from uncertainty in the independent variables, but not from uncertainty in the functional dependence, a derived distribution approach leads to the probability density function of the dependent variable. In this case, the functional form relating independent and dependent variables is assumed known with certainty. In such instances, it is possible to derive the probability density function of the dependent variable(s) from that of the independent variable(s) (Ang and Tang, 1975).

Several research applications use the derived distribution approach to estimate flood frequency curves; these show much promise. The pioneering study for flood frequency is Eagleson (1972). Bras (1990) discusses some of the potential applications of derived distributions in hydrology.

4.7 PMF Analysis Technique

The PMF is defined by Reclamation as "the maximum runoff condition resulting from the most severe combination of hydrologic and meteorologic conditions that are considered reasonably possible for the drainage basin under study" (Cudworth, 1989). Other agencies have developed somewhat different definitions, but all consider the PMF to be a "maximum runoff condition" that is "reasonably possible."

In Reclamation practice, the basic model to convert PMP to runoff is the unit hydrograph. It is recognized that many other techniques, including sophisticated computerized models, are available for making this conversion. The unit hydrograph concept represents the modeling of the rainfall-runoff process as a linear system. The fact that the rainfall-runoff process is actually non-linear is one of the acknowledged shortcomings of the concept. However, if properly applied, the concept provides entirely satisfactory results for developing flood hydrographs resulting from extreme rainfall events.

During the period from the mid-1940s to the late 1990s Reclamation engineers designed and built most of the large storage dams currently in Reclamation's inventory. During this period, Reclamation published three editions of the *Design of Small Dams*. That publication has served as a textbook and as a technical guide for numerous States and many foreign countries. Many States, consultants, and other agencies still use the methods and PMF philosophies expressed in the recent editions of those publications. The basic PMF methodologies described in those publications have served as the basis for thousands of dams in the U.S. and other countries designed by both Reclamation and non-Reclamation engineers. These publications are still in widespread use. Reclamation engineers often employed somewhat different techniques and nomenclature for deriving design floods, but the intent was nearly always to design for the PMF determined by the then current techniques. Some exceptions were made for small dams and diversion structures where it was believed that failure of the structure caused by overtopping would not produce any loss of life or major economic damages.

The steps involved in deriving the PMF hydrograph for a single basin have been described in many sources. The following steps are modified from the list given by the National Research Council (NRC, 1988). This list briefly summarizes the PMF calculation process currently followed by Reclamation and many other dam building agencies:

1. Divide the drainage area into subbasins, if necessary, and determine the appropriate drainage areas.

2. Derive a runoff model (unit hydrographs for Reclamation studies).

3. Determine the PMP using criteria contained in NOAA Hydrometeorological Report (HMR) series.

4. Arrange the PMP increments into a logical storm rainfall pattern.

5. Estimate for each time interval the losses from rainfall, due to such actions as surface detention and infiltration within the watershed.

6. Deduct the losses from rainfall to estimate rainfall excess values for each time interval.

7. Apply rainfall excess values to the runoff model for each subbasin.

8. Add to the storm runoff hydrograph allowances for stream base flow, runoff from prior storms, etc., to obtain the synthesized flood hydrograph for each subbasin.

9. Route the flood from each subbasin to a point of interest.

10. Compare the computed PMF peak and volume to the applicable envelope curve of peak and volume flows, if available.

11. Route the resulting inflow hydrograph through the reservoir storage, outlets, and spillways to obtain estimates of maximum storage, elevations and discharges, and durations at the dam.

Many factors influence the ultimate magnitude of the PMF hydrograph, but the intensity and duration of the rainfall are the most important. Considerable analysis and discussion of the derivation and application of PMP estimates has taken place in the past. The original definition of PMP dates back to the late 1930s. In 1981, Reclamation, the National Weather Service, and the U.S. Corps of Engineers adopted a mutually acceptable, uniform definition of the widely used term PMP. The PMP, as defined by these three agencies at that time, is “theoretically, the greatest depth of precipitation for a given duration that is physically possible over a given size storm area at a particular geographical location at a certain time of the year.” PMP must always be termed as an estimate because there is no direct means of computing and evaluating the accuracy of the results. Since the mid-1980s, Reclamation has considered that the series of

HMRs prepared and updated by the National Weather Service provide the best estimates of PMP potential within the limits of each report. Figure 4-13 displays the current coverage of the continental United States by this series of reports.

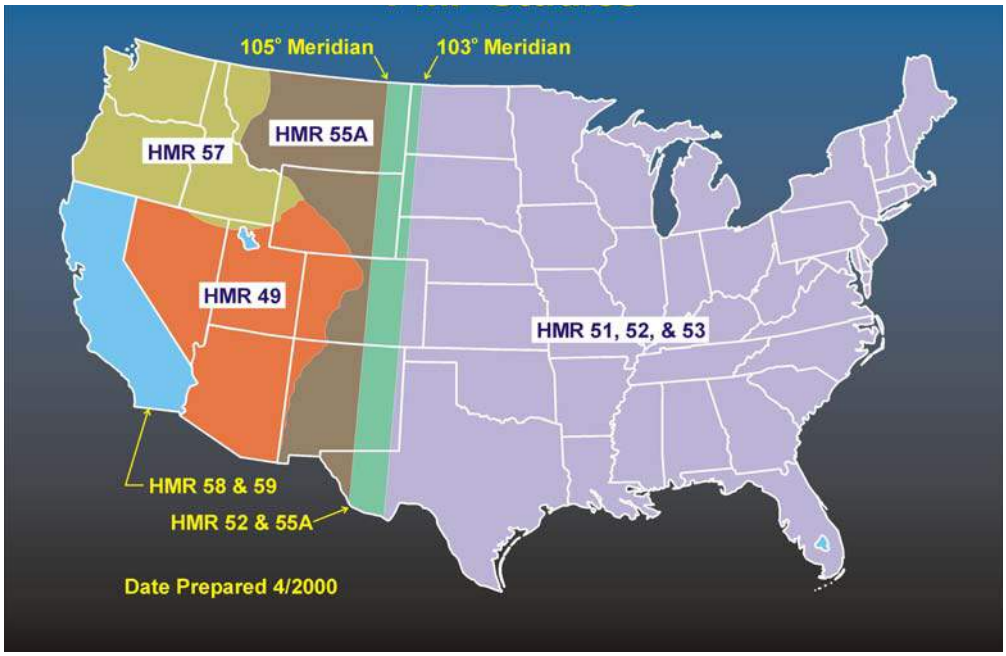

Figure 4-13.—Regions covered by generalized PMP studies.

Other aspects of the PMP to PMF conversion that are unique to Reclamation are discussed in the following paragraphs.

After determining the total PMP depths for specific time intervals from the appropriate HMR, a smooth depth-duration curve is created. This curve is then read at time intervals equal to the desired computation interval for the PMF hydrograph. Each individual precipitation total for each time increment is subtracted from the preceding time increment total PMP. The result is the incremental values of PMP to be used in the computation of the PMF hydrograph. Figure 4-14 displays a typical depth-duration curve from which incremental PMP can be determined.

The temporal rainfall pattern most commonly used with Reclamation PMF studies places the maximum increment of rainfall at the 2/3 point of the storm and arranges the remaining increments of precipitation in descending order about this point. This distribution is applied throughout the United States and results from an examination of individual drainage area regionalized storm criteria combined with various hydrological tests. This arrangement, when combined with the unit hydrograph procedures, will produce a maximum runoff condition for the basin being studied that is still reasonable based on meteorological experience. Figure 4-15 displays this temporal distribution.

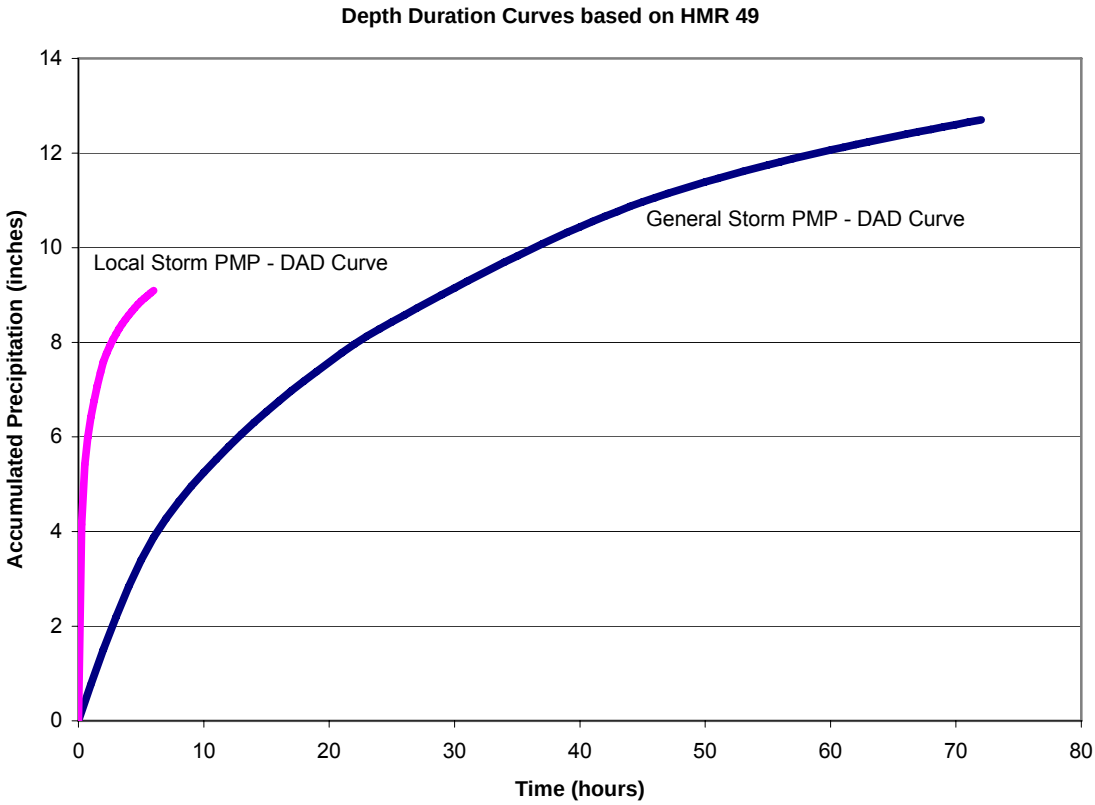

Figure 4-14.—Typical PMP depth duration curves.

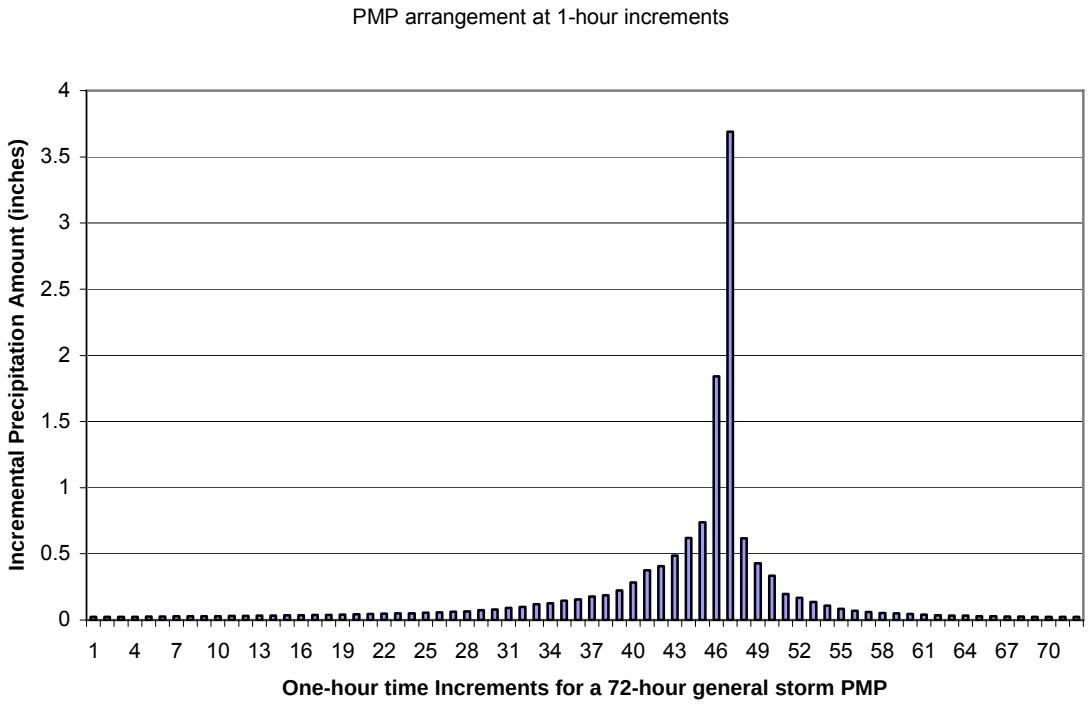

Figure 4-15.—Typical PMP temporal arrangement for a 72-hour storm.

In Reclamation PMF studies for large basins with many subbasins, consideration is given to "centering of the PMF" by allowing the spatial distribution of the PMP to vary across the entire basin. The storm is centered over a single subbasin, and the PMP for that subbasin is calculated along with the PMP for the total basin. PMP amounts over the other subbasins are calculated in a manner that preserves the total basin volume of the PMP but allows for heavier amounts over the subbasins nearest the assumed center of the storm. This calculation is termed "successive subtraction."

Another unique feature of some PMF studies is the use of an elliptical storm pattern as specified in the appropriate HMR. The use of this pattern allows the PMP to vary within a large area in a manner that does not depend on subbasin sizes or shapes but, rather, on historic observations of large storms. This type of PMP calculation is most common for large general storms in the HMR 51-52 area. Local storm PMPs can also use a theoretical elliptical shape in the HMR 49 and HMR 59 areas. For these types of studies, the PMP storm is usually centered over the basin. Volume centerings will center the entire PMP storm over the subbasin nearest to the center of the entire basin. Peak centerings will allow the PMP to be centered over the subbasin nearest to the dam. Volume centerings will typically produce a PMF hydrograph with the largest total volume. Peak centerings will typically produce a PMF with a higher peak but a lower volume. Both PMF hydrographs need to be routed through the dam.

Another good feature of the PMF calculations is that a series of dams all on the same river can be studied. By allowing the PMP to be centered over subbasins above each individual dam, the most severe cause of flooding at that dam can be obtained. Concurrent floods above the other dams on the same river basin can then be calculated for the same PMP event. Once the PMF hydrographs from the upstream dams are formed and routed through those structures, the complete PMF series of hydrographs for the downstream dam can be obtained. This is not always the case with methods based solely on statistical methods.

Local storm hydrographs are also computed for most Reclamation Dams if the HMR series provides specific data for deriving a separate local storm. Such storms are generally considered the thunderstorm type events and are limited in durational and areal coverage. Local storms will generally produce more intense precipitation and are usually most critical for smaller drainage basins. Local storms are considered spring or summer events and may become critical for dams and reservoirs where higher water surfaces are allowed in the spring and summer.

Lag time computations and unit hydrographs for Reclamation PMF studies have come from many past investigations of large floods. Basic unit hydrographs for sites where sufficient data were recorded were derived by standard means after subtracting out any base flows or snowmelt flows. With some knowledge of the basin average rainfall total and duration, the resulting hydrograph could be reduced to a unit hydrograph. The unit hydrographs were then put into a dimensionless form unique to Reclamation, with the flow ordinate being expressed as a dimensionless volume of flooding divided by the amount of flooding that could be expected from 1 inch of excess runoff in 24 hours (expressed as $ft^3/s\text{-}day/ft^3$ or often abbreviated as q). The time ordinate was expressed as a percent of the basin lag time plus 1/2 of the unit duration for that basin. Figure 4-16 is a sample of such a dimensionless graph. Over 60 dimensionless graphs are available to Reclamation engineers, but this number has been reduced to only 6 for publication in the *Flood Hydrology Manual* and in the latest edition of *Design of Small Dams*.

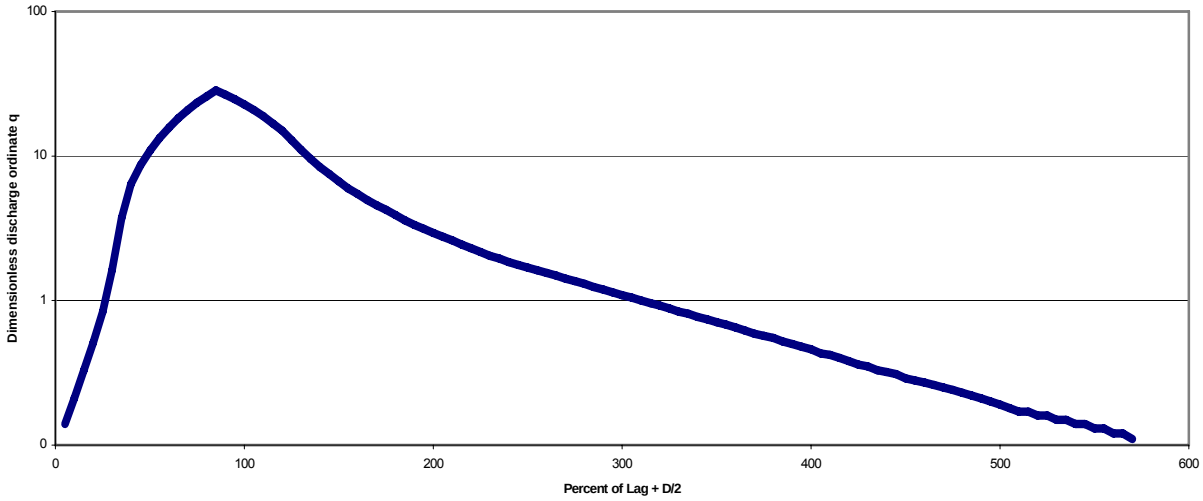

Figure 4-16.—Reclamation dimensionless graph.

The physical definition of the lag time used by Reclamation in PMF studies is the time from the mid-point of a unit of excess rainfall to the mid-point of the total volume of the resulting runoff hydrograph from that single unit of excess rainfall. With this definition in mind, much of the historic flood data collected by Reclamation engineers in the 1940 to 1970 time period was used to define relationships between the physical measurement of the length of the main channel, L (mi); the length to a point on the main channel opposite of the basin centroid, Lca (mi); and the basin slope S (ft/mi). Such data were plotted on log-log graphs, and straight lines on these plots were drawn based on different basin vegetation and soil conditions. Figure 4-17 is a sample of such a plot from the Reclamation *Flood Hydrology Manual*.

The locations of the straight lines on these plots reflect the basin vegetation, soils, overall slope and, to some degree, the basin area and type of PMF being calculated. Such graphs also represent floods from much smaller events than the PMF, and some judgment must be applied to the lag numbers. PMF conditions will usually require somewhat shorter lag times than computed for more common flood events. Lag times for Reclamation PMF studies are based on this type of historical knowledge, reviews of other PMF studies prepared in the area, and reviews of pertinent basin topography, soils, and land use maps. For final design-level PMF studies, field trips to the basin in question by a qualified hydrologist are required to ensure that the information from the maps and other calculated basin parameters is valid. Generalized equations based on the lag curves such as displayed above are available to provide a computational procedure for calculating a lag time for each subbasin and storm type in the basin being studied.

With a computed lag time, drainage area, and dimensionless graph selected, the final unit hydrograph for each subbasin can be calculated. Procedures for this calculation are given in Reclamation's *Flood Hydrology Manual* and in *Design of Small Dams*.

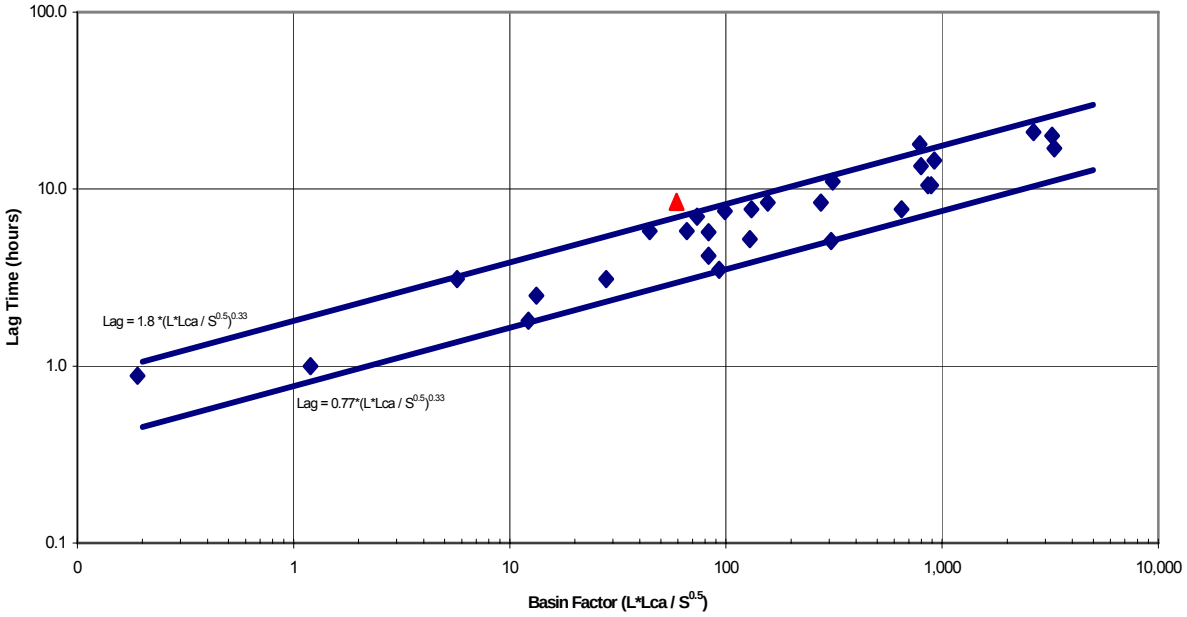

Figure 4-17.—Lag time versus basin factor data for Great Plains Region
(from Reclamation *Flood Hydrology Manual*, 1989).

Loss rates for Reclamation studies always assume saturated basin conditions caused by antecedent flooding. Most often, the loss rates are derived by studying basin soils maps available from previous Soil Conservation Service (SCS) soils mapping reports or, more recently, by using the NRCS STATSGO computerized soils database. The SCS divided the soils into four basic hydrologic groups for rainfall-runoff studies. These groups range from very porous sandy or gravely soils with high infiltration rates to very tight clay soils with very low porosity and low loss rates for rainfall-runoff studies. The four soil categories have been assigned ranges of minimum loss rates. By determining the percentage or amount of the different soils in each subbasin, an average minimum loss rate can then be selected or computed from the published minimum loss rate ranges. Initial loss rates are seldom used in Reclamation PMF studies. The definition of the PMF requires the assumption of saturated soil conditions before the onset of the PMP. Under such an assumption, the initial loss rates will be completely satisfied, leaving only a minimum constant loss rate to be considered. It is recognized that more sophisticated loss rate algorithms exist, but for the PMF computation and assumptions, the use of a constant loss rate based on minimum losses for the upper soil layers in the basin is considered adequate.

Antecedent flooding is also considered for general storm PMF hydrograph computations in Reclamation studies. The general storm most often occurs at a time of the year when flooding is most likely to occur in the basin. It is likely that previous storms or a melting snow pack will provide some antecedent streamflow before the onset of the PMP. For basins without significant snowmelt contributions, the antecedent flood comes from a study of applicable streamflow records or, if needed, rainfall-runoff analysis. The desire is to derive a 100-year event by statistical means or by rainfall-runoff modeling if limited stream gage data are available. This derived flood hydrograph is then placed a number of days in front of the onset of the PMP. In

most parts of the central United States, there is a 3-day separation between the peak of the antecedent flood and the start of the PMP. This length of time between the antecedent rain flood hydrograph peak and the start of the PMP will vary near coastal areas. Figure 4-18 displays this type of application.

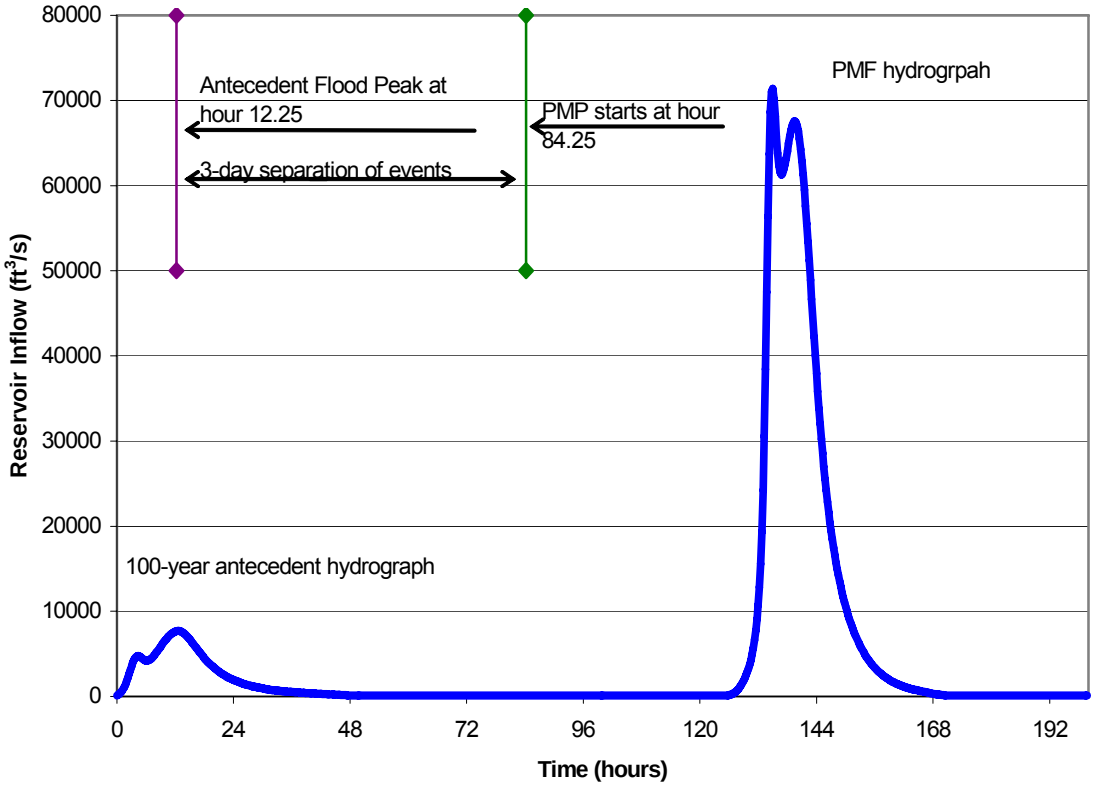

Figure 4-18.—PMF with antecedent 100-year floods.

In areas where snowmelt adds to the volume of the flooding, the antecedent flood in Reclamation PMF studies is often derived from an analysis of stream gage data. The data are limited to the season when snowmelt adds to the flooding. A large historic snowmelt flood may be selected or a statistical analysis of the volume of flooding for several different durations may be undertaken. The result is a 100-year flood volume for a duration longer than the base length of the calculated PMF rain flood hydrograph. If a historic flood event is selected, the daily flows for the hydrograph will be adjusted by a ratio such that the resulting volume for the selected duration is a 100-year volume that can be determined by a statistical analysis of appropriate gage records. The historic flood hydrograph may also be rearranged in time to provide a more normal hydrograph shape. If no historic flood hydrograph is appropriate, then the antecedent snowmelt hydrograph may be derived as a balanced hydrograph. If a snowmelt hydrograph is used as an antecedent flood, Reclamation places that hydrograph under the rain-generated portion of the PMF such that the peaks will exactly coincide. Figure 4-19 displays such a derived historic flood hydrograph for a 15-day antecedent event. Figure 4-20 displays the placement of the derived balanced hydrograph to coincide with the peak of the rain-generated PMF hydrograph for a basin.

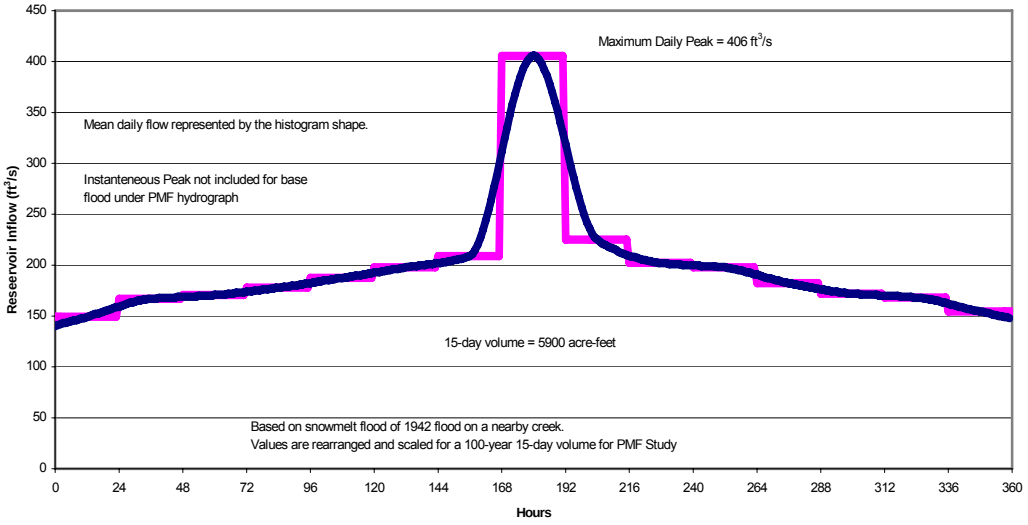

Figure 4-19.—100-year 15-day derived snowmelt flood from an historic snowmelt flood event.

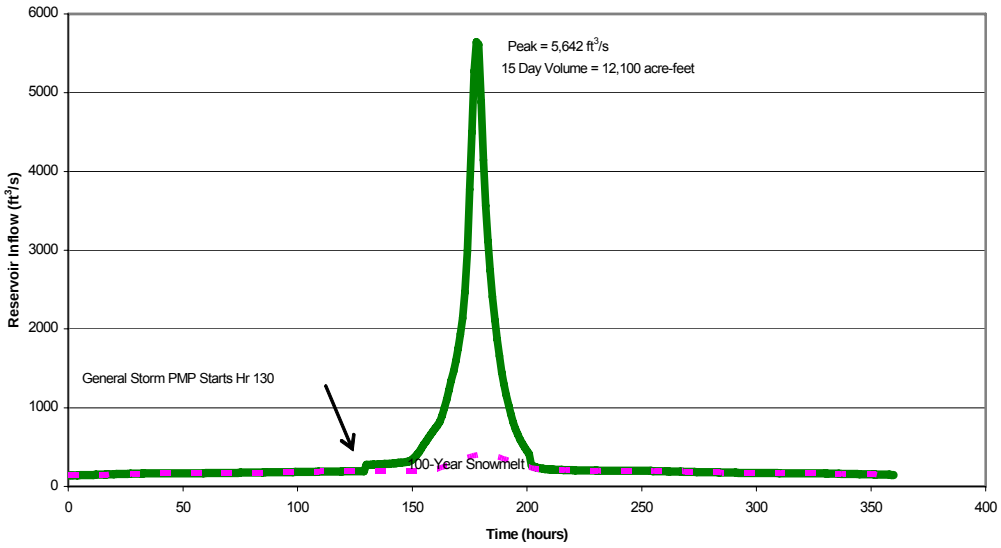

Figure 4-20.—General storm PMF with 100-year snowmelt antecedent flood.

When a snowmelt flood is required, the loss rate for the measured or estimated snow-covered areas in the basin is reduced to a constant 0.05 inch per hour. This is assumed to account for the fact that the 100-year snowmelt is already in progress at the start of the PMP and most of the available constant loss rate will have already been taken up by the melting snow.

In areas where deep snow packs are known to occur, such as the high Sierra Mountains in California, Reclamation will use a snowmelt computation program. This program will account for the effect of rain falling on a snow pack that may not be fully ripened and ready to melt at the start of the PMP. The snowmelt program requires additional meteorology data such as wind and temperature sequences compatible with the PMP derivation. The HMR series will provide good

information in this regard. Additional study of the historic snow gage records in or near the basin being studied is also required. The depth and initial density of the snow pack at various elevations in the basin are used in the computations. Such snowmelt computations provide additional depths of water to be added to the arranged PMP sequence. The combined snowmelt and PMP depths are then used with the unit hydrograph procedures to derive the desired PMF hydrographs.

Routing of floods between subbasins is also required. If sufficient data for several large flood events are available, routing coefficients for the Muskingum Method can be derived. Usually, little information is available for large floods at more than one gage in the basin being studied. In lieu of Muskingum routing, the most common procedure is an analytical procedure referred to as the Tatum Method. This method requires only an assumed travel time between the various subbasins and will attenuate the routed hydrographs by a simple arithmetical computation. This procedure does not affect the volume of the flooding, but it does have some impact on the PMF peak.

Envelope curve comparisons of the PMF peak and sometimes a volume comparison are also made. The comparison is only to ensure the hydrologist that the PMF peak or volume is not below experienced flood levels in the region of concern. If the PMF peak falls below an envelope curve of peak flows for a nearby region, some additional thought must be given to the derivation of the PMF or the derivation of the envelope curve values. There are no rules about how far above the envelope curve a PMF peak should be. This would depend on the derivation of the envelope curve. Envelope curves covering large regions might have additional high-peak flows and the PMF comparison would be closer. Smaller regions would most likely have PMF peaks much higher than the envelope curve.

5. Characterization of Hydrologic Hazards

Since no single approach is capable of providing the needed characterization of extreme floods over the full range of AEPs required for risk assessment, results from several methods and sources of data should be combined to yield a hydrologic hazard curve. The application of several independent methods applicable to the same range of AEPs will increase the credibility and resulting confidence of the results. The previous section of this report describes the available approaches for estimating the hydrologic hazard.

To compute a hydrologic hazard curve for risk assessment, Reclamation makes use of all available studies for the site of interest. Often, the PMF and initial flood frequency studies are the only hydrologic studies available before the start of a probabilistic investigation. If a dam passes the PMF or a flood with an AEP low enough to meet dam safety risk criteria, no further studies may be needed. The intent of the hydrologic hazard analysis is to provide information that will allow decision makers to make appropriate dam safety decisions while minimizing study costs.

The remainder of this section of the report describes Reclamation's approach toward characterizing the hydrologic hazard for a particular site of interest. The process begins with

Flood frequency analysis and hydrograph scaling for the CFR and may progress through more detailed studies if the need arises. If detailed studies are already available for a particular site, these studies would be summarized and would form the basis of the hydrologic hazard characterization.

5.1 Integration of the PMF into Hydrologic Hazard Evaluations

The PMF is recognized as the upper limit of flood potential at a site, for storm durations defined by the Probable Maximum Precipitation (Bureau of Reclamation, 2002b). This means that Reclamation uses the PMF as the upper limit to extreme floods for risk assessment, corrective action decisions, and dam safety modifications. If a dam does not have a hydrologic safety deficiency using the PMF as the hydrologic loading condition, no further hydrologic studies are warranted for evaluation of spillway capacity. If a flood frequency analysis produces peak flows or volumes that exceed the PMF, then the PMF should be used in evaluating the hydrologic risk and as a theoretical and practical upper limit to statistical extrapolations. Before applying the PMF as the upper limit, the hydrologist should ensure that it has been developed using current procedures with up-to-date data and for a PMP duration suitable for the site of interest.

5.2 Characterization of Hydrologic Risk for the CFR

Hydrologic hazard curves and flood hydrographs are developed for use in evaluating and prioritizing the need for dam safety modifications at Reclamation and other U.S. Department of the Interior facilities. These guidelines provide an approach for developing hydrologic hazard information that will allow decision makers to determine appropriate courses of action to assure the safety of the dam while minimizing study costs. If detailed hydrologic studies are available for the site of interest, they should be reviewed for adequacy, then summarized and used for the CFR. If no study is available, a hydrologic hazard curve and flood hydrographs should be constructed using flood frequency analysis and hydrograph scaling procedures. The remainder of this section explains the procedure for developing hydrologic hazard information for the CFR using these procedures.

The characterization of hydrologic risk is first provided in terms of estimated peak discharges, which are then used to estimate flood volumes. Peak discharges are estimated using a mixed-population model, and the results are subsequently input to a linear scaling algorithm of volume critical hydrographs. The hydrologic hazard characterization for the CFR is usually accomplished with minimal effort, about 15 staff days or less.

The mixed-population model used to estimate peak discharges is described by an LP-III distribution for return periods from 1 to 100 years and an LN-2 distribution for return periods greater than 100 years. Historical data are used to calibrate the LP-III model, and an informed hydrologic estimate of a single flood potential point (SFPP) with a return period of greater than 100 years must be made. The fitting of the LP-III model to the historical data is carried out using the Method of Moments (MOM) with which a regional skew may be used to fix or weight the distribution. The fitting of the LN-2 distribution is carried out analytically between the 100-year flood estimate and the SFPP. The value of the SFPP may take the form of a paleoflood non-exceedance bound, a paleoflood estimate, a historical data point with an estimated return period

greater than 100 years, or any other estimate of a flood with a return period greater than 100 years believed to characterize the extreme values of the flood potential. Once the initial data requirements are met, a list of peak-discharge estimates is calculated and the results are provided in tabular as well as graphical format (table 5-1, figure 5-1). The analysis is extended beyond the SFPP to floods with AEPs as small as 10^{-8}, but peaks are not allowed to exceed the PMF for the site of interest.

Table 5-1.—Example peak-discharge estimates in tabular form

Annual exceedance probability	Return period	Peak discharge estimate (ft^3/s)
0.01	100	26,500
0.005	200	31,100
0.002	500	37,700
0.001	1,000	43,200
0.0005	2,000	49,200
0.0002	5,000	57,700
0.0001	10,000	64,800
0.00005	20,000	72,300
0.00002	50,000	83,200
0.00001	100,000	92,000
0.000001	1,000,000	126,000
1E-07	10,000,000	167,800
1E-08	100,000,000	218,800

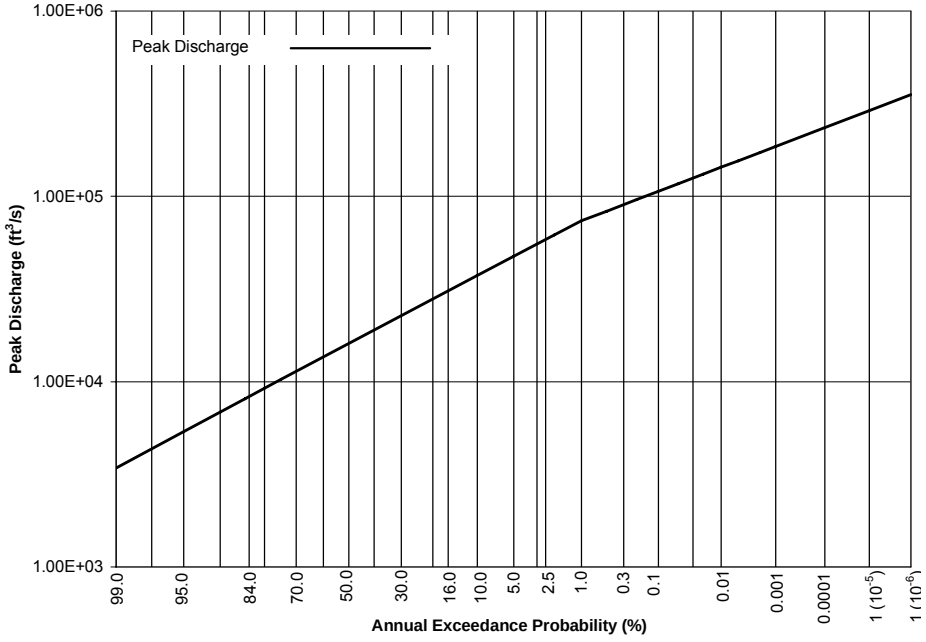

Figure 5-1.—Example of peak-discharge estimates in graphical form.

To make a volume estimate, a time series flood hydrograph estimate is required. The time series flood estimate may be a historical flood hydrograph or a PMF hydrograph; either must be believed to describe the rainfall-runoff response of the basin of interest at a wide range of return periods. Flood hydrographs are linearly scaled so that the peaks match the estimates from the peak-discharge analysis described above. When the hydrograph duration permits, 1-, 3-, 5-, 7-, and 15-day volumes are calculated as the maximum volume of water transported during the desired continuous time period.

When a rain-on-snow PMF hydrograph or rain-on-snow historical hydrograph is used as an input, the analysis technique requires two hydrograph ordinates for each time period – one for the snowmelt portion and one for the rainfall portion. Only the rainfall portion of the hydrograph is scaled to achieve the desired peak. The snowmelt portion of the hydrograph remains intact. For all other input hydrographs, the entire hydrograph is scaled linearly to match peak estimates. When volume estimates are calculated, the results are provided in tabular as well as graphical format (table 5-2, figure 5-2). Graphical results (peak and volume flows) can be provided within a combined chart (figure 5-2) or as two separate charts, as desired by the client (figure 5-1 and figure 5-3).

The major assumption involved with scaling PMF hydrographs to various return periods is that the dimensionless hydrograph used to develop the PMF is appropriate to describe the rainfall-runoff response of the basin at all return periods. Because the generation of a hydrograph from a dimensionless hydrograph involves only the convolution with time distributed rainfall rates, assumptions are further made that the rainfall spatiotemporal distribution does not change with flood magnitude, and soil characteristic response is linear in nature. The latter assumption may be appropriate when floods of interest begin with saturated ground conditions. When these assumptions are violated, predictions may be inaccurate by orders of magnitude. Similar assumptions can be made when scaling a historical hydrograph. These assumptions are mainly that the storm that caused the flood is similar in temporal and spatial characteristics to the storm that would cause a flood of a different return period and that the initial soil conditions are also similar. Soil infiltration responses are known to be highly non-linear in the unsaturated condition; therefore, as with the PMF scaling, it is the initial condition for which the soils are saturated that this type of scaling is most appropriate.

Reclamation uses the PMF as the upper limit of flood potential at a site for storm durations defined by the PMP. If peak flows or volumes calculated using probability or statistical-based hydrology methods exceed those of the PMF, the PMF is used in evaluating the hydrologic risk and as a theoretical and practical upper limit to statistical extrapolations. If the PMF has been properly developed, it represents the upper limit to runoff that can physically occur at a particular site.

Hydrograph ordinates for the peak-scaled hydrographs, produced during the volume analysis, are also provided for the CFR hydrologic hazard evaluation. Ordinates for the scaled hydrographs have the same duration and number of ordinates as hydrograph data provided for input to scaling analysis, thus requiring no interpolation. The scaled hydrographs have an AEP associated with them, so they are suitable for use in reservoir routing studies and for dam safety risk assessment.

Table 5-2.—Example of combined peak-discharge and volume estimates in tabular form

RETURN PERIOD (yrs)	PEAK DISCHARGE (cfs)		1-Day Volume (acre ft)	3-Day Volume (acre ft)	5-Day Volume (acre ft)	7-Day Volume (acre ft)	15-Day Volume (acre ft)
100	73,890		44,300	72,530	84,940	101,130	137,590
200	83,220		49,740	80,900	94,070	109,920	146,730
500	96,140		57,260	92,470	106,690	122,070	159,360
1,000	106,370		63,220	101,640	116,700	131,710	169,380
2,000	117,040		69,440	111,200	127,120	141,740	179,810
5,000	131,840		78,060	124,450	141,590	155,670	194,290
10,000	143,590		84,910	134,980	153,070	166,730	205,790
20,000	155,840		92,040	145,950	165,050	178,260	217,770
50,000	172,830		101,940	161,180	181,650	194,250	234,400
100,000	186,310		109,800	173,250	194,830	206,940	247,590
1,000,000	235,220		138,290	217,070	242,630	252,970	295,450
10,000,000	291,000		170,790	267,040	297,150	305,460	350,020
100,000,000	354,340		207,690	323,780	359,050	365,060	411,990

5.3 Detailed Hydrologic Studies

After developing the hydrologic hazard information for the CFR, more detailed hydrologic studies may be necessary to better define the hydrologic problem, reduce uncertainty, develop solutions, or make decisions. The amount of effort expended on analyzing a hydrologic hazard is dependent on the nature of the problem and potential cost of the solution. Reclamation uses a staged approach toward solving this problem. Initially, very little effort is expended to determine the magnitude of the hydrologic hazard. If additional hydrologic studies are needed, a project plan is developed that tailors the study to the particular needs of the project. The scope of work attempts to address the specific dam safety issue at the least possible cost while providing sufficient information to the dam safety decision makers to make informed safety decisions.

Flood characterization for risk assessments uses the length of the data record and other characteristics of the data to determine the range of credible extrapolation used in the flood frequency analysis. Because Reclamation risk assessments may require estimation of floods with AEPs as small as 1 in 100,000,000, extrapolation of flood frequency relationships is required well beyond the limits warranted by the data. These guidelines provide a reasonable and reliable approach for characterizing the hydrologic hazard beyond the range of extrapolation suggested by the data for use in dam safety risk assessments. Reliable flood frequency estimates are needed for very small AEPs for dam safety decisionmaking, and these estimates should convey an estimate of the uncertainty in the analysis for the consideration of the decision maker.

The uncertainties associated with flood estimates are likely to be substantial and an important attribute to convey into the risk assessment. Flood characterization should include a "best estimate" of the AEP of floods of different magnitudes and a description of the uncertainty in such results. Such uncertainties need to be honestly represented and considered throughout the risk assessment process.

Further analyses might be necessary if the hydrologic hazard information provided during the CFR is insufficient to define and quantify hydrologic dam safety issues and make decisions. Additional studies may become necessary to address reservoir routing effects of upstream dams, reduce uncertainty in the flood estimates, verify statistical results before committing large capital expenditures to dam safety modifications, etc. When planning the next study, the goal is to achieve a balance between the amount of hydrologic analysis needed to address the issues and make decisions, and the level of effort required to conduct the study. Generally, studies progress from those requiring a low level of effort to those requiring a higher level of effort. As the studies get more detailed, the results should become more precise and contain less uncertainty.

Since each study site is different, no single approach can be identified to address all hydrologic issues. The method chosen should consider climatic and hydrologic parameters, drainage area size, amount of upstream regulation, data availability, and level of confidence needed in the results. The previous chapter of this report described the methods available in Reclamation to develop hydrologic hazard curves.

Table 5.3 lists various methodologies that were considered for characterizing extreme floods to support dam safety risk assessment. A flood frequency analysis must be combined with each of these methodologies to assign annual exceedance probabilities to the floods.

Table 5-3.—Alternative methods to develop hydrologic hazard information

Method of Analysis and Modeling	**Risk Analysis/Design Level[1]**	**Level of Effort[2]**
Flood frequency analysis with historical/paleoflood data - Graphical method; - EMA; - FLDFRQ3	CFR, IE, CAS, FD	Low
Hydrograph Scaling and Volumes	CFR, IE, CAS, FD	Low
GRADEX Method	IE, CAS, FD	Moderate
Australian Rainfall-Runoff Method	IE, CAS, FD	Moderate
Stochastic Event-Based Precipitation Runoff Modeling with SEFM	CAS, FD	High
Stochastic Rainfall-Runoff Modeling with CASC2D	CAS, FD	High
Probable Maximum Flood	CFR, IE, CAS, FD	Moderate

Notes:

1. Risk analysis/design level: CFR - Comprehensive Facility Review, IE - Issue Evaluation, CAS - Corrective Action Study, and FD - Final Design.

2. Level of effort: Low requires 10-20 staff-days to complete the analysis; moderate requires 21-75 staff-days; and high requires more than 75 staff-days.

Hydrologic studies usually will proceed from flood frequency and hydrograph scaling to an analysis using either the GRADEX or Australian Rainfall-Runoff Method. The advantages of these approaches are that they use regional rainfall data in developing flood estimates and yield flood hydrographs. Both approaches work best on small drainages (less than 2,000 mi^2), and the Australian Rainfall-Runoff Method works better if snowmelt floods are important.

The SEFM and CASC2D are more sophisticated hydrologic modeling techniques used to address hydrologic issues driven by large potential dam failure consequences. These approaches are more suitable for CAS and final designs. They also allow for better quantification of hydrologic uncertainty. These approaches require a lot of data and are generally more costly than the others.

When multiple methods have been used to determine the hydrologic hazard, sound physical and scientific reasoning for weighting or combining results is needed. Clearly, a measure of judgment is required to ensure that appropriate information is included in the dam safety decisionmaking process. Reclamation develops various weighting schemes to evaluate the results of multiple analyses and uses a team of hydrologists to select the weighting scheme that best characterizes the hydrologic conditions for the site of interest. The selection is based on the experiences of the team members and the assumptions used in each of the analyses. The A.R. Bowman case study that follows illustrates this approach.

6. Case Studies

Three case studies are presented to illustrate the use of several methods. The study sites are Los Banos, Fresno, and A.R. Bowman Dams. Each study begins with a flood frequency analysis and hydrograph scaling. Different solution techniques were used to answer follow-up questions for each of the following case studies.

6.1 Los Banos Dam

Los Banos Dam is an earthfill structure with an uncontrolled spillway. It was completed between 1964 and 1965. This dam is located 7 miles southwest of the town of Los Banos, California, on Los Banos Creek. The drainage basin upstream from the dam has a total area of approximately 156 mi^2. The spillway crest elevation is 353.5 feet and the dam crest elevation is 384.0 feet. The spillway discharge capacity at the dam crest elevation is 11,800 ft^3/s. The total capacity of the dam at water surface elevation 353.5 feet is 34,600 acre-feet. The active capacity between elevations 296 and 353.5 feet is 26,300 acre-feet. The current PMFs for Los Banos Dam were computed in 1996 (Bureau of Reclamation, 1996a). The results of these PMF studies are summarized in table 6-1.

The PMFs were computed using a standard storm arrangement. Routing results indicate that Los Banos Dam would be overtopped by a flood with a magnitude about 37.6 percent of the general

storm PMF (Bureau of Reclamation, 1996b). The general storm PMF would overtop the dam by 6.2 feet for 30 hours. The thunderstorm PMF does not overtop the dam.

Table 6-1.—Probable maximum flood summary for Los Banos Dam, California

Flood Type	HMR	Peak Inflow (ft^3/s)	Volume (acre-feet)	
			With 100-year antecedent storm event	Without 100-year antecedent storm event
General storm	58	75,800	146,700 (7 day)	138,000 (4.3 days)
Thunderstorm	58	75,200	27,400 (24 hr)	—

Because Los Banos Dam is overtopped by the general storm PMF, flood probabilities are needed to understand and quantify the risk of overtopping and hydrologic hazard for dam safety. A flood frequency and volume frequency analysis was completed using the procedures recommended for a CFR.

6.1.1 Los Banos Hydrologic Hazard Curves Using Flood Frequency Analysis and Hydrograph Scaling

A recent flood study, including paleoflood data, peak-flow frequency, and hydrographs, was completed for a risk analysis (Weghorst and Klinger, 2002). The streamflow and paleoflood data from that study are summarized below and then used to compute a hydrologic hazard curve. Because streamflow gage records for Los Banos Creek at Los Banos Dam were limited, the records from the gaging station on Orestimba Creek, near Newman, California (U.S. Geological Survey [USGS] station No. 11274500), were used in this example. This gage is located just north of Los Banos Dam, has a drainage area of about 134 mi^2, and provides 71 years (1932 to 2002) of unregulated peak discharge records. The peak discharge data were adjusted by the square root of the drainage area ratio (Cudworth, 1989); this factor was $(156/134)^{0.5} = 1.078$.

There are several sources of regional and reconnaissance-level paleoflood data that may be applied to estimates of flood frequency at Los Banos Dam including reconnaissance-level data on Los Banos Creek and supporting data from site-specific soil stratigraphic information on the Cantua Stream Group, located about 55 miles south of Los Banos Creek (Weghorst and Klinger, 2002). The hydrometeorologic setting for the Cantua Stream Group and Los Banos Creek, in general, appears to be very similar to each other; however, no field verification was performed to confirm this. Each of the basins is located on the eastern flank of the central Coast Ranges, and the drainage basin areas are close enough in size that differences in their runoff characteristics would be negligible given similarities in rock types, basin aspect and slope, average elevation, and vegetation and land use. Therefore, the paleoflood peak discharge bounds and age estimates from the Cantua Stream Group are believed to be applicable to Los Banos Creek (Weghorst and Klinger, 2002). Paleoflood bounds were established by scaling (Cudworth, 1989) the peak discharges for paleoflood data on the Cantua Stream Group to the Los Banos basin. It appears that peak discharges in the range of 42,000 to 60,000 ft^3/s on Los Banos Creek have not been exceeded in the last 1,800 – 2,800 years.

A hydrologic hazard curve for Los Banos Dam was constructed using the flood frequency analysis and hydrograph scaling procedures recommended for a CFR. Peak flow and paleoflood data and a PMF general storm hydrograph were used to estimate the hazard curve (figure 6-1). Estimated peak flows and volumes can exceed the PMF peak and volume at this site (table 6-1 and table 6-2). Therefore, the PMF was considered as an upper limit for design and risk analysis (Bureau of Reclamation, 2002).

Hydrographs for these floods were then routed through Los Banos Reservoir and spillway. The results from this characterization of the hydrologic hazard and flood hydrograph routing indicate that Los Banos Dam may potentially be overtopped by a flood with a return period of about 2,800 years (based on peak flow). Using these results, Los Banos Dam does not meet Reclamation hydrologic hazard criteria for overtopping because it does not pass a 10,000-year flood (at a minimum). Because this dam does not meet Reclamation criteria, additional studies for Los Banos are required to further assess the flood risk, estimate the need for any structural modifications, and determine suitable probability-based design hydrographs for any potential modification or design alternatives.

6.2 A.R. Bowman Dam

The case study for A.R. Bowman Dam is an example of a project where several hydrologic studies have been completed. The dam is an earthfill structure with an uncontrolled spillway. It was completed in 1961. This dam is located about 20 miles upstream from Prineville, Oregon, on the Crooked River. The drainage basin upstream of the dam has a total area of approximately 2,635 mi^2. The spillway crest elevation is 3234.8 feet, and the dam crest elevation is 3264.0 feet. The spillway capacity at the dam crest elevation is 11,500 ft^3/s. The total capacity of the dam at water surface elevation 3257.9 feet is 233,100 acre-feet. The current PMFs for A.R. Bowman Dam were computed in 1994. The results of these studies are summarized in table 6-3.

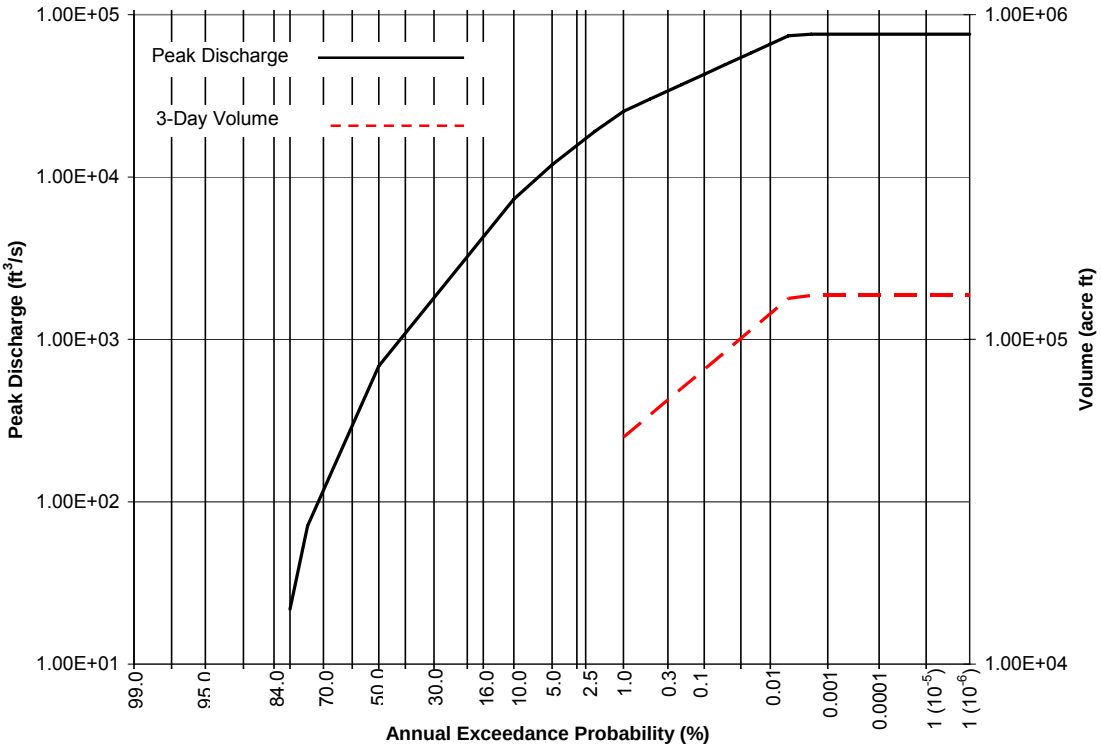

Figure 6-1.—Example of hydrologic hazard curve for Los Banos Dam, California.

Table 6-2.—Peak and volume (3-day) estimates at Los Banos Dam, California, for specified probabilities

Annual exceedance probability	Return period	Peak discharge estimate (ft^3/s)	3-day volume estimate (acre-feet)
0.01	100	25,400	50,100
0.005	200	30,100	58,500
0.002	500	37,000	70,800
0.001	1,000	42,800	80,800
0.0005	2,000	49,100	91,700
0.0002	5,000	58,300	107,200
0.0001	10,000	65,900	120,000
0.00005	20,000	74,100	133,700
0.00002	50,000	75,800	136,500

Table 6-3.—Probable maximum flood summary A.R. Bowman Dam, Oregon

Flood type	HMR	Peak inflow (ft^3/s)	Volume (acre-feet)	
			With 100-year antecedent conditions	Without 100-year antecedent conditions
February General storm	57	255,000	770,000 (15 day)	138,000 (4.3 days)
June General storm	57	83,300	185,600 (15 day)	185,600 (15 day)
August General storm	57	75,000	—	112,600 (15 day)

Routings of the PMF hydrographs indicated that the February general storm event, with a starting water surface elevation of 3211.17 feet, would overtop the dam by 18.6 feet. A.R. Bowman Dam would only pass approximately 10 to 25 percent of the February general storm PMF without overtopping. The June and August PMFs did not overtop the dam.

Because A.R. Bowman Dam is overtopped by the February general storm PMF, flood probabilities are needed to understand and quantify the risk of overtopping and hydrologic hazard for dam safety. Several investigations have been undertaken since about 1991 to determine PMF design modification alternatives, including overtopping protection and parapet walls. In addition, detailed probabilistic flood studies using alternative approaches (stochastic event flood modeling and paleoflood studies) were completed at A.R. Bowman Dam to better estimate the flood risk.

Three methods for estimating the hydrologic hazard are discussed in this section: flood frequency analysis and hydrograph scaling, SEFM, and peak-flow frequency analysis with detailed paleoflood data. Flood risk results from the three methods and implications for potential modifications at A.R. Bowman Dam are then discussed.

6.2.1 A.R. Bowman Hydrologic Hazard Curves Using Flood Frequency Analysis and Hydrograph Scaling

Peak flow data at A.R. Bowman Dam were obtained from three USGS gaging stations:

- Crooked River at Post, Oregon (USGS station No. 14079500)
- Crooked River above Prineville Reservoir near Post, Oregon (USGS station No. 14079800)
- Crooked River near Prineville, Oregon (USGS station No. 14078050)

These gages are the closest to A.R. Bowman Dam; the first two are located upstream from the reservoir, and the gage near Prineville is located downstream from the dam. The combined gages provide 38 years (1909 to 1972, with many missing years) of unregulated peak discharge records. The peak discharge data for the upstream gages were adjusted by the square root of the drainage area ratio (Cudworth, 1989). The December 1964 flood was treated as a historic peak with a return period of approximately 140 years (largest since about 1860).

The reconnaissance-level paleoflood data that may be applied to estimate flood frequency at A.R. Bowman Dam are based on the detailed paleoflood data presented below. Information from the paleohydrologic bound with the largest discharge was used and was dated based on the Mount Mazama volcanic eruption 7,600 years ago. Based on this information, it appears that a peak discharge between 27,000 and 36,000 ft^3/s on the Crooked River has not been exceeded in the last 7,600 to 10,000 years.

A hydrologic hazard curve for A.R. Bowman Dam was constructed using the techniques outlined in section 5. This example calculation was completed after the results of the SEFM and paleoflood study were completed. This example represents the first step that might be performed in future flood studies for Reclamation dam safety. Peak flow and paleoflood data and a general storm PMF hydrograph were used to estimate the hazard curve (figure 6-2 and table 6-4).

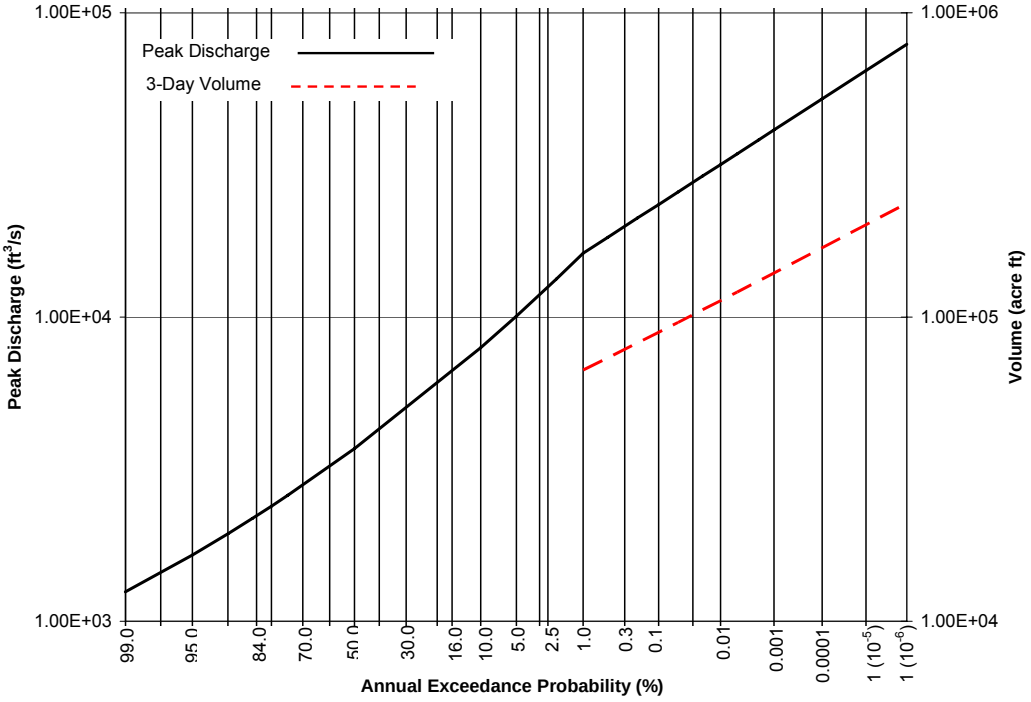

Figure 6-2.—Example of a hydrologic hazard curve for A.R. Bowman Dam, Oregon.

6.2.2 A.R. Bowman Hydrologic Hazard Estimates Based on a Stochastic Event Flood Model

MGS Engineering Consultants, Inc., was contracted in November 1997 (Schaefer and Barker, 1997) to perform a hydrologic stochastic analysis to develop magnitude frequency curves for flood peak discharge, runoff volume, and maximum reservoir elevation. The SEFM was developed using a deterministic rainfall-runoff model (HEC-1) and treated input parameters that were selected by Monte Carlo sampling procedures as a probabilistic distribution of values rather than fixed values. The SEFM is described in section 4.5. After the initial modeling runs and results at A.R. Bowman Dam were made, the precipitation depth-area relationships were refined (Schaefer and Barker, 1998) and new flood frequency relationships were developed.

The results from the SEFM include peak flow, volume, and reservoir elevation frequency curves. These graphs are shown below and include polynomial equations fitted to model output that are applicable in the range of AEP from 10^{-2} to 10^{-5} (Schaefer and Barker, 1998). From these results, the dam may be potentially overtopped with a maximum reservoir elevation probability equal to 0.0005 (2,000-year return period) (figure 6-4).

Peak discharge estimate:

$$Q_p = 2322\,Log^2(AEP) - 2241\,Log(AEP) + 950$$

Flood Runoff Volume Estimate:

$$Q_v = 8385\,Log^2(AEP) - 59700\,Log(AEP) - 39490$$

Maximum reservoir elevation estimate:

$$ELEV_{\max} = -0.3993\,Log^4(AEP) - 6.193\,Log^3(AEP) - 33.67\,Log^2(AEP) - 89.81\,Log(AEP) + 3159.2$$

Table 6-4.—Peak and volume (3-day) estimates at A.R. Bowman Dam, Oregon, for specified probabilities

Annual exceedance probability	Return period	Peak discharge estimate (ft^3/s)	3-day volume estimate (acre-feet)
0.01	100	16,000	65,100
0.005	200	18,100	71,300
0.002	500	21,000	79,700

6.2.3 A.R. Bowman Hydrologic Hazard Estimates Using Bayesian Statistical Estimation

To gain information on the magnitude of low probability floods for risk analysis, the Dam Safety Office, in 1995, requested a paleoflood study on the Crooked River at A.R. Bowman Dam. The paleoflood study was an alternative approach to the SEFM. The paleoflood report has not been published because of changing priorities in the Dam Safety Office.

For the Crooked River paleoflood study, two reaches downstream from A.R. Bowman Dam were selected for detailed hydraulic modeling. These reaches are about 2 and 35 miles downstream from the dam. At these study reaches, there is geomorphic, stratigraphic, and botanic evidence to limit the paleostage of floods throughout the Holocene epoch (the past 10,000 years). In one of the downstream reaches, it is possible to reconstruct the magnitude of the December 1861 flood based on the presence of driftwood piles. In addition to these downstream study reaches, a third study reach was identified just upstream from Prineville Reservoir, where the stage of paleofloods during the late Holocene epoch can be related to the peak discharge estimates from the December 1964 flood.

Stratigraphy and soils were described at eight sites along the Crooked River, including the three study reaches. At these sites, the soils were described in detail and material was collected for radiocarbon dating. In total, there are 54 radiocarbon ages for the Crooked River paleoflood study. In addition to these radiocarbon ages, the Mazama ash forms an important stratigraphic datum along the river downstream from A.R. Bowman Dam. The calibrated ages of radiocarbon samples associated with the Mazama ash throughout the western U.S. yield an age of about 7,650 years. The hydraulic geometry of the Crooked River channel is remarkably consistent at all the study sites. This implies long-term stability of the Crooked River channel and of the mechanisms that produce large floods on the Crooked River.

The paleoflood data that have been collected and analyzed to date are summarized in table 6-5.

Table 6-5.—Detailed paleoflood estimates at A.R. Bowman Dam, Oregon

Type	Preferred age (years before present)	Age range (years)	Preferred discharge (ft^3/s)	Discharge range	
				Low (ft^3/s)	High (ft^3/s)
1862 historical bound	140	—	15,000	13,000	18,000
Paleohydrologic bound	1,100	980 – 1,210	20,700	18,000	25,000
Paleohydrologic bound	3,150	2,650 – 3,650	25,000	22,000	30,000
Paleohydrologic bound	3,500	3,350 – 5,050	27,000	25,000	32,500
Paleohydrologic bound	9,000	7,600 – 10,000	30,000	27,000	36,000
Historical flood	140	—	20,700	18,000	25,000
Paleoflood	1,100	980 – 1,210	20,700	18,000	25,000

The paleoflood data were combined with peak flows from three gaging stations. A frequency analysis was performed using FLDFRQ3 (O'Connell, 1999; O'Connell et al., 2002). The peak-flow frequency results for a particular distribution (log-Pearson) are shown in figure 6-5 and summarized in table 6-6. Based on this peak-discharge frequency curve and scaling model hydrographs, the dam might be overtopped at exceedance probabilities greater than 0.0001 (more frequently than the 10,000-year return period).

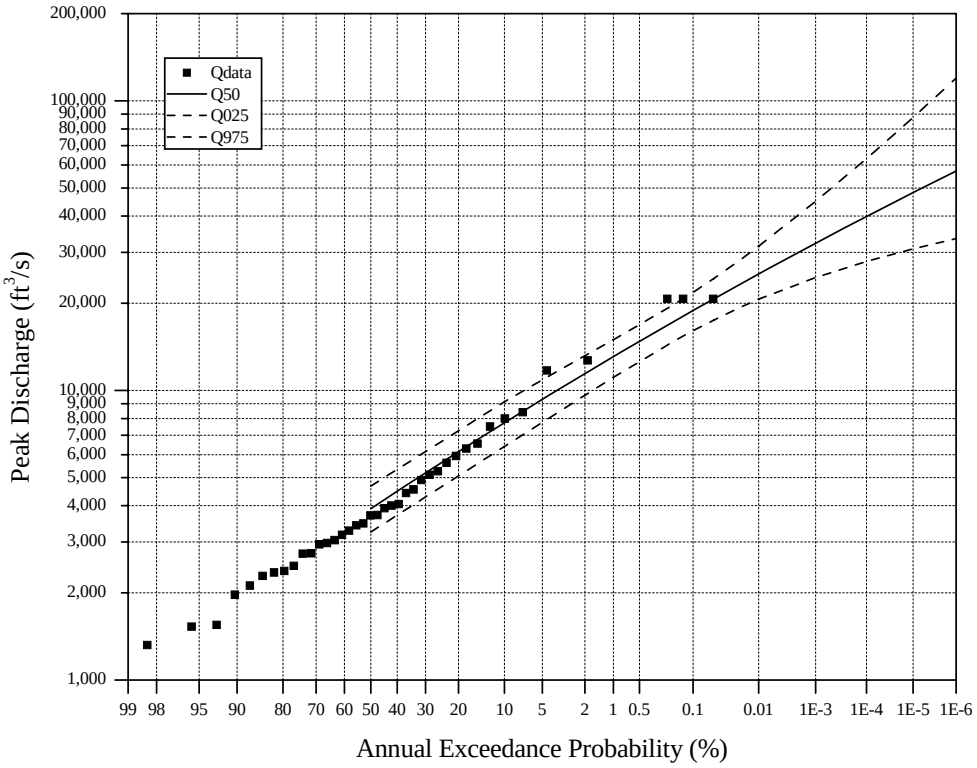

Figure 6-5.—Peak-discharge frequency curve based on paleoflood data for A.R. Bowman Dam, Oregon.

Table 6-6.—Peak discharge estimates based on paleoflood data at A.R. Bowman Dam, Oregon, for specified probabilities

Annual Exceedance Probability	Return Period	Median (50%) LP3 Model Peak Discharge Estimate (ft^3/s)	2.5% LP3 Model Peak Discharge Estimate (ft^3/s)	97.5% LP3 Model Peak Discharge Estimate (ft^3/s)
0.01	100	13,100	11,100	15,000
0.002	500	17,100	14,600	19,500
0.001	1,000	18,900	16,100	21,800
0.0005	2,000	20,700	17,500	24,400

0.0001	10,000	25,200	20,700	31,500
0.00001	100,000	32,200	24,500	44,900
0.000001	1,000,000	39,800	27,900	63,200
0.0000001	10,000,000	48,200	30,800	87,500
0.00000001	100,000,000	57,100	33,400	119,700

6.2.4 Combined Hydrologic Hazard Estimates for Risk Analysis and Dam Safety Implications

Both the SEFM and paleoflood study indicate that A.R. Bowman Dam potentially might not meet Reclamation hydrologic hazard criteria for overtopping because it does not pass the 10,000-year flood (at a minimum). The results from the three approaches (flood frequency analysis and hydrograph scaling, SEFM, and paleoflood study) were combined to provide a single estimate of the hydrologic hazard curve for risk analysis. The weighting schemes are simple numerical weights given to each model result. Three weighting schemes were analyzed for A.R. Bowman: (1) enveloping all results (figure 6-6), (2) weighting the SEFM and paleoflood peak flow curves equally (50 percent each) (figure 6-7), and (3) choosing a "best estimate" between the SEFM and paleoflood peak flow curves equal to the upper 97.5 percent confidence limit from the Bayesian analysis (figure 6-8). The third option was selected to represent the peak discharge flood frequency based on results and decisions made in 1999 for a risk analysis. A "combined" hydrologic hazard curve is shown in figure 6-9, which also includes a volume frequency analysis based on results of the SEFM.

Because A.R. Bowman Dam might not meet Reclamation criteria, additional engineering studies are ongoing to estimate the need for any potential structural modifications at this site. Probability-based design hydrographs for any potential modification or design alternatives were selected based on a combination of the weighting results shown above. Corrective action studies are ongoing.

6.3 Fresno Dam

Fresno Dam is located on the Milk River in north-central Montana, approximately 14 miles west of the town of Havre (figure 6-10). The compacted earthfill dam was constructed from 1937 to 1939. It is approximately 110 feet high. Previous studies have indicated that the dam could safely pass Reclamation's 1985 PMF hydrograph. Normally, Reclamation would not have conducted additional hydrologic studies for this dam; however, project beneficiaries wanted to examine the possibility of enlarging the dam.

6.3.1 Fresno Dam Hydrologic Hazard Curves Using Flood Frequency Analysis and Hydrograph Scaling

A hydrologic hazard curve for Fresno Dam was constructed using flood frequency analysis techniques. Peak flow and paleoflood data and a general storm PMF hydrograph were used to estimate the hazard curve (figure 6-11 and table 6-7).

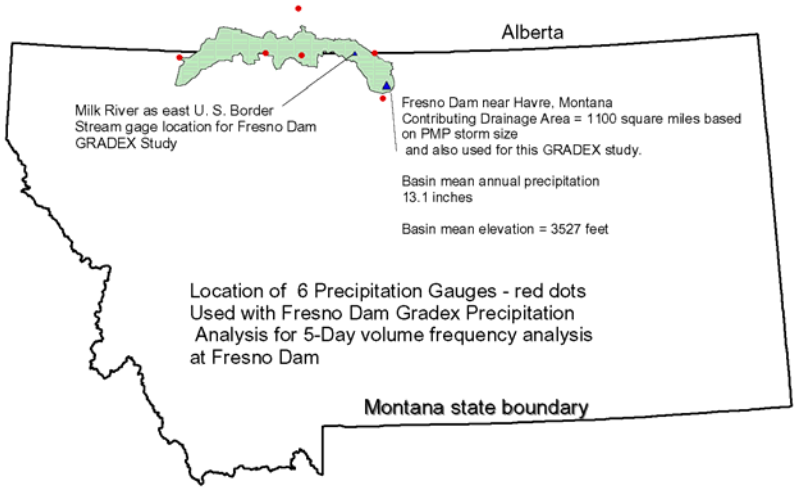

Figure 6-10.—Site and watershed depiction of Fresno Dam, Montana.

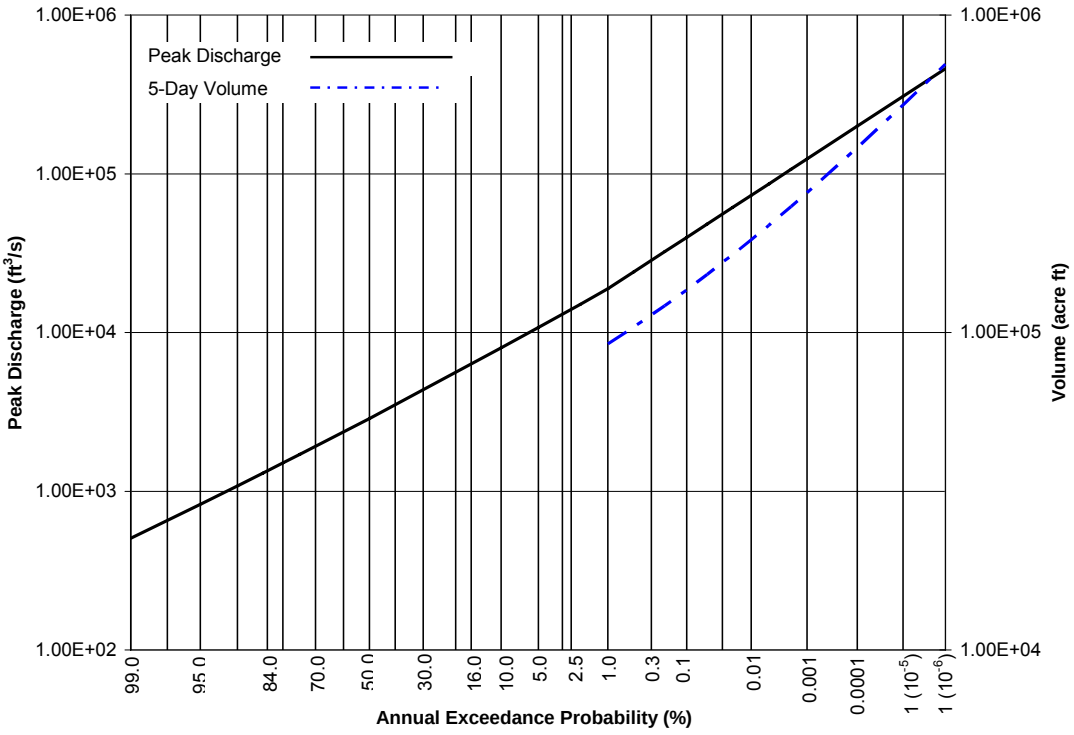

Figure 6-11.—Example of hydrologic hazard curve for Fresno Dam, Montana.

Table 6-7.—Peak and volume (5-day) estimates at Fresno Dam, Montana, for specified probabilities

Annual Exceedance Probability	Return Period	Discharge Estimate	5-Day Volume Estimate (acre ft)
0.01	100	18,900	92,000
0.005	200	24,100	103,900
0.002	500	32,300	121,400
0.001	1000	39,700	136,100
0.0005	2000	48,200	152,300

0.00001	100000	124,200	276,000
0.000001	1000000	199,600	382,100
0.0000001	10000000	307,800	520,800
0.00000001	100000000	459,400	700,300

Peak flow data at Fresno Dam were obtained from the USGS gaging station, Milk River at Eastern U.S. Border Crossing (USGS station No. 06135000). The gage provides peak flow records from 1910 through 2002. No adjustments were performed on these data, as the associated drainage area and streamflow records were believed to accurately represent the conditions at Fresno Dam.

The reconnaissance-level paleoflood data that may be applied to estimate flood frequency at Fresno Dam are based on detailed chronology developed at archaeological sites on the Milk River. Based on this information, it appears that a peak discharge between 40,000 and 70,000 ft^3/s on the Milk River has not been exceeded in the last 2,000 to 4,000 years.

Fresno Dam has a spillway discharge capacity of 51,360 ft^3/s at the maximum water surface elevation of 2591 feet. Comparing this value with the peak-discharge flood frequency curve indicates that the spillway is capable of passing a flood with a return period of only slightly longer than 2,000 years. At the time of this study, the methods for determining the volume frequency relationship had not been developed, so hydrographs were not available for reservoir routing. Therefore, we decided to develop hydrographs using the GRADEX Method.

6.3.2 Fresno Dam Hydrologic Hazard Analysis Using the GRADEX Method

Daily flow records that approximate the daily inflows to Fresno Dam come from the stream gage on the Milk River at the Eastern U.S. Border Crossing (USGS station No. 06135000). This gage record has daily flow data from August 1909 through September 2001. A total of 86 years of daily flow data is available, with a few missing years. The contributing drainage area at the gage site is considered to be 2,525 mi^2, and the gage is located about 54 river miles upstream from Fresno Dam. The total possible contributing drainage area at Fresno Dam is considered to be 2,911 mi^2 for the rainfall-runoff modeling calculations in this study. These daily flow records were checked with available reservoir inflow records for concurrent years.

The information needed from the stream gage record is a set of independent flood volumes, representing the volume of flooding caused by rainfall for independent storms in the basin. The process starts by setting a threshold flow value and then counting the number of events that have continuous days of flow above that value. A threshold flow value was set and adjusted until about 86 independent flood events above this value were determined. The average duration of all of the independent flood events was then calculated. This average duration of independent flood events for the Milk River above Fresno Dam was found to be between 4 and 5 days, with a threshold value of 1,307 ft^3/s. The value of 5 days was selected for further use in the study as the critical duration for both rainfall and flood events.

The GRADEX Method required that the number of multi-day rain events at each gage be equal to the number of common years of record for the selected gages. The number of multi-day rain events was made equal by selecting a threshold 5-day total rainfall for each gage such that exactly fifty 5-day rain totals were above the threshold value for each gage. Figure 6-10 displays the locations of the six precipitation gage stations selected for the GRADEX analysis at Fresno Dam. Table 6-8 lists the six stations used for the remainder of this analysis along with some pertinent information including the MAP.

Table 6-8.—Rainfall data description

Selected Rainfall Stations with a Period of Record Including 1950-2000 Used with Fresno Dam GRADEX Study for high return period volumes Fresno basin mean basin elevation = 3527 feet Fresno basin mean annual precip. = 13.1 inches					
Station	**State/Prov.**	**Latitude**	**Longitude**	**Elevation (feet)**	**M.A.P. (inches)**
Babb	MT	48.93	113.36	4300	18.27
Gold Butte	MT	48.98	111.4	3498	13.38
Kremlin	MT	48.52	110.1	2860	11.56
Simpson	MT	49	110.22	2815	10.24
Sweetgrass	MT	49	111.97	3466	13.98
Foremost	ALB	49.48	111.45	2899	14.68

Using the 5-day precipitation totals, 5-day flow volumes, drainage area, and other data described above, the GRADEX Method computations were made as outlined in Naghettini (1994) and Naghettini et al. (1996). For this study, a special situation arises with respect to selection of the contributing drainage area above Fresno Dam.

Based on all previous Reclamation IDF and PMF studies for Fresno Dam, the authors of this study believe that a single-storm precipitation pattern will not cover the entire basin. For this GRADEX study, a total contributing drainage area of 1,100 mi^2 was selected, based primarily on the use of the hypothetical elliptical patterns used with the PMP studies.

Table 6-9 and figure 6-12 display the summary results from the calculations for Fresno Dam. The volume of the PMF volume centered hydrograph from the 1985 Reclamation PMF study is plotted as a straight line on the frequency curve for comparison. It should be noted that the PMF is based on a 3-day rainfall, and the Fresno Dam frequency curve is based on 5-day total rainfall amounts. The GRADEX Method is intended to give flood volume data for very large return periods, in excess of 200 years. More common methods, such as a LP-III distribution fit to available streamflow data, should be used for the lower return periods, 100 years and less in this study.

Table 6-9.—Five-day volume frequency curve for Fresno Dam, Montana, based on GRADEX Method

Return Period (years)	Five-day Volume (acre-ft)	Upper Bound (acre-ft)	Lower Bound (acre-ft)
500	188,700	320,100	112,400
1,000	214,700	358,700	131,100
5,000	275,100	448,200	174,700
10,000	301,100	486,800	193,500
20,000	327,100	525,400	212,300
50,000	361,600	576,400	237,200
100,000	387,600	615,000	256,000
500,000	448,000	704,600	299,600
1,000,000	474,100	743,100	318,500

In most normal years, snowmelt may contribute a large amount to the total volume of inflows to Fresno Reservoir. Another assumption in the GRADEX Method is that the precipitation that is measured at the gages is in liquid form and ready for runoff, or if it is snow, the snow will melt during the critical storm-time period and add to the runoff volume. A simple scheme to separate purely snowmelt runoff from rain or rain-on-snow runoff was used with the 86 years of daily flows at the Milk River at Eastern U.S. Border Crossing gage. The 7-day maximum of purely snowmelt flow was then determined for each year and expressed as a constant flow for 7 days. The 86-year-long series of 7-day maximum snowmelt flows at the gage site was then analyzed using a standard LP-III analysis. The lower curve in figure 6-13 displays the frequency curve of maximum 7-day purely snowmelt flows. The curve is quite flat. This is expected for purely snowmelt driven volumes. There is a physical limit to how much snow can be melted with normal ranges of climate variables. The snowmelt volume frequency curves will become quite flat for larger return periods. The 7-day flows were then converted to volumes in acre-feet and a similar frequency curve was also plotted in figure 6-13.

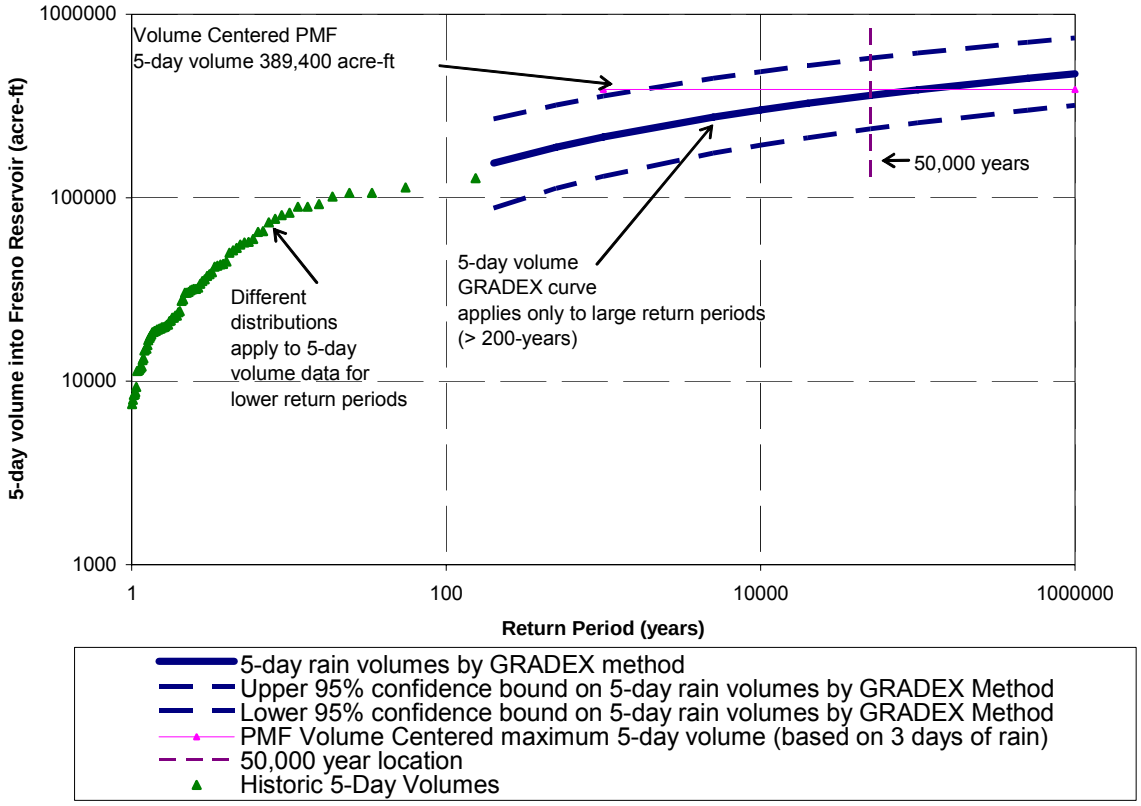

Figure 6-12.—Fresno Dam, Montana, 5-day rain-generated volumes by GRADEX Method.

The 5-day volumes of the GRADEX rain flood volumes from this study were then added to the plot. This is the blue curve near the top of figure 6-13. A combined probability curve was then computed and is shown as the red curve on the top of figure 6-13. The combined probability curve expresses the probability (or return period) of getting a particular total flood volume by combining a 7-day snowmelt with a 5-day rain flood volume. The combined probability curve very closely follows the 5-day rain flood volume curve for the large return periods.

Hourly inflow hydrographs were developed for Fresno Dam for the desired return periods by applying indexed rainfall amounts to the HEC-HMS models calibrated to the 1906 and 1964 rainfall flood events. The rainfall amounts for the 1964 and 1906 storm hyetographs were uniformly increased in each subbasin until the 5-day volume of the respective return periods, determined by the GRADEX Method, was achieved. Figure 6-14 displays the results for the 1964 flood computations. Figure 6-15 displays the results of increasing the 1964 precipitation amount to calculate hydrographs with the GRADEX volumes for specified return periods.

The peak versus volume relationship was developed using a LOWESS technique (Cleveland, 1979). The 86 years of peak and 5-day volume data from the USGS gage at the Milk River at Eastern Border were plotted. In addition, the 30 peak-flow and 5-day volumes generated from

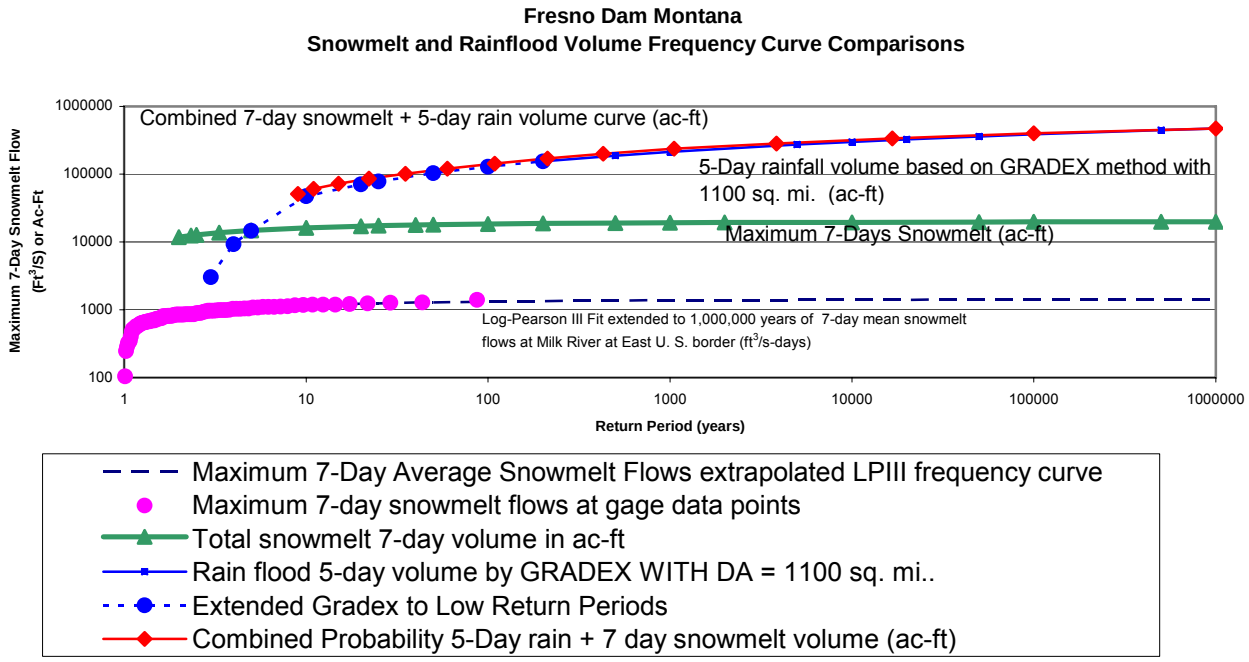

Figure 6-13.—Fresno Dam, Montana, snowmelt and rainflood volume frequency curve comparisons.

the HEC-HMS models originally calibrated to both the 1906 and 1964 flood events were run. In each run, the lag time was varied or the rainfall was increased in a systematic manner to cover a range of possible values for greater storm events. A LOWESS fit was done using the entire set of peak versus volume points and is shown in figure 6-16. This relationship was used to determine the peak discharge estimates that correspond to the selected 5-day return period volumes computed using the GRADEX Method.

The results of this calculation can be used to derive a peak-flow flood frequency curve. The information for the peak flow and volumes for the return periods of interest in this study is summarized in table 6-10. In this study, the reported paleohydrology information indicated a non-exceedance peak flood bound with an age between 2,000 and 4,000 years and a magnitude between 40,000 and 70,000 ft^3/s. The paleohydrology information was in agreement with the GRADEX results.

For Fresno Dam, the results of the GRADEX Method were used for the risk assessment because flood volumes were needed to evaluate the safety of the dam. Since only peak flow data were available at the time of the first analysis, the GRADEX study was conducted. Hydrographs could then be routed through the reservoir to take advantage of the flood attenuation effects of the large surcharge storage in the reservoir.

Table 6-10.—Fresno Dam, Montana, GRADEX Method results

Return Period (year)	Peak Inflow (cfs)	5-Day Volume (acre-ft)
1,000	61,000	214,700
10,000	83,000	301,100
50,000	98,000	361,600

7. Summary

This report summarizes Reclamation's approach toward developing hydrologic hazard curves for use in evaluating dam safety issues. The procedure relies on extracting information from existing studies to the fullest extent possible. The characterization of hydrologic risk for a CFR can usually be accomplished with minimal effort. CFR hydrologic hazard curves display peak

flow and volume relationships for a full range of Annual Exceedance Probabilities necessary for decision making. The procedures and analysis techniques defined in this report allow for the possibility, and even plausibility, that peak discharge and volume estimates may exceed the PMF. This is a function of the uncertainty and inconsistency among and between analysis techniques. Therefore, in these cases, the PMF is believed to represent the upper limit to hydrologic risk.

The procedure for developing hydrologic hazard curves considers the dam safety decision criteria, potential dam failure mode, and dam characteristics, available hydrologic data, possible analysis techniques, resources available for analysis, and tolerable level of uncertainty. Dam safety decision criteria determine the probabilistic range of floods needed to address hydrologic issues (Bureau of Reclamation, 2003a). The potential dam failure mode and dam characteristics impact the type of hydrologic information needed to assess the problem. The specific elements selected to be incorporated in an analysis of hydrologic hazards should consider the tolerable level of uncertainty. Reducing the uncertainty in the estimates may require additional data collection and use of more sophisticated solution techniques. It is believed that increasing the level of effort and the sophistication of analysis techniques increases the reliability and level of confidence associated with the results.

Reclamation currently uses a combination of seven hydrologic methods to develop hydrologic hazard curves. These general techniques include: flood frequency analysis with historical and paleoflood data, hydrograph scaling and volumes, the GRADEX Method, the Australian Rainfall-Runoff Method, stochastic event-based precipitation runoff modeling with the SEFM, stochastic rainfall-runoff modeling with CASC2D, and the PMF. Each method is described within these guidelines.

The hydrologic methods described in these guidelines are not all inclusive. New techniques for developing hydrologic hazard information can be added to these guidelines as they are developed by the hydrology community.

The amount of effort expended on analyzing a hydrologic hazard depends on the nature of the problem and the potential cost of the solution. A staged approach toward evaluating a hydrologic safety issue is recommended. Initially, very little effort is expended to determine the magnitude of the hydrologic hazard. Reclamation attempts to make use of all available studies for the site of interest. Often, the PMF and initial flood frequency studies are the only hydrologic studies available before the start of a probabilistic investigation. When other hydrologic studies have been performed, available data will be used to decrease uncertainty in results as well as to provide an overall assessment of hydrologic risk.

Dam safety evaluations usually begin with a characterization of hydrologic risk. If detailed studies have been conducted for the site of interest, they are summarized and presented to the risk assessment team. About two-thirds of Reclamation’s dams can safely accommodate the PMF; when the PMF is selected as the IDF, no additional work may be required unless other hydraulic issues need evaluation. Additional hydrologic work begins with a flood frequency analysis and hydrograph scaling to develop a peak-discharge relationship and frequency flood hydrographs. It is believed that this type of information is sufficient to address hydrologic issues and make dam safety decisions at about 80 percent of the remaining dams. For the sites that still

have potential safety problems, project plans can be developed for studies to address the specific hydrologic issues. These studies require more work and more sophisticated solution techniques than flood frequency analysis and hydrograph scaling.

When planning more detailed studies, it is recommended that the goal be to achieve a balance between the amount of hydrologic analysis needed to address the issues and the level of effort required to conduct the study. As the studies get more detailed, the results should become more precise and contain less uncertainty. An example is a hydrologic study that proceeds from flood frequency analysis and hydrograph scaling to an analysis using the GRADEX Method, the Australian Rainfall-Runoff Method, a stochastic rainfall-runoff model, or any other statistical estimation technique available.

When multiple methods are used, alternative hazard curves are developed by weighting results from the individual analyses. A team of hydrologists evaluates the alternatives and selects a weighting scheme that is most representative of the site for use in the risk assessment. Selection of the final hydrologic hazard curve depends on the experience of the hydrologists and the assumptions that went into each analysis.

Three case studies, Los Banos, Fresno, and A.R. Bowman Dams, have been presented to illustrate the variety of methods available. These sites were chosen to demonstrate the use of the various techniques for characterization of the flood hazard. The A.R. Bowman example shows how multiple studies were combined into a single-flood hazard curve for use in risk assessment.

A FRAMEWORK FOR CHARACTERIZATION OF EXTREME FLOODS FOR DAM SAFETY RISK ASSESSMENTS

Robert E. Swain[5], David Bowles[6], and Dean Ostenaa[7]

Abstract

Risk-based decisions require different types of information than standards-based decisions. Traditional sources of information used for estimating probabilities of extreme floods include gaged streamflow records, indirect discharge measurements, and precipitation records. Generally these data sources have records that are less than 100 years in length. This framework for flood characterization for risk assessments uses the length of the data record and other characteristics of the data to determine the credible extrapolation limits used in the flood frequency analysis. Because risk assessments require estimation of floods with annual exceedance probabilities of 1 in 10,000, or less, emphasis is placed on developing probabilistic estimates using regional hydrometeorological data and paleoflood information. The uncertainties associated with descriptions of flood flow exceedance probabilities are likely to be substantial and an important attribute to convey into the risk assessment.

No single approach is capable of providing estimates of extreme floods over the full range of annual exceedance probabilities required for risk assessment. Therefore, results from a number of approaches need to be combined to yield a composite flood characterization; this means several methods and sources of data are needed. The application of several independent methods applicable to the same range of annual exceedance probabilities will increase the credibility and resulting confidence in the results.

Introduction

The U.S. Bureau of Reclamation is now making extensive use of quantitative risk assessment in support of dam safety decision making (Von Thun and Smart, 1996). An important input to Dam Safety Risk Assessment is the development of probabilistic extreme flood estimates. This shifts the focus for dam safety flood evaluation from routing a single "maximum" event (i.e. the probable maximum flood, PMF) to consideration of the entire range of plausible inflow flood events, and ultimately to the magnitude-frequency relationship of maximum reservoir stages.

[5]Technical Specialist - Flood Hydrology, Bureau of Reclamation, P.O. Box 25007, Denver CO ; 80225-0007; E-mail-rswain@do.usbr.gov

[7]Lead Geologist, Geophysics, Paleohydrology and Seismotectonics Group, D-8330, Bureau of Reclamation, P.O. Box 25007, Denver CO 80225-0007; E-mail-dostenaa@do.usbr.gov

For floods, the risk assessment process involves selecting a spillway evaluation flood (SEF) based on the probability of dam failure and the severity of the incremental consequences of dam failure. Past practice also examined consequences, but without formal consideration of probability of failure; if consequences were judged to be large, the SEF was chosen as the PMF.

Reclamation has identified the need for a review of its present procedures for developing probabilistic extreme flood estimates and their associated uncertainties for use in dam safety risk assessment. Where practical, Reclamation would like to develop improved procedures. The overall objective is to develop a practical, robust, consistent, and credible framework for developing probabilistic extreme flood estimates for Dam Safety Risk Assessment. The desired outcome is a robust framework in which components can be improved in the future as the state-of-the-art develops.

The framework was developed by inviting a group of approximately 20 professionals with extensive experience in the theoretical and practical aspects of physical, paleo-, and statistical flood hydrology and hydrometeorology to participate in a one-week workshop held at Utah State University in June 1997. Participants from North America, Australia, and the United Kingdom reviewed current Reclamation practice, and evaluated various advances in developing probabilistic extreme flood estimates for their potential role in the needed framework. A smaller group met in Denver to develop the details of the framework. This paper summarizes the findings of these groups.

Risk Assessment Stages

Present Reclamation risk assessment practice uses a staged approach for conducting risk assessments (USBR, 1997a). Project schedule and budget constraints are considered in determining the type of flood assessment prepared at each stage. While each risk assessment is unique, the following stages are generally used in Reclamation risk assessments:

a) **Screening Level Risk Assessment**: An evaluation of risk that includes definition of load probabilities and consequences for all load classes (flood, earthquake, and static). Structure failure probabilities and associated uncertainties are also considered in a global sense, but detailed event trees are not usually prepared. An emphasis at this stage is to maximize the use of available information, without conducting new analyses or collecting additional data. The intent is to identify areas where risks are potentially high and to determine the need for further evaluations and data collection. Results of these evaluations are used to determine Reclamation's risk profile and to "screen" out dam safety issues where additional funding and effort appears to have little potential for reducing dam safety risks.

b) **Scoping Level Risk Assessment**: A more detailed evaluation of risks is performed for the dam safety issues identified in a screening level risk assessment. This level of risk assessment typically involves more detailed treatment of event trees, load probabilities, structural response, and consequences. The intent is to invest sufficient effort so that the risk assessment team understands the major contributors to risk to enable formulation of risk reduction strategies and to determine the need for additional analyses and investigations.

c) **Decision Level Risk Assessment**: At this level, more detailed evaluation of risks is performed to provide decision makers with the information necessary to reach a dam safety decision for a structure. The decision may be related to continuing project operations, correcting dam safety deficiencies, selecting among risk reduction alternatives, or determining the need for interim actions to reduce risk while long term plans are developed. The intent is to provide decision makers with sufficient pertinent risk information such that the risk reduction objective can be effectively considered along with other Reclamation objectives. At this level of risk assessment, detailed loading information, structural response analyses, and consequence evaluations are developed for all significant issues. This type of risk assessment focuses on reducing uncertainties in the risk estimates and evaluating risk reduction actions.

Data Sources

The proposed framework for developing probabilistic extreme flood estimates for risk assessment uses the length of record and other characteristics of the data to determine the extrapolation limits for flood frequency analysis. Traditional sources of information used for flood hazard analyses include streamflow and precipitation records. Generally, these data sources have records that are less than 100 years in length, although in some cases these records can be extended to about 150 years using historical information. Regional precipitation and streamflow data can create pooled data sets from short periods of observation, and paleoflood data can extend records of floods to periods of up to several thousand years.

Streamflow Data

Many different types of streamflow information are used in developing probabilistic extreme flood estimates for risk assessment. Streamflow data are used in flood hazard assessment as input for frequency studies or as the basis for developing flood hydrographs. The usual source of these data is the streamflow records collected and maintained by the U.S. Geological Survey. However, similar data are collected and archived by many other Federal and State government agencies and some non-government organizations. Streamflow records consist of data collected at established gaging stations and indirect measurements of streamflow at other sites. Streamflow data can include estimates of peak discharge, as well as average or mean discharge for various time periods. Most streamflow measurements on U.S. streams began after 1900 with only a few records dating back that far. Most often, streamflow records at a single site range in length from about 20 to 60 years. Completeness of the data set may vary from station to station.

Climate Data

Precipitation and weather data used in hydrologic models can include rainfall, snowfall, snow water equivalent, temperature, solar radiation, and wind speed and direction from individual weather stations, as well as remote sensing information and radar information for broader regions. Data types available from various sources vary greatly in record length and quality throughout the United States. Some of these types of data (i.e., snowfall, snow water equivalent, solar radiation, and wind)

are limited to record lengths of less than about 30 years; basic rainfall and temperature data are available for some stations for up to 150 years, but in most cases are limited to less than 100 years.

Historical Data

Historical data can provide a means for extending the length of record for many types of data, in particular for observations of the most extreme events. These data are most commonly used to extend streamflow records of peak discharge prior to organized stream gaging. Historical observations can provide information for other types of data such as weather patterns and the frequency of extreme storm events, or changes in land use or vegetation that may be significant to runoff modeling calculations. However, as with any type of historical data, the accuracy and validity of the observations must be carefully assessed and compared to the other types of data used in the analysis.

Paleoflood Data

Paleoflood hydrology is the study of past or ancient flood events which occurred prior to the time of human observation or direct measurement by modern hydrological procedures (Baker, 1987). Unlike historical data, paleoflood data do not involve direct human observation of the flood events. Instead, the paleoflood investigator studies geomorphic and stratigraphic records (various indicators) of past floods, as well as the evidence of past floods and streamflow derived from historical, archeological, dendrochronologic, or other sources. The advantage of paleoflood data is that it is often possible to develop records that are 10 to 100 times longer than conventional or historical records from other data sources in the western United States. In addition, the paleoflood record is a long-term measure of the tendency of a river to produce large floods. In many cases, paleoflood studies can provide a long-term perspective, which can put exceptional annual peak discharge estimates in context and assist in reconciliation of conflicting historical records.

Paleoflood data generally include records of the largest floods, or commonly the limits on the stages of the largest floods over long time periods. This information can be converted to peak discharges using a hydraulic flow model. Generally, paleoflood data consist of two independent components. One component is a peak discharge estimate; the second is a time period or age over which the peak discharge estimate applies. Paleoflood studies can provide estimates of peak discharge for specific floods in the past, or they can provide exceedance and non-exceedance bounds for extended time periods. Each of these differing types of paleoflood data must be appropriately treated in flood frequency analyses.

Extrapolation Limits for Different Data Types

The primary basis for a limit on credible extrapolation of extreme flood estimates derives from the characteristics of the data and the record length used in the analysis. The data used in the analysis provide the only basis for verification of the analysis or modeling results, and as such, extensions beyond the data cannot be verified. Different risk assessments require flood estimates for different ranges of annual exceedance probability (AEP), and therefore analysis procedures and data sources should be selected to meet project requirements. The greatest gains to be made in providing

credible estimates of extreme floods can be achieved by combining regional data from multiple sources. Thus, analysis approaches that pool data and information from regional precipitation, regional streamflow, and regional paleoflood sources should provide the highest assurance of credible characterization of low AEP floods.

For many Reclamation dam safety risk assessments, flood estimates are needed for AEPs of 1 in 10,000 and ranging down to 1 in 100,000, or even lower. Developing credible estimates at these low AEPs generally require combining data from multiple sources and a regional approach. Table 1 lists the different types of data which can be used as a basis for flood frequency estimates, and the typical and optimal limits of credible extrapolation for AEP, based on workshop discussions or subsequent communications. The limits presented in the table represent a general group consensus; however, opinions differed amongst workshop participants. In general, the optimal limits are based on the best combination(s) of data envisioned in the western U.S. in the foreseeable future. Typical limits are based on the combination(s) of data which would be commonly available and analyzed for most sites.

Many factors can affect the equivalent independent record length for the optimal case. For example, gaged streamflow records in the western United States only rarely exceed 100 years in length, and extrapolation beyond twice the length of record, or to about 1 in 200 AEP, is generally not recommended (IACWD, 1982). Likewise, for regional streamflow data the optimal limit of credible extrapolation is established at 1 in 1,000 AEP by considering the number of stations in the region, lengths of record, and degree of independence of these data (Hosking and Wallis, 1997). For paleoflood data, only in the Holocene epoch, or the past 10,000 years, is climate judged to be sufficiently like that of the present climate, for these types of records to have meaning in estimates of extreme floods for dam safety risk assessment. This climatic constraint indicates that an optimal limit for extrapolation from paleoflood data, when combined with at-site gaged data, for a single stream should be about 1 in 10,000 AEP. For regional precipitation data, a similar limit is imposed because of the difficulty in collecting sufficient station-years of clearly independent precipitation records in the orographically complex regions of the western United States. Combined data sets of regional gaged and regional paleoflood data can be extended to smaller AEPs, perhaps to about 1 in 40,000, in regions with abundant paleoflood data. Analysis approaches that combine all types of data are judged to be capable of providing credible estimates to an AEP limit of about 1 in 100,000 under optimal conditions.

In many situations, credible extrapolation limits may be less than optimal. Typical limits would need to reflect the practical constraints on the equivalent independent record length that apply for a particular location. For example, many at-site streamflow record lengths are shorter than 100 years. If in a typical situation the record length is only 50 years, then the limit of credible extrapolation might be an AEP of about 1 in 100. Similarly, many paleoflood records do not extend to 10,000 years, and extensive regional paleoflood data sets do not currently exist. Using a record length of about 4,000 years, a typical limit of credible extrapolation might be an AEP of 1 in 15,000 based on regional streamflow and regional paleoflood data.

The information presented in Table 1 is intended as a guide; each situation is different and should be assessed individually. The limits of extrapolation should be determined by evaluating the length of record, number of stations in a hydrologically homogeneous region, degree of correlation between stations, and other data characteristics which may affect the accuracy of the data.

Ideally, one would like to construct the flood frequency distribution for all floods that could conceivably occur. However, the limits of data and flood experience for any site or region place practical limits on the range of the floods to which AEPs can be assigned. There does not appear to be sufficient data to justify computation of AEPs less than 1 in 100,000. In general, the scientific limit to which the flood frequency relationship can be credibly extended, based upon any characteristics of the data and the record length, will fall short of the probable maximum flood (PMF) for a site. PMF estimates provide a useful reference to past practice and can be compared with extreme floods characterized for risk assessment. However, the workshop participants concluded that there is limited scientific basis for assigning an AEP to the PMF. For precipitation data, similar limitations apply to extrapolations that approach values described by probable maximum precipitation.

Table 1. Hydrometeorological Data Types and Extrapolation Limits for Flood Frequency Analysis

Type of Data Used for Flood Frequency Analysis	Limit of Credible Extrapolation for Annual Exceedance Probability	
	Typical	Optimal
At-site streamflow data	1 in 100	1 in 200
Regional streamflow data	1 in 750	1 in 1,000
At-site streamflow and at-site paleoflood data	1 in 4,000	1 in 10,000
Regional precipitation data	1 in 2,000	1 in 10,000
Regional streamflow and regional paleoflood data	1 in 15,000	1 in 40,000
Combinations of regional data sets and extrapolation	1 in 40,000	1 in 100,000

Methods of Analysis

At Site Flood Frequency Analysis

Frequency analysis is an information problem: if one had a sufficiently long record of flood flows, or perhaps rainfall for a basin, then a frequency distribution for a site could be determined with good precision, so long as change over time due to anthropogenic or natural processes did not alter the distribution of floods. In most situations available data are insufficient to precisely define the annual exceedance probability of large floods. This forces hydrologists to use practical knowledge of the physical processes involved, and efficient and robust statistical techniques, to develop their estimates (Stedinger et al., 1993).

Fitting a distribution to data sets allows both a compact and smoothed representation of the frequency distribution revealed by the available data, and a systematic procedure for extrapolation to frequencies beyond the range of the data set. Given a family of distributions, one can estimate the parameters of that distribution so that required quantiles and expectations can be calculated with the "fitted" model. Appropriate choices for distribution functions can be based upon examination of the data using probability plots, the physical origins of the data, previous experience, or prescriptive guidelines.

Several general approaches are available for estimating the parameters of a distribution. A simple approach is the *method of moments,* which uses the available sample to compute estimators of the distribution's parameters. The Federal guidelines published in Bulletin 17B (IACWD, 1982) recommend fitting a Pearson type 3 distribution to the common base 10 logarithms of the peak discharges. It uses at-site data to estimate the sample mean and variance of the logarithms of the flood flows, and a combination of at-site and regional information to estimate skewness.

Another method that may be used to estimate the parameters of a distribution for at-site frequency analysis is the Expected Moments Algorithm (EMA). EMA (Cohn et al., 1997) is a moments-based estimation procedure and is identical to the existing Bulletin 17B (IAWCD, 1982) approach when no high or low outliers are present. The EMA method was developed to utilize historical and paleoflood information in a censored data framework. This approach explicitly acknowledges the number of known and unknown values above and below a threshold, similar to a maximum-likelihood approach. Three types of at-site flood information are used: systematic stream gage records; information about the magnitudes of historical floods; and knowledge of the number of years in the historical period when no large flood occurred.

Still another method, which has strong statistical motivation, is the *method of maximum likelihood*. Maximum likelihood estimators (MLEs) have very good statistical properties in large samples, and experience has shown that they generally do well with records available in hydrology. In many cases MLEs cannot be reduced to simple formulas, so estimates must be calculated using numerical methods (Stedinger et al., 1988; O'Connell, 1997).

L-moments are another way to summarize the statistical properties of hydrologic data. Sample estimators of L-moments are linear combinations (and hence the name L-moments) of the ranked observations, and thus do not involve squaring or cubing the observed values as do the product-moment estimators. As a result L-moment estimators of the dimensionless coefficients of variation and skewness are almost unbiased and have very nearly a normal distribution (Hosking and Wallis, 1997).

Regional Flood Frequency Analysis

In hydrology, sufficient information is seldom available at a site to adequately determine the frequency of rare events using frequency analysis. This is certainly the case for the extremely rare events which are of interest in dam safety risk assessment. The National Research Council (1988) has proposed several general strategies, including substituting space for time for estimating extreme floods. One substitutes space for time by using hydrologic information at different locations in a region to compensate for short records at a single site.

Three approaches (Cudworth, 1989) have been considered for regional flood frequency analysis: (1) average parameter approach; (2) index flood approach; and (3) specific frequency

approach. With the average parameter approach, some parameters are assigned average values based upon regional analyses, such as the log-space skew or standard deviation. Other parameters are estimated using at-site data, or regression on physiographic basin characteristics**,** perhaps the real or log-space mean. The index flood method is a special case of the average parameter approach. The specific frequency approach employs regression relationships between drainage basin characteristics and particular quantiles of a flood frequency distribution.

Index Flood Method. The index flood procedure is a simple regionalization technique with a long history in hydrology and flood frequency analysis (Dalrymple, 1960). It uses data sets from several sites in an effort to construct more reliable flood-quantile estimators. A similar regionalization approach in precipitation frequency analysis is the station-year method, which combines precipitation data from several sites without adjustment to obtain a large composite record to support frequency analyses. The concept underlying the index flood method is that the distributions of floods at different sites in a "region" are the same except for a scale or index-flood parameter which reflects the size, rainfall and runoff characteristics of each watershed. Generally the mean is employed as the index flood (Hosking and Wallis, 1997).

Average Shape Parameter. As at-site records increase in length, procedures that estimate two parameters, with at-site data to be used with a regional shape parameter, have been shown to perform better that index flood methods in many cases (Stedinger and Lu, 1995). For record lengths of even 100 years, 2-parameter estimators with a good estimate of the third shape parameter**,** are generally more accurate than are 3-parameter estimators (Lu and Stedinger, 1992; Stedinger and Lu, 1995). However, whether or not it is better to also regionalize the coefficient of variation depends upon the heterogeneity of the regions and the coefficients of variability of the flows. In regions with high coefficients of variation (and high coefficients of skewness) index flood methods are more attractive.

Regional Regression. Regional analysis can be used to derive equations to predict the values of various hydrologic statistics (including means, standard deviations, quantiles, and normalized regional flood quantiles) as a function of physiographic characteristics and other parameters. Stedinger and Tasker (1985, 1986a, 1986b) developed a specialized Generalized Least Squares (GLS) regression methodology to address the regionalization of hydrologic statistics. Advantages of the GLS procedure include more efficient parameter estimates when some sites have short records, an unbiased model-error estimator, and a better description of the relationship between hydrologic data and information for hydrologic network analysis and design.

Design Event-Based Precipitation-Runoff Modeling

Precipitation-runoff modeling is typically used as an event-based method for determining extreme floods. A single set of hydrometeorological parameters and watershed characteristics are used to simulate a design flood event. The major inputs to a design event-based precipitation-runoff model are: (1) climate data (rainfall, snowfall, and other variables needed to predict snowmelt); (2) losses (infiltration/interception); (3) physical watershed characteristics for runoff and routing simulations (drainage areas, watershed and channel slopes, lag times, antecedent moisture, etc.); (4) precipitation-runoff transformation function; and (5) runoff conveyance/routing mechanisms. Model output includes runoff hydrographs at user-specified locations, maximum peak discharges, and total

runoff volumes. Examples of this type of model include HEC-1 (USACE, 1990) and RORB (Laurenson and Mein, 1995).

Stochastic Event-Based Precipitation-Runoff Modeling

In the stochastic approach, hydrologic model inputs are treated as random variables. Monte Carlo sampling procedures are used to allow the input variables to vary in accordance with their observed distributions, including the observed dependencies among some climatic and hydrologic parameters. The use of the stochastic approach with regional precipitation information allows the estimation of flood magnitude-frequency curves for flood peak discharge, flood runoff volume, and reservoir level. An example of this type of model is discussed by Barker et al. (1997).

Atmospheric Storm Modeling and Continuous Precipitation-Runoff Modeling

This method combines the work of atmospheric modelers and regional precipitation analysis to derive a precipitation magnitude-frequency curve (Chin et al., 1997). The atmospheric model is used to generate storms over the watershed, and the findings from the regional analysis are used to estimate the annual exceedance probability of point and areal precipitation generated by the model. Using distributed precipitation-runoff modeling, snowpack and other antecedent conditions can be combined to estimate a simulated flood frequency curve using a Monte Carlo approach.

Data Generation and Continuous Simulation Modeling

The data generation and continuous simulation modeling approach is based on Monte Carlo generation of long and detailed sequences of hydrometeorological variables, including precipitation, air temperature, and wind speed and direction. In order to represent spatial differences across the watershed adequately, it is necessary to generate hydrometeorological variables for several sites concurrently. Hydrological models of watershed behavior and hydraulic models of confluences, wave effects and reservoir outlets are used to simulate the reservoir water level continuously. An estimated magnitude-frequency relationship of maximum reservoir stages is input to the risk assessment (Calver and Lamb, 1996).

Combining Methods and Data Types

No single approach is capable of providing the needed characterization of extreme floods over the full range of annual exceedance probabilities that may be required for risk assessment. In particular, characterization of floods with AEPs less than 1 in 10,000 can be expected to require that results from a number of approaches, based on multiple data sources, need to be combined to yield a composite flood frequency description. The application of several independent methods and types of data applicable to the same range of annual exceedance probabilities will increase the credibility and resulting confidence in the results.

Table 2 lists various methodologies that were considered for characterizing extreme floods to support dam safety risk assessment. A flood frequency analysis must be combined with each of these methodologies to assign annual exceedance probabilities to the floods.

The framework developed for Reclamation does not propose a specific methodology for rigorously combining information from these differing data sources and methodologies in an overall statistical framework. In some cases the information may be combined statistically, and in other cases one set of results may be used as a bound on the frequency distribution obtained by analysis of other data. Clearly, this process will require a measure of judgement. Regardless of the approach taken for combining results, it should incorporate sound physical and scientific reasoning for weighting or combining results.

All floods characterized for the risk assessment process should display the uncertainties resulting from the analysis. As the risk assessment moves from the screening and scoping levels to the decision level, uncertainty should be reduced and better quantified so that appropriate information is included in the dam safety decision-making process.

Table 2. Applicability of Hydrologic Methods of Analysis to Various Risk Assessment Levels

Method of Analysis	Risk Assessment Level		
	Screening	Scoping	Decision
Flood frequency analysis	Yes	Yes	Yes
Design event-based precipitation-runoff modeling	No	Yes	Yes
Stochastic event-based precipitation-runoff modeling	No	Yes	Yes
Distributed simulation modeling	No	No	Yes
Atmospheric modeling and distributed precipitation-runoff modeling	No	No	Yes

Evaluation of Uncertainty

Uncertainty can be evaluated by applying Monte Carlo analysis to the overall risk assessment calculations. For example, consider the estimation of threat to life consequences and probability of failure associated with an existing dam and various risk reduction alternatives. One is concerned with uncertainty due to such risk assessment inputs as flood frequency distribution parameters, system response estimates, population at risk, warning time, and estimated loss of life. Then in each iteration of Monte Carlo analysis, one could generate likely values of each of these inputs and evaluate the threat to life and probability of failure. The expected annual life loss and the annual exceedance probability of failure, which are both used as Reclamation Public Protection Guidelines (USBR, 1997b), could be computed for each iteration. By generating many replicates, one obtains samples that describe the possible values of these risk measures (performance metrics).

Averaging over the replicates provides "expected" values of the quantities reflecting both the modeled probability distributions of the phenomena (risk assessment inputs) that are considered to be random variables, and the uncertainty in the parameters describing those distributions. The sample standard deviations describe the variability of the performance metrics. Replicates can be

used to estimate frequency distributions which can be used for describing and evaluating the decision implications of uncertainty in the risk assessment inputs.

Calibration to Flood Frequency Quantiles

The ability of a flood event model to reproduce historic events certainly gives some confidence to the validity of subsequent estimates. However, even in a well gaged watershed the annual exceedance probabilities of the calibration floods are likely to range between 1 in 5 to 1 in 20, and only occasionally up to 1 in 100. While it would be expected that floods of these magnitudes will activate some floodplain storage, the non-linear nature of drainage basin flood response is such that the routing characteristics of larger events may be considerably different. Thus, while calibration of a model provides valuable information on the flood response of a drainage basin, caution is needed when using the calibrated model to estimate floods of much larger magnitudes (Pilgrim and Cordery, 1993).

Calibration to flood frequency quantiles using design rainfall inputs can provide important information on flood response characteristics for extreme design events (Nathan and Bowles, 1997; Nathan, 1992). With this approach, design rainfall information is prepared for a specified AEP, and then used with a given set of model parameters and input assumptions to derive a design hydrograph. The peak (or volume) of the design hydrograph can then be compared to the corresponding quantile obtained from a combined at-site/regional flood frequency analysis. The model inputs associated with the greatest uncertainty can be varied within appropriate limits to ensure agreement with the selected flood quantile. Model calibration should be undertaken for a range of AEPs to ensure a consistent variation of parameters with flood magnitude or AEP.

For risk-based studies based on a "design storm concept", it is necessary to adopt an AEP-neutral approach, where the objective is to derive a flood with an AEP equivalent to its concomitant precipitation (Nathan and Bowles, 1997). The factors that influence the transfer between precipitation and runoff can be characterized by probability distributions, and ideally the design hydrograph should be determined by considering the joint probabilities of all the input factors. Monte-Carlo methods are ideally suited to the AEP-neutral objective, as they accommodate the observed variability of the inputs while still preserving the interdependencies between parameters. Simpler approaches may be appropriate, where the decrease in rigor is offset by the computational convenience and the transparency of the adopted functional relationships. For the least important parameters it may be appropriate to adopt a single representative (mean) value instead of the full distribution. However, the relationship between rainfall and runoff is non-linear, and adoption of a single representative value for the major inputs will introduce bias into the transformation. Accordingly, for more important inputs it is necessary to adopt a joint probability approach. The nature of the method can be tailored to suit the relative importance of the parameter concerned.

Conclusions

A framework has been developed for characterizing extreme floods for the purposes of dam safety risk assessment. By incorporating regional information on precipitation, floods, and paleofloods with good at-site records, it is possible to provide scientifically credible flood estimates to annual exceedance probabilities as low as 1 in 100,000, although higher AEP limits may exist in

many cases. In general, the scientific limit to which the flood frequency relationship can be extended based upon available data will fall short of the PMF for a site. PMF estimates provide a useful reference to past practice and can be compared with floods characterized for risk assessment; however, there is limited scientific basis for assigning an annual exceedance probability to the PMF.

No single approach is capable of providing the needed characterization of extreme floods over the full range of AEPs required for risk assessment. Therefore, the results from several methods and sources of data should be combined to yield a composite characterization. The application of several independent methods applicable to the same range of AEPs will increase the credibility and resulting confidence of the results.

Uncertainties associated with descriptions of flood flow exceedance probabilities are likely to be substantial and an important attribute for the characterization of extreme floods. Flood characterization should include a "best estimate" of the annual exceedance probability of floods of different magnitudes and a description of the uncertainty in such results. Such uncertainties need to be honestly represented and considered throughout the risk assessment process.

Acknowledgments

The U.S. Bureau of Reclamation's Dam Safety Office sponsored the Workshops and other activities which have resulted in the proposed framework for characterization of extreme floods for dam safety risk assessment. Some twenty professionals from the U.S., Canada, Australia and Europe participated in this effort and each contributed in some way to the resulting framework. These individuals were: David Achterberg, Victor Baker, David Bowles, David Cattanach, Sanjay Chauhan, John England, David Goldman, Chuck Hennig, Don Jensen, Lesley Julian, Jong-Seok Lee, Dan Levish, Jim Mumford, Rory Nathan, Dan O'Connell, Dean Ostenaa, Duncan Reed, Mel Schaefer, Lou Schreiner, Jery Stedinger, Robert Swain, Jim Thomas, and Ed Tomlinson. This paper was also presented at the Eighteenth U.S. Committee on Large Dams Annual Meeting and Lecture held in Buffalo, New York and is included in the conference proceedings.

Bureau of Reclamation Hydrologic Research

Presented at the FEMA Workshop on Hydrologic Research Needs for Dam Safety

By
Robert E. Swain, Louis C. Schreiner, and Daniel R. Levish

Introduction

The U.S. Bureau of Reclamation is now making extensive use of quantitative risk assessment in support of dam safety decision-making (Von Thun and Smart, 1996). An important input to Dam Safety Risk Assessment is the development of probabilistic extreme flood estimates. The focus has shifted from routing a single "maximum" event (i.e. the probable maximum flood, PMF) to consideration of the entire range of plausible inflow flood events, and ultimately to the magnitude-frequency relationship of maximum reservoir stages.

Reclamation has identified the need for a review of its present procedures for developing probabilistic extreme flood estimates and their associated uncertainties for use in dam safety risk assessment. Where practical, Reclamation would like to develop improved procedures. The following sections of this paper describe ongoing hydrologic research activities for use in dam safety analysis.

Flood Hydrology Database

A variety of hydrologic data are used as input in flood frequency analyses, probabilistic hydrographs, stochastic rainfall-runoff models and other hydrology studies aimed at making flood hazard probability statements for use in risk analyses. The physical understanding and modeling of extreme flood events requires collection and review of a variety of flood hydrology data including peak discharge and mean daily stream flow records, precipitation (rainfall and snowfall) and temperature data, soil data, paleoflood information, extreme rainfall data, and many other sources of information. A searchable database that includes organized and connected lists of available data, visual selection capability, and links to the data would allow faster and more thorough assessment.

The purpose of this research is to continue development of a hydrology database that will include a variety of hydrology data such as peak discharge estimates, paleoflood data, precipitation and temperature data, as well as potential sources of infiltration characteristics and other geologic properties of drainage basins. These data would be used as input into flood frequency analyses, probabilistic hydrograph development, and prediction of basin response in stochastic modeling of extreme flooding. This project focuses on the development of a flood hydrology database that identifies, summarizes, and links hydrologic data that is needed for developing flood frequency analyses and probabilistic hydrographs, as input for stochastic rainfall-runoff models, and other hydrology studies. The eventual goal of this project is to provide spatial and temporal data for use in probabilistic flood hazard studies in the 17 western states.

A variety of data including information on extreme peak discharge have been gathered for the Sierra Nevada region of northern California. Paleoflood data have been gathered throughout the western U.S., as well as in a database at the University of Arizona, tree.ltrr.arizona.edu/~katie/paleofld.html. Currently, Reclamation has a paleoflood database in Microsoft Access and hydrology database in Arcview exist as separate databases. These databases need to be integrated into one database in order to efficiently store and access information for flood-related studies. In addition, computer code and a user interface have been developed for the hydrology database that will allow the user to access records by graphically selecting an area. By the end of 2002, a preliminary user-friendly database is scheduled for completion. This data information system will require updating and continual maintenance.

Revision and Update of Precipitation-Frequency Studies for the United States and Its Possessions

Since the mid 90's, meteorologists in both Reclamation's Flood Hydrology Group and River Systems & Meteorology Group have been addressing the need to revise and update precipitation-frequency estimates for the United States. The demand for this work is obvious in that precipitation-frequency atlases presently used by Reclamation are woefully outdated, with the far majority of the previous studies dating back 30 to 40 years ago, and lack extensions to important meteorological parameters (duration, area, return period, etc.). This information is used in establishing hydrologic design criteria for the safety evaluation of water control structures (dams, canals, levees, culverts, etc.), design of other types of construction (roads, bridges, flood warning systems, etc.), and for establishing project operational criteria. Results of this work will provide consistent precipitation-frequency information that can be incorporated in risk assessments that are used in current/future flood hydrology studies.

The project is a cooperative effort among several federal, state, and local agencies involved in water resource management. The National Weather Service (NWS), Hydrometeorological Design Studies Center (HDSC) is the lead agency for accomplishing the work with participation from other agencies (financial, in-kind-services) dependent on their interest/needs to provide support for the particular region under investigation. Because of the large amounts of data to process and the need to test new meteorological and statistical analysis techniques, the United States and its Possessions were broken into nine separate zones. Presently, four of these zones are under development in varying degrees. These zones include: Semiarid Southwest, the Ohio River Basin and Surrounding States, Hawaii, and Puerto Rico and the Virgin Islands. Work on a fifth study region, the Upper Midwest, has been started by Reclamation to assemble maximum daily precipitation (prior to 1949) data. For the next couple of years, Reclamation expects to continue with data set development for the Upper Midwest, but concentrate its effort on development of Depth-Area (DA) relationships used to adjust point precipitation-frequency values to representative areal average precipitation-frequency estimates.

The Semiarid Southwest, Ohio River Basin and Surrounding States, and Puerto Rico and the Virgin Islands zones are scheduled for completion in 2002. Hawaii is scheduled for completion in 2003. Current updates/progress reports concerning all work underway is available at: http://www.nws.noaa.gov/oh/hdsc. The precipitation-frequency work as completed will be published as NOAA Atlas 14, Volume (#). It is expected that the entire Atlas will be completed by 2006.

Probabilistic Flood Hydrographs

Flood runoff hydrographs integrate the drainage basin and channel response to precipitation and snowmelt, given some initial, variable state of moisture throughout the watershed. Probabilistic flood hydrographs are developed to assess the adequacy of the spillway and reservoir flood/surcharge space to temporarily store a portion of the flood volume, and to attenuate or pass the hydrograph peak without overtopping the dam. Flood hydrographs are needed for situations where: the reservoir inflow peak discharge is greater than the maximum spillway capacity; the reservoir has a large, carry-over storage; and/or the reservoir has dedicated flood control space. The focus of this research is to develop a simplified approach for estimating probabilistic hydrographs that can be used for appraisal or feasibility level studies, and to develop a simplified method of extrapolating flood frequency curves.

Basic streamflow hydrograph methods (e.g., Chow et al., 1988; Bras, 1990) are used to estimate properties for probabilistic hydrographs. These methods include peak and one-day mean discharge identification, selection of hydrograph shape and duration, base flow identification and separation, and direct runoff volume estimation. Peak discharge and mean-daily streamflow records are used because this source is the best information on flood magnitudes that are likely to occur in the future, based on what occurred in the past (Pilgrim and Cordery, 1993).

The key idea is calibration or scaling of hydrographs to match a particular peak discharge for a given probability. The approach relies completely upon the specification of a peak flow frequency curve that describes the probabilities of interest. Peak discharge estimates, n-day maximum mean flows, and observed hydrographs at the site of interest are used as a sample to represent potential extreme flood shapes and volumes. The largest peak and volume hydrographs are utilized as a basis to scale.

There are five major assumptions for developing the hydrographs: (1) the probability of peak discharge is sufficient to represent a probability of the composite hydrograph; (2) unit hydrograph (e.g., linearity) assumptions apply to the basin; (3) direct runoff volumes can be estimated from daily flow hydrographs; (4) peak discharge - maximum mean n-day flow relationships can be extrapolated; and (5) the recorded streamflow observations, historical information, and paleoflood data provide an adequate sample to base extrapolations to extreme floods.

The anticipated completion date for this project is early 2002.

Improved Flood Frequency Extrapolations and Runoff Modeling

The purpose of this research project is to develop improved methods to extrapolate flood frequency curves and develop extreme flood hydrographs. The major approach to flood frequency extrapolation will be based on a combination of rainfall extrapolation and derivation from physically based runoff mechanisms. Rainfall-runoff models will be used to derive the peak discharge frequency distribution from input basin characteristics and precipitation, and be used as the basis for frequency curve extrapolation. The CASC2D rainfall-runoff model will be evaluated and tested for application at Reclamation sites, and compared with a stochastic event runoff model (SEFM) developed by Dr. Melvin Schaefer for Reclamation. CASC2D is a 2-dimensional, distributed rainfall-runoff model that has successfully reproduced the 1997 Fort Collins flood. The main precipitation and stochastic components used in SEFM will be added to CASC2D. It is anticipated that model selection and extrapolation functions can be derived from the watershed topography, hydraulic routing characteristics, and precipitation characteristics at Reclamation dams. Input rainfall will be derived from frequency analysis or from stochastic storm generation. Flood frequency and hydrograph uncertainty bounds will be approximated by simulation. Models will be compared on a large (>500 mi^2) basin where paleoflood data are available.

Progress has been made in developing hydrograph-scaling techniques for appraisal and feasibility studies that require low effort and expense. These techniques have been applied to several projects such as Pineview/Deer Creek, Red Willow, North Platte, and Folsom Dams. Internal and external reviewers have pointed out several shortcomings of that work including, assumptions of linear runoff and extrapolation, use of observed hydrographs, failure to separate rainfall and snowmelt, and the challenges of using the techniques at larger basins (greater than about 500 mi^2). This research project attempts to address many of these concerns.

This research can be applied to Dam Safety projects where flood peaks and hydrographs are needed with return periods that exceed 1,000 years. The extrapolation research can be applied to sites where loss of life is large, as floods with return periods greater than 10,000 years are sometimes needed. The research will be span three fiscal years and conclude in 2004.

Rainfall-Runoff Modeling Using National Weather Service 1,000-year Return Period Precipitation Estimates at Causey Dam, Utah

Recently, the Flood Hydrology Group completed a study where the frequency estimates were extrapolated to a return period of 200,000 years. The method used a two-point extrapolation to 200,000 years using the mean of the gage data and the mean of the paleoflood range. This was the first attempt to extrapolate frequency data beyond a 10,000-year return period and several assumptions were made that may not be accurate. For example, the stream gage data in the Wasatch Range are dominated by snowmelt events, yet the distribution selected in the study was based on rainfall distributions. The

intention of this study is to provide another independent data point and to verify the conclusions reached in the previous analysis.

This investigation will use the draft precipitation values developed by the National Weather Service (NOAA Atlas 14, Vol 1, DRAFT) to produce a 1,000-year assumed thunderstorm event at Causey Dam, Utah. These values will be input to a rainfall-runoff model (HEC-1 or FHAR) to develop the 1,000-year thunderstorm flood event for Causey Dam. This peak discharge estimate will be compared with the frequency analysis developed for Causey Dam. Causey Dam was selected as the test case because there is existing at site paleoflood data to use in comparison, the drainage area is relatively small (137 mi^2), and it has a significant amount of streamflow and other comparative data developed. The estimated completion date would be June 2001.

Probabilistic Flood Hazard Workshop

The introduction of risk analysis for dam safety signaled a significant change in the way the Dam Safety Office and the Technical Service Center conduct flood hazard assessments. The purpose of this project is to compile, review, and evaluate current state-of-the-knowledge on probabilistic techniques used in flood hazard assessment. External experts in various aspects of flood hazards will be brought in to Reclamation on an individual basis. It is intended that each person present a Technical Update Lecture (1-2 hours). Members of the Flood Hydrology Group will subsequently meet with them to discuss their research in detail and potential technology transfer to Reclamation.

About 12 experts participated in the workshop last year. These experts have helped the Flood Hydrology Group map out future methods, improve current methods, and plan a program for probabilistic flood hazard analysis to meet Dam Safety Office needs.

I. Introduction

Purpose of Guidelines - The Bureau of Reclamation (Reclamation) is responsible for about 370 storage dams and dikes that form a significant part of the water resources infrastructure for the western United States. As the owner of these facilities, Reclamation is committed to providing the public and the environment with adequate protection from the risks which are inherent to collecting and storing large volumes of water for later distribution and/or release. This document presents:

- The basis and guidance for a risk-based approach to decisionmaking
- Guidelines for evaluating risks at Reclamation dams
- Guidelines for developing and presenting the risk estimates
- Guidelines for interpreting/assessing the risk results
- Example actions that can be taken to address risk at dams
- Guidelines for maintaining a focus on risk reduction when implementing agency actions

The guidelines are intended to ensure adequate and consistent levels of public protection when evaluating and modifying existing dams and appurtenant structures and when designing new dams and/or structures.

Considering a Full Range of Loading Conditions - Historical design and analysis methods have focused on selecting a level of protection based on loadings from extreme events and conditions. These extreme events comprise the upper bound of loadings considered to be reasonably probable. The civil engineering profession generally agrees that dams and dikes designed to withstand extreme loadings meet an acceptable standard of public safety. In addition to ensuring public safety for extreme events, Reclamation also is committed to providing public safety for smaller events and loading conditions, which occur more frequently. For example, an enlarged spillway designed for a probable maximum flood loading condition may increase the risks to the public for lesser events. Risk assessment provides a framework for addressing the most effective way to provide public protection over the full range of loading conditions.

Need for Probabilistic Methods - As a water resources management agency, Reclamation strives to provide decisionmakers with pertinent information that is founded upon current or emerging water resources management and public safety practices. Over the past decade, there has been an increasing trend in water resources analysis toward using probabilistic design methods to evaluate the effectiveness of expending funds for enhancing public safety. There has also been greater recognition that even the most restrictive design standards result in some likelihood of failure even though the likelihood may be very small.

Application - This document addresses the incorporation of risk-based evaluations into Reclamation's dam safety decisionmaking process to help assess public risks and allocate resources. While there are many issues that may be evaluated in a risk context, this document focuses on the life loss and the public trust components of decisionmaking. Similar applications of risk-based analysis techniques may be used to address economic consequences within the

framework of the *Principles and Guidelines* for water resources planning.[1] Risk-based analysis may also be used to evaluate environmental and social issues in accordance with the National Environmental Policy Act (NEPA) by addressing the likelihood of the possible outcomes that may result from the various loads that a dam experiences. The implementation of risk-based analysis should consider both usefulness and cost effectiveness in its use.

II. Risk Assessment Framework for Dam Safety Decisionmaking

A. Background

The mission of the Reclamation Dam Safety Program is:

> "To ensure that Reclamation facilities do not present unreasonable risks to the public, public safety, property, and/or the environment."

The Dam Safety Program is authorized under the Reclamation Safety of Dams Act of 1978.[2] This Act was passed in response to several dam failures in the 1960's and 1970's, including the failure of Teton Dam, a large Reclamation storage dam. The Act provides for action to be taken when it is determined that a structure presents an unacceptable risk:

> "In order to preserve the structural safety of Bureau of Reclamation dams and related facilities, the Secretary of the Interior is authorized to perform such modifications as he determines to be reasonably required."

To determine the risks associated with its structures, Reclamation has established procedures to analyze data and assess the condition of its structures. Prior to the failure of Teton Dam, consideration of dam safety issues was addressed though periodic examinations and project specific requests for Congressional funding to make necessary modifications to dams. The failure of Teton Dam demonstrated a need for a more comprehensive approach to evaluating and addressing dam safety issues.

In 1979, a committee of Federal agency representatives commissioned by the President developed the *Federal Guidelines for Dam Safety* to promote prudent and reasonable dam safety practices among Federal agencies. While the Federal Guidelines recognized that risk-based analysis was a recent addition to the tools available for assessing dam safety, they encouraged Agencies to conduct research to refine and improve the techniques necessary to apply risk-based analysis to dam safety issues:

> "The agencies should individually and cooperatively support research and development of risk-based analysis and methodologies as related to the safety of dams. This research should be directed especially to the fields of hydrology, earthquake hazard, and potential for dam failure. Existing agency work in these fields should be continued and expanded more specifically into developing risk concepts useful in evaluating safety issues."[3]

Reclamation has established a risk-based framework to meet the objectives of its program, the Dam Safety Act, and the Federal Guidelines. Risk-based procedures are used to assess the safety of Reclamation structures, to aid in making decisions to protect

[3] Federal Guidelines for Dam Safety, Ad Hoc Interagency on Dam Safety, Federal Coordinating Council for Science Engineering and Technology, Washington, D.C., June 25, 1979.

the public from the consequences of dam failure, to assist in prioritizing the allocation of resources, and to support justification for risk reduction actions where needed. Risk assessment for dam safety decisionmaking integrates the analytical methods of risk-based analysis along with the sound professional judgment of engineers, contractors and review boards in determining reasonable actions to minimize risk at Reclamation facilities.

B. Terminology

The following terminology is provided for terms that are used throughout these guidelines for defining the risk-based framework for dam safety decisionmaking:

Risk – The product of the likelihood of an adverse event and the consequences of that event

Failure Mode - A potential failure mode is a physically plausible process for dam failure resulting from an existing inadequacy or defect related to a natural foundation condition, the dam or appurtenant structures design, the construction, the materials incorporated, the operations and maintenance, or aging process, which can lead to an uncontrolled release of the reservoir.

Risk Analysis – A procedure to identify and quantify risks by establishing potential failure modes, providing numerical estimates of the likelihood of an event in a specified time period, and estimating the magnitude of the consequences. The risk analysis should include all potential events that would cause unintentional release of stored water from the reservoir.

Risk Evaluation – The establishment of Reclamation guidelines for agency response to estimated risks.

Risk Assessment – The use of risk estimation for a given dam in the decisionmaking that leads to agency response according to risk evaluation guidelines.

Consequences – Estimated losses that result from an adverse event leading to a dam failure scenario.

Failure Probability, Consequences, and Risk Estimates – The mean values calculated from Monte Carlo or similar analyses that include explicit treatment of input uncertainty. Also, the calculated numerical values when single point estimates are used in the calculations and the point values are considered reasonable and plausible estimates of the mean rather than extreme values in a range. These estimated mean values are also called the expected values. *(Note: This definition must be applied in order to achieve effective and consistent application of these guidelines.)*

C. Risk Framework

Risk analysis is a tool that enables technical specialists and decisionmakers to better understand possible failure mechanisms and the elements of risk involved in the various issues related to dam safety. It provides an overall picture of risks, the potential impacts of proposed actions, and the resulting costs (economic, social and other). The results of risk analyses can contribute to efficient accomplishment of the dam safety program by quantifying engineering judgments that allow for the evaluation of:

- Factors contributing the greatest risk at a given site,
- The facilities with the greatest risk,
- Identification of additional analyses and/or data collection that are needed to better understand critical uncertainties,
- Anticipated risk reduction effectiveness of alternative courses of action,
- Allocations of dam safety program funds that will contribute the greatest overall risk reductions.

The risk framework consists of several steps leading to agency decisions regarding appropriate actions to be taken to address dam safety risks at Reclamation's high- and significant-hazard dams. These steps are summarized as follows:

Risk Identification – As part of the ongoing dam safety evaluations for each high- and significant-hazard dam, Reclamation identifies the conceivable modes of dam failure. These failure modes are then monitored (through performance monitoring and examinations) for any indication of changes in performance that would be indicative of a dam progressing toward a failure condition or toward a significant risk to the public. If such indications are found, the issue is referred for further evaluation of the estimated risk. If failure modes are deemed likely, action to reduce risk may be taken.

Risk Estimation – Once a dam safety issue has been identified, it is necessary to assess and quantify the risk to the public as information to be used by the decisionmakers. The quantification of risk involves the estimation of the likelihood (probability) of an unintentional release of stored water and an estimation of the consequences resulting from the unintentional release. To facilitate developing the risk estimates, it is frequently convenient to break the estimating process down into three components including: estimating the likelihood of an initiating condition existing or an event occurring, estimating the likelihood of an unintentional release of the reservoir given the event or initiating condition, and estimating the consequences (life loss) given the unintentional release of the reservoir.

Risk Evaluation – Once risks have been estimated for a dam, decisionmakers need a framework for evaluating the risks to determine if action is required to reduce risks. There is currently no commonly accepted industry standard for determining what risks are considered acceptable.

The guidelines portion of this document provides for evaluation of risk by two measures. The first measure, the annual probability of failure, addresses the public's expectation that Reclamation dams should not fail by evaluating the probability of an unintended release of the reservoir. It also addresses the expectation that risk to the most exposed individual will be managed. The second measure addresses the expected value of life loss expressed on an annual basis which combines the annual failure probability estimates with estimates of the expected life loss consequences given a dam failure. The first measure addresses agency and individual risk, while the second measure addresses the life loss component of societal risk.

Risk Reduction Actions – When decisionmakers have determined that a risk reduction action is required, there are usually a number of prudent alternative actions that can be taken. Dam safety decisionmaking involves the selection of an appropriate course of action for a given issue based on the magnitude of the risk, the degree of confidence in (or uncertainties associated with) the estimated risk, and the likelihood of additional information providing a significantly enhanced understanding of the risks associated with the identified issues.

Roles of analysis approaches - Although risk-based and standards-based (design standards, codes or criteria) approaches are often considered to be competing approaches, each have a role in Reclamation's decisionmaking process. Risk assessment is a diagnostic tool used throughout the evaluation, design, and construction process that helps decisionmakers formalize and document dam safety decisions. Standards are used to ensure that the selected corrective actions are well designed and implemented. In other words, risk-based approaches help decision makers choose the appropriate courses of action while standards-based approaches assure sound implementation of those actions.

D. Decisionmaking

Policy - Reclamation policy for dam safety decisionmaking delegates decisionmaking responsibility to the Regional Directors in collaboration with the Chief, Dam Safety Office and the appropriate Area Manager.[4] The Technical Service Center (TSC) staff provides significant technical advice that is critical to decisionmaking. The risk framework serves as a tool for aiding decisionmakers in the determination of needs for risk reduction actions as well as the evaluation of different risk reduction actions that could be taken to address the identified issues.

Public Trust Responsibility - Decisionmaking to accomplish the Dam Safety Program is complex and must consider risk to the public as well as economic, environmental, and cultural impacts. Thus, it is difficult to be prescriptive when developing guidance for making decisions. While the technical analysis of risks associated with a dam can not become the sole decisionmaking factor, it must be recognized that addressing these risks in a technically consistent and timely fashion is an important part of sustaining the public's trust in Reclamation to manage these facilities in the best interest of the nation.

[4] Decisions Related to Dam Safety Issues, Reclamation Manual / Policy FAC P02, Bureau of Reclamation, Denver, Colorado, June 23, 1998.

This public trust responsibility includes operating Reclamation facilities with reasonable assurance of the safety of persons in the vicinity of and downstream of the dams.

Process - Dam safety decisionmaking is similar to many other aspects of water resources management in that decisions regarding reasonable courses of action are not always initially agreed upon by all stakeholders. The most important part of the decisionmaking process is recognizing that it will generally involve building consensus regarding the appropriate actions to be taken. However, in the event of an emergency, the time for developing consensus may be severely shortened or nonexistent. Such a situation would require the Regional Director to act quickly to avoid or minimize consequences.

III. Public Protection (Risk Evaluation) Guidelines

Measures of Risk - These guidelines focus on two assessment measures of risks related to Reclamation structures: 1) the probability of a dam failure and 2) the life loss consequences resulting from the unintentional release. The annual probability of failure guideline addresses agency exposure to dam failure. As a water resource provider, Reclamation must maintain and protect its dams and dikes that store water. The second measure addresses the life loss component of societal risk. Protection of human life is of primary importance to public agencies constructing, maintaining, or regulating civil works.

Risk Analysis Methods - Reclamation's risk analysis process involves the development of event trees that identify all of the known and potential events, states of nature (existing conditions, site characterization, etc), dam responses, exposure conditions, and consequences. The overall risk from the facility is defined as the accumulation of all risks associated with each of the possible paths through the event trees. The methods to analyze the risks associated with annual dam failure probability and life loss are briefly described in the following two sections. Additional information on the methodology for performing risk analysis can be found in *"Dam Safety Risk Analysis Methodology."*[5]

Potential Applications - Although these guidelines focus on life loss as a dam failure consequence, other consequences, such as environmental and economic consequences, may be applied on specific projects where the decisionmaking process would be enhanced by presentation of the entire breadth of consequences and risks. Economic and/or environmental risk assessment may be performed when the potential for life loss does not provide sufficient or appropriate input for a decision regarding modification of a structure.

A. Evidence of a Developing Failure Mode

If there is evidence of a developing failure mode, there is a clear need to take action to reduce risk. These situations should be brought to the immediate attention of the dam safety decisionmakers to assure a timely response by the agency. Once the evidence is determined to be credible, efforts should focus on those risk reduction actions that can be taken to quickly reduce the potential for life loss or an unintended release of the reservoir regardless of any risk estimates.

B. Annual Probability of Failure (Previously Tier 2)

Measurement Purpose - To manage an effective Dam Safety Program on behalf of the Federal government and to assure public confidence in the performance of public works, dam failures and associated large consequences need to be avoided. A high level of national safety and stewardship of public assets is expected of Reclamation as an agency

[5] Dam Safety Risk Analysis Methodology, Bureau of Reclamation, Denver, Colorado, Version 3.3, September 1999.

specifically entrusted to manage a large inventory of dams. Unintended release of the reservoir can cause significant downstream damage and disruption to routine activities. Once an unintended reservoir release occurs, public trust is compromised and public expectations may impose severe and costly constraints on projects. The greater the inventory of dams and the time of exposure, the more difficult it becomes to ensure that the agency will not experience a dam failure.

Measurement Definition - For comparison to this guideline, the annual probability of failure is defined as the probability of a structural failure or condition that results in an unintentional release of the reservoir that would be expected to result in loss of life. The annual probability of failure is totaled for all specific loading conditions (seismic, static, hydrologic, improper operation, etc.) The probability of events that are not expected to cause life loss are not included, even though there may be some unintended loss of reservoir storage. For example, if a structure accommodates large flows through rockfill without breaching and without causing life loss, then the flow condition would not be included in the probability of failure calculation. Events or conditions that can result in an unintentional reservoir release are referred to as failure modes. These include failure due to loadings from normal and extreme events.

Guideline - To ensure a responsible performance level across the inventory of Reclamation Dams, it is recommended that decisionmakers consider taking action to reduce risk if the estimate of annual failure probability exceeds 1 chance in 10,000. Table 1 provides guidelines to evaluate the need and urgency to implement risk reduction activities based on the annual failure probability estimates:

Table 1. – Guidelines to evaluate Annual Probability of Failure Estimates	
Estimates for annual probability of failure > 0. 0001	The justification to implement risk reduction actions increases as the estimates become greater than .0001. Actions considered reasonable and prudent should be considered for implementation when the annual probability of failure estimate is in this range. A variety of possible actions may be appropriate (see Section IV.D).
Estimates for annual probability of failure < 0. 0001	The justification to implement risk reduction actions diminishes as the estimates become smaller than .0001. Risk reduction action costs, uncertainties in the risk estimates, scope of consequences, operational and other water resources management issues play an increased role in decisionmaking. Actions considered reasonable and prudent should be considered for implementation when the annual probability of failure is in this range.

C. Estimated Risk (Annualized life loss - Previously Tier 1)

Measurement Purpose - Reclamation's primary dam safety concern is to ensure that its structures do not cause life loss. The estimated risk is calculated for each specific loading category (seismic, static, hydrologic, improper operation, etc.) at a dam based on the estimated life loss from dam failure.

Measurement Definition – For dam safety decisionmaking, risk of life loss is measured as the product of the probability of dam failure and the consequences (life loss) associated with that failure. This product is the expected annualized life loss at a given dam for a given loading condition and is referred to as the estimated risk of life loss.

Guidelines - Table 2 provides guidelines to evaluate the need and urgency to implement risk reduction activities based on the estimated risk:

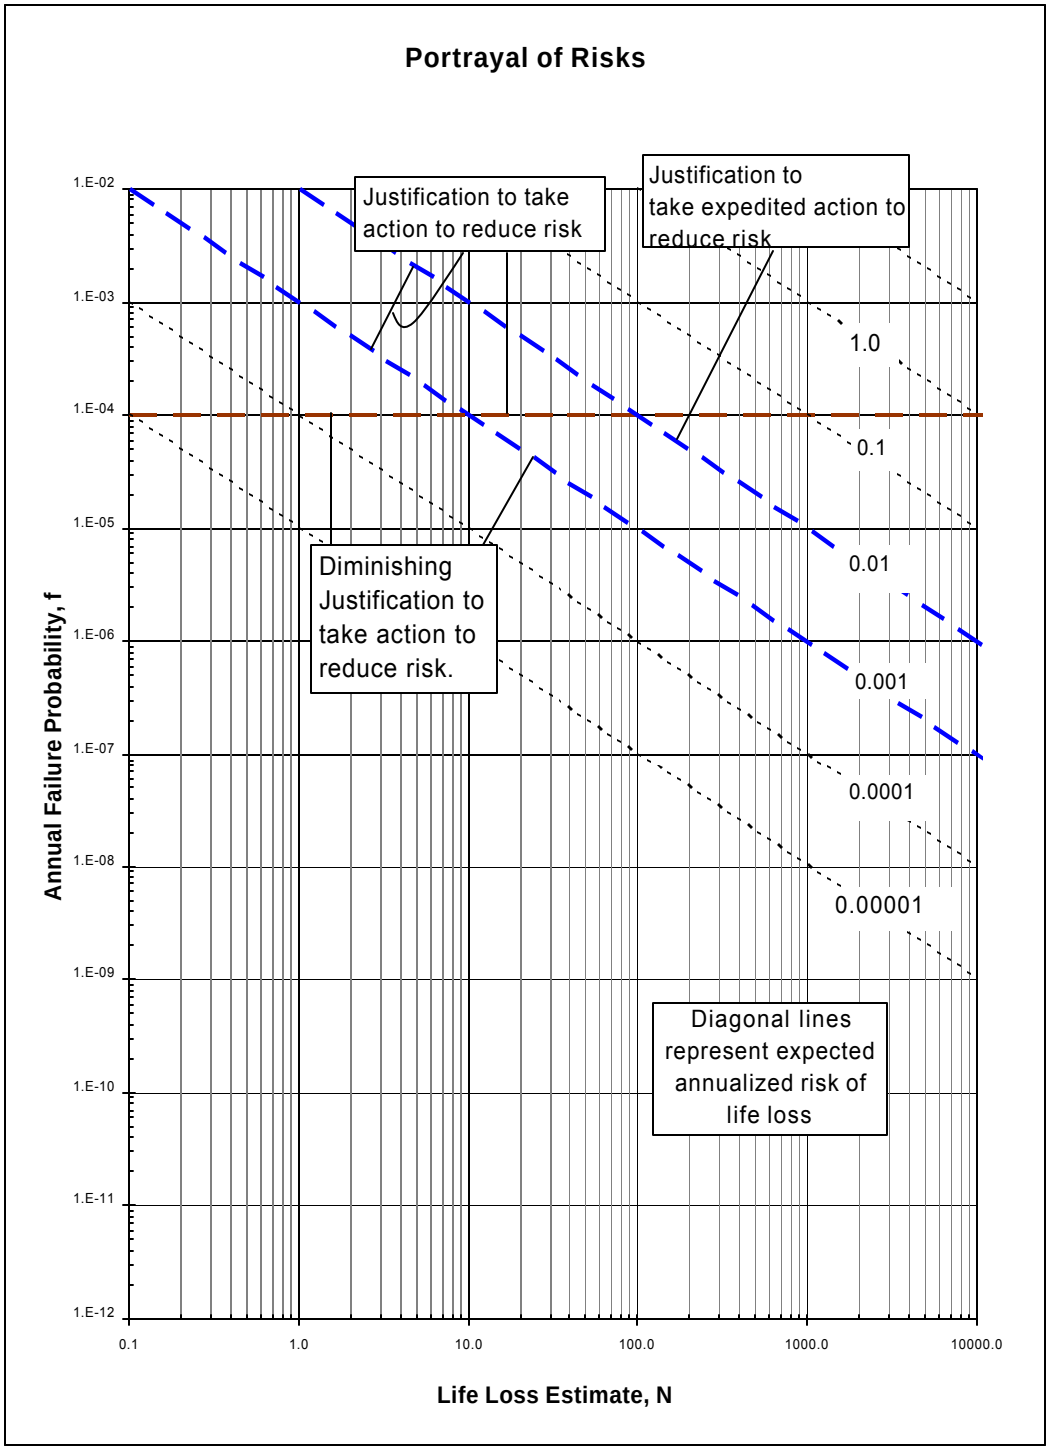
Table 2. – Guidance for Estimated Risk	
Estimated risk is portrayed to be >. 01 lives/year	Reclamation considers that there is justification for taking expedited action to reduce risk. While there is a full range of possible risk reduction actions that can be taken (see section IV.D), Reclamation should focus on those that can quickly reduce risk or improve understanding of the uncertainties associated with the risk. As confidence increases that the risk is in this range, actions considered should concentrate more on reducing the risk than reducing the uncertainties. Any reassessment of the risk should be done prior to increased storage if at all possible, and every effort should be made to complete the reassessment within 90 days of determining the need for expedited risk reduction action.
Estimated risk is portrayed between .01 and .001 lives/year	Reclamation considers that there is justification for taking action to reduce risk. When the range of risk estimates falls in this range, there are a wide variety of possible actions which may be appropriate. However, the actions can be scheduled into the dam safety program and coordinated with other needs at the facility or at other facilities. Actions to reduce risks should be implemented on a schedule that is consistent with budgeting and appropriations processes. Typically, risk reduction should be accomplished within 7 years of a decision that risks need to be reduced. When there is an indicated need for risk reduction, the time spent on additional loading definition, data collection, and risk assessment should be completed in a reasonable timeframe. While it is desirable for this timeframe to be within a year, other times may be considered reasonable by decisionmakers based on the severity of the identified risks. Decisions on adequate time frames should be documented in appropriate decision documents.
Estimated risk is portrayed to be < .001 lives/year	The justification to implement risk reduction actions or conduct additional studies diminishes as estimated risks become smaller than .001. Risk reduction action costs, uncertainties in the risk estimates, scope of consequences, operational and other water resources management issues play an increased role in decisionmaking. Actions considered reasonable and prudent should be considered for implementation when the risk is in this range.

Risk to Small Populations - When life loss estimates are low (less than 10) for a given

loading category, a threshold estimated risk of .001 can potentially expose a small population to failure events with relatively high probabilities. Risk to an individual from dam failure for these cases may be similar to other societal risks such as auto accidents and disease. Accordingly, risks associated with a Reclamation storage facility could contribute significantly to the life risks of an individual in the exposed population. In these cases, the guidelines related to annual probability of failure (section IV.A) serve as an upper limit of exposure to such small populations.

IV. Determining Appropriate Actions

A. Development and Presentation of Risk Estimates



Use of Risk Estimates - Risk analysis provides a means to quantify judgment and to identify the parameters that contribute to risk at a site. The intent of a risk assessment is to review the failure modes for a dam, to decompose the failure modes into separate events, to assign probabilities to the events, and to provide a range of risk estimates so that risks can be compared to these guidelines. Valuable outcomes of the risk assessment include an improved understanding of the critical issues at a dam and a clearer identification of the issues that are the most significant contributors to risk. This knowledge can be used to focus attention on those issues, which, if mitigated, will provide the greatest reduction of risk to the public.

CFR Risk Estimates - Since the risk estimating process during the Comprehensive Facility Review (CFR) is not a detailed team effort, it may have a higher level of uncertainty than an issue evaluation risk analysis. The results of a CFR risk assessment should be presented as the mean estimate or the expected value of risk. If the senior engineer feels that significant assumptions need to be made, resulting in more than one possible scenario to be considered, a range of risk estimates may be presented. If a range of estimates is provided, the CFR must clearly state the specific assumptions or reasons that form the basis of the range of estimates. If the risk estimate is presented as a single point, decision makers should be cognizant of the fact that the estimate actually has a degree of uncertainty associated with it.

Issue Evaluation Risk Estimates - Detailed team risk analyses should also address the uncertainty associated with the risk estimate. Typically in issue evaluation team risk analyses, probability density functions are assigned to the estimates in an event tree. Techniques such as Monte Carlo simulation can be used to show the variability in a number of trials that sample the assigned probability density functions. The risk estimate is defined to be the arithmetic mean of the values computed for all trials. Sensitivity studies may be performed by assigning other reasonable density functions and noting the change in both the variability of the trial estimates and the calculated mean risk estimate. Such sensitivity studies provide the decisionmakers with an estimate of a range of the risk estimate based on the risk model used by the team. If the scatter plots of the Monte Carlo calculation trials are presented, it should be carefully explained that the individual points are not risk estimates as defined in Section II.B. These scatter plots may be useful in analysis and may help communicate the key factors influencing the risk estimates.

Displaying Risk Estimates - The range of risk estimates (annual probability of dam failure and expected annual life loss) should be presented for each load category on an f-N diagram as shown in Figure 1. The f-N diagram illustrates the probability of dam failure, the potential consequences, and the expected annual life loss risk associated with a given load category on one diagram. The guidelines for considering risk reduction action are illustrated as dashed bold lines on the f-N diagram.

Figure 1. - The f-N Chart for Displaying Probability of Failure, Life Loss, and Risk Estimates

Communicating the Basis of Risk Estimates - It is important to note that the key objective of the risk analysis is to communicate the current understanding of risk to the decisionmakers. Decisions will be facilitated by elaboration on the reasons the risk might be higher or lower and the additional information that might better define the risk. For example, the range of risk estimates might not be continuous if there is an important lack of information or if there are alternate interpretations of the available information about a structure. There could be one range of risk estimates that is high and another that is low with the difference being the assumption about the information that is lacking or the interpretation of the available information. This sort of risk estimate communication can be very useful to the decisionmakers when proposals for gathering additional data or for more detailed technical analysis are considered.

B. Assessment (Use and Interpretation) of Risk Results

Action Based Decisionmaking - Dam Safety issues may be identified as Reclamation operates, maintains, monitors, inspects, or analyzes a structure. When issues arise, further data collection, investigation, and related analysis may be required to better understand the public safety or economic implications. Reclamation will address the identified issues by taking an action, prioritizing and scheduling an action, or by documenting a decision that no action is necessary. In general, many issues are raised without implications on continued operation of the facility. The dam safety decisionmakers should consider the potential severity of issues being addressed in the context of the dam safety program objectives and determine if continued normal operation of the facility is appropriate. If a decision is made to continue normal operations while issues are being addressed, then that decision should be documented.

Prioritization - Reclamation has limited financial resources available to address issues. It is critical to not only identify future actions but also to identify the priority or the time frame associated with these actions. The priority for initiating actions to address risks depends in part on available resources and on the risks throughout Reclamation's dam inventory. The intent is to make the greatest reduction in risk throughout the inventory of Reclamation dams within the resource limitations of the program while at the same time assuring that no dam presents an unreasonable risk.

Uncertainty - The quantification of risk estimates is dependent on data and analysis regarding the design, construction, and current condition of a dam, as well as the identified loads that the dam could be subjected to over its operating life. All of this information has some level of uncertainty associated with it. It is acknowledged that the quantification of risk estimates is subjective and is a function of group dynamics, the experience and associated judgment of group members, and the available information for a dam. Thus, uncertainty in the risk estimates is expected. As a consequence, there can be a range of actions that may be suggested for a given range of risk estimates.

Assessing Ability to Reduce Uncertainty - When making a decision regarding future actions, one should consider the risk estimates, the issues most influencing the risks, the

sensitivity of the risks to particular inputs, the cost of additional actions, and the potential for reducing uncertainty. Uncertainty may be reduced by performing additional actions such as collecting more data, by performing more analysis, or by performing a more detailed analysis of the risks. However, there are occasions when additional efforts may not result in significant reduction in uncertainty. It is important to recognize when this is the case and consider the anticipated value of the additional efforts to reduce uncertainty as a factor in selecting a course of action.

Risk Estimate Ranges (range of means) Straddling the Guidelines - In gathering the information necessary for dam safety decisionmaking, the decisionmaker will never have complete or perfect data on which to base the decision. Accordingly, there is some degree of uncertainty in the risk estimates for each dam. When significant uncertainties or assumptions related to a lack of data or interpretations of data result in a range of risk estimates, the results may straddle the guideline values with portions of the risk estimates range portrayed both above and below the guidelines. In these cases, it is important for decisionmakers to assess the portion of the risk estimate range that exceeds the guidelines to determine if it is significant enough to warrant further action or studies. The entire range should be used to assess the need for future actions as well as an aid in setting the priority for initiating the actions. If the range extends into the zone that justifies expedited risk reduction, studies to better define the risk should be the minimum response of the agency.

Level of Analysis Considerations - Because CFR analyses are not detailed team efforts, decisions based on CFR-based risk assessments are typically related to improvements in monitoring, collection of additional data, or performance of additional analyses to reduce uncertainty or improve confidence in the risk estimates. Decisions to change operations or initiate modifications are generally not made as a result of these analyses.
Issue evaluation risk analyses are more extensive analyses of risk and draw on a broader range of expertise. These analyses may require additional data collection, additional analyses, and include a more detailed breakdown and analysis of risks. Risk estimates developed during this activity are often computed using a Monte Carlo simulation and should include sensitivity studies to determine a potential range for the risk estimate.

Risk Reduction Objective - It is important to reduce risk as low as can reasonably be achieved if it is decided to pursue a risk reduction action. As a result, it is desirable to lower the entire range within which the risk estimate would be expected to fall given the uncertainties. An evaluation of the effect of modification alternatives on the range of the risk estimate will enter into the selection of the preferred alternative. In other words, selection of a preferred alternative should focus on moving the range of the risk estimate sufficiently below the guidelines to assure that the dam safety issue doesn't resurface due to slight differences in interpretations of the risk.

Consideration of Future Developments - Future growth in the downstream flood plain, increases in the loading estimates, and changes in the state-of-the-art, may result in increases in risk estimates. Thus, the more risk reduction achieved, the less likely it becomes that future studies will conclude that the risks no longer meet Reclamations guidelines. Risk reduction goals should be considered on a cost versus risk reduction

basis. Ideally, a menu of options, associated costs, and impacts on risk should be considered by the decisionmakers so that prudent decisions can be made.

C. Large Downstream Populations

When the probability of a given loading category is relatively high and there is high potential for downstream life loss, a very low probability of unintended release is required by these guidelines. In such cases, Reclamation focuses on ensuring that there are sufficient protective (defensive design) measures incorporated into the structure. These protective measures either increase confidence in the structure's ability to perform satisfactorily without unintended releases, or increase confidence in Reclamation's ability to detect adverse performance with sufficient lead time to intervene and either prevent an unintended release or provide adequate warning to the public.

In some cases, risk reduction actions may be taken to increase confidence in the performance of the structure even though the dam shows no significant signs of adverse performance. In these cases, decisionmakers should work with the technical experts to ensure that there are sufficient redundancies in the design and operations of the facility to instill confidence in the future performance of the structure.

D. Examples of Alternative Actions

With increased justification for action, there is a need to propose alternative actions that will adequately address the risk and/or probability of failure at the dam. It is important to recognize that there is a broad range of actions that can be taken. These actions can range from further investigations to better understand the uncertainties associated with the risks to decisions to modify structures. In many cases, the chosen course may involve a combination of several actions.

Dam safety decisionmaking generally involves the selection of an appropriate course of action for a given issue based on the magnitude of the risk, the degree of confidence in (or uncertainties associated with) the estimated risk, and the likelihood of additional information providing a significantly enhanced understanding of the issues. The state of knowledge regarding the dam safety issues can lead to a variety of possible actions. While the risks associated with each individual facility pose a unique situation, the following are some of the types of actions which can be taken to either improve Reclamation's understanding of the uncertainties associated with the estimated risk, or to improve confidence in the ability of a structure to perform satisfactorily.

Risk Management Activities:

> **Refine Analyses** – If a risk estimate warrants action primarily due to uncertainties in key elements contributing to the risk, decisionmakers may consider gathering additional information in a timely fashion to assist in quickly reassessing the risk. In pursuing this activity, the decisionmakers should satisfy themselves that there are no immediately developing failure modes. Any expedited reassessment of the risk should be done prior to increased storage if at all possible, and every effort should be made to complete the reassessment within

90 days of determining the need for action. If the reassessment indicates expedited risk reduction action is needed, a decision concerning the risk reduction measures should be made and documented.

Reservoir restrictions - While a reservoir restriction is technically an operational change, it can result in a significant and immediate change in the risk at a dam. The risk reduction results from a reduction in the loading condition and the failure probability. Another benefit is that the reduced storage and reduced head leads to less potential for adverse consequences in the event of poor performance of the structure. However, the loss of storage can have a dramatic impact on water users and the environment. Therefore, consideration of a reservoir restriction requires consideration of both the expected reduction in risk and the certainty of the lost project benefits that accrue from limiting storage in the reservoir.

Increased monitoring - If the risks associated with a failure mode are such that successful intervention would likely be possible or better warning could be provided to local authorities, a potential course of action is to improve Reclamation's ability to detect the existence of the conditions which would be indicative of the failure mode developing (i.e. seepage, deformation, etc.)

Operational changes - In some cases, risks can be reduced at a dam by making changes in the operational and/or maintenance practices at a dam. Examples include establishing minimum gate openings to minimize potential for cavitation, checking gates for drift from their set positions, or alternate procedures for filling reservoirs to lower risks at critical times of the year.

Revised Emergency Action Plan (EAP) - The potential for adverse consequences can be minimized by reviewing the potential failure modes and by developing clear guides to decisionmaking for the types of emergency situations that can be envisioned. Existing EAPs have been developed to detect emergency events based on site specific loading conditions. If a new loading condition or potentially adverse response has been identified for a dam, then the EAP initiating conditions, emergency response levels, expected actions for each response level, and hazard specific appendices can be revised to reflect the current conditions or concerns at the facility. While this course of action will not reduce the probability of an adverse response of the structure, it can help to ensure that people understand the risks at the dam and know how to respond appropriately. This may result in a reduction of the life loss risk.

Loading definition - An important part of understanding risk lies in determining the frequency with which unlikely events affect a dam. In some cases, it is beneficial to gather data that will improve the understanding of the frequency-magnitude relationship of the loading conditions that can potentially lead to failure modes. This information would be used to reanalyze the risks.

Data collection - When there is a lack of knowledge of key properties of a facility, there can be considerable uncertainty in its performance. A prudent

action may be to collect information so the performance of the dam can be better predicted. This additional data would be used to reanalyze the risks.

Structural Modifications - When non-structural actions are not expected to adequately address the risks at a facility, structural modifications to the dam may be considered when additional information will not change the risk outcome. The intent of such modifications is to increase confidence in the satisfactory performance of the structure under the applied loading conditions. Throughout the design and construction process, the risks should be evaluated to assure that design and construction decisions are consistent with the risk reduction objectives.

E. Formulation of Appropriate Risk Reduction Alternatives

Role of Risk Estimates - A key to formulating risk reduction alternatives is using the risk analysis information to assure that proposed alternatives will result in effective risk reduction. When developing the alternatives, the event trees should be reviewed to evaluate which events or conditions are the most significant contributors to the overall risk and/or probability of failure. In some cases, very significant risk reductions can be accomplished by focusing on a specific event or condition. In other cases, with multiple sources of risk, several issues may have to be addressed simultaneously in order to reduce risk and the associated probability of failure to appropriate levels.

Accumulation of Risk Over Time - During a risk reduction action, one should remember that Reclamation's goal is to reduce overall risk. This includes the sum of the risk from before, during, and after a risk reduction action. To minimize this total, it is important to proceed promptly with a risk reduction action when the risk values are high because delay in risk reduction increases the time accumulation of risk. Likewise, it is important to consider risks during construction, because these risks contribute to the accumulation of risk over time. Addressing an annualized potential for dam failure that could be relatively small by incurring a much higher probability of dam failure during the period of time that the dam is being modified may not be appropriate because it raises accumulated risk during the life of the dam to a level higher than would be incurred by not pursuing risk reduction action at all. This factor may influence the choice of modification alternatives and reservoir operations during construction. It should not be used to support a "do nothing'' alternative.

F. Unrecognized Risks

Reclamation recognizes that there will always be a potential for risk associated with unknown conditions at a dam that have not been recognized in the analysis. Therefore, an active examination, monitoring, and evaluation program should be in place to provide a mechanism for early detection of developing and/or potential problems. This early detection information should be used to assess changes in the perceived risks at individual dams, and to prioritize funding for the Dam Safety Program for risk reduction activities. The CFR process provides a framework for assuring that there is a periodic opportunity to reassess risk due to changes in the state-of-the-art of dam design or

changes in dam performance. If no such changes are applicable and no new risks are recognized, then the CFR risk assessment serves as a confirmation of previous risk analyses.

D.10. U.S. Fish and Wildlife Service

1.1 What is the purpose of this chapter? This chapter describes the policy and division of responsibilities for managing the Fish and Wildlife Service's (Service) Dam Safety Program.

1.2 What is the Service policy? Our policy is to:

A. Ensure that no dam creates an unacceptable risk to public safety and welfare, property, the environment, or cultural resources, and

B. Maintain high standards in the practices and procedures we use for planning, engineering design, construction, repairs, operation, maintenance, emergency preparedness, and evaluation of existing dams.

1.3 What are the authorities for the Dam Safety Program?

A. National Dam Inspection Act of 1972 (Public Law 92-367).

B. Executive Order 12148, Federal Emergency Management, July 20, 1979.

C. Water Resources Development Act, Dam Safety Act of 1986 (Public Law. 99-662).

D. Water Resources Development Act of 1996 (Public Law. 104-303).

E. Federal Guidelines for Selecting and Accommodating Inflow Design Floods for Dams, Federal Emergency Management Agency 97, Interagency Committee on Dam Safety, October 1998.

F. Recommended Guidelines for Dam Safety--Inspection of Dams, Corps of Engineers, 1974.

G. The Dam Safety Act of 2006 (Public Law 109-460).

H. Federal Guidelines for Dam Safety, Federal Emergency Management Agency 93, April 2004.

I. 753 DM, Dam Safety and Security Program.

1.4 Who is responsible for the Dam Safety Program?

A. The **Director** ensures there are resources and policy in place to implement our Dam Safety Program.

B. The **Assistant Director – Business Management and Operations** is responsible for the overall integrity of our Dam Safety Program.

C. Regional Directors are responsible for:

(1) The safety and operation of facilities in their Regions, including dams, dikes, levees, and other water diversion and control structures.

(2) Budget requests for maintenance funding for dams, including routine annual maintenance and correcting Priority 1 and Priority 2 deficiencies identified in the Safety Evaluation of Existing Dams (SEED) inspections.

(3) Appointing a Regional Dam Safety Officer.

D. The **Chief, Division of Engineering** is responsible for:

(1) Managing our Dam Safety Program,

(2) Developing and interpreting dam safety policy, and

(3) Appointing the Service Dam Safety Officer.

E. The **Service Dam Safety Officer (SDSO)** is responsible for:

(1) Developing and recommending plans, technical guidelines, standards, and procedures for our Dam Safety Program.

(2) Ensuring that our Dam Safety Program complies with applicable laws, policies, and technical recommendations governing Federal dam safety activities.

(3) Preparing technical guidelines and standards for and implementing the SEED inspection and rehabilitation programs by:

(a) Performing periodic SEED inspections and notifying the Project Leader of the inspection findings,

(b) Managing and maintaining an inventory and a comprehensive database on all Service dams, and

(c) Serving as a liaison with other Service programs for dam inspections and rehabilitation.

(4) For high and significant hazard dams:

(a) Preparing budget requests for:

(i) Project planning,

(ii) Engineering design,

(iii) Analysis and studies,

(iv) Construction management for emergency repairs, and

(v) Safety rehabilitation and construction.

(b) Developing Standing Operating Procedures (SOPs) and Emergency Action Plans (EAPs) and updating them for major repairs or rehabilitation.

(c) Project planning, design, and construction for new dams and for rehabilitation, modification, or emergency repairs to existing dams.

(5) For low hazard dams, providing independent review of project planning, engineering design, and construction management for dam safety rehabilitation and construction.

(6) Serving as the Service's representative on:

(a) Dam safety technical committees,

(b) Departmental working groups, and

(c) As liaison with other Government agencies.

(7) Assisting Regional Dam Safety Officers in implementing SOPs and Emergency Action Plans.

(8) Performing periodic Emergency Action Plan exercises (see 361 FW 2).

(9) Providing technical engineering support and expertise to the Regions.

(10) Providing dam safety training to the Regions, Project Leaders, and dam operating staff.

F. At the discretion of the Regional Director, **Assistant Regional Directors – Budget and Administration** are responsible for providing advice and guidance to the Regional Engineers and the Regional Dam Safety Officers in their Regions in exercising their dam safety responsibilities.

G. At the discretion of the Regional Director and working through the Assistant Regional Director – Budget and Administration, **Regional Engineers** are responsible for:

(1) Implementation and oversight of the Region's Dam Safety Program and designation and supervision of the Regional Dam Safety Officer.

(2) Technical support and assistance to the Regional Director, Regional office supervisors, and Project Leaders for the operation and maintenance of dams within the Region.

(3) Assisting the Regional Dam Safety Officer in developing and implementing SOPs and Emergency Action Plans.

H. Regional Dam Safety Officers (RDSO):

(1) Must have experience in and knowledge of the planning, design, construction, safety inspection, and operation of dams.

(2) Are responsible for:

(a) Providing technical support to the Regional Director to ensure that the Region's dam safety program complies with applicable laws, policies, and technical recommendations governing Federal dam safety activities.

(b) Providing technical assistance to Project Leaders for dam operation and maintenance.

(c) Assisting the Service Dam Safety Officer in developing and updating SOPs and Emergency Action Plans and assisting Project Leaders to implement them.

(3) Are the designated emergency planning officers, who:

(a) Annually test, verify, update and certify Emergency Action Plans, and

(b) Provide technical and decisionmaking support to Project Leaders during unusual or emergency events.

(4) Provide technical leadership and oversight of project planning, engineering design, and construction management for dam safety for low hazard inventory and non-inventory dam:

(a) Rehabilitation,

(b) Modifications,

(c) Emergency repairs, and

(d) New construction.

(5) Review observation and instrumentation data from dams, and contact the Division of Engineering and the Service Dam Safety Officer to request consultation.

I. Project Leaders are responsible for:

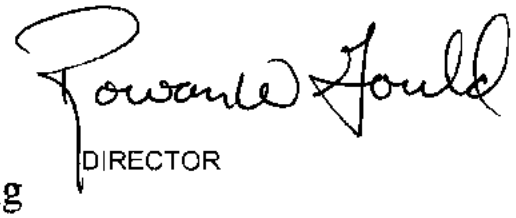
(1) Operating, maintaining, and keeping the dams for which they are responsible safe.

(2) Sending to the Regional Director funding requests for:

(a) Routine annual and regular maintenance,

(b) Operations and monitoring, and

(c) Priority 1 and Priority 2 recommendations identified in SEED inspections (see 361 FW 2 for more information about SEED inspections).



(3) Ensuring operating staff are adequately trained on all relevant dam safety matters.

(4) Ensuring the safety of employees and visitors who may be impacted by dam failure or misoperation.

(5) Implementing Emergency Action Plans, security plans, and SOPs.

(6) Ensuring that all of the monitoring and recording of dam instrumentation data is complete and sent to the Regional Dam Safety Officer and the Service Dam Safety Officer in accordance with SOPs.

(7) Performing periodic informal inspections in accordance with SOPs.

Acting DIRECTOR

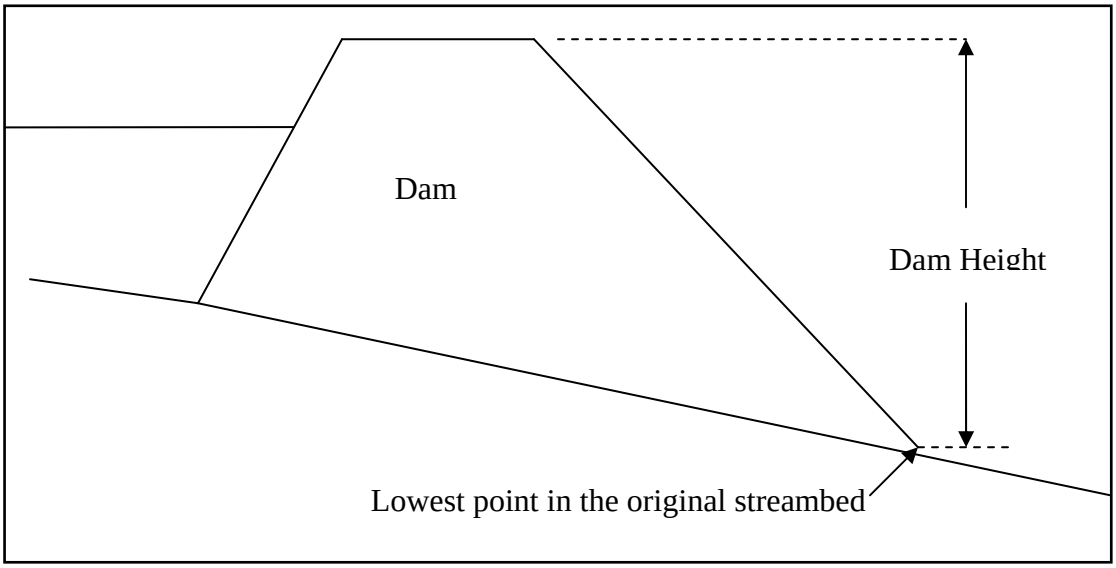
Date: September 12, 2008

2.1 What is the purpose of this chapter? This chapter describes the standards and requirements of our Dam Safety Program.

2.2 What terms do you need to know to understand this chapter?

A. Cross-dike or interior dike. A cross-dike or interior dike:

(1) Is an artificial embankment constructed to subdivide a reservoir or provide vehicular access across a reservoir,



(2) Does not provide any additional water storage above the maximum storage of the dam that creates the reservoir, and

(3) May be considered a dam if the difference in the water surface elevation from upstream to downstream of the dike can be more than 3 feet.

B. Dam. A dam is an artificial barrier, including appurtenant works, constructed to impound water for permanent storage or flood control storage.

C. Dam Height. A dam's height is the vertical distance between the lowest point on the dam crest and the lowest point in the original streambed measured at the toe of the dam (see Figure 1).

Figure 1: Dam Height

D. Hazard Classification. Hazard classification is a rating based on the potential loss of life or property damage downstream of a dam if the dam were to fail or be misoperated. We do not determine hazard classification based on the existing condition of a dam and its appurtenant structures.

E. **Hydraulic Height**. A dam's hydraulic height is the vertical distance between the maximum design water level and the lowest point in the original streambed measured at the toe of the dam.

F. Inflow Design Flood. The Inflow Design Flood is the rate of water coming into the reservoir over time that the dam must be able to safely pass through a combination of spillway and outlet works and attendant surcharge storage.

G. Inventory Dam. We include a dam in the Service Inventory of Dams and the National Inventory of Dams if it meets the following criteria:

(1) It has a storage capacity at maximum water storage elevation in excess of 15 acre-feet, and:

(a) It exceeds 25 feet in height from the natural bed of the stream (or a watercourse) to the maximum water storage elevation measured at the downstream toe of the dam, or

(b) If it is not across a stream channel or watercourse, it exceeds 25 feet in height measured from the lowest elevation of the outside limit of the dam, to the maximum water storage elevation; or

(2) It exceeds an impounding capacity at maximum water storage elevation of 50 acre-feet **and** a height measured as section 2.2 G(1) above describes in excess of 6 feet; and

(3) It has a high or significant hazard classification.

H. Maximum Water Storage Elevation. The maximum water storage elevation is the highest elevation of water that the dam can impound, including temporary storage of flood water.

I. Maximum Design Water Level. The maximum design water level is the highest elevation of water determined as a result of safely passing the Inflow Design Flood (see section 2.15A).

J. Noninventory Dam. Noninventory dams are:

(1) Low hazard dams that do not meet the criteria in section 2.2G, and

(2) Interior dikes or cross dikes located within an impoundment.

K. Probable Maximum Flood (PMF). The Probable Maximum Flood is the runoff flow of water that we expect from the most severe combination of critical meteorologic and hydrologic conditions that are reasonably possible in a drainage area under study.

L. Structural Height. The structural height of a dam is the vertical distance between the lowest point on the crest of the dam and the lowest point of the excavated foundation.

2.3 How does the Service classify dams? We classify dams based on hazard potential and a dam's size.

A. Hazard Classification. The hazard classification for a dam gives us the minimum requirements for security, investigation, design, and construction.

(1) The Regional Dam Safety Officer (RDSO) or a member of the Service's Dam Safety inspection team provides a preliminary hazard classification recommendation.

(2) The Division of Engineering analyzes the hazard classification, when appropriate, in accordance with the latest version of the Federal Emergency Management Agency (FEMA) 333, Department of the Interior (753 DM), and the Bureau of Reclamation (BOR) guidelines, (i.e., Downstream Hazard Classification

Guidelines, Assistant Commissioner Engineering and Research (ACER) Technical Memorandum (TM) #11).

(3) A hazard classification panel assigns a formal hazard classification to all Service dams by using the RDSO's preliminary hazard classification recommendation, the Division of Engineering's hazard classification analysis, and other data.

(a) The panel consists of a Service Dam Safety Officer (SDSO) designee(s), the affected RDSO and an RDSO from another Region. The panel provides a written determination to the SDSO.

(i) A majority vote of the panel is required to classify new dams, and

(ii) A unanimous vote of the panel is required to change the hazard classification of existing dams.

(b) The hazard classification panel determines the formal classification of a dam in accordance with the guidelines in section 2.3A(2).

(4) The RDSO reviews the hazard classification of low hazard inventory dams and noninventory dams at least every 6 years.

(5) The RDSO or the SDSO may request the reclassification of a dam.

B. Size Classification. The RDSO or a member of the Service's Dam Safety inspection team determines the size classification of a dam. They use the dam height or the water storage capacity at maximum water storage elevation, whichever yields the larger size classification, to determine the size of a dam.

(1) Small dams are structures that are less than 40 feet high or that impound less than 1,000 acre-feet of water.

(2) Intermediate dams are structures that are 40 to 100 feet high or that impound 1,000 to 50,000 acre-feet of water.

(3) Large dams are structures that are more than 100 feet high or that impound more than 50,000 acre-feet of water.

2.4 What is the Service's Safety Evaluation of Existing Dams (SEED) inspection program?

A. The SEED Inspection program.

(1) Purpose. The purpose of the SEED Program is to ensure protection of life and property and to assure the integrity of our inventory dams and appurtenant structures (also see The Federal Guidelines for Dam Safety FEMA 93, 2004). Periodic inspections disclose conditions that might disrupt operation or threaten dam safety.

(2) Correction of Deficiencies. We must correct any deficiencies noted as a result of inspections. The Division of Engineering will set priorities and completion dates to correct deficiencies in accordance with the relative level of failure potential and downstream consequences. To determine priorities for maintenance, repair, or removal, the Division of Engineering looks at the adequacy of structures and facilities to continue serving the purpose for which they were constructed and identifies the extent of deterioration.

B. Types of Inspections. There are four types of inspections:

(1) Informal inspections are visual examinations carried out during day-to-day operations. They provide frequent surveillance of the general appearance and functioning of the dam and its appurtenances to identify, as soon as possible, any readily observable changes. For each high and significant hazard dam, Project Leaders and staff perform these inspections in accordance with the dam's Standing Operating Procedures (see section 2.5).

(2) Formal SEED inspections assess the safety and integrity of all aspects of a dam. Formal inspections are comprehensive searches for evidence of deterioration of materials, developing weaknesses, and unsafe hydraulic or structural conditions. Engineers perform these inspections which include:

(a) Field examinations,

(b) Photographic or video recording of all physical features,

(c) Examination of any adjacent endangering conditions,

(d) Review and evaluation of all recorded performance data, including engineering loadings, analytical methods, instrumentation and spillway discharge measurements,

(e) Evaluation of the performance of the dam and a comparison of the long-term examination record with current conditions,

(f) An overall condition rating, and

(g) Recommendations to maintain or improve the integrity of the dam.

(3) Intermediate SEED inspections are visual site investigations conducted to identify deterioration of materials, developing weaknesses, and unsafe hydraulic or structural conditions.

(a) Engineers perform these inspections which consist of:

(i) Field examinations,

(ii) Photographic or video recording of all physical features, and

(iii) Examination of any adjacent endangering conditions.

(b) Intermediate inspections do not include a comprehensive evaluation of the engineering loadings and analytical methods to predict dam performance.

(4) Special inspections are made following (or during, if possible) unusual floods, significant earthquakes, mishaps, or the appearance of unexpected dam performance. These inspections determine the extent of any damage and the need for emergency repair or other action.

C. Frequency of Inspections.

(1) Project Leaders and dam operators perform informal inspections routinely during day-to-day operations in accordance with SOPs.

(2) The frequency of formal and intermediate inspections is based on the hazard classification of the dam.

(a) High and significant hazard dams are inspected every 3 years, alternating between a formal SEED inspection and an Intermediate SEED inspection.

(b) Low hazard dams are inspected every 6 years, alternating between a formal SEED inspection and an Intermediate SEED inspection. (The SDSO may change the frequency based on size and condition of the dam.)

(3) The frequency of special inspections depends on the occurrence of an unusual event (e.g., seepage through the dam has become turbid). Those responsible for the dam must be alert to identify situations or events that may require special inspections.

D. Reporting Dangerous or Unusual Conditions.

(1) The SEED Inspector must immediately report dangerous or unusual conditions to the Project Leader and the RDSO.

(2) In response to a dangerous or unusual condition, the RDSO must immediately:

(a) Initiate appropriate response in accordance with the dam's Emergency Action Plan (see section 2.6 and 361 FW 3), and

(b) Contact the SDSO and the Regional Safety Manager if an inspection indicates imminent danger or threat of serious injury or significant property damage.

E. Inspection Reports.

(1) Use written checklists for informal inspection reports. They contain enough information to determine whether or not further action is necessary and may be obtained from the SDSO or the RDSO.

(2) Formal and intermediate inspection reports are written reports prepared in a format consistent with established Service guidelines.

F. Inspectors.

(1) Inspectors for Informal Inspections: These inspectors:

(a) May be Project Leaders, dam operators, and other Service personnel who are in the vicinity of the dam in the course of their regular activities. The RDSO may request an individual to conduct informal inspections of a dam.

(b) Should have a basic knowledge of dams so they can recognize unusual conditions, abrupt changes from previous conditions, and obvious new defects such as seepage, cracks, and displacements.

(2) Inspectors for Formal, Intermediate, and Special Inspections:

(a) High and Significant Hazard Dams: Staff from the Division of Engineering, RDSOs, or consultants perform SEED inspections for high and significant hazard dams. Members of the inspection team must include a Registered Professional Engineer trained in the safety inspection of dams.

(b) Low Hazard Dams: Staff from the Division of Engineering, RDSOs, or consultants perform SEED inspections for low hazard dams. Dam safety professionals must perform the inspections under the direct supervision of a Registered Professional Engineer trained in the safety inspection of dams.

2.5 What are the requirements for writing Standing Operating Procedures (SOPs)?

A. The SDSO must:

(1) Prepare SOPs for all high and significant hazard dams using the Service format.

(2) Update SOPs associated with major repair or rehabilitation to high and significant hazard dams.

B. The RDSO must annually review and update, as appropriate, the SOPs for each high and significant hazard dam within the Region.

2.6 What are the requirements for writing and implementing Emergency Action Plans? The SDSO must prepare Emergency Action Plans for all high and significant hazard dams (see 361 FW 3 for more information about Emergency Action Plans).

A. The RDSO:

(1) Must annually review the Emergency Action Plan for each high and significant hazard dam within the Region in accordance with procedures outlined in the Emergency Action Plans.

(2) Is responsible for:

(a) Annual testing, verification, and certification of Emergency Action Plans by November 1st.

(b) Submitting a verification statement, in accordance with the SOPs, along with any revisions to the Emergency Action Plans, to the SDSO annually on or before November 30th.

(c) Distributing revisions of the Emergency Action Plan to the plan holders.

B. The SDSO is responsible for:

(1) Performing Emergency Action Plan periodic tests every 6 years concurrent with Formal SEED inspections and tabletop exercises concurrent with Intermediate SEED inspections, and

(2) Updating Emergency Action Plans associated with major repair or rehabilitation to high and significant hazard dams.

2.7 What is the approval process and procedure for building new dams?

A. Review and Approval. Table 2-1 shows who must review and approve or decline to approve all plans, designs, drawings, and construction specifications for Service dams by performing a Qualified Engineering Review and Approval:

Table 2-1: Who Must Review and Approve Plans, Designs, Drawings, and Specifications	
Type of Dam	**Approving Official(s)**
Noninventory dams	The RDSO

Table 2-1: Who Must Review and Approve Plans, Designs, Drawings, and Specifications	
Type of Dam	**Approving Official(s)**
Low hazard inventory dams	The RDSO and SDSO
High and significant hazard dams	The SDSO (The SDSO must also obtain an independent review by an outside organization, such as the Bureau of Reclamation, the Army Corps of Engineers, or a consultant.)

B. Project Planning, Design, and Construction.

(1) The SDSO or a designee serves as the project manager for planning (including environmental impacts), design, permitting and construction of high and significant hazard dams.

(2) The Regional Engineer designates the RDSO or another qualified engineering staff person to be the project manager for planning (including environmental impacts), design, permitting and construction of all low hazard, inventory dams, and noninventory dams.

(3) The RDSO classifies all new dams as either inventory or noninventory dams. The RDSO sends this determination, along with the vital statistics of the dam, to the SDSO. The SDSO adds the dam to the Service inventory, if appropriate.

2.8 How does the Service address newly acquired dams? Before acquiring new lands, we must identify any dams being conveyed with the property. We must inspect and classify the dams and clearly identify any needed rehabilitation or repair costs before we acquire the land.

A. The RDSO must ensure that a SEED inspection is performed as part of the Engineering Assessment we conduct for all proposed land acquisitions (see 341 FW 2). See section 2.4 for more information about the SEED inspection program

(1) The SEED inspection should describe:

(a) The condition of the dam,

(b) The cost of any work required to bring the dam up to Service safety standards, and

(c) Future costs and liabilities associated with the dam.

(2) The RDSO must review the SEED report and approve it before it can be included with the Engineering Assessment. The Engineering Assessment must clearly state any significant deficiencies and costs associated with the dam(s) and must be included in the Decision Document the Region's Engineering Division gives to the Regional Director for approval (see 341 FW 1).

B. The RDSO must ensure that SEED II studies are performed on all newly acquired dams. The SEED II study is a detailed assessment of the design and condition of the dam and normally includes hydrologic and hydraulic, structural, and geotechnical analyses (stability, seepage, liquefaction, etc).

C. The acquisition contract or other legally enforceable agreement should include the cost associated with work required to bring the dam up to Service safety standards, including modifications, repairs, and development of Emergency Action Plans and SOPs. Land acquisition budget requests should include the costs for SEED inspections and SEED II studies (see 341 FW 3).

2.9 What is the process for rehabilitating, modifying, or repairing an inventory dam?

A. We must follow the same approval process and procedures for major rehabilitation, modification, or emergency repair of inventory dams as for new dams (see section 2.7).

B. Major rehabilitation or modification may include:

(1) Raising a dam crest,

(2) Enlarging or replacing spillways and outlets, and

(3) Constructing auxiliary or emergency spillways.

C. Major rehabilitation, modification, or emergency repair does not include annual operation and maintenance work such as repairs to gates, repair of erosion on embankments, simple concrete repair, etc.

2.10 How do Project Leaders request funding for safety modifications, operations and monitoring, and rehabilitation of dams? Table 2-2 shows who should request funding for modifying and operating dams.

Table 2-2 Requesting Funding		
Type of Project	**Responsible Official(s)**	**How Requested**
A. Routine maintenance, operations and monitoring and minor repairs of high and significant and low hazard dams	Project Leaders and Regional Service Asset Maintenance Management System (SAMMS) Coordinators	Resource Management funds through SAMMS
B. Priority 1 and 2* recommendations except recommendations for engineering studies or major repair or rehabilitation	Project Leaders and Regional SAMMS Coordinators	Resource Management funds through SAMMS the year they are identified in SEED inspections
C. Planning, design, and construction of major rehabilitation or modification to low hazard dams and appurtenances and noninventory dams	Project Leader, in consultation with the RDSO and the Regional Engineer	Resource Management or Construction funds through SAMMS or the Construction 5-year Plan
D. Planning, design, and construction of major rehabilitation or modification to high and significant hazard dams and appurtenances	SDSO, through the Chief, Division of Engineering	Construction funds through the Construction 5-year Plan

***P1** Recommendations indicate that the normal condition of the structure is impaired and the safety of the structure is in jeopardy.
P2 Recommendations are mainly maintenance deficiencies.

2.11 How does the Service coordinate with State Dam Safety Programs? We consult on the design and safety of dams with the Dam Safety Program officials in the States in which we own, operate, or propose to construct a dam. We also invite State officials to participate in safety inspections and Emergency Action Plan exercises.

2.12 What are the requirements for privately funded dams on Service property?

A. To allow construction of a privately funded dam on Service property the proposed dam must satisfy the requirements in section 2.7, and the SDSO must review and approve a Professional Engineer's certification of the dam. The Professional Engineer must be licensed by the State in which the dam will be located.

B. The certification must at least attest to the following:

(1) The hazard and size classification of the dam;

(2) The proposed project has been designed by a Professional Engineer, qualified in dam design and construction, to meet Federal standards for dam design, construction, and rehabilitation including, but not limited to, the Federal Guidelines for Dam Safety (FEMA 93, 2004) and Service design standards;

(3) The project design and specifications have been reviewed and approved by the State dam safety program staff;

(4) There is a dedicated funding source for future operation, inspection, maintenance, and repairs of the dam;

(5) If the dam is a high or significant hazard dam, there is an Emergency Action Plan in effect for the dam that meets the requirements of Emergency Action Planning for Dam Owners (FEMA 64, 2004); and

(6) Federal and State permits will be obtained prior to construction.

2.13 How are privately owned dams on Service property inspected?

A. The non-Federal entity who owns the dam or lessee is responsible for ensuring the dam complies with State regulations and the Federal Guidelines for Dam Safety (FEMA 93 April, 2004). Although Service inspection teams do not inspect private dams, the SDSO maintains a list of the dams.

B. Responsibilities for dam safety must be identified in the Memorandum of Understanding or lease agreement that authorizes use of Service lands. Responsibilities should include ensuring the owner/lessee contacts the Project Leader and the RDSO if significant dam safety deficiencies or unusual circumstances are identified on a private dam on Service property.

2.14 What are the requirements for State dam projects to which the Service provides funding?

A. We may provide funds to supplement approved State dam safety projects on a cost-sharing basis through the Federal Aid Program.

B. For all inventory dams for which we provide funds (see section 2.2G), we must obtain:

(1) Reasonable assurances that the State has a dedicated funding source to safely operate and maintain the dam and that there is an Emergency Action Plan for any high and significant hazard dams, and

(2) Certification from the State Dam Safety Official, signed by a Registered Professional Engineer licensed in the requesting State, that proposed projects involving the construction, enlargement, or rehabilitation of any dam (including appurtenant works) satisfies the criteria for our inventory and meets Federal requirements. The certification must attest to the following:

(a) The hazard and size classification of the dam are correct and its present condition and deficiencies have been accurately identified;

(b) The proposed project has been designed by a Professional Engineer, qualified in dam design and construction, to meet Federal standards for dam design, construction, and rehabilitation including, but not limited to, the Federal Guidelines for Dam Safety (FEMA 93, 2004), and any other technical requirements identified in the Federal Aid project agreement documents;

(c) A Registered Professional Engineer qualified in the design and construction of dams completed the State's technical review of the project design and specifications;

(d) There is a dedicated funding source that will provide for future operation, inspection, maintenance, and repairs of the dam;

(e) If the dam is a high and significant hazard dam, there is an Emergency Action Plan in effect for the dam that meets the requirements of Emergency Action Planning for Dam Owners (FEMA 64, 2004); and

(f) Federal and State permits will be obtained prior to construction.

C. The requirements in section 2.14B do not apply to noninventory Federal Aid dams.

2.15 What are the technical standards for the Dam Safety Program? The planning, design, construction, and rehabilitation of all inventory dams must follow the technical standards below and in 361 FW 1 and 3.

A. Inflow Design Flood. The Inflow Design Flood is the rate of inflow discharge into the reservoir over time that the dam must be able to safely pass through a combination of spillway and outlet works and attendant surcharge storage.

(1) Service inventory dams must meet the Inflow Design Flood standards in Exhibit 1.

(2) The Project Leader must obtain a waiver from the Inflow Design Flood standards in Exhibit 1:

(a) For high or significant hazard dams from the Chief, Division of Engineering and the SDSO.

(b) For low hazard inventory dams from the SDSO and the RDSO.

(3) Approval of Inflow Design Floods other than those in Exhibit 1 may be granted only after performing an incremental damage assessment or risk-based analysis to determine if a waiver is appropriate.

(a) Studies and mapping must clearly demonstrate that consequences of dam failure at flood flows larger than the selected Inflow Design Flood will not increase projected loss of life and will have no significant incremental increase on property damage. All Inflow Design Floods must follow FEMA 97, Federal Guidelines for Selecting and Accommodating Inflow Design Floods for Dams or a more conservative approach. Analysis must include existing structures and inhabitants and projected inhabitants and structures based on approved planning documents and over at least the next 20 years. The incremental

increase in property damage versus the potential frequency of floods must be clearly identified in a management decision chart.

(b) The RDSO or the SDSO must provide the proposed Inflow Design Flood using an incremental damage assessment or risk-based analysis to the affected State dam safety office for review and discussion.

(c) The minimum Inflow Design Flood for high and significant hazard dams must at least meet the 100-year flood frequency.

B. Freeboard Requirements. Freeboard is the vertical distance from the water surface to the top of the dam. Freeboard should meet the requirements of ACER TM No. 2, Freeboard Criteria and Guidelines for Computing Freeboard Allowances for Storage Dams, BOR 1992 or the latest revision.

C. Low-Level Outlets. All inventory dams must have a low-level outlet that can evacuate the major portion of the reservoir storage volume by gravity flow.

(1) Only the SDSO may approve waivers to this requirement.

(2) Criteria for reservoir draining should recognize site-specific conditions, economic aspects, and project needs to provide an acceptable balance between costs and rates of draining and filling. Draining times established for a dam reflect downstream channel capacity, level of risk to the dam, and hazard potential to the downstream areas. A low-level outlet works, in conjunction with other release facilities, should meet the requirements in Criteria and Guidelines for Evacuating Storage Reservoirs and Sizing Low-level Outlet Works, ACER TM No. 3, the Department of the Interior, BOR 1990 or the latest revision.

(3) For small low-hazard inventory dams, the low-level outlet works, in conjunction with other release facilities, should be located and sized to draw down the reservoir within 1 to 4 months, at a minimum, to the lower of the following levels:

(a) The reservoir level commensurate with a storage capacity that is 10 percent of that at the normal reservoir level, or

(b) The reservoir level with less than 50 percent of the hydraulic height.

D. Risk Analyses: The Division of Engineering may use risk assessments to identify appropriate repair criteria. The assessments predict the annual probability of loss of life and failure probabilities of the structure over a projected 50-year period.

(1) The average annual loss of life probability must be less than or equal to 1 in 1,000.

(2) The annual failure probability of the structure must be less than or equal to 1 in 10,000.

Acting DIRECTOR

Date: September 12, 2008

D.11. U.S. Forest Service

FSM 7500 - WATER STORAGE AND TRANSMISSION
CHAPTER ZERO CODE

7506 - REFERENCES 10
7509 - HANDBOOKS 10
7509.1 - Internal Service-wide Handbooks 10
7509.11 - Dams Management Handbook (FSH) 10

This title establishes policies, standards, and criteria for the investigation, design, construction, emergency planning and response, maintenance, and operation of water storage and transmission structures administered or permitted by the Forest Service. Water storage structures include class A, B, C, and D dams, including settling ponds and tailing dams. Water transmission structures include ditches, flumes, tunnels and penstocks.

7501 – AUTHORITY

The installation and operation of water storage and transmission facilities on National Forest System lands are carried out under the authorities and limitations of various laws and the regulations of the Secretaries of Agriculture and Army, as well as the Federal Energy Regulatory Commission. Key authorities are as follows:

1. Presidential Memorandum of October 4, 1979, directed Federal Agencies to implement the "Federal Guidelines for Dam Safety" published on June 25, 2979, by the Ad Hoc Interagency Committee on Dam Safety of the Federal Coordinating Council for Science, Engineering, and Technology, Washington, D.C., June 25, 1979, and to report implementation progress to the Federal Emergency Management Agency (FEMA).

2. Departmental Regulation 1043-18 establishes the U.S. Department of Agriculture (USDA) Dam Safety Committee, requires member agencies to name a Dam Safety Officer, assigns the Soil Conservation Service (SCS) Dam Safety Officer as the USDA contact for FEMA, and requires the Forest Service Dam Safety Officer to participate in technical dam safety activities with FEMA.

3. Title 36, Code of Federal Regulations, Part 251 and FSM 2700 establish that, authorized uses of lands managed by the Forest Service include special uses such as reservoirs, canals, ditches, flumes, pipelines and other facilities for the impoundment, storage, transportation, or distribution of water.

4. Title 18, Code of Federal Regulations, Part 4 provide that Federal Energy Regulatory Commission (FERC) regulations related to licenses and permits for dams, pipelines, and other water storage and transmission facilities related to power generation establish authority to require conditions for issuing a FERC license (FSM 2770).

5. Title 33, Code of Federal Regulations, Part 208 establishes that the Army Corps of Engineers has the authority to prescribe regulations for the use of storage allocated for flood control at all reservoirs constructed wholly or in part with Federal funds, with the regulations normally implemented by letters of understanding between the Corps of Engineers and the project owners.

6. Water Resources Development Act of 1992 (33 U.S.C. 2201) directs participation in updating and maintaining of the National Dam Inventory.

7502 – OBJECTIVES

Manage water storage or transmission structures administered or permitted by the Forest Service to:

1. Prevent sudden failure resulting in loss of life or extensive damage to property or the environment.

2. Efficiently and effectively achieve planned benefits such as fisheries enhancement, improved recreational opportunities, and increased livestock watering.

3. Protect the government's investment and interest in facilities.

4. Minimize the potential liability of the Forest Service from failures of Forest Service owned and permitted dams.

7503 – POLICY

The policies in this section apply with equal force whether the dam has a permanent reservoir or is a detention dam for temporary storage of flood waters. Except for inventory of dams, these standards and criteria may be modified on a case-by-case basis for moderate and low-hazard class D dams. Any dam up to but not more than 6 feet high, regardless of storage capacity, or which has a maximum storage capacity not greater than 15-acre feet, regardless of height, may be excluded from this policy unless there is a potentially significant downstream hazard.

1. Ensure that the design, construction, operation, and maintenance of Forest Service owned dams and dams authorized by special use permits or other instruments meet acceptable standards or withdraw them from service to the degree necessary to safeguard life and property.

2. Use funds from benefiting function(s) for technical work related to dams owned by the Forest Service and authorized under special use permit (FSM 7515).

3. Fully coordinate technical reviews, construction monitoring, and inspections with environmental and resource management review processes.

4. Do not relieve an owner of a dam from the responsibility for providing and maintaining a safe structure.

5. Do not duplicate reviews performed by State and other Federal Agencies, or the Engineer retained by the proponent, if those reviews meet Forest Service objectives and standards.

6. Use the Memorandum of Understanding with the Soil Conservation Service (SCS) as the basis for coordinating SCS-sponsored projects on National Forest System lands (FSM 1541).

7. Ensure the following conditions are met when existing dams are acquired by the Forest Service:

a. When dams are acquired voluntarily such as through land exchange--

(1) Ensure the overall decisionmaking process includes an engineering study that addresses the structural condition of the dam.

(2) Identify any hazards to existing downstream life and property, and identify potential hazards if future development should occur.

(3) If the dam requires rehabilitation, identify costs of repairs.

(4) Identify long-term costs of maintaining and operating the dam.

(5) Identify any benefiting functions (FSM 7515).

b. If a dam is acquired involuntarily, such as by abandonment, ensure proper administrative and legal steps have been followed and that the ownership has been vested in the United States (FSM 2716.4).

8. Comply with the policies on the following aspects of water storage and transmission facilities management identified in the cross-referenced sections of the Forest Service Manual:

a. Facilities located in wilderness areas (FSM 2320.3, 2323.42, 2326).

b. Flood plain management (Executive Order 11988 issued May 24, 1977) (FSM 2527).

c. Wetlands protection (Executive Order 11990, issued May 24, 1977) (FSM 1950, 2527).

d. Special uses management (FSM 2700).

7504 – RESPONSIBILITY

Exhibit 01 summarizes responsibilities assigned in this chapter.

7504 - Exhibit 01

Summary of Responsibilities

Activity	Chief (DE)	DSO	RF (RDE)	FS
1. Appoint Dam Safety Officer.	O			
2. Advise and update Chief.	X			
3. Represent Forest Service on Interagency Coordinator matters.	X			
4. Establish procedures.		X		
5. Ensure Service-wide coordination.		X		
6. Monitor and report.		X		
7. Review and approve design and safety evaluations, and approve water storage and transmission projects prior to use:				
a. Class A, B, C, and high hazard D dams.			O (RE)	
b. Design approval of water transmission and class D moderate and low hazard dams.			X	O
c. Inspect **ALL** dams and water transmission projects (A, B, C, and D).			X	O
8. Establish policy, standards, and criteria for:				
a. Dam safety and water transmission			O	
b. Design, construction, operation, and maintenance of class D moderate and low hazard dams.			O	

7504 - Exhibit 01--Continued

Activity	Chief (DE)	DSO	RF (RDE)	FS
9. Determine that work meets standards for the life of the project.			O	
10. Maintain dams inventory.			O	
11. Monitor and report on quality and effectiveness of dam management program.			O	
12. Provide training and assistance with emergency action plans.			O	
13. Ensure dams are operated and maintained in accordance with guidelines and standards.				X
14. Designate qualified personnel.				X
15. Ensure qualified personnel participate in management of permitted facilities.				X
16. Ensure inspections are completed at designated intervals by qualified personnel.				X
17. Ensure emergency action plans are prepared, maintained, and tested.				X
18. Maintain documents and records.				X

Notes:		
	X	Delegable
	O	Not Delegable
	DE	Director of Engineering, WO
	DSO	Dam Safety Officer
	RDE	Regional Director of Engineering
	FS	Forest Supervisor

7504.1 – Chief

The Chief reserves the authority to appoint a Dam Safety Officer for the Forest Service through the Washington Office, Director of Engineering.

7504.2 - Washington Office, Director of Engineering

It is the responsibility of the Director of Engineering to:

1. Advise the Chief of the adequacy of administrative and technical procedures used to manage dams and water transmission structures.

2. Periodically update the Chief on compliance with water storage and transmission objectives through reports such as the Biennial Report on Dams Safety provided to the Federal Emergency Management Agency.

3. Represent the Forest Service on interagency coordination matters within the Department of Agriculture on dams and water transmission structures.

7504.3 - Dam Safety Officer

It is the responsibility of the Dam Safety Officer to:

1. Establish procedures for conducting the dam safety activities of the Forest Service.

2. Coordinate Service-wide engineering aspects of the dam safety activities with other units, agencies, departments, and organizations.

3. Monitor and report on the quality and effectiveness of Regional administrative and technical practices.

7504.4 - Regional Foresters

It is the responsibility of Regional Foresters to:

1. Review and, if appropriate, approve or certify the acceptability of emergency action plans, designs, and safety evaluations for all classes of projects (FSM 7511), and also approve completed water storage and transmission projects prior to their use. This authority may be redelegated only to the Regional Staff Director for engineering activities. Authority for design approval or certification of water transmission and class D moderate- and low-hazard dams and inspections of all projects may be delegated to Forest Supervisors.

2. Establish policy, standards, and criteria for:

a. Dam safety and water transmission activities in the Region.

b. Design, construction, operation, and maintenance of class D moderate- and low-hazard dams.

3. To ensure that all construction, reconstruction, or major maintenance works:

a. Conform to sound engineering practice and Forest Service standards and criteria.

b. Function according to acceptable principles for the life of the structure.

4. Maintain a Regional dams inventory that contains, as a minimum, the elements found in FSM 7515.1.

5. Monitor and report on the quality and effectiveness of Forest administrative and technical engineering practices.

6. Provide training and assistance in preparing, maintaining, and testing emergency action plans by Forest Service and permit holder personnel.

7504.5 - Forest Supervisors

It is the responsibility of Forest Supervisors to:

1. Ensure that all water storage and transmission structures, government-owned or permitted by the Forest Service, are operated and maintained in accordance with the Federal Guidelines For Dam Safety (FSM 7501) and other applicable regulations and standards.

2. Designate qualified personnel to adequately accomplish the construction, operation, inspection, and management of Forest Service-owned dams.

3. Ensure that qualified personnel are participating in the management of permitted dams and water transmission facilities.

4. Ensure that all dams are inspected at designated intervals by qualified people.

5. Ensure that required emergency action plans are prepared and maintained, that personnel are trained, and that plans are tested at the designated intervals.

6. Maintain documentation and records of dams (FSM 7515).

7505 - DEFINITIONS

(FSM 7520.01 and FSH 7509.11).

Dam. Any artificial barrier, including appurtenant works, which impounds or diverts water.

Dam Height. (Also called Hydraulic Height.) For administrative classification of dams, height is the vertical distance in feet measured from the natural bed of the stream or watercourse at the downstream toe of the barrier or, if not across a stream channel or watercourse, from the lowest elevation of the outside limit of the barrier to the maximum water storage elevation.

Forest Service-owned Dams. Those facilities owned by the Government which are the complete responsibility of the Forest Service; as opposed to facilities owned by the Government but built and maintained by other Federal agencies, or facilities built under special use permit or United States Department of the Interior (USDI) easement.

Holder. The holder of a special-use permit to develop or operate a water storage or transmission facility on National Forest lands.

Independent Review. An engineering review conducted by qualified engineers not directly involved in the design of the project.

Inspect. To view closely and critically to detect errors or to determine quality and condition.

Maximum Storage Capacity. The total storage space, measured in acre-feet, in a reservoir at the maximum water storage elevation including storage of flood waters above the normal full storage elevation.

Maximum Water Storage Elevation. The water surface elevation for the reservoir at the dam face for the inflow design flood (FSM 7524.3).

Monitor. To compare performance with sources of information, and data, for conformance with accepted practice and principles, and to check for reasonable accuracy.

Normal Full Storage Elevation. The elevation of the crest of the lowest uncontrolled spillway (FSM 7523.01).

Qualified Engineer. A person who, by reason of training and experience, is assigned by the Forest Supervisor or Regional Forester to perform certain specific technical functions within the authorizing Line Officer's delegated authority. Technical qualifications should be appropriate for the technical requirements of the functions assigned. Consider the consistency of qualifications with engineers assigned similar work in State and private practice.

7517.1 - Forest Service Dams 12
7517.2 - Special Use Dams 12
7518 - STRUCTURAL FAILURE REPORT 12

7511 - CLASSIFICATION OF PROPOSED PROJECTS

The potential effect of water storage and transmission structures on the safety and economy of downstream areas varies with the size of the structure and with the amount and value of human-built improvements and natural amenities that exist downstream. The required scope of investigations, precision of design, quality and capacity of components, and subsequent cost vary with the hazard assigned to the dam.

Minimum acceptable criteria for design, operation, maintenance, and monitoring of dams are based on the administrative size and hazard classifications. All factors that might influence the potential hazard classification must be evaluated during the design and design review of the dam. The hazard rating should be consistent with the potential for loss of human life and damage to property that could be caused by a failure of the dam.

7511.1 - Administrative Classification

For administrative purposes, classify dams as follows:

1. Class A Projects. Dams that are 100 feet or higher or impound 50,000 acre-feet or more of water.

2. Class B Projects. Dams that are 40 feet but less than 100 feet high, or impound 1,000 but less than 50,000 acre-feet of water.

3. Class C Projects. Dams that are 25 feet but less than 40 feet high, or impound 50 but less than 1,000 acre-feet of water.

4. Class D Projects. Dams that are less than 25 feet high and impound less than 50 acre-feet of water.

7511.2 - Hazard Assessment Classification

Classify dams according to hazard potential based on the loss of human life or property damage that could occur if the structure failed.

1. Low Hazard. Dams built in undeveloped areas where failure would result in minor environmental or economic loss, damage would be limited to undeveloped or agricultural lands, and significant improvements are not planned in the foreseeable future. Loss of human life would be unlikely.

2. Moderate Hazard. Dams built in areas where failure would result in serious environmental damage or appreciable economic loss with damage to improvement, such as commercial and industrial structures, public utilities and transportation systems. No urban development and no more than a small number of habitable structures are involved. Loss of human life would be unlikely.

3. High Hazard. Dams built in areas where failure would likely result in loss of human life or excessive economic loss. Generally this would involve urban or community development with more than a small number of habitable structures.

7511.3 - Transmission Structures Classification

Classification of transmission structures such as pipelines and canals is left to the discretion of the Regional Directors of Engineering.

7512 - REVIEW AND APPROVAL OF PROPOSED PROJECTS

Plans and designs for new water storage and transmission projects proposed by the Forest Service or others, or for changes in, or major repair of, existing works must be reviewed and approved by the authorized officer (FSH 2709.11, sec. 53.2, clause B37) prior to construction. Approval shall be based on administrative review (FSM 7512.1) and engineering review (FSM 7512.2).

Coordination with other agencies is required to determine that:

1. Project plans are consistent with policies stated in FSM 7503.

2. Project plans include securing any needed water rights or permits from the State for water development or use (FSM 2540).

3. The projects are compatible with Forest plans.

4. The construction of the project can be effectively coordinated with other National Forest activities.

7512.1 - Environmental Review

Ensure that the scope and intensity of the environmental (FSM 1950) and administrative work for each project is complete and appropriate.

7512.2 - Regional Engineering Review

The scope and intensity of the engineering review varies with the complexity, extent, and hazard classification of the structures. See FSM 7504 for design review and approval authorities.

Engineering review and approval by the Regional Staff Director for engineering activities are not required for:

1. Water projects authorized by Federal law and under the jurisdiction of the Bureau of Reclamation, Corps of Engineers, or the Federal Energy Regulatory Commission.

2. Watershed-protection and flood-prevention projects (Pub. L. 566), flood-control projects (authorized by the Flood Control Act of 1944), or other projects reviewed and approved by the Soil Conservation Service (FSM 7503).

3. Dams not located on National Forest land even if all or part of the reservoir occupies National Forest land, unless salient features such as flooding of National Forest land require Forest Service involvement as part of the permitting process.

7512.21 - Independent Review

All high hazard dams and moderate hazard dams designated by the Regional Forester shall have an independent engineering review made by a qualified engineer (FSM 7505) not directly involved in the design process.

Independent reviews of special use projects may be accomplished by qualified Forest Service engineers, States or other agencies, or consultants not employed by the primary design firm.

7512.22 - Regional Design Certification

When review indicates the design is adequate, the Regional Staff Director for engineering activities shall certify approval or acceptability of the project drawings and specifications prior to their use by signing them. When drawings are issued in a bound set, the signing of the cover sheet may serve to certify the entire set.

Design changes made after the initial review or during construction must also be approved or certified as acceptable by the Regional Staff Director for engineering activities.

Designs submitted by special use applicants (FSM 2700) will be prepared and signed or stamped by a licensed engineer with professional experience consistent with the requirements for analyzing the size of the structure and the hazard involved.

Approval of designs prepared by Forest Service units indicates that the design is judged to be adequate from the standpoint of safety, economy, and function.

7512.3 - Washington Office Review

Review by the Washington Office is not required. Requests for assistance in Regional reviews may be made at any stage of design.

The dam safety officer may make design reviews of specific dams for the purpose of monitoring Regional programs.

7513 - SUPERVISION OF PROJECT CONSTRUCTION

Maintain continuing liaison between personnel concerned with project planning, design, construction, and operation. Individuals from each concerned discipline must know and understand the relevant activities of the others to determine technical adequacy.

Qualified engineers are required for:

1. Supervising site investigation work.

2. Designing all dams and water transmission systems.

3. Supervising or monitoring the inspection of construction activities.

4. Supervising or monitoring safety inspections, emergency action plans, and operation and maintenance plans.

7514 - FUNDING AND BUDGETING

Program funding to accomplish the safety requirements for Forest Service-owned dams shall be charged to the appropriate benefiting function(s). Budget for dam safety at the lowest budget level. The most current programming and budget directions for Forest Service dam administration, inspections, maintenance, and development are in each year's Program Budget Instructions. Regions and Forests may use management codes to track dam work in general, or to track by specific project, for example, new structures, modifications, safety repairs, and routine repairs.

Program funding from benefiting functions may be used for technical and safety related work for the administration of special use permits for dams and water transmission structures (FSM 7503, FSM 2720, and FSM 2780).

7515 - DOCUMENTATION AND RECORDS

Maintain and use the following records to identify and resolve problems with water storage and transmission structures:

1. Dams inventory.
2. Project files.
3. Operation and maintenance (O&M).
4. Inspections.
5. Emergency action plans.

7515.1 - Dams Inventory

The dams inventory provides the primary basis for administration of dams. Each Region shall maintain and update annually an inventory for class A, B, C, and D dams (permitted and Forest Service-owned) located on National Forest System lands (FSM 7504.4 and FSH 7509.11, sec. 11). Other dams owned or licensed by other Federal agencies may be inventoried for information purposes. Data elements for the dam inventory shall be those required to annually update the National Inventory of Dams (Pub. L. 99-662 and FSH 7509.11, sec. 08) maintained for all dams in the United States by the Federal Emergency Management Agency, Priority 1 and Priority 2 maintenance and repair needs and cost estimates for Forest Service-owned dams, and other data elements (FSM 7116) included in the Forest Service inventory for dams.

7515.2 - Project File

Maintain a project file for each Forest Service-owned or permitted dam (FSH 7509.11, ch. 10) or transmission structure. The file should be updated as needed over the life of the project with information on problems encountered, hazard assessment, repairs, operational changes, instrumentation, and inspections.

The responsibility for maintaining a project file for a dam under a special-use permit rests with the owner. However, Forests shall keep a supplemental file for each special use dam for such things as inspections, maintenance performed, and agreements.

7515.3 - Operation and Maintenance Plans

An operation plan and a maintenance plan are required. The responsibility for preparation of operation and maintenance plans rests with the owner. The plans for new dams shall be prepared during the design phase. The plans may be combined and may cover more than one structure if they are of a similar type (FSH 7509.11, ch. 20).

7515.31 - Operation Plan

Revise an operation plan as required by changes in project status or maintenance condition. Plans should reflect current operating agreements.

7515.31a - Special Use Structures

The authorization holder is responsible for preparation of the operation plan. The plan shall be coordinated with applicable State agencies. It shall be reviewed by a qualified engineer or authorized special-use personnel, as delegated, and approved by the authorized officer (FSM 2705).

A qualified engineer shall monitor each special use structure at least once every 5 years to ensure that it complies with the technical requirements of the permit. High hazard and controversial projects may necessitate more frequent monitoring.

7515.32 - Maintenance Plan

Review and update the maintenance plan annually to determine that current conditions are covered.

7515.32a - Special Use Structures

The authorization holder shall prepare the operating and/or maintenance plan in coordination with applicable State agencies. It shall be reviewed by a qualified engineer or qualified Forest Officer, as delegated, and approved by the authorizing official.

7515.33 - Maintenance Categories

The categories of maintenance needs are defined as:

1. Priority 1, Emergency. Maintenance needed to correct deficiencies affecting the safety of the structure or the public, or to correct conditions that may become critical to the safety of the structure or the public in the immediate future. Deficiencies in this category shall be corrected as soon as identified or the structure shall be withdrawn from service or the storage decreased to the extent needed to operate within acceptable parameters.

2. Priority 2, Nonemergency. Maintenance needed to restore functional use of the works, correct unsightly conditions, or prevent more costly damage. Integrity of the structure or public safety is not threatened.

3. Routine. Minor housekeeping-type maintenance normally included in the maintenance plan.

7516 – INSPECTIONS

Develop a systematic dam inspection program to identify routine maintenance and disclose conditions which might threaten life and property, so that timely corrective action can be taken (FSH 7509.11, ch. 40).

Some State regulations require State engineering inspection of non-Federal dams located on National Forest System lands. Some local agencies, such as municipal or county water agencies, flood control districts, and irrigation districts, make regularly scheduled inspections of works under their jurisdiction. When the scope and quality of such inspections are comparable to Forest Service requirements, the Regional Forester should work with appropriate State or local agencies to prevent duplication of effort. Such agreements should include provisions for periodic joint inspections.

Do not include in the Forest Service inspection program structures that are operated or inspected regularly by other Federal agencies, such as the Federal Energy Regulatory Commission, Bureau of Reclamation, or Corps of Engineers.

Include three types of inspections in the dam inspection program:

1. Informal and Special Inspections.

2. Operation and Maintenance Inspections.

3. Safety Inspections and Hazard Assessment.

7516.1 - Informal and Special Inspections

7516.11 - Informal Inspections

When any employees are in the vicinity of a Forest Service or special use dam, they should observe the overall condition and function of the structure. Any unusual conditions that seem critical or dangerous should be reported immediately to the Forest Officer responsible for dams. Particular attention should be given to evidence of (or changes in) leakage, erosion, sinkholes, boils, seepage, slope instability, undue settlement, displacement, tilting, cracking, deterioration, and improper functioning of drains and relief wells.

7516.12 - Special Inspections

Special inspections should be performed immediately after a dam has passed unusually large floods, the occurrence of an earthquake, sabotage, or when unusual events have been reported by operators or in informal inspections.

7516.2 - Operation and Maintenance Inspections

A qualified engineer shall periodically review operation, maintenance, and inspection records, and make a thorough inspection of each structure located on National Forest System land. Prepare a maintenance report for Forest Service dams to aid in scheduling routine maintenance, programming special repairs, and updating the inventory.

Authorizations for special use structures shall include requirements for owner-acquired inspection in accordance with the inspection plan. A qualified engineer (FSM 7505) shall monitor inspection reports to ensure compliance with technical standards (FSM 7504). When inspections are accomplished by State or local agencies under working agreements, the State or local agency report form is normally acceptable.

Compliance with established operation plans sometimes cannot be verified by inspection at the same frequency as inspection of maintenance. For structures which have administrative limitations on storage, reservoir stage, or water release imposed by the State or the Forest Service, operation logs and water stage or metering-device records (when required) should be checked periodically throughout the year.

7516.21 - Operation and Maintenance Inspection Schedule

Establish a reasonable and workable inspection schedule considering factors such as: type of structure, hazard rating, watershed characteristics, climate, purpose of reservoir, and type of spillway. The schedule should be based on a consideration of: (1) the conditions peculiar to the structure(s) involved, (2) the need for coordinating the work with other Forest inspections and evaluations, and (3) national and Regional guidelines and standards.

As a minimum, structures classed as high hazard (FSM 7511.2) shall be inspected annually, and also following earthquakes and periods of unusually heavy runoff.

7516.22 - Followup Action

When an inspection discloses operation or maintenance deficiencies, the Forest Supervisor shall:

1. For Forest Service structures, establish a reasonable maintenance schedule based on the priority of identified maintenance, and schedule appropriate restoration and repairs.

2. For special use structures, inform the owner promptly by letter and, if applicable, furnish a copy to the State. The notice should:

   a. Describe the deficiencies, and explain the nature and urgency of needed changes or repairs.

   b. Require the holder to submit a proposed maintenance schedule.

   c. Require the holder to certify by letter when the identified maintenance has been completed.

Any dam having deficiencies which seriously affect the integrity of the structure must be promptly repaired, or wholly or partially removed from service until repairs are made (FSM 7503). See FSM 2715 for direction on taking administrative action.

7516.23 - Dams Not Under Forest Service Jurisdiction

When a dam is located on private land or is under the jurisdiction of another Federal agency (and not subject to inspection by the Forest Service), and conditions endangering Forest Service lands are observed, the owner or the agency having jurisdiction over the dam shall be promptly notified. Notify the Regional Director and the Director, Division of Dam Safety, for the Federal Energy Regulating Commission (FERC) of any dams on Forest Service lands that are not under FERC license but appear to be under FERC jurisdiction.

7516.3 - Safety Inspections and Hazard Assessment

The Federal Guidelines for Dam Safety require the periodic inspection and evaluation of dams for the purpose of protecting human life and property. The documented safety inspection entails a review by highly trained specialists of all pertinent information, including records on design, construction, instrumentation, operation, maintenance, and inspection; and a detailed field inspection of the dam and appurtenant structures. Base the inspection on current design standards and practices. Adjust the effort and degree of detail involved for a safety inspection in accordance with the structure's size and hazard classification.

7516.31 - Inspection and Hazard Assessment Schedule

Prepare a schedule for safety inspection or hazard classification review for each dam. Perform and record safety inspections for high hazard dams at intervals not exceeding 5 years. Some dams may require more frequent safety inspections, depending on experience or project history, such as active seepage on face of dam or active surface erosion.

Perform and document hazard classification reviews at least every 5 years for moderate and low hazard dams.

1. Forest Service Dams. The Forest Service is responsible for safety inspections of Forest Service-owned dams. Safety inspections performed by other responsible agencies or licensed engineers by contract are acceptable.

2. Special Use Dams. The authorization holder is responsible for having safety inspections performed by a qualified engineer at the frequency prescribed in the special use authorization. Safety inspections performed by other responsible federal or State agencies are acceptable.

7516.32 - Report Review and Approval

The Regional Staff Director for engineering activities is responsible for review and approval of safety inspection reports (FSM 7504.3).

7517 - EMERGENCY ACTION PLANS

Prepare, test, and maintain emergency action plans for all high hazard dams. Emergency action plans, whether prepared by the Forest Service, permit holder, State, or other party should be prepared in a degree of detail commensurate with the hazard and coordinated with local officials. The schedule for personnel training and emergency action plan testing shall be the same as for inspections and hazard assessments (FSM 7516.21). See FSH 7509.11, ch. 50, for procedures and information to be included in a plan and how to test the plan. The emergency action plan will include flood inundation maps.

For new or proposed dams, prepare the emergency action plan during the design stage (FSM 7521.03). The plan must reflect construction activities for new dams and major reconstruction for existing dams.

Plans should be updated promptly after each change in involved personnel or their phone number. Personnel and phone number changes shall be made on the plan annually, as a minimum. A comprehensive review of the emergency action plan shall be made whenever safety inspections and hazard assessments are performed or reviewed (FSM 7516). Any changes in the plan must be provided to all plan holders. The comprehensive review shall include an assessment of the need for training and plan testing.

7517.1 - Forest Service Dams

The Forest Supervisor is responsible for preparing and testing the emergency action plan.

7517.2 - Special Use Dams

The authorization holder is responsible for preparing and testing the plan Emergency Action plan.

7518 - STRUCTURAL FAILURE REPORT

In case of the failure of a dam or a major appurtenant structure, promptly investigate and report the event as required in FSH 7509.11, ch. 60. See FSM 6730 for additional details on independent investigations.

7525 - CHANNEL PLANNING, INVESTIGATION, AND DESIGN 10

7521 – SCHEDULING

Schedule management and engineering steps to:

1. Design dam in an effective and economic manner.

2. Ensure compliance with program objectives, environmental concerns, and public safety.

7521.03 – Policy

Ensure that the design of dams complies with the forest plan, feasibility studies, environmental impact assessments, site investigations, and that appropriate coordination and review occurs at all stages of the design process. Final design review and approval by the Regional Office and State and Federal regulatory agencies, as appropriate, must precede construction (FSH 7509.11, sec. 10). Reviews shall be appropriate for the size and hazard classification of the dam. Prepare the emergency action plan during the design phase when required (FSM 7517 and FSH 7509.11, ch. 50).

7522 - DESIGN RECORDS

Keep design records orderly and current to allow efficient review at any stage. Design records must be complete and understandable, since they may form the basis for later actions such as design changes, modification or addition of appurtenant works, investigation of structural deficiencies, periodic safety evaluations, hazard assessment, emergency action plans, and possible litigation. Scope and detail of the design record will vary with the complexity and risk of the project.

Design related correspondence should contain a full presentation of the pertinent facts and discussion, and document progress in selection of alternatives or other matters affecting the design.

A final design summary should provide a permanent record of the design analysis and decisions, and an index to the design records.

7523 – PLANNING

In the planning stage, consider alternate sites and structure types to meet objectives, minimize project costs, and minimize social and environmental impacts (FSM 1950). Constraints may include minimum stream flow requirements, water rights, forest plan requirements, project funds, the dam hazard class and environmental issues such as wetlands. The environmental analysis process should consider these constraints as well as the benefits of reservoir storage. Consider flood storage for Forest Service-owned dams when the potential benefits exceed additional construction costs.

Gather data needed to assess alternatives and to plan data collection for design from available maps, records, and site reconnaissance. Field surveys and subsurface investigations may be necessary, depending on complexity and risks of the project.

7523.05 - Definitions

(FSM 7505 and FSH 7509.11, sec. 05).

Freeboard. The vertical distance in feet between the maximum water storage level and the top of the dam.

Inflow Design Flood. (IDF). The largest flood, measured in cubic feet per second, that a given project is designed to pass safely. The reservoir inflow-discharge hydrograph used to estimate the spillway discharge capacity requirements, and corresponding maximum surcharge elevation in the reservoir.

Normal Storage. The storage space, measured in acre-feet, in a reservoir as measured from the low point of the upstream toe of the dam or from the inlet invert of the outlet conduit, whichever is lower, up to the crest of the lowest uncontrolled spillway.

Probable Maximum Flood. (PMF). The most severe flood, measured in cubic feet per second, that is considered reasonably possible at a site as a result of meteorological and hydrologic conditions.

7524 - GENERAL DESIGN STANDARDS

The level of design detail increases from preliminary to final design and with increasing size, value, and Forest Service hazard classification of the structure. The level of detail of the investigation, design, design reports, and drawings shall be adequate to construct a safe dam within acceptable factors of safety for the size and hazard classification of the structure. Design standards and procedures of the Soil Conservation Service, Bureau of Reclamation, and the Corps of Engineers are acceptable for water and sediment storage dams on National Forest lands.

U.S. Bureau of Mines design standards may be most appropriate for tailings dams. Other generally accepted standards and methods may be accepted on a case-by-case basis. Other authorities that have jurisdiction may require additional or more stringent standards.

7524.1 - Hydrology and Flood Routings

Use generally accepted procedures appropriate for the dam site, such as those established by the Soil Conservation Service, the National Weather Service, and the Bureau of Reclamation, for determining the design storm event and sizing the spillway. Consider site specific evaluations for accepting smaller inflow design hydrographs. Several analysis methods and flood routing trials may be required to establish the most appropriate design flood and to size the spillway.

7524.11 - Incremental Damage Analysis

Perform an analysis using one storm event with two flood routing conditions, that is (1) where the dam overtops without failure, and (2) where the dam overtops with failure, to determine flood damage and potential loss of life resulting from the sudden release of water stored in the reservoir. Incremental damage is the "additional" damage resulting from the greater flood stage of routing the flood with dam failure over that expected from routing without dam failure. In addition to flows from the reservoir, consider also flows from the tributaries downstream of the reservoir in the incremental analysis. The flood routings should extend downstream to a point at which no further significant incremental damage will occur.

7524.2 - Hazard Assessment

Determine a high hazard rating, and tentative moderate or low hazard rating, as defined in FSM 7511.2, based on the clear weather breach flood damage from the dam to a point downstream where the flood is contained within the channel banks. Consider the reservoir full to the crest of the uncontrolled spillway, and calculate the realistic time required for complete breach to occur for the type and size of dam. Consider and document reasonably foreseeable downstream development as well as existing development in the assessment.

Check moderate and low hazard ratings for a possible high hazard rating based on "Incremental Damage Analysis" determined by routing the inflow design storm without a dam failure, and with an overtopping dam failure. If analysis indicates that the failure of the dam causes no loss of human life or no additional excessive economic loss when compared to overtopping without failure, then the dam shall not be classified as high hazard (FSM 7524.32, ex. 01).

7524.3 - Spillway Sizing

7524.31 - Spillway Sizing Standards

Size the spillway to safely pass the inflow design flood shown in exhibit 01.

7524.31 - Exhibit 01

Minimum Required Inflow Design Flood

Hazard Potential	Size Class	Inflow Design Flood
HIGH	A	PMF*
	B	PMF
	C	PMF
	D	PMF
MODERATE	A	3/4 PMF
	B	1/2 PMF
	C	1/2 PMF
	D	1/2 PMF
LOW	A	100 YEAR**
	B	100 YEAR
	C	50 YEAR
	D	50 YEAR

* Probable Maximum Flood
** Return Frequency in Years

7524.32 - Exceptions to Spillway Sizing Standards

Smaller inflow design floods may be used if documented analysis shows that:

1. Overtopping the dam crest by the appropriate comparison flood as described in FSM 7524.31, exhibit 01 will not cause failure of the dam.

2. Through incremental damage analysis, failure would not cause additional loss of human life, and property damage is less than the cost of building additional spillway capacity.

To determine exceptions to spillway sizing standards (FSM 7524.31, exhibit 01), use the decision tree in FSM 7524.32, exhibit 01 for evaluating hazard classification and spillway size requirements based on incremental damage analysis for determining exceptions to FSM 7524.31, exhibit 01.

7524.32 - Exhibit 01

Decision Tree For Incremental Analysis

(1) Route a storm causing a full spillway (spillway at design capacity) through the dam without a dam failure. Is there potential loss of human life from this flood?

yes — no

(2) Route the same storm causing a full spillway through the dam with an overtopping dam failure. Is there potential loss of human life from this flood?

yes — no

(3) Is the potential loss of human life greater from the flood with an overtopping dam failure than from the flood without a dam failure?

yes — no

(4) Can a spillway size be found in which the potential loss of human life from the routed store is no greater with dam failure than from the routed storm without a dam failure?

no — yes

(5) This is a high hazard dam requiring a probable maximum flood size spillway.

(6) Use this storm to evaluate incremental damage, the additional damage that can be expected from the overtopping dam failure above the damage expected from the flood without a dam failure. What is the hazard classification based on incremental damage? Use the higher hazard classification from clear weather breach and incremental damage analysis.

Low — Moderate — High

(7) Is the savings from constructing this size spillway in comparison to constructing the spillway required from FSM 7524.31, exhibit 01, less than the incremental loss potential, including the cost of repairing the breached dam?

yes — no

(8) This size spillway can be constructed.

(9) Use the spillway size from FSM 7524.31, exhibit 01.

Existing dams which can pass at least 75 percent of the design flood will not need to be modified to increase spillway capacity to the 7524.31, exhibit 01 minimums until major reconstruction is implemented.

7524.33 - Spillway Design

The uncontrolled spillway capacity shall be sufficient to pass the inflow design flood. Flow capacity from unattended gates shall not be included in the design capacity calculation. Flow capacity from automatic gates or resident-attended gates may be included in the spillway design capacity calculation. For a reservoir without a flood pool, start routing the inflow design flood at the lowest uncontrolled spillway crest elevation. For a reservoir with a flood pool, start routing the inflow design flood at the elevation of the water surface that would exist after 10 days of drawdown from the 100-year flood pool.

7524.4 - Investigation and Design Criteria

Apply the site investigations and design criteria of sections 7524.41 through 7524.48 to new dams, enlargement of existing dams, or for dams considered structurally unsafe. Any variance from these criteria must be submitted to the Regional Staff Director for engineering activities for approval.

7524.41 - Site Investigation

Investigate and test a potential dam site to the extent appropriate to the size and hazard of the dam as well as for possible geologic features that influence the risk of failure. Low hazard dams and class C moderate hazard dams require, as a minimum, a field geology report with soil borings or test pits penetrating to bed rock or a distance equal to half the height of the dam. Additionally, class A and B moderate and all high hazard dams require borings that penetrate to bedrock or 1-1/2 times the height of the dam, whichever is shallower, and adequate field and laboratory testing of materials to determine stability and to perform a seepage analysis.

7524.42 - Structure Stability

Soil Conservation Service guidelines may be used to design low hazard earth dam side slopes. Analyze moderate and high hazard dam embankment stability to demonstrate that all pertinent static and dynamic loading conditions will not exceed allowable shearing stresses in the embankment or foundation. Ensure the factors of safety and allowable shear stresses used in the design are appropriate for the construction and operating conditions. In most cases, embankments should be designed for unrestricted rates of reservoir filling and drawdown.

7524.43 - Earthquake Design

Consider earthquake hazards in site investigation and analysis for all high and moderate hazard dams. Consider also earthquake related concerns such as fault displacement; soil liquefaction; cracking potential; type of structure; structure stability, abutment stability, and reservoir slope stability; overtopping effects; and required defensive measures such as emergency action plans.

7524.44 – Geosynthetics

Geosynthetic fabrics may be used in constructing low hazard dams. Geosynthetic fabrics may be used in moderate and high hazard dams for applications involving the structural stability of the dam (i.e., impermeable membrane cutoffs and internal filter drains) only after consultation with other Federal agencies or private engineering consultants experienced in designing dams and geosynthetic fabric installations.

7524.45 - Outlet Works

All dams except moderate hazard class D and low hazard class C and D dams and debris dams shall have outlet works capable of releasing the top 5 feet of the reservoir capacity within 5 days, and shall also be capable of draining at least two-thirds of the normal storage volume. When selecting minimum pipe diameter, also consider the potential for plugging and ease of inspection. Corrugated metal pipe is restricted to moderate hazard class D and low hazard class C and D dams, unless otherwise approved by the Regional Staff Director for engineering activities. Include the life-cycle cost when considering its use. Locate outlet control works on the upstream side of the dam.

7524.46 – Flashboards

Flashboards with shear pins or failure supports are not permitted in uncontrolled spillways. Other types of flashboards must be approved by the Regional Staff Director for engineering activities.

7524.47 – Access

Provide all weather road access for operation and maintenance of high hazard dams. Moderate hazard dams may be accessible by seasonal roads, and low hazard dams should be accessible for construction equipment. Access to dams in wilderness areas varies with circumstances and will be handled case by case.

7524.48 – Instrumentation

Where necessary, provide instrumentation for measurement of physical changes that could affect dam safety. Depending on the size, hazard and design of the dam, and the foundation conditions, consider installing an instrumentation system to observe changing conditions in the foundation, embankment, and abutments during construction, initial reservoir filling, and during project operation.

7524.49 - Additional Design Items

In addition to the criteria in FSM 7524.41-7524.48, the following items should be considered in dam design: sediment storage; residual freeboard above design flood stage for wave action; wave erosion protection; slope erosion protection; spillway erosion protection; internal erosion protection; and added embankment height to compensate for settlement. Earthen dam crest width (W) shall be a minimum of 10 feet and increase in width based on dam height (H), $W = (H + 35)/5$. Earthen dams over 100 feet high shall have a minimum crest width of 28 feet. Limit projected frequency of use of unlined earth and vegetated spillways to once in 50 years.

7525 - CHANNEL PLANNING, INVESTIGATION, AND DESIGN

See FSH 7509.11, section 82 for direction on channel layout.

FSM 7500 - WATER STORAGE AND TRANSMISSION
CHAPTER 7530 - CONSTRUCTION

Table of Contents

7530.2 - Objectives 2
7530.3 - Policy 2
7530.5 - Definitions 2
7531 - CONSTRUCTION MANAGEMENT 2
7531.1 – Inspection 2

7532 - INSPECTION OF CONSTRUCTION OPERATIONS 4
7532.1 - Forest Service Inspection of Special Use Projects 4

7530.2 - Objectives

1. To determine that the intent of a project design is met.

2. To ensure that new field information acquired on site during construction is properly incorporated in the design.

7530.3 - Policy

1. Construction inspection personnel shall maintain close coordination with design personnel, especially for design changes, throughout the period of project construction.

2. Forest Service officers shall not permit water to be stored behind a dam or water flow introduced into a canal or similar structure until the requirements outlined in FSM 7531.3 are met.

7530.5 - Definitions

Certificate of Compliance. An affidavit stating that a completed project conforms to the applicable specifications.

Continuous Inspection. The continuous presence of the inspector, or inspectors, at the work site while work is in progress.

Periodic Inspection. The intermittent presence of the inspector during the progress of the work.

7531 - CONSTRUCTION MANAGEMENT

7531.1 – Inspection

Provide inspection by personnel especially trained for, and regularly assigned to, similar work. Ensure continuous or periodic inspection is appropriate for the construction work in progress (FSM 7532).

Where an independent design review team has been established for a project, the team shall be given the latitude for direct contact with construction inspection personnel and for inspecting the project at their discretion.

7531.11 - Special Use Projects

1. Forest Service Monitoring. Monitor special use construction sufficiently to determine that:

a. Inspection by the holder's inspector is adequate, effective, and is conducted by qualified personnel.

b. The holder's engineer promptly submits planned construction schedules to the Forest Service.

c. The holder's engineer keeps the Forest Service informed of construction progress so that any required joint inspection at critical periods can be planned.

d. The holder's engineer obtains Forest Service approval of design changes prior to implementing those changes.

e. Proper attention is given to protection of adjacent lands and facilities from damage by construction operations.

2. State Coordination. Coordinate Forest Service monitoring and joint inspections with State and other involved agency representatives to promote efficiency and consistent communications.

7531.2 - Records and Reports

7531.21 - Forest Service Projects

Records and reports shall conform to the requirements of FSH 6309.31 and FSH 6309.32.

A final construction report shall be prepared for projects requiring Regional Forester approval (FSM 7504).

Keep the final construction report, including photographs taken during construction, in the project file for reference (FSH 7509.11, ch. 10).

7531.22 - Special Use Projects

Ensure that the holder complies with the terms and conditions of the permit as set out in FSH 2709.11, sec. 53.1, clause B37 to provide the Forest Service required information and record keeping.

7531.3 - Certification of Construction

Ensure that the holder complies with the terms and conditions of the permit as set out in FSH 2709.11, sec. 53.1, clause B37 for inspection of construction of the dam.

Approval of drawings and specifications does not authorize operation of the completed works. The structure may be operated only after the Regional Staff Director for engineering activities has certified in writing that the structure is acceptable for water storage or transmission, and approval is received from an authorizing official (FSM 7505). Additional construction approvals may be necessary from the State or other involved agencies.

The Regional Staff Director for engineering activities shall take such action as deemed necessary to verify compliance prior to granting approval to operate the structure.

7532 - INSPECTION OF CONSTRUCTION OPERATIONS

The primary responsibility for inspection rests with the party proposing construction. The Forest Service may monitor a special use holder's inspection procedures and documentation to verify adequacy.

7532.1 - Forest Service Inspection of Special Use Projects

1. Continuous Inspections. Continuous inspection is required when the quality of any work cannot be determined accurately by periodic inspection, or the work cannot readily be removed and replaced if rejected. Examples include:

a. Excavating the foundation when the depth must be determined during the course of the work or when the foundation is under water.

b. Placing compacted earthfill and filters.

c. Placing and bedding pipe.

d. Mixing and placing concrete and pneumatically applied mortar.

2. Periodic Inspections. Periodic inspection may be suitable for certain other types of work depending on the circumstances at the site, the construction schedule, or the contractor's level of ability. Examples include:

a. Clearing and grubbing.

b. Stripping or structure removal.

c. Constructing the forms.

d. Placing the steel reinforcements.

96306-2:n:01/28/2008:MCS/aw LRS2008-337

HB454
By Representatives Wood, Canfield, McCutcheon, Laird, Bridges and Fite
RFD Commerce
Rd 1 14-FEB-08

SYNOPSIS: This bill would provide for the inventory and classification of dams by the Water Resources Division of the Alabama Department of Economic and Community Affairs; to define terms associated with the safety of dams; to provide that no action for damages could be brought against the state by reason of any action taken or not taken by the state pursuant to this act; to authorize the promulgation of rules; and to provide for criminal and civil violations.

Amendment 621 of the Constitution of Alabama of 1901, now appearing as Section 111.05 of the Official Recompilation of the Constitution of Alabama of 1901, as amended, prohibits a general law whose purpose or effect would be to require a new or increased expenditure of local funds from becoming effective with regard to a local governmental entity without enactment by a 2/3 vote unless: it comes within one of a number of specified exceptions; it is approved by the affected entity; or the Legislature appropriates funds, or provides a local source of revenue, to the entity for the purpose.

The purpose or effect of this bill would be to require a new or increased expenditure of local funds within the meaning of the amendment. However, the bill does not require approval of a local governmental entity or enactment by a 2/3 vote to become effective because it comes within one of the specified exceptions contained in the amendment.

A BILL
TO BE ENTITLED
AN ACT

To provide for the inventory and classification of dams by the Water Resources Division of the Alabama Department of Economic and Community Affairs for the purpose of assuring the safety of state dams; to define certain terms associated with dams and dam safety; to provide that no action for damages shall be bought against the state by reason of any action taken or not taken by the state pursuant to this act; to authorize the promulgation of rules; to provide criminal and civil penalties for violations; and in connection therewith would have as its purpose or effect the requirement of a new or increased expenditure of local funds within the meaning of Amendment 621 of the Constitution of Alabama of 1901, now appearing as Section 111.05 of the Official Recompilation of the Constitution of Alabama of 1901, as amended.

BE IT ENACTED BY THE LEGISLATURE OF ALABAMA:

Section 1. This act shall be known and may be cited as the "Alabama Dam Inventory and Classification Act."

Section 2. (a) It is the purpose of this act to provide for the inventory and classification of dams in order to protect the health, safety, and welfare of all the citizens of the state.

(b) The Legislature finds and declares that the inventorying and classification of dams is properly a matter for regulation under the police powers of the state for the safety, protection, and welfare of the citizens of Alabama.

Section 3. As used in this act, the following terms shall have the following meanings:

(1) ABANDON or ABANDONMENT. To render a dam non-impounding by dewatering and making the dam incapable of impounding water.

(2) ADVERSE CONSEQUENCES. Negative impacts that may occur upstream, downstream, or at locations remote from a dam as a direct and proximate result of the existence or operation of the dam. The primary concerns for adverse consequence are loss of human life, loss of critical infrastructure, property damage, and lifeline disruption.

(3) ALTERATIONS or REPAIRS. Alterations, modifications, or repairs to existing dams or appurtenant works as may directly affect the safety of the dam or reservoir, as determined by the office.

(4) APPROVAL. Authorization in writing issued by the director to an owner who has applied to the office for permission to construct, reconstruct, enlarge, repair, alter, modify, remove, maintain, operate, or abandon a dam, and which specifies the conditions or limitations under which work is to be performed by the owner or under which approval is granted.

(5) APPURTENANT WORKS. The term includes, but is not limited to, such structures as spillways, either in the dam or separate therefrom; the reservoir and its rim; low-level outlet works; and liquid conduits such as tunnels, pipelines, or penstocks, either through the dam or its abutments.

(6) BREACH. Partial removal of a dam, creating a channel through the dam.

(7) CERTIFICATE. For a high hazard potential dam the term means a written authorization issued by the director to construct or operate, or both, a dam. For all other dams the term means a written acknowledgement of dam construction or removal solely for inventorying purposes.

(8) CONSTRUCT or CONSTRUCTION. The design, building, alteration, reconstruction, or enlargement of any dam for the impoundment or diversion of water or liquid substance and shall include any activity which, other than routinely as part of an approved maintenance program, repairs or restores the dam, or alters its design, shape, or structural characteristics.

(9) CRITICAL INFRASTRUCTURE. Systems and assets associated with or impacted by dams or impoundments, whether physical or virtual, so vital to Alabama that the incapacity or destruction of such a system or asset would have a debilitating impact on security, economic stability, public health or safety, or any combination of those matters, consistent with the "Critical Infrastructure Protection Act of 2001."

(10) DAM. Any artificial barrier, including appurtenant works, which impounds or diverts water, wastewater, or liquid-borne materials and which meets any of the following criteria:

a. Has an impounding capacity at maximum water storage elevation of at least 50 acre-feet.

b. Is 25 feet or more in height.

c. Will create a probable loss of human life in the event of failure or improper operation, regardless of height or storage capacity.

d. Will create a probable loss of critical infrastructure in the event of failure or of improper operation, regardless of height or storage capacity.

(11) DIRECTOR. The Director of the Office of Water Resources or his or her designee. The director or designee must be an engineer. The director must have a current license to practice engineering in the State of Alabama.

(12) ENGINEER. A qualified professional engineer. The term qualified professional engineer as used in this act is intended to mean an individual who has a background in civil engineering and meets all the following qualifications:

a. Is a licensed professional engineer in the state.

b. Is competent in areas related to dam investigation, design, construction, and operation for the type of dam being investigated, designed, constructed, or operated.

c. Has at least seven years of relevant experience in areas such as investigation, design, construction, reconstruction, enlargement, repair, alteration, maintenance, operation, breach, removal, or abandonment of dams.

d. Either (i) understands adverse dam incidents, failures, and the potential causes and consequences of failures; or (ii) is the state conservation engineer of the Department of Conservation and Natural Resources.

(13) ENLARGE or ENLARGEMENT. Any change in or addition to an existing dam or impoundment which raises or may raise the maximum water storage elevation of the liquid impounded by the dam or reservoir.

(14) HAZARD POTENTIAL. Possible adverse consequences that result from the release of water or stored contents due to failure or improper operation of the dam or appurtenant works. The hazard potential classification of a dam does not reflect in any way on the current condition of the dam and its appurtenant works, such as, but not limited to, the safety, structural integrity, or flood routing capacity.

(15) HEIGHT. The term means either (i) the distance from the natural bed of the impoundment, stream, or watercourse measured at the downstream toe of the dam to the maximum water storage elevation; or (ii) the distance from the lowest elevation of the outside limit of the dam, if the dam is not across a stream channel or watercourse, to the maximum water storage elevation.

(16) HIGH HAZARD POTENTIAL DAM. A dam assigned the high hazard potential classification where failure or improper operation will cause probable loss of human life.

(17) LOCAL UNIT OF GOVERNMENT. Any political subdivision of this state including, but not limited to, a county, city, town, or municipality, if the political subdivision provides local governmental services in a geographically limited area of this state as its primary purpose and it has the power to act primarily on behalf of that area.

(18) LOW HAZARD POTENTIAL DAM. A dam not assigned the moderate or high hazard potential classification.

(19) MAXIMUM WATER STORAGE ELEVATION. The elevation of the top of the dam.

(20) MODERATE HAZARD POTENTIAL DAM or SIGNIFICANT HAZARD POTENTIAL DAM. A dam assigned the moderate hazard potential classification where failure or improper operation results in no probable loss of human life but will cause probable loss of critical infrastructure.

(21) OFFICE. The Office of Water Resources, a division of the Alabama Department of Economic and Community Affairs or its successor.

(22) OPERATE or OPERATION. To take actions to control the impoundment or diversion of a liquid substance by a dam.

(23) OWNER. Any person who owns, controls, operates, maintains, or manages or proposes to construct, reconstruct, enlarge, repair, alter, remove, or abandon a dam or reservoir.

(24) PERSON. Any and all persons, natural or artificial, including any individual, entity, firm, association, organization, partnership, business, trust, corporation, company, any federal agency, authority, or corporation created by the United States of America, and the state and all political subdivisions, regions, districts, municipalities, counties, and public agencies thereof.

(25) PROBABLE LOSS OF CRITICAL INFRASTRUCTURE. The loss of critical infrastructure is likely to occur, is reasonably expected to occur, or is the actual result of any action or inaction.

(26) PROBABLE LOSS OF HUMAN LIFE. Loss of human life that will likely occur, is reasonably expected to occur, or is the actual result of any action or inaction.

(27) RECONSTRUCTION. Removal and replacement of an existing dam.

(28) REMOVE or REMOVAL. Complete elimination of a dam embankment or appurtenant works, or both.

(29) RESERVOIR or IMPOUNDMENT. Any basin which contains or will contain impounded water, wastewater, or liquid-borne materials by virtue of its having been impounded by a dam.

(30) RESPONSIBLE AUTHORITY. Those state, county, city, or other offices that are charged with maintaining public safety and that are listed in any emergency action plan required by this act or any rule promulgated pursuant to this act.

(31) RULES. The most recent policies, requirements, regulations, administrative rules, or standards adopted by the office pursuant to the Alabama Administrative Procedure Act, codified as Chapter 22, Title 41, Code of Alabama 1975, as amended, in order to enforce this act.

(32) STATE. The State of Alabama.

(33) SURFACE MINING ACT. Chapter 16, Title 9 of the Code of Alabama 1975, as amended.

Section 4. (a) In addition to any other powers and duties provided in this act, the director shall perform

the following duties:

(1) Exercise general supervision over the administration and enforcement of this act and the rules promulgated under this act.

(2) Advise, consult, cooperate, contract, and enter into cooperative agreements with persons, local units of government, and other governmental agencies or committees, including, but not limited to, the State Soil and Water Conservation Committee, the Alabama Department of Environmental Management, the Department of Conservation and Natural Resources, the Alabama Department of Transportation, the Alabama Association of Conservation Districts, or the Unites States Army Corps of Engineers for the purposes of carrying out this act.

(3) Take such other actions as may be necessary to carry out this act.

(4) Specify conditions under which any employee of the office or its agents may enter upon lands of owners of dams.

(5) Direct, conduct, and supervise investigations, as the director deems necessary to carry out the duties as prescribed in this section.

(b) In the performance of its duties, the office shall establish, adapt, modify, and repeal, by the promulgation of rules, such policies, requirements, conditions, or standards governing the inventory and classification of dams covered under this act, including, but not limited to, the following:

(1) Standards to govern the inventory of dams.

(2) Report necessary dam information to the National Performance of Dams Program, as requested.

(3) Report inventory and other necessary information to the National Inventory of Dams, as requested.

Section 5. (a) The office shall inventory the dams in the state and classify each dam into one of the following categories:

(1) Low hazard potential.

(2) Moderate hazard potential.

(3) High hazard potential.

(b) The office may gather necessary updated information regarding the characteristics of a dam and its surroundings in order to verify classification.

(c) The office may use information furnished to it by other persons to accomplish the purpose of this act and this section including, but not limited to, the classification of dams as set forth in subsection (a).

Section 6. (a) The following low hazard potential dams are not required to be included in the inventory of dams maintained pursuant to this act:

(1) Any dam which is less than six feet in height, regardless of its storage capacity.

(2) Any dam which has an impounding storage capacity at maximum water storage elevation of less than 15 acre-feet, regardless of its height.

(b) The following dams shall be exempt from all regulatory requirements of this act, except as necessary to maintain the inventory of dams pursuant to this act:

(1) Any dam owned and operated by any department or agency of the United States government, provided those dams are regulated in a manner that meets or exceeds the requirements of this act.

(2) Any dam licensed by the Federal Energy Regulatory Commission, or for which a license application is pending with the Federal Energy Regulatory Commission.

(c) Any dam regulated and permitted under the Surface Mining Act is exempt from this act so long as the dam is subject to regulation by the Surface Mining Act. However, if a dam so constructed is classified by the director as a high hazard potential dam, the owner, upon the completion of the mining activity in connection with which the dam was constructed, shall either drain and reclaim the impoundment formed by the dam pursuant to the mined land use plan approved under the Surface Mining Act or stabilize the impoundment as a lake pursuant to the mined land use plan and the rules promulgated under this act. If the impoundment is reclaimed as a lake and the dam which created the impoundment remains in place as a high hazard potential dam, then before the lake is deemed to be reclaimed so as to release the owner from his or her obligations under the Surface Mining Act, the owner shall certify to the director and the owners of the properties on which the high hazard potential dam is located that the high hazard potential dam is in full compliance with this act.

(d) The owners of exempt dams shall be required to submit information to the agency in accordance with rules promulgated under this act for purposes of maintaining the inventory.

Section 7. (a) The director, or any authorized agent or contractor, is authorized and shall be permitted by the owner to make a visual inspection of a high hazard potential dam.

(b) This act shall not be construed as exempting any existing dam from compliance with applicable engineering design standards or requirements.

(c) With regard to moderate and low hazard potential dams, the office is not required to perform structural inspections of a moderate or low hazard potential dam.

Section 8. (a) It shall be unlawful for any person to refuse entry or access to any authorized representative of the office who requests entry for purposes of fulfilling the requirements of this act and who presents appropriate identification. It shall also be unlawful to obstruct, hamper, or interfere with any representative while in the process of carrying out his or her official duties, including, but not limited to, classification determination pursuant to this act and the rules promulgated under this act.

(b) Any person who is aggrieved or adversely affected by an order or action of the director or the office may seek a review of the order or action in accordance with the Alabama Administrative Procedure Act, codified as Chapter 22, Title 41, Code of Alabama 1975, as amended, in order to enforce this act.

Section 9. (a) Nothing in this act shall be construed to constitute a waiver of the sovereign immunity of the state or the office.

(b) No legal or administrative action shall be brought against the state, the office, the director, or any

member, officer, or employee of the state or the office for damages sustained through the partial or total failure of any dam or for any action or inaction or responsibility pursuant to this act, including specifically, but not limited to, any action taken or not taken by the office, the director, or the employees, officers, or representatives of the office.

(c) Nothing in this act and any order, action, or advice of the director or the office or any representative thereof may be construed to relieve an owner of the legal duties, obligations, or liabilities incident to the ownership or operation of the dam.

Section 10. Any person who engages in any violation of this act or the rules promulgated under this act shall be guilty of a Class C misdemeanor. Each day of a continued violation shall constitute a separate offense.

Section 11. As an alternative to criminal enforcement pursuant to Section 10, the director may impose civil penalties in accordance with the following provisions:

(1) Whenever the director has reason to believe that any person has violated any provision of this act or rules adopted pursuant to this act, or that a person has negligently or willfully failed or refused to comply with any final order of the director, the director may cause a hearing to be conducted before a hearing officer appointed by the office. Upon a finding that a person has violated any provision of this act, the rules promulgated under this act, or any certificate condition or limitation established pursuant to this act, or that a person has negligently or willfully failed or refused to comply with a final administrative order of the director, the hearing officer shall issue a written decision. The hearing and any administrative or judicial review thereof shall be conducted in accordance with applicable Alabama law.

(2) All civil penalties recovered under this section by the office or by the Attorney General shall be deposited into the State Treasury to the credit of the State General Fund, except that portion representing the reasonable costs incurred to recover the penalties. That portion representing recovery costs shall be deposited to the credit of the operating fund of the office or the Attorney General, whichever incurred such costs.

Section 12. Any owner whose dam is in existence as of the effective date of this act will be required to comply with this act and the rules promulgated under this act once notification has been given as to the classification of the dam by the agency.

Section 13. Although this bill would have as its purpose or effect the requirement of a new or increased expenditure of local funds, the bill is excluded from further requirements and application under Amendment 621, now appearing as Section 111.05 of the Official Recompilation of the Constitution of Alabama of 1901, as amended, because the bill defines a new crime or amends the definition of an existing crime.

Section 14. The provisions of this act are severable. If any part of this act is declared invalid or unconstitutional, that declaration shall not affect the part which remains.

Section 15. All laws or parts of laws which conflict with this act are repealed and superseded by this act.

Section 16. This act shall become effective immediately following its passage and approval by the Governor, or its otherwise becoming law.

11 AAC 93.157. Hazard classification

(a) In order to determine design, operation, inspection, maintenance, emergency action, and reporting criteria under AS 46.17 and 11 AAC 93.151 - 11 AAC 93.201, the department will periodically review and classify each artificial barrier according to the barrier's potential danger to life or property, and will assign the barrier one of the following hazard potential classifications:

(1) a Class I (high) hazard potential classification, if the department determines that the failure or improper operation of the barrier will result in probable loss of human life;

(2) a Class II (significant) hazard potential classification, if the department determines that the failure or improper operation of the barrier will result in

(A) a significant danger to public health;

(B) the probable loss of or probable significant damage to homes, occupied structures, commercial property, high-value property, major highways, primary roads, railroads, or public utilities, other than losses described in (3)(B) of this subsection;

(C) other probable significant property losses or damage, other than losses described in (3)(B) of this subsection; or

(D) probable loss of or significant damage to waters identified under 5 AAC 95.011(a) as important for the spawning, rearing, or migration of anadromous fish; or

(3) a Class III (low) hazard potential classification if the department determines that the failure or improper operation of the barrier will result in

(A) limited impacts to rural or undeveloped land, rural or secondary roads, and structures;

(B) property losses or damage limited to the owner of the barrier; or

(C) insignificant danger to public health.

(b) As necessary to obtain accurate information for a review and classification under (a) of this section, the department will require the owner of an artificial barrier to submit the following information, on a form provided by the department and sealed by an engineer qualified under 11 AAC 93.193(a) :

(1) the type and height of the barrier and the impounding capacity of the reservoir at the maximum storage elevation;

(2) the name of the water body, the location of the barrier and a description of the area downstream;

(3) a proposed hazard potential classification, and any supporting information for that proposed classification; supporting information may include maps, an inundation map prepared in substantial accordance with 11 AAC 93.195, a dam break analysis, photographs, and engineering calculations.

(c) The department may reject a hazard potential classification proposed under (b)(3) of this section and require the owner to submit additional information if the department determines that the

(1) engineer who sealed that information is not qualified under 11 AAC 93.193(a) ; or

(2) information previously provided is insufficient for the department to assign that hazard potential classification.

(d) The department may assign an artificial barrier a higher hazard potential classification than one proposed under (b)(3) of this section. The department will assign the barrier a hazard potential classification based on the level of information readily available regarding the barrier and its potential hazards.

History: Eff. 8/16/89, Register 111; am 10/2/2004, Register 171

Authority: AS 46.17.010

AS 46.17.030

AS 46.17.050

AS 46.17.070

Editor's note: As of Register 186 (July 2008), and acting under AS 44.62.125 (b)(6), the regulations attorney made technical changes to 11 AAC 93.157(a) (2)(D), to reflect Executive Order 114 (2008). Executive Order 114 transferred functions related to protection of fish habitat in rivers, lakes, and streams from the Department of Natural Resources to the Department of Fish and Game.

11 AAC 93.159. Owner's periodic safety inspections

(a) The owner of a Class I or Class II dam shall provide for a periodic safety inspection of the dam at least once every three years. The owner of a Class III dam shall provide for a periodic safety inspection of the dam at least once every five years. The department may order a dam owner to provide for a periodic safety inspection more often than required by this subsection if the department determines that the dam might be unsafe or that more frequent inspections are necessary to protect public safety. Each periodic safety inspection and other work required by this section is at the owner's sole expense. Each periodic safety inspection must be detailed and comprehensive, and must meet the department's guidelines for periodic safety inspections. Those guidelines, set out in Chapter 10, Section 10.4 of the department's *Guidelines for Cooperation with the Alaska Dam Safety Program,* dated September 26, 2003 are adopted by reference.

(b) The periodic safety inspections required by this section must be performed by an engineer who has been approved under 11 AAC 93.193(b) . Before an inspection, the owner shall submit to the department, in writing, the qualifications of the engineer and the scope of the periodic safety inspection. The department will approve the scope of the inspection if the department determines that the scope is adequate to determine the safety of the dam and for the engineer to make reliable recommendations regarding operation and maintenance of the dam, inspections of the dam, and other aspects related to the safety of the dam.

(c) Within 30 days after the visual inspection of the dam is completed, the owner shall submit a periodic

safety inspection report to the department for approval, with as many copies as the department requires. The periodic safety inspection report must be sealed by the engineer approved under 11 AAC 93.193(b) to conduct the inspection. The engineer shall, in the report, make

(1) specific conclusions regarding the safety of the dam, including conclusions with respect to the condition of the dam and the potential for and consequences of any dam failure; and

(2) recommendations for any additional inspections, monitoring, studies, or construction that may be required to improve the safety of the dam.

(d) In response to a periodic safety inspection report, the department may

(1) approve the report, if the department determines that the report adequately reflects the safety of the dam and provides for the maintenance or improvement of the safety of the dam;

(2) request additional detail or clarification in the report;

(3) issue an order requiring the owner to perform additional inspections, studies, or analyses, or to submit additional information that the department determines is necessary to adequately assess the safety of the dam;

(4) revoke, under 11 AAC 93.173(k) , a certificate of approval to operate a dam; or

(5) issue a construction, operation, repair, maintenance, shutdown, or dam removal order that the department considers necessary to protect against dam failure or to protect life and property.

(e) Repealed 10/2/2004.

AS 46.17.060

AS 46.17.070

Editor's note: Copies of Chapter 10, Section 10.4 of the department's *Guidelines for Cooperation with the Alaska Dam Safety Program,* adopted by reference in 11 AAC 93.159(a) , are available from the Department of Natural Resources, Division of Mining, Land and Water, Dam Safety and Construction Unit, 550 West 7th Avenue, Anchorage, Alaska 99501.

11 AAC 93.160. General requirements

Repealed 8/16/89.

11 AAC 93.161. State inspections

(a) The department may inspect a dam or artificial barrier, regardless of its size or hazard potential classification, after providing notice to the owner under AS 46.17.060 .

(b) If the department determines that providing two weeks' notice under AS 46.17.060 is not practical because the dam or barrier presents a potential immediate danger to life or property, the department will give the owner of the dam or barrier as much notice before the inspection as is reasonable under the circumstances.

(c) The owner of a dam shall reimburse the department for costs that the department incurs in making an inspection under this section, including the costs of conducting related dam safety studies and analyses and employing consulting engineers or contractors, if the department determines that a condition may exist that could adversely affect the safety of the dam and the

(1) owner has failed or refused to perform a periodic safety inspection in accordance with 11 AAC 93.159; or

(2) periodic safety inspection report submitted under 11 AAC 93.159(c) is inadequate, and the owner has failed to respond to a department order or request for additional information.

History: Eff. 8/16/89, Register 111; am 10/2/2004, Register 171

Authority: AS 46.17.010

AS 46.17.030

AS 46.17.050

AS 46.17.060

11 AAC 93.163. Emergency remedial action

(a) The department may take emergency remedial action to protect life or property from the risks created by the dam's operation or potential failure, if the department determines that one or more of the following conditions exist:

(1) the condition of a dam is sufficiently dangerous to preclude adequate time for the issuance of an order to the owner under 11 AAC 93.159(d) regarding the maintenance or operation of the dam;

(2) actual or potential flooding threatens the condition of the dam;

(3) the owner will not voluntarily comply with an order or does not have the present means to comply with an order from the department.

(b) In taking emergency remedial action under this section, the department may take supervisory control of the dam from the owner, over the owner's objection if necessary, until the emergency no longer exists. During the department's supervisory control of the dam, the owner, agents, and employees of the owner shall comply with all of the department's orders.

(c) The owner shall reimburse the state for the costs of any reasonably necessary emergency remedial action taken under this section, including the costs of any consultant, contractor, emergency response

agency, or other entity retained or requested by the department to respond to the emergency.

History: Eff. 8/16/89, Register 111; am 10/2/2004, Register 171

Authority: AS 46.17.010

AS 46.17.030

AS 46.17.050

AS 46.17.060

AS 46.17.070

11 AAC 93.164. Owner's emergency action plan

(a) The owner of a Class I or Class II dam shall develop and maintain an emergency action plan in accordance with this section.

(b) The department will approve an emergency action plan if

(1) the plan adequately protects life and property, given the particular risks presented to life or property if the dam fails or in anticipation of imminent dam failure;

(2) the plan provides adequately for the coordination of emergency responders in the community;

(3) the plan contains information that the department considers necessary to minimize danger to life and property; that information must include, if required by the department, a

(A) detailed inundation map, prepared in substantial accordance with 11 AAC 93.195;

(B) dam break analysis; and

(C) schedule for exercise and revision of the plan; and

(4) for a Class I dam, the plan is developed and maintained in accordance with

(A) the Federal Emergency Management Agency's *Federal Guidelines for Dam Safety: Emergency Action Planning for Dam Owners* (FEMA 64), as revised as of October 1998 and adopted by reference; or

(B) other requirements that the department determines are necessary to protect life or property.

(c) The owner of a Class I or II dam shall review the emergency action plan at least annually, and shall submit any revision of the plan to the department for approval.

(d) The owner of a Class I or II dam shall exercise the emergency action plan to a level specified by the department as sufficient to maintain adequate preparation for an actual emergency, and shall revise the emergency action plan at least every three years, or at a frequency that the department determines sufficient to maintain adequate preparation for an actual emergency. The plan shall be revised after the

exercise in order to address any problems or areas for improvement identified during the exercise, and shall be submitted to the department for approval. Revised plans must be distributed to all persons with responsibilities identified in the plan.

(e) The owner of a Class II dam may include the emergency action plan in the operations and maintenance manual required under 11 AAC 93.167, 11 AAC 93.171, or 11 AAC 93.173.

11 AAC 93.195. Inundation maps and inflow design flood information

(a) An inundation map prepared under 11 AAC 93.157(b) or 11 AAC 93.164 must

(1) indicate the extent of flooding below a dam after failure under the normal operating level of the reservoir, under the inflow design flood, and under other scenarios as the department considers necessary to evaluate danger to life and property;

(2) identify downstream structures or other development, flood wave depth and arrival times, roads, evacuation routes, staging areas, and other information required by the department to minimize danger to life and property; and

(3) be based on a dam break analysis, if required.

(b) For purposes of 11 AAC 93.164 and 11 AAC 93.171, the information for determining the inflow design flood shall be developed in substantial accordance with

(1) the Federal Emergency Management Agency's *Federal Guidelines for Dam Safety: Selecting and Accommodating Inflow Design Floods for Dams* (FEMA 94), as revised as of October 1998 and adopted by reference; or

(2) methods approved by the department that adequately assess and characterize the design hydrology, and that are based on the hazard potential classification assigned under 11 AAC 93.157.

(c) In this section, "inflow design flood" means the flood flow above which the incremental increase in the downstream flood caused by a failure of the dam does not result in any additional danger downstream.

11 AAC 93.197. Operation and maintenance manuals

(a) An owner that is required under 11 AAC 93.167, 11 AAC 93.171, or 11 AAC 93.173 to prepare or provide an operation and maintenance manual must describe in that manual, in detail, how a dam will

be operated, inspected and maintained, including

(1) a physical description of the dam;

(2) any operating limitations on the dam;

(3) critical design criteria;

(4) a schedule and procedures for routine safety inspections, monitoring, and maintenance of the dam;

(5) detailed instructions and maintenance procedures for operating valves, gates, or other equipment;

(6) maintenance procedures, calibration information, and instructions for instrumentation and for monitoring and alarm systems;

(7) site-specific visual inspection checklists; and

(8) other information requested by the department to provide sufficient detail regarding dam operation, inspection, and maintenance for the protection of life and property.

- Unless the context requires otherwise, in AS 46.17 and 11 AAC 93.151 - 11 AAC 93.201,

(1) "alteration" has the meaning given in AS 46.17.900 ;

(2) "appurtenant works" has the meaning given in AS 46.17.900 ;

(3) "Class I dam" means a dam assigned a Class I (high) hazard potential classification under 11 AAC 93.157;

(4) "Class II dam" means a dam assigned a Class II (significant) hazard potential classification under 11 AAC 93.157;

(5) "dam" has the meaning given in AS 46.17.900 ;

(6) "department" means the Department of Natural Resources;

(7) "enlargement" has the meaning given in AS 46.17.900 ;

(8) "modification" means an enlargement or alteration;

(9) "owner" has the meaning given in AS 46.17.900 ;

(10) "record drawings" means plan, profile, and cross-section drawings that show the final configuration of a dam as constructed, including

(A) lines, grades, elevations, and size;

(B) types of material used for construction;

(C) reservoir area; and

(D) details of all appurtenant works, including spillways, outlet pipes, monitoring devices, and other equipment;

(11) "repair" has the meaning given in AS 46.17.900 ; "repair" does not include routine maintenance;

(12) "routine maintenance" means any work performed on a dam that

(A) is generally of a housekeeping nature; and

(B) does not affect or have the potential to affect the safety of the dam;

(13) "sealed" means prepared by an engineer or a person under that engineer's direct supervision, and bearing the signature and seal of that engineer as required by AS 08.48.221 and 12 AAC 36.185.

Article 4
Temporary Water Use

Section

210. Temporary water use.

220. Procedure for temporary water use.

11 AAC 93.210. Temporary water use

(a) Procedures to authorize the temporary use of water, as provided in 11 AAC 93.220, will apply if the use continues for less than five consecutive years and the water applied for is not otherwise appropriated.

(b) A water right or priority is not established by a temporary water use authorization issued under 11 AAC 93.220. Authorized temporary water use is subject to amendment, modification, or revocation by the department if the department determines that amendment, modification, or revocation is necessary to supply water to lawful appropriators of record or to protect the public interest.

(c) Upon the commissioner's receipt of a written request from the permittee, an authorization for temporary use of water will, in the commissioner's discretion, be extended one time for good cause for a period of time not to exceed five years. The request for an extension of the authorization for temporary use of water must be accompanied by the fee prescribed by 11 AAC 05.010.

11 AAC 93.220. Procedure for temporary water use

ALASKA DAM SAFETY LAWS AND REGULATIONS 2007

Citation

Laws establishing the Alaska Dam Safety Program (ADSP) are found in the Alaska Statutes (AS) Title 46 Chapter 17, effective May 31, 1987. Regulations are in the Alaska Administrative Code (AAC) Title 11, Chapter 93, Article 3, which were last amended October 2, 2004.

History

During the 1970s, several dams failed in both Alaska and the Lower 48. These incidents resulted in numerous deaths, including one in Alaska, and millions of dollars in property damage. As early as 1973, Alaska passed laws that attempted to regulate the construction of dams in the state. In 1975, Senate Bill 362 titled "An Act Relating to Supervision of Safety of Dams and Reservoirs" attempted to delegate responsibility to the Department of Public Works, but failed to pass the Ninth Legislative Session. On May 29, 1978, Governor Jay S. Hammond signed an agreement for the Alaska Department of Transportation and Public Facilities to jointly review specific dams with the USACE. Subsequent discussions within the state led to the conclusion that the ADNR had authority related to dam safety through the Water Use Act (AS 46.15) and 11 AAC 72.060, Dam Construction (1973). However, the ADNR expressed a great deal of concern because the statutes and regulations inadequately addressed important dam safety issues such as routine safety inspections, operation and maintenance, and liability.

On December 29, 1979, revised dam safety regulations became effective under Article 3 of 11 AAC 93, Dam Safety and Construction. By 1982, the Water Management Section of the Division of Land and Water Management began to organize the ADSP. The efforts of the entire staff of the central region Water Management Section were directed toward the dam safety program. Nevertheless, the section's civil engineer expressed concern about the ability of the ADNR to address important technical issues associated with dam safety, and the current regulations were again sharply criticized as inadequate. During the early 1980s, the ADNR (with support from consultants) conducted Phase I inspections and site visits of practically every dam that could be identified in the state, including those identified in the National Inventory of Dams. The USACE listed 175 dams in Alaska in 1981. By 1984, the ADSP was staffed with three positions and a $350,000 general fund budget.

In 1987, the state legislature passed the Alaska Dam Safety Act and AS 46.17, which elaborated on the basis for the state to "supervise" the safety of dams in Alaska. The state was required to employ a professional engineer for this purpose, but the staffing of the ADSP was reduced to that one individual and the budget was cut significantly. In 1989, the dam safety regulations were again promulgated under Article 3 of 11 AAC 93. These statutes and regulations were more comprehensive than previous versions, and were based on a model state dam safety program developed by the ASDSO and extensive review of dam safety regulations from other states.

The content of Article 3 of 11 AAC 93 was reviewed in detail and updated between 2000 and 2004. The regulations were revised to include important changes and clarifications about the hazard potential classification; dam owner's periodic safety inspections and emergency action plans; applications for construction, modification, repair, removal, and

abandonment of dams; certificates of approval issued by the department; incident reporting; qualifications for dam design and inspection engineers; and other important information. The original publication of the Guidelines for Cooperation with the Alaska Dam Safety Program (September 2003) was based on a draft version of the revised regulations. The current guidelines (June 2005) are revised to be consistent with the current, final version of the regulations adopted in October 2004.

Definitions

A *dam* is "an artificial barrier, and its appurtenant works, which may impound or divert water and which has or will have an impounding capacity at maximum water storage elevation of 50 acre-feet and is at least 10 feet in height measured from the lowest point at either the upstream or downstream toe of the dam to the crest of the dam; is at least 20 feet in height; or poses a threat to lives and property as determined by the department after an inspection" (AS 46.17.900(3)).

Dam height is the maximum vertical distance from the natural bed of the water course the upstream or downstream toe of the barrier, whichever yields the greater measurement, to the top of the barrier; or if the barrier is not across a watercourse, the maximum vertical distance from the lowest elevation of the outside limit of the barrier to the top of the barrier. (11 AAC 93.153).

Dam Classification

Dams are classified by hazard potential according to the following (11 AAC 93.157):

Class I for a dam whose failure would, in the opinion of the commissioner, result in probable loss of human life;

Class II for a dam whose failure would result in a significant danger to public health; the probable loss of or probable significant damage to homes, occupied structures, commercial property, high-value property, major highways, primary roads, railroads, or public utilities; other probable significant property losses or damage other than losses limited to the owner of the barrier; or, probable loss of or significant damage to waters identified under 11 AAC 195.010(a) as important for spawning, rearing, or migration of anadromous fish.

Class III for a dam whose failure would result in limited impacts to rural or undeveloped land, rural or secondary roads, and structures; property losses or damage limited to the owner of the barrier; or insignificant danger to public health.

Design Criteria

Hydrologic: From 11 AAC 93.195, the inflow design flood shall be developed in substantial accordance with:

(1) the Federal Emergency Management Agency's Federal Guidelines for Dam Safety: Selecting and Accommodating Inflow Design Floods for Dams (FEMA 94), as revised as of October 1998 and adopted by reference; or

(2) methods approved by the department that adequately assess and characterize the design hydrology, and that are based on the hazard potential classification assigned under 11 AAC 93.157.

In this section, "inflow design flood" means the flood flow above which the incremental increase in the downstream flood caused by a failure of the dam does not result in any additional danger downstream. For a Class I (high) hazard potential dam, the “probable maximum flood” is considered the maximum standard; for a Class III (low) hazard potential dam, a “100-year flood” is considered the minimum standard.

Seismic: From 11 AAC 93.171, seismic parameters for the location of the dam, including the peak ground acceleration, the maximum credible earthquake, the maximum design earthquake, and the operating basis earthquake, must be determined in substantial accordance with the guidelines from the United States Army Corps of Engineers' Earthquake Design and Evaluation for Civil Works Projects, publication ER 1110-2-1806, dated July 31, 1995 adopted by reference, or must be determined in substantial accordance with another approach approved by the department.

Other: From 11 AAC 93.171, an applicant must obtain approval of a proposal prepared by the qualified engineer that outlines the proposed scope of work, methodologies, levels of analysis, and approach to design and construct, repair, or modify a dam to adequately provide for the protection of life and property; the proposal must be based on the proposed size and type of the dam, and based on the hazard potential classification, and must include a description of the design quality assurance and quality control to be conducted during the design.

Jurisdiction/Powers of Department

The Department of Natural Resources supervises the safety of dams and reservoirs (AS 46.17.020). The department has the power to adopt regulations and issue orders necessary to carry out its duties (AS 46.17.030). A person may not construct, enlarge, repair, alter, remove, maintain, operate, or abandon a dam or reservoir without the approval of the department (AS 46.17.040). The department has the power to make inspections (AS 46.17.050). The department may enter a dam or reservoir premises without notice if there is reason to believe that a dam or reservoir may be unsafe or presents an imminent threat to life or property (AS 46.17.060). The department may order the owner to take action to protect life and property if it determines the dam or reservoir is unsafe (AS 46.17.070) and may invoke judicial action to enforce the laws and regulations (AS 46.17.080). The department may take supervisory control of the dam from the owner in emergency situations (11 AAC 93.163).

Permit/Approval Process

No person may abandon a dam, remove a dam, or begin the construction, enlargement, modification, or repair (except routine maintenance) of a dam without first applying for the commissioner's permission on a form provided by the commissioner, paying the applicable fees under 11 AAC 05.010, and receiving a certificate of approval from the commissioner for the proposed action. 11 AAC 93.171 defines a detailed application process that includes the following information and documents, unless the department determines that an item or document is not required for the protection of life or property: 1) an initial application package, 2) a preliminary design package, 3) a detailed design package, 4) a final construction package, 5) pre-construction plans, and 6) post-construction documentation. Additional details for each of these packages are described in the regulations. In addition, the applicant must propose a schedule for filing the information and documents required under this section that provides adequate opportunity for the department to review the safety

of the dam and for issuing the required certificates of approval. Furthermore, the applicant must demonstrate financial ability or provide financial assurance, for certain actions, for new dams or for modifications that increase the size of the reservoir or raise the hazard potential classification of the dam. The application must be prepared and sealed by a "qualified engineer" defined in 11 AAC 93.193.

Fees

The completed application form must be accompanied by a non-refundable deposit on the application fee described under 11 AAC 05.010(a)(8)(J), calculated based on preliminary estimates of the applicable costs. Before a Certificate of Approval to Construct a Dam is issued by the Department, the applicant must submit an application fee supplement based on a certified cost estimate of the project. The total fee is based on a based on a declining scale of the estimated project cost; i.e., 2% of first $100,000 of the estimated cost, 1% of the next $400,000, 0.5% of the next $500,000, and 0.25% of all costs in excess of $1,000,000. The cost estimate must include labor and materials for construction, engineering, site investigations, surveying, construction quality assurance and quality control, and other direct expenses.

Inspection Process

The owner of a Class I or Class II dam shall perform a periodic safety inspection on the dam at least once every three years. The owner of a Class III dam shall perform a safety inspection on the dam at least once every five years. All inspections required by the regulations must be accomplished at the owner's sole expense (11 AAC 93.159). The safety inspections must be performed by a qualified engineer with sufficient experience in dam design, construction, and safety appropriate for the type of dam inspected (11 AAC 93.193). If the commissioner determines that a condition may exist that may affect the safety of a dam, or determines that the owner inspection required by 11 AAC 93.159 has been inadequate, the commissioner may inspect the dam, at the owner's expense (11 AAC 93.161).

Frequency of Inspections

Hazard Classification	*Inspection Cycle*
High	3 years
Significant	3 years
Low	5 years

Owner's Non-Compliance/Violations/Penalties

The department has the authority to issue orders for remedial measures to be performed at the owner's expense (11 AAC 93.163). A person is guilty of a Class A misdemeanor if the person knowingly violates a provision of the laws or regulations (AS 46.17.150).

Emergencies

In an emergency situation the commissioner will, at the commissioner's discretion, take remedial action that the commissioner determines is necessary to protect life and property from the risks posed by the dam's operation or potential failure (11 AAC 93.163). The commissioner may take supervisory control of the dam from the owner, over the owner's

objection if necessary, until the emergency passes (11 AAC 93.163). Emergency action plans are required for all Class I and II dams. (11 AAC 93.164).

Liability

The laws and regulations "do not relieve the owner of a dam or reservoir of the duties or liabilities incident to the ownership or operation of the dam or reservoir." (AS 46.17.120). State liability is addressed in the laws or regulations. (AS 46.17.110)

Oversight

A person may not bring an action against the state, the department, or agents or employees of the state, for the recovery of damages caused by the partial or total failure of a dam or reservoir, or by the operation of a dam or reservoir, or by the operation of a dam or reservoir, or by an act or omission in connection with approval of construction, issuance of enforcement orders relating to maintenance or operation of the dam or reservoir, or control or regulation of the dam or reservoir. A person may bring an action against the state for the recovery of damages caused by an action undertaken by a dam owner that was negligently ordered by the state over the owner's objection (AS 46.17.110).

E.3. Arizona

ARIZONA

Citation

The Arizona dam safety law is contained in Arizona Revised Statutes Title 45, Waters, Chapter 6, Dams and Reservoirs, Article I, Supervision of Dams, Reservoirs and Projects, ARS 45:1201-1223. The rules pertaining to the dam safety program are contained in the Arizona Rules and Regulations Pertaining to the Supervision of Dams, Chapter 15, R12-15-151 and 152-15-1201 through 1226. These rules and regulations were originally adopted on Nov. 2, 1978 and substantially revised in 2000.

Definitions/Dam Classification

Arizona Statutes Section 45-1201 defines a *dam* as any artificial barrier, including appurtenant works for the impounding or diversion of water, twenty-five feet or more in height or the storage capacity of which will be more than fifty acre-feet, but does not include
(a) any barrier that is or will be less than six feet in height, regardless of storage capacity
(b) any barrier that has or will have a storage capacity of fifteen acre-feet or less, regardless of height
(c) any barrier for the purpose of controlling liquid-borne material
(d) any barrier that is a release-contained barrier
(e) any barrier that is owned, controlled, operated, maintained or managed by the United States Government or its agencies or instrumentalities if a safety program that is as least as stringent as the state safety program applies and is enforced against the agent or instrumentality.

Dam height is defined as the vertical distance from the lowest elevation of the outside limit of the barrier at its intersection with the natural ground surface to the spillway crest elevation.

Release contained barrier is defined as a barrier that has the storage capacity that in the event of a failure would be contained within the property of its owner.

Hazard Classification Criteria
Hazard classification criteria are given in the Rules (R12-15-1206).

Category	Economic Loss
Very Low - Low	Minimal (underdeveloped to occasional structures or agriculture)
Significant	Appreciable (notable agriculture, industry, or other structure)
High	Excessive (extensive community, industry, agriculture), with probable loss of life

The size of each dam is defined according to the U.S. Army Corps of Engineers National Inventory of Dams standard.

Jurisdiction/Powers of Department

The law states that it is unlawful to construct, reconstruct, repair, operate, maintain, enlarge, remove, or alter any dam except upon prior approval of the director. The director is responsible for the approval process including adopting and revising rules and issuing general orders to effectuate this law. The director is also directed by law to supervise the operation and maintenance of all jurisdictional dams to safeguard life and property.

The law gives the director the right and responsibility to conduct investigations and assemble data to make a proper review of the design and construction process and may enter private property for such purposes.

It also gives the director the ability to issue a notice of noncompliance to prescribed provisions of approval to the owner or construction contractor and can order immediate compliance or can order work stoppage until compliance has been effected and approved by the director. Failure to follow this directive may render the approval revocable.

The director can order construction to cease and desist and can order the owner to appear at a hearing before the department to state his case for non-compliance. The decision is then up to the director as to continuation of the project.

The director is authorized to take any legal action necessary to enforce these statutory provisions.

Approval Process

Arizona law cites characteristics of the process to approve construction, reconstruction, repair, operation, maintenance, enlargement, removal, or alteration of a dam including what shall be included in the application process plus what should be in the plans and specifications and what other materials are required by the director. Rules R12-15-1207 describe the application process in detail--what should be in the application and how the filing fee is calculated. Rules R12-15-1215 describe what should be in the plans and specifications for construction, alteration, etc.
In these rules, it states that all plans and specifications accompanying an application for approval shall be prepared by or under the direction of a professional engineer, registered under Arizona law.

The law pertaining to repair specifies that the approval process may be waived if repair is needed immediately in order to safeguard life and property. The director must be informed prior to this action taking place.

Application Fees

The law gives the director the authority to establish filing fees based on the estimated cost of the dam. The fee shall not exceed 2% of this established cost. The fee must be paid before consideration of the application. All fees will be deposited in the dam repair fund. The following fee structure has been established by the rules (R12-15-151):

Application filing fee is based on:
1) Review of plans, studies of dam costs (in dollars):

-first $ 100,000	2.0%
-next $ 400,000	1.5%
-next $500,000	1.0%
-over $600,000	0.5%
2) Safety Inspections	
Per inspection	$100
Plus, per foot of height	$ 2
3) Other Charges	
Photocopies	.25 each
Computer reports:	
First page of report	$15
Additional pages	.25 each
Certified "True Copies"	$2.75/ Page

Approval of Application
By law, the director must inspect the dam upon completion of construction. If the inspection passes, the approval is made and a license is issued for use (the rules detail this process, R12-15-1214). The approval plan may be revised if after inspecting the work he believes amendments, modifications or changes are necessary.

According to law, the application must be approved in not less than 10 days from receipt nor retained more than 60 days unless more information is needed. Construction must commence within one year of approval and the director must be notified at least 10 days before construction begins. Time frame rules provide limits of 120 days for administrative review, and 60 days for substantive review.

Inspection Process
According to law, the director shall inspect after construction, repair , remodeling. or alteration, during operation and maintenance, and upon filing of a legitimate complaint concerning the safety of the dam. The rules specify criteria for the inspection process. Guidelines were developed to accompany the rules stating operation and maintenance frequency--they are as follows:

Hazard Potential	Storage Dam Inspection Frequency (at least once each)
Low – Very low	Five Years
Significant	Three Years
High	One Year

The rules state that the owner is responsible for safety during construction and after completion of the dam and inspection during and after construction, enlargement, repair, alteration, or removal in accordance with the plans and specifications as approved by the director.

Violations/Penalties
Arizona law defines a violation as failure to follow the law concerning construction, repair, enlargement, alteration, or removal of a dam or failure to carry out an order of the director. The violator is guilty of a class 2 misdemeanor for each day the violation continues.

If the director feels a violation has taken place, he must give the owner written notice to appear at a hearing before the department to show cause why the owner should not be penalized or be directed to cease and desist work. The director is then responsible for all decisions based on the hearing. If the violation continues, the director may retain a temporary restraining order or a permanent injunction from the state superior court.

The law states that a person determined to violate the law may be assessed a penalty not to exceed $1,000 per day of the violation. These monies go to the state general fund. A judge may stay the decision of the director upon appeal on a showing of good cause.

Emergencies
The law requires that the director determine if a dam is dangerous or if floods threaten its safety and can then employ immediate remedial measures to correct the problem. The law goes on to explain exactly what the director can do to the dam in this instance and says that he is in full charge of the dam until it is rendered safe or the emergency has terminated.

The law also states that the director may spend monies from the dam repair fund (Sect. 45-1212.01).

The owner is ultimately responsible for the costs of the remedial work. The law states that a lien shall be put against the owner's property to cover these costs. As he pays back the debt, the money collected goes back to the dam repair fund.

Liability

Section 45-1215 of the law states that no action shall be brought or maintained against the state, or any of its departments, agencies or officials thereof, or any of their employees or agents, for damages sustained through the partial or total failure of a dam or its maintenance by reason of control and regulation thereof by any of them pursuant to duties imposed upon them under the provisions of this chapter.

Nothing in this article shall relieve the owner or operator of a dam from the legal duties, obligations and liabilities arising from such ownership or operation.

Oversight

Section 45-1210-1211 explains the process by which a petition can be filed against any decision made by the director. It also explains has a board of review is formed to hear the petition.

Miscellaneous

Financing

The law states that the director may require a surety company bond in amount sufficient to secure the costs to the state in assuming the safety of a dam left partially constructed. This is required when the director questions the financial stability of the owner or contractor or otherwise deems the bond advisable.

The law also establishes funds to help finance the repair of unsafe dams:

The dam repair fund is made up of monies appropriated by the legislature and monies collected from a lien as described under "Emergencies" and is used for emergency remedial work. The dam repair fund also includes appropriate funds, inspection fees, filing fees, and principal and interest collected from dam repair loans. This money may be used for loans and grants (described below). Monies in these funds are exempt from Section 35-190 relating to lapsing of appropriations.

Non-emergency dam repair loans let the director grant loans to dam owners to defray the costs of repair which are necessary for safety reasons but not emergencies. Loans are for terms of not more than 20 years. The law goes on to prescribe interest rates, contractual arrangements, fund maintenance procedures, and defaulting procedures.

Dam repair grants may be granted for the same purposes as above and may be in addition to the loans.

Arizona Secretary of State - Ken Bennett

ARTICLE 1. FEES

R12-15-101. Reserved
through
R12-15-150. Reserved

R12-15-151. Fee Schedule

A. The Department shall only accept or take action on an application or filing upon payment of the appropriate fee as listed below. Payment may be made by cash, check, or by entry in an existing Department fee-credit account established pursuant to R12-15-152.

B. The following fees shall be paid:

1. SURFACE WATER FEE ($)
   - a. Application for permit to appropriate
     - i. Less than 50 acre feet 50.00
     - ii. 50 acre feet or more 75.00
   - b. Permit to appropriate
     - i. Less than 50 acre feet 25.00
     - ii. 50 acre feet or more 50.00
   - c. Claim of water right for a stockpond and application for certification 10.00
   - d. Certificate of water right for stockpond 30.00
   - e. Issue certificate of water right (except stockpond) 50.00
   - f. Application for severance and transfer of water right . 500.00
   - g. Application to transport water out of state 500.00
   - h. Assignment
     - i. Assignment of application for permit to appropriate, statement of claim, or claim of water right for a stockpond 10.00
     - ii. Assignment and reissuance of permit to appropriate 20.00
     - iii. Assignment and reissuance of certificate of water right (except stockpond) 35.00
     - iv. Assignment and reissuance of certificate of water right for a stockpond 20.00
2. GROUNDWATER
   - a. Application for groundwater withdrawal permit, modifications and renewals (except

applications for hydrologic testing and temporary dewatering permits) 150.00
b. Application for permit for hydrologic testing and temporary dewatering, modifications, and renewals 50.00
c. Groundwater withdrawal permit 50.00
d. Convey groundwater withdrawal permit (except for permits for temporary electrical energy generation, temporary dewatering, hydrologic testing, and groundwater replenishment district withdrawals) 35.00
e. Application for notice of authority to irrigate in an irrigation nonexpansion area 50.00
f. Convey or reissue notice of authority to irrigate in an irrigation nonexpansion area 35.00

3. WATER EXCHANGES
a. Statement of water exchange contract 100.00
b. Application for water exchange permit 150.00
c. Water exchange permit 100.00
d. Renew or modify water exchange permit 100.00
e. Notice of water exchange 150.00

4. WELLS
a. Reissue drilling card 10.00
b. Permit to drill new or replacement well 30.00
c. Registration of exempt well No charge
d. Registration of nonexempt well 10.00
e. Late registration of any well (post 7/16/82) 10.00
f. Well assignments (single or group of wells by same owner) 10.00
g. Well driller's licenses (except single well license) 50.00
h. Reissue or renew unexpired well driller's license 10.00
i. Reactivate expired well driller's license 20.00
j. Single well license No charge
k. Well capping 300.00
minimum
plus actual
expenses
over 300.00

5. GRANDFATHERED RIGHTS
a. Application for certificate of grandfathered right 75.00
b. Late application for certificate of grandfathered right 100.00
c. Convey or reissue certificate of grandfathered right 35.00
d. Application for type 1 nonirrigation grandfathered right associated with retired irrigation l and 50.00
e. Application to retire an irrigation grandfathered right from irrigation to nonirrigation 100.00
f. Application for restoration of retired irrigation grandfathered right 50.00
g. Purchase of flexibility account credit balance 100.00

6. SUBSTITUTION OF ACRES
a. Application to substitute irregularly shaped acres in an irrigation nonexpansion area or an active management area 50.00
b. Application to substitute flood-damaged acres in an irrigation nonexpansion area or an active management area 100.00
c. Application to substitute CAP acres in an irrigation nonexpansion area 50.00
d. Application to substitute, or to reverse substitution of, CAP acres in an active management area 100.00

7. ADEQUATE AND ASSURED WATER SUPPLY
Applications, certificates, licenses, reports, and permits relating to assured and adequate water supply . . . . . The applicable fee prescribed in Article 7 of this Chapter.

8. UNDERWATER WATER STORAGE SAVINGS AND REPLENISHMENT PROGRAM
a. Application for underground storage facility permit 750.00
b. Underground storage facility permit 500.00
c. Convey underground storage facility permit 300.00
d. Application for groundwater savings facility permit 500.00
e. Groundwater savings facility permit 350.00
f. Convey groundwater savings facility permit 300.00
g. Application for water storage permit 250.00
h. Water storage permit 100.00
i. Convey water storage permit 300.00
j. Application for recovery well permit
i. First 10 wells 50/well
ii. Over 10 wells 10/well
k. Recovery well permit
i. First 10 wells 50/well
ii. Over 10 wells 10/well

9. CERTIFICATES OF GROUNDWATER OVERSUPPLY
a. Application for certificate of groundwater oversupply 150.00
b. Certificate of groundwater oversupply 50.00

10. LAKES
a. Application for permit to fill or refill a body of water

i. Poor quality groundwater 150.00
ii. Interim 50.00
b. Permit to fill or refill a body of water
i. Poor quality groundwater 75.00
ii. Interim 30.00
c. Application for determination of substantial capital investment to fill or refill a body of water 50.00
d. Application and permit for temporary emergency use of water to fill a body of water 50.00
11. SAFETY OF DAMS
a. Application for review No charge
b. Application filing fee - review of plans and studies based upon dam cost
i. First $100,000 2.0%
ii. Next $400,000 1.5%
iii. Next $500,000 1.0%
iv. Remainder over $1,000,000 .5%
c. Safety Inspections
i. Per inspection 100.00
ii. Plus, per foot of height 2.00
12. WEATHER MODIFICATION
a. Application for weather modification license 100.00
b. License to manufacture or sell weather modification equipment 10.00
13. COPIES
a. Photocopies .25/page
b. Microfiche copies .30/page
c. Computer reports:
i. First page of report 15.00
ii. Additional page .25 each
d. Certified copies 2.75/page

C. In addition to the fees listed above, the applicant shall pay the Department the actual cost of mailing and/or publishing any legal notice required by statute.

R12-15-215. Expired

Historical Note

Adopted effective June 13, 1984 (Supp. 84-3). Section number corrected (Supp. 93-1). Section expired under A.R.S. § 41-1056(E) at 7 A.A.R. 2159, effective February 28, 2001 (Supp. 01-2).

R12-15-216. Expired

Historical Note

Adopted effective June 13, 1984 (Supp. 84-3). Section expired under A.R.S. § 41-1056(E) at 7 A.A.R. 2159, effective February 28, 2001 (Supp. 01-2).

R12-15-217. Expired

Historical Note

Adopted effective June 13, 1984 (Supp. 84-3). Section expired under A.R.S. § 41-1056(E) at 7 A.A.R. 2159, effective February 28, 2001 (Supp. 01-2).

R12-15-218. Expired

Historical Note

Adopted effective June 13, 1984 (Supp. 84-3). Section expired under A.R.S. § 41-1056(E) at 7 A.A.R. 2159, effective February 28, 2001 (Supp. 01-2).

R12-15-219. Expired

Historical Note

Adopted effective June 13, 1984 (Supp. 84-3). Section expired under A.R.S. § 41-1056(E) at 7 A.A.R. 2159, effective February 28, 2001 (Supp. 01-2).

R12-15-220. Expired

Historical Note

Adopted effective June 13, 1984 (Supp. 84-3). Section expired under A.R.S. § 41-1056(E) at 7 A.A.R. 2159, effective February 28, 2001 (Supp. 01-2).

R12-15-221. Expired

Historical Note

Adopted effective June 13, 1984 (Supp. 84-3). Section expired under A.R.S. § 41-1056(E) at 7 A.A.R. 2159, effective February 28, 2001 (Supp. 01-2).

R12-15-222. Expired

Historical Note

Adopted effective June 13, 1984 (Supp. 84-3). Section expired under A.R.S. § 41-1056(E) at 7 A.A.R. 2159, effective February 28, 2001 (Supp. 01-2).

R12-15-223. Expired

Historical Note

Adopted effective June 13, 1984 (Supp. 84-3). Section expired under A.R.S. § 41-1056(E) at 7 A.A.R. 2159, effective February 28, 2001 (Supp. 01-2).

R12-15-224. Ex Parte Communications

A. During the course of a contested case or appealable agency action, a party shall not make an ex parte communication or knowingly cause an ex parte communication to be made to the Director or other Department employee or consultant who is or may reasonably be expected to be involved in the decision-making process of the contested case or appealable agency action.

B. During the course of a contested case or appealable agency action, the Department personnel listed in subsection (A) shall not make an ex parte communication or knowingly cause an ex parte communication to be made to a party or a person who will be materially and directly affected by the outcome of the contested case or appealable agency action.

C. Any of the Department personnel listed in subsection (A) of this Section who receives a written communication prohibited by this Section shall file a copy of the communication in the public docket and serve a copy on the Director, the Chief Counsel, and all parties to the contested case or appealable agency action. Any of the Department personnel listed in subsection (A) of this Section who receives an oral communication prohibited by this Section shall file a summary, stating the substance of the communication, in the public docket and serve a copy on the Director, the Chief Counsel, and all parties to the contested case or appealable agency action.

D. Upon receipt of an ex parte communication or a copy or summary of an ex parte communication made or knowingly caused to be made by a party in violation of this Section, the Director, to the extent consistent with the interests of justice and the policy of the underlying statutes and rules, may require the party to show cause why the party's claim or interest in the contested case or appealable agency action should not be dismissed, denied or disregarded because of the violation.

E. For purposes of this Section, "ex parte communication" means any written or oral communication relating to the merits of a contested case or appealable agency action, except:

1. Communications made in the course of official proceedings in the contested case or appealable agency action;
2. Communications made in writing, if a copy of the communication is promptly served on the Director, the Chief Counsel, and all parties to the contested case or appealable agency action;
3. Oral communications made after adequate notice, stating the substance of each communication, to all parties and the Chief Counsel;
4. Communications relating solely to procedural matters; and
5. As otherwise authorized by law.

Historical Note

Adopted effective June, 1984 (Supp. 84-3). Amended by final rulemaking at 13 A.A.R. 3022, effective October 6, 2007 (Supp. 07-3).

ARTICLE 3. STOCKPOND AND OTHER SURFACE WATER RULES

R12-15-301. Expired

Historical Note

Adopted effective October 8, 1982 (Supp. 82-5). Amended effective April 3, 1987 (Supp. 87-2). Amended effective May 7, 1990 (Supp. 90-2). Section expired under A.R.S. § 41-1056(E) at 7 A.A.R. 2012, effective February 28, 2001 (Supp. 01-2).

R12-15-302. Expired

Historical Note

Adopted effective October 8, 1982 (Supp. 82-5). Amended effective May 7, 1990 (Supp. 90-2). Section expired under A.R.S. § 41-1056(E) at 7 A.A.R. 2012, effective February 28, 2001 (Supp. 01-2).

R12-15-303. Multiple Applications for Water Rights

A. If two or more applications are filed with the Director pursuant to A.R.S. §§ 45-152 or 45-273 or both by or for the same applicant and for a right to use the same water, the Director shall consolidate the applications. If the applicant is otherwise entitled to both a permit to appropriate and a certificate of stockpond water right, the Director shall issue to the applicant either the permit to appropriate or the certificate of stockpond water right, whichever would give the applicant the higher priority.

B. If one or more applications are filed with the Director pursuant to A.R.S. §§ 45-152 or 45-273 or both by or for the same applicant and for a right to use the same water for which the applicant holds a permit to appropriate, a certificate of water right or a certificate of stockpond water right, the Director shall deny the application or applications unless the applicant relinquishes every permit to appropriate, certificate of water right and certificate of stockpond water right which the applicant holds for that same water. The applicant may relinquish every permit to appropriate, certificate of water right and certificate of stockpond water right on the condition that the Director issues a permit to appropriate or certificate of stockpond water right to the applicant for the same water. In that case, the relinquishment shall be effective when the Director issues the permit to appropriate or certificate of stockpond water right.

C. For purposes of this rule, "same water" means the same quantity of water from the same source for use at the same place for the same purpose. Water for which a right is applied or held pursuant to an application or permit to appropriate, certificate of water right or certificate of stockpond water right may be the same water in whole or in part as water for which a right is applied or held pursuant to a separate application or permit to appropriate, certificate of water right or certificate of stockpond water right.

Historical Note

Adopted effective April 3, 1987 (Supp. 87-2). Section R12-15-310 renumbered to R12-15-303 and amended effective May 7, 1990 (Supp. 90-2).

ARTICLE 4. LICENSING TIME-FRAMES

R12-15-401. Licensing Time-frames

The following time-frames apply to licenses issued by the Department. In this Article, "license" has the meaning prescribed in A.R.S. § 41-1001. The licensing time-frames consist of an administrative completeness review time-frame, a substantive review time-frame, and an overall time-frame.

1. Within the administrative completeness review time- frames set forth in subsection (7), the Department shall notify the applicant in writing whether the application is complete or incomplete. If the application is incomplete, the notice shall specify what information or component is required to make the application complete.
2. An applicant with an incomplete application shall supply the missing information within 60 days from the date of the notice, or within such further time as the Director may specify, unless another time limit is specified by statute or applicable rule. If the applicant fails to complete the application within the specified time period, the Director may deny the application. Denial of an application under this provision does not preclude the applicant from filing a new application.
3. Within the overall time-frames set forth in subsection (7), unless extended by mutual agreement under A.R.S. § 41-1075, the Department shall notify the applicant in writing that the application is granted or denied. If the application is denied, the Department shall provide written justification for the denial and a written explanation of the applicant's right to a hearing or the applicant's right to appeal.
4. In computing any period of time prescribed by this rule, the day of the filing, notice or event from which the designated period of time begins to run shall not be included. The last day of the computed period shall be included, unless it is a Saturday, Sunday, or a legal holiday, in which event the period runs until the end of the next day which is not a Saturday, Sunday, or legal holiday. When the prescribed administrative completeness review time-frame or substantive review time-frame is less than 11 days, intermediate Saturdays, Sundays and legal holidays shall be excluded from the computation. The overall time-frame is the sum of the administrative completeness review time-frame and the substantive review time-frame calculated as prescribed by this Section.
5. Except as otherwise noted, the licensing time-frames do not include time for hearings. Time-frames in cases where a hearing is held are increased by 120 days.
6. The licensing time-frame rules are effective after December 31, 1998, as prescribed by A.R.S. § 41-1073(A), and apply to all applications filed after that date.
7. The licensing time-frames are set forth in Table A.

Historical Note

Adopted effective December 31, 1998; filed with the Office of the Secretary of State July 28, 1998 (Supp. 98-3). Amended by final rulemaking at 11 A.A.R. 5395, effective February 4, 2006 (Supp. 05-4).

Table A. Licensing Time-frames

No.	License	Legal Authority	Completeness Review (Days)*	Substantive Review (Days)*	Overall Time-frame (Days)*
1	Filling a body of water with poor quality water	A.R.S. § 45-132(C)	30	60	90
2	Interim water use in body of water	A.R.S. § 45-133	30	60	90
3	Temporary emergency permit for use of surface water or groundwater in body of water	A.R.S. § 45-134	10	20	30
4	Permit to appropriate water (non-instream flow)	A.R.S. §§ 45-151 and 45-153	30	420	450
5	Permit to appropriate water (instream flow)	A.R.S. §§ 45-151 and 45-153	50	530	580
6	Change in use of water	A.R.S. § 45-156(B)	30	375	405
7	Exception to limitation on time of completion of construction	A.R.S. § 45-160	5	15	20
8	Primary reservoir permit	A.R.S. § 45-161	30	420	450
9	Secondary reservoir permit	A.R.S. § 45-161	30	420	450
10	Certificate of water right (non-instream flow)	A.R.S. § 45-162	20	100	120
11	Certificate of water right (instream flow)	A.R.S. § 45-162	20	190	210
12	Reissuance of permit or certificate held by the United States or State of Arizona	A.R.S. § 45-164(C)	10	80	90
13	Severance and transfer	A.R.S. § 45-172 (excluding 172.6)	30	390	420
14	Stockpond certificate	A.R.S. § 45-273	30	190	220
15	Transporting water from this state **	A.R.S. § 45-292	120	300	420
16	Waiver of water conserving plumbing fixture requirement	A.R.S. § 45-315	10	3	13
17	Irrigated acreage in an irrigation non-expansion area	A.R.S. § 45-437	30	90	120
18	Substitution of acres in an irrigation non-expansion area/flood damage	A.R.S. § 45-437.02	30	90	120
19	Substitution of acres in an irrigation non-expansion area/impediments to efficient irrigation	A.R.S. § 45-437.03	30	90	120
20	Reversal of substitution of acres irrigated with Central Arizona Project water	A.R.S. § 45-452(G)	30	90	120
21	Type 1 non-irrigation grandfathered right associated with irrigation land retired 1965-1980	A.R.S. §§ 45-463, 45-476.01, and 45-476	30	90	120
22	Type 2 non-irrigation grandfathered right	A.R.S. §§ 45-464, 45-476.01, and 45-476	30	90	120
23	Irrigation grandfathered right	A.R.S. §§ 45-465, 45-476.01, and 45-476	30	90	120
24	Substitution of acres in an active management area/flood damaged acres	A.R.S. § 45-465.01	30	90	120
25	Substitution of acres in an active management area/impediments to efficient irrigation	A.R.S. § 45-465.02	30	90	120
26	Type 1 non-irrigation right retired after 6/12/80	A.R.S. § 45-469	30	90	120
27	Restoration of retired irrigation grandfathered right	A.R.S. § 45-469(O)	30	90	120
28	Revised certificate for new or additional points of withdrawal for a Type 2 right	A.R.S. § 45-471(C)	45	135	180
29	Conveyance of irrigation grandfathered right for electrical energy generation	A.R.S. § 45-472(B)(2)	30	90	120
30	Conveyance of irrigation grandfathered right for non-irrigation use within service area	A.R.S. § 45-472(C)	30	90	120
31	Contract to supply groundwater	A.R.S. § 45-492(C)	15	90	105
32	Extension of service area to provide disproportionally large amount of water to large user	A.R.S. § 45-493(A)(2)	15	90	105
33	Addition/exclusion of acres by irrigation district	A.R.S. § 45-494.01(A)	30	90	120
34	Delivery of groundwater from an irrigation district to a general industrial use permit holder	A.R.S. § 45-497(B)	15	60	75
		A.R.S. §§ 45-513 and 45-			

35	Issuance/renewal/modification of dewatering permit	527	30	70	100
36	Issuance/renewal/modification of mineral extraction and metallurgical processing permit	A.R.S. §§ 45-514 and 45-527	30	70	100
37	Issuance/renewal/modification of general industrial use permit	A.R.S. §§ 45-515, 45-521, 45-522, 45-523, 45-524, and 45-527	30	70	100
38	Issuance/renewal/modification of poor quality groundwater withdrawal permit	A.R.S. §§ 45-516 and 45-527	30	70	100
39	Issuance/renewal/modification of temporary permit for electrical energy generation	A.R.S. §§ 45-517 and 45-527	30	70	100
40	Issuance/extension/modification of temporary dewatering permit	A.R.S. §§ 45-518 and 45-527	30	70	100
41	Emergency temporary dewatering permit	A.R.S. § 45-518(D)	3	7	10
42	Issuance/renewal/modification of drainage water withdrawal permit	A.R.S. §§ 45-519 and 45-527	30	70	100
43	Issuance/renewal/modification of hydrologic testing permit	A.R.S. §§ 45-519.01, 45-521, 45-522, 45-524, and 45-527	30	30	60
44	Change of location of use	A.R.S. §§ 45-520(A), 45-521, and 45-527	30	30	60
45	Conveyance of a groundwater withdrawal permit	A.R.S. § 45-520(B)	30	30	60
46	Transportation of groundwater withdrawn in McMullen Valley Basin to an active management area	A.R.S. § 45-552(B)	45	105	150
47	Transportation of groundwater withdrawn in Harquahala irrigation non-expansion area to an initial active management area	A.R.S. § 45-554(B)	45	105	150
48	Transportation of groundwater withdrawn in Big Chino subbasin to an initial active management area	A.R.S. § 45-555(B)	45	105	150

ARTICLE 7. ASSURED AND ADEQUATE WATER SUPPLY

R12-15-701. Definitions - Assured and Adequate Water Supply Programs
In addition to any other definitions in A.R.S. Title 45 and the management plans in effect at the time of application, the following words and phrases in this Article shall have the following meanings, unless the context otherwise requires:

1. "Abandoned plat" means a plat for which a certificate or water report has been issued and that will not be developed because of one of the following:
   a. The land has been developed for another use; or
   b. Legal restrictions will preclude approval of the plat.
2. "ADEQ" means the Arizona Department of Environmental Quality.
3. "Adequate delivery, storage, and treatment works" means:
   a. A water delivery system with sufficient capacity to deliver enough water to meet the needs of the proposed use;
   b. Any necessary storage facilities with sufficient capacity to store enough water to meet the needs of the proposed use; and
   c. Any necessary treatment facilities with sufficient capacity to treat enough water to meet the needs of the proposed use.
4. "Adequate storage facilities" means facilities that can store enough water to meet the needs of the proposed use.
5. "Affiliate" means a person who, directly or indirectly through one or more intermediaries, controls, is controlled by or is under common control with the person specified.
6. "AMA" means an active management area as defined in A.R.S. § 45-402.
7. "Analysis" means an analysis of assured water supply or an analysis of adequate water supply.
8. "Analysis holder" means a person to whom an analysis of assured water supply or an analysis of adequate water supply is issued and any current owner of land included in the analysis.
9. "Analysis of adequate water supply" means a determination issued by the Director stating that one or more criteria required for a water report pursuant to R12-15-713 have been demonstrated for a development.
10. "Analysis of assured water supply" means a determination issued by the Director stating that one or more criteria required for a certificate of assured water supply pursuant to R12-15-704 have been demonstrated for a development.
11. "Annual authorized volume" means, for an approved remedial action project, the annual authorized volume specified in a consent decree or other document approved by ADEQ or the EPA, except that:
    a. If no annual authorized amount is specified in a consent decree or other document approved by ADEQ or the EPA, the annual authorized volume is the largest volume of groundwater withdrawn pursuant to the approved remedial action project in any year prior to January 1, 1999.
    b. If the Director increases the annual authorized volume pursuant to R12-15-729(C), the annual authorized volume is the amount approved by the Director.
12. "Annual estimated water demand" means the estimated water demand divided by 100.
13. Approved remedial action project" means a remedial action project approved by ADEQ under A.R.S. Title 49, or by the EPA under CERCLA.
14. "Authorized remedial groundwater use" means, for any year, the amount of remedial groundwater withdrawn pursuant to an approved remedial action project and used by a municipal provider during the year, not to exceed the annual authorized volume of the project.
15. "Build-out" means a condition in which all water delivery mains are in place and active water service connections exist for all lots.
16. "CAP water" means:
    a. All water from the Colorado River or from the Central Arizona Project works authorized in P.L. 90-537, excluding enlarged Roosevelt reservoir, which is made available pursuant to a subcontract with a multi-county water conservation district.
    b. Any additional water not included in subsection 16(a) of this Section that is delivered by the United States Secretary of the Interior pursuant to an Indian water rights settlement through the Central Arizona Project.
17. "Central Arizona Groundwater Replenishment District" or "CAGRD" means a multi-county water conservation district acting in its capacity as the entity established pursuant to A.R.S. § 48-3771, et seq., and responsible for replenishing excess groundwater.
18. "Central distribution system" means a water system that qualifies as a public water system pursuant to A.R.S. § 49-352.
19. "CERCLA" or "Comprehensive Environmental Response, Compensation, and Liability Act of 1980" has the same meaning as prescribed in A.R.S. § 49-201.
20. "Certificate" means a certificate of assured water supply issued by the Director for a subdivision pursuant to A.R.S. § 45-576 et seq. and this Article.
21. "Certificate holder" means any person included on a certificate, except the following:
    a. Any person who no longer owns any portion of the property included in the certificate, and
    b. Any potential purchaser for whom the purchase contract has been terminated or has expired.
22. "Certificate of convenience and necessity" means a certificate required by the Arizona Corporation Commission, pursuant to A.R.S. § 40-281, which allows a private water company to serve water to customers within its certificated area.
23. "Colorado River water" means water from the main stream of the Colorado River. For purposes of this Article, Colorado River water does not include CAP water.
24. "Committed demand" means the 100-year water demand at build-out of all recorded lots that are not yet served water within the service area of a designation applicant or a designated provider.
25. "County water augmentation authority" means an authority formed pursuant to A.R.S. Title 45, Chapter 11.
26. "Current demand" means the 100-year water demand for existing uses within the service area of a designation applicant or designated provider, based on the annual report for the previous calendar year.
27. "Depth-to-static water level" means the level at which water stands in a well when no water is withdrawn by pumping or by free flow.
28. "Designated provider" means:
    a. A municipal provider that has obtained a designation of assured or adequate water supply; or
    b. A city or town that has obtained a designation of adequate water supply pursuant to A.R.S. § 45-108(D).
29. "Designation means a decision and order issued by the director designating a municipal provider as having an assured water supply or an adequate water supply.
30. "Determination of adequate water supply" means a water report, a designation of adequate water supply, or an analysis of adequate water supply.
31. "Determination of assured water supply" means a certificate, a designation of assured water supply, or an analysis of assured water supply.
32. "Development" means either a subdivision or an unplatted development plan.
33. "Diversion works" means a structure or well that allows or enhances diversion of surface water from its natural course for other uses.
34. "Drought response plan" means a plan describing a variety of conservation and augmentation measures, especially the use of backup water supplies, that a municipal provider will utilize in operating its water supply system in times of a water supply shortage. The plan may include the following:
    a. An identification of priority water uses consistent with applicable public policies.
    b. A description of sources of emergency water supplies.
    c. An analysis of the potential use of water pressure reduction.
    d. Plans for public education and voluntary water use reduction.
    e. Plans for water use bans, restrictions, and rationing.
    f. Plans for water pricing and penalties for excess water use.
    g. Plans for coordination with other cities, towns, and private water companies.
35. "Drought volume" means 80% of the volume of a surface water supply, determined by the director under R12-15-716 to be physically available on an annual basis to a certificate holder or a designated provider.
36. "Dry lot development" means a development or subdivision without a central water distribution system.
37. "EPA" means the United States Environmental Protection Agency.
38. "Estimated water demand" means:
    a. For a certificate or water report, the Director's determination of the 100-year water demand for all uses included in the subdivision;
    b. For a designation, the sum of the following:
       i. The Director's determination of the current demand;
       ii. The Director's determination of the committed demand; and
       iii. The Director's determination of the projected demand during the term of the designation; or
    c. For an analysis, the Director's determination of the water demand for all uses included in the development.
39. "Existing municipal provider" means a municipal provider that was in operation and serving water for non-irrigation use on or before January 1, 1990.
40. "Extinguish" means to cause a grandfathered right to cease to exist through a process established by the director pursuant to R12-15-723.
41. "Extinguishment credit" means a credit that is issued by the Director in exchange for the extinguishment of a grandfathered right and that may be used to make groundwater use

consistent with the management goal of an AMA.
42. "Firm yield" means the minimum annual diversion for the period of record which may include runoff releases from storage reservoirs, and surface water withdrawn from a well.
43. "Management plan" means a water management plan adopted by the director pursuant to A.R.S. § 45-561 et seq.
44. "Master-planned community" has the same meaning as provided in A.R.S. § 32-2101.
45. "Median flow" means the flow which is represented by the middle value of a set of flow data that are ranked in order of magnitude.
46. "Member land" has the same meaning as provided in A.R.S. § 48-3701.
47. "Member service area" has the same meaning as provided in A.R.S. § 48-3701.
48. "Multi-county water conservation district" means a district established pursuant to A.R.S. Title 48, Chapter 22.
49. "Municipal provider" has the same meaning as provided in A.R.S. § 45-561.
50. "New municipal provider" means a municipal provider that began serving water for non-irrigation use after January 1, 1990.
51. "Owner" means:
    a. For an analysis, certificate, or water report applicant, a person who holds fee title to the land described in the application; or
    b. For a designation applicant, the person who will be providing water service pursuant to the designation.
52. "Perennial" means a stream that flows continuously.
53. "Persons per household" means a measure obtained by dividing the number of persons residing in housing units by the number of housing units.
54. "Physical availability determination" means a letter issued by the Director stating that an applicant has demonstrated all of the criteria in R12-15-702(C).
55. "Plat" means a preliminary or final map of a subdivision in a format typically acceptable to a platting entity.
56. "Potential purchaser" means a person who has entered into a purchase agreement for land that is the subject of an application for a certificate or an assignment of a certificate.
57. "Projected demand" means the 100-year water demand at build-out, not including committed or current demand, of customers reasonably projected to be added and plats reasonably projected to be approved within the designated provider's service area and reasonably anticipated expansions of the designated provider's service area.
58. "Proposed municipal provider" means a municipal provider that has agreed to serve a proposed subdivision.
59. "Purchase agreement" means a contract to purchase or acquire an interest in real property, such as a contract for purchase and sale, an option agreement, a deed of trust, or a subdivision trust agreement.
60. "Remedial groundwater" means groundwater withdrawn pursuant to an approved remedial action project, but does not include groundwater withdrawn to provide an alternative water supply pursuant to A.R.S. § 49-282.03.
61. "Service area" means:
    a. For an application for an analysis of adequate water supply, a water report, or a designation of adequate water supply, the area of land actually being served water for a non-irrigation use by the municipal provider and additions to the area that contain the municipal provider's operating distribution system for the delivery of water for a non-irrigation use;
    b. For an application for a designation of adequate water supply pursuant to A.R.S. § 45-108(D), the area of land actually being served water for a non-irrigation use by each municipal provider that serves water within the city or town, and additions to the area that contain each municipal provider's operating distribution system for the delivery of water for a non-irrigation use; or
    c. For an application for a certificate or designation of assured water supply, "service area" has the same meaning as prescribed in A.R.S. § 45-402.
62. "Subdivision" has the same meaning as prescribed in A.R.S. § 32-2101.
63. "Superfund site" means the site of a remedial action undertaken pursuant to CERCLA.
64. "Surface water" means any surface water as defined in A.R.S. § 45-101, including CAP water and Colorado River water.
65. "Water Quality Assurance Revolving Fund site" or "WQARF site" means a site of a remedial action undertaken pursuant to A.R.S. Title 49, Chapter 2, Article 5.
66. "Water report" means a letter issued to the Arizona Department of Real Estate by the Director for a subdivision stating whether an adequate water supply exists pursuant to A.R.S. § 45-108 and this Article.

Historical Note

Adopted effective February 7, 1995 (Supp. 95-1). Amended by emergency rulemaking at 11 A.A.R. 2706, effective June 29, 2005 for 180 days (Supp. 05-2). Emergency renewed for 180 days at 12 A.A.R. 144, effective December 23, 2005 (Supp. 05-4). Emergency expired. Amended by final rulemaking at 12 A.A.R. 3475, effective September 12, 2006 (Supp. 06-3).

R12-15-702. Physical Availability Determination

A. A person may apply for a physical availability determination by submitting an application on a form prescribed by the Director with the fee required by R12-15-730, and providing the following information with the application:
    1. The proposed source of water for which the applicant is seeking a determination of physical availability,
    2. Evidence that the applicant has complied with subsection (C) of this Section, and
    3. Any other information that the Director reasonably deems necessary to determine whether water is physically available in the area that is the subject of the application.
B. Each applicant shall sign an application for a physical availability determination. If an applicant is not a natural person, the applicant's authorized officer, managing member, partner, trust officer, trustee or other person who performs similar decision-making functions for the applicant shall sign the application. If the applicant submits a letter, signed by the applicant and dated within 90 days of the date the application is submitted, authorizing a representative to submit applications for permits regarding the land to be included in the determination, the authorized representative may sign the application on the applicant's behalf.
C. An applicant for a physical availability determination shall demonstrate the following:
    1. The volume of water that is physically available for 100 years in the area that is the subject of the application, according to the criteria in R12-15-716.
    2. That the proposed sources of water will be of adequate quality, according to the criteria in R12-15-719.
D. After a complete application is submitted, the Director shall review the application and associated evidence to determine whether the applicant has demonstrated all of the criteria in subsection (C) of this Section. If the Director determines that the applicant has demonstrated all of the criteria in subsection (C) of this Section, the Director shall issue a physical availability determination.
E. Any person applying for a determination of assured water supply or a determination of adequate water supply may use an existing physical availability determination for purposes of R12-15-716. The Director shall consider any changes in hydrologic conditions for purposes of R12-15-716.
F. The issuance of a physical availability determination does not reserve any water for purposes of this Article.

Historical Note

Adopted effective February 7, 1995 (Supp. 95-1). Section repealed; new Section made by final rulemaking at 12 A.A.R. 3475, effective September 12, 2006 (Supp. 06-3).

R12-15-703. Analysis of Assured Water Supply

A. A person proposing to develop land that will not be served by a designated provider may apply for an analysis of assured water supply before applying for a certificate. An applicant for an analysis must be the owner of the land that is the subject of the application or have the written consent of the owner. The commissioner of the Arizona State Land Department may apply for an analysis for land owned by the state of Arizona or may consent to the inclusion of such land in an application.
B. An applicant for an analysis shall submit an application on a form prescribed by the Director with the fee required by R12-15-730, and attach the following:
    1. A title report, condition of title report, limited search title report, or recorded deed, dated within 90 days of the date the application is submitted, demonstrating the ownership of the land that is the subject of the application;
    2. A description of the development, including:
        a. A map of the land uses included in the development,
        b. A list of water supplies proposed to be used by the development,
        c. A summary of land use types included in the development, and
        d. An estimate of the water demand for the land uses included in the development; and
    3. Evidence that the applicant has complied with subsection (E) of this Section.
C. An applicant shall sign the application for an analysis. If an applicant is not a natural person, the applicant's authorized officer, managing member, partner, trust officer, trustee, or other person who performs similar decision-making functions for the applicant shall sign the application. If the applicant submits a letter, signed by the applicant and dated within 90 days of the date the application is submitted, authorizing a representative to submit applications for permits regarding the land to be included in the analysis, the authorized representative may sign the application on the applicant's behalf.
D. After a complete application is submitted, the Director shall determine the estimated water demand of the development.
E. The Director shall issue an analysis if an applicant demonstrates one or more of the following:
    1. Sufficient supplies of water are physically available to meet all or part of the estimated water demand of the development for 100 years, according to the criteria in R12-15-716.
    2. Sufficient supplies of water are continuously available to meet the estimated water demand of the development for 100 years, according to the criteria in R12-15-717.
    3. Sufficient supplies of water are legally available to meet the estimated water demand of the development for 100 years, according to the criteria in R12-15-718.
    4. The proposed sources of water are of adequate quality, according to the criteria in R12-15-719.
    5. Any proposed groundwater use is consistent with the management plan in effect at the time of the application, according to the criteria in R12-15-721.
    6. Any proposed groundwater use is consistent with the management goal, according to the criteria in R12-15-722.
F. For 10 years after the Director issues an analysis, or a longer period allowed under subsections (H) or (I) of this Section:
    1. If groundwater is a source of supply in the analysis and the applicant demonstrates that groundwater is physically available under subsection (E)(1) of this Section, the Director shall consider that supply of groundwater reserved for the use of the proposed development in subsequent determinations of physical availability pursuant to R12-15-716(B).
    2. If an analysis holder applies for a certificate for a subdivision located on land included in the analysis, the Director shall presume that a criterion demonstrated in the analysis remains satisfied with respect to the subdivision, unless the Director has received new evidence demonstrating that the criterion is not satisfied. If the Director issues the certificate, the Director shall reduce the volume of groundwater reserved pursuant to subsection (F)(1) of this Section by the amount of the estimated water demand for the certificate that will be met with groundwater.
G. The Director shall reduce the amount of groundwater considered reserved for use of the development upon request by the analysis holder. If the analysis holder requesting a reduction is not the person to whom the analysis was issued, the Director shall reduce the amount of reserved groundwater only if the person to whom the analysis was issued or that person's designee consents to the request for reduction. The person to whom the analysis was issued shall notify the Director in writing of the name of the person's designee for purposes of this subsection.
H. The analysis holder may apply to the Director for a five-year extension of the time period in subsection (F) of this Section by submitting an application on a form prescribed by the Director no

earlier than 36 months before the end of the time period and no later than 30 days before the end of the time period. If an extension is granted, the analysis holder may apply to the Director for an additional five-year extension by submitting an application on a form prescribed by the Director no earlier than 36 months before the end of the extended time period and no later than 30 days before the end of the extended time period. The Director shall extend the time period for no more than two successive five-year periods under this subsection if the analysis holder demonstrates one of the following:

1. The analysis holder has made a substantial capital investment in developing the land included in the analysis.
2. The analysis holder has made material progress in developing the land included in the analysis.
3. Progress in developing the land included in the analysis has been delayed for reasons outside the control of the analysis holder.

I. After the Director grants two five-year extensions pursuant to subsection (H) of this Section, the Director may extend the time period for additional five-year periods if the analysis holder files a timely application pursuant to subsection (H) of this Section and demonstrates one of the criteria in subsections (H)(1), (H)(2), or (H)(3) of this Section.

J. The Director shall review an application for an analysis or an application for an extension pursuant to subsections (H) or (I) of this Section pursuant to the licensing time-frame provisions in R12-15-401.

Historical Note

Adopted effective February 7, 1995 (Supp. 95-1). Amended by emergency rulemaking at 11 A.A.R. 2706, effective June 29, 2005 for 180 days (Supp. 05-2). Emergency renewed for 180 days at 12 A.A.R. 144, effective December 23, 2005 (Supp. 05-4). Emergency expired. Section repealed; new Section made by final rulemaking at 12 A.A.R. 3475, effective September 12, 2006 (Supp. 06-3).

R12-15-703.01. Repealed

Historical Note

New Section made by final rulemaking at 7 A.A.R. 3038, effective June 18, 2001 (Supp. 01-2). Section repealed by final rulemaking at 12 A.A.R. 3475, effective September 12, 2006 (Supp. 06-3).

R12-15-704. Certificate of Assured Water Supply

A. An application for a certificate shall be filed by the current owner of the land that is the subject of the application. Potential purchasers and affiliates may also be included as applicants.

B. An applicant for a certificate shall submit an application on a form prescribed by the Director with the fee required by R12-15-730 and provide the following:

1. One of the following forms of proof of ownership for each applicant to be listed on the certificate:
   a. For an applicant that is the current owner, one of the following:
      i. A title report, condition of title report, limited search title report, or recorded deed, dated within 90 days of the date the application is filed, demonstrating that the applicant is the owner of the land that is the subject of the application; or
      ii. Evidence that the CAGRD has reviewed and approved evidence that the applicant is the owner of the land that is the subject of the application;
   b. For an applicant that is a potential purchaser, evidence of a purchase agreement; or
   c. For an applicant that is an affiliate of another applicant, a certification by the other applicant of the affiliate status;
2. A plat of the subdivision;
3. An estimate of the 100-year water demand for the subdivision;
4. A list of all proposed sources of water that will be used by the subdivision;
5. Evidence that the criteria in subsections (F) or (G) of this Section are met; and
6. Any other information that the Director reasonably determines is necessary to decide whether an assured water supply exists for the subdivision.

C. Each applicant shall sign the application for a certificate. If an applicant is not a natural person, the applicant's authorized officer, managing member, partner, trust officer, trustee, or other person who performs similar decision-making functions for the applicant shall sign the application. If an applicant submits a letter, signed by the applicant and dated within 90 days of the date the application is submitted, authorizing a representative to submit applications for permits regarding the land to be included in the certificate, the authorized representative may sign the application on the applicant's behalf.

D. The Director shall give public notice of an application for a certificate as provided in A.R.S. § 45-578.

E. After a complete application is submitted, the Director shall review the application and associated evidence to determine:

1. The estimated water demand of the subdivision;
2. The amount of the groundwater allowance for the subdivision, as provided in R12-15-724 through R12-15-727; and
3. Whether the applicant has demonstrated all of the requirements in subsection (F) or subsection (G) of this Section.

F. Except as provided in subsection (G) of this Section, the Director shall issue a certificate if the applicant demonstrates all of the following:

1. Sufficient supplies of water are physically available to meet the estimated water demand of the subdivision, according to the criteria in R12-15-716;
2. Sufficient supplies of water are continuously available to meet the estimated water demand of the subdivision, according to the criteria in R12-15-717;
3. Sufficient supplies of water are legally available to meet the estimated water demand of the subdivision, according to the criteria in R12-15-718;
4. The sources of water are of adequate quality, according to the criteria in R12-15-719;
5. The applicant has the financial capability to construct adequate delivery, storage, and treatment works for the subdivision, according to the criteria in R12-15-720;
6. The proposed use of groundwater withdrawn within an AMA is consistent with the management plan in effect at the time of the application, according to the criteria in R12-15-721; and
7. The proposed use of groundwater withdrawn within an AMA is consistent with the achievement of the management goal, according to the criteria in R12-15-722.

G. If the Director previously issued a certificate for the subdivision, the Director shall issue a new certificate to the applicant if the applicant demonstrates that all of the requirements in subsection (F) are met or that all of the following apply:

1. Any changes to the plat for which the previous certificate was issued are not material, according to the criteria in R12-15-708;
2. If groundwater is a proposed source of supply for the subdivision, the proposed groundwater withdrawals satisfied the physical availability requirements in effect at the time the complete and correct application for the previous certificate was submitted;
3. Any proposed sources of water, other than groundwater, are physically available to satisfy the estimated water demand that will not be satisfied with groundwater, according to the criteria in R12-15-716;
4. Any proposed sources of water other than groundwater are continuously available to satisfy the estimated water demand that will not be satisfied with groundwater, according to the criteria in R12-15-717;
5. The proposed uses of groundwater withdrawn within an AMA were consistent with the achievement of the management goal according to the criteria in effect at the time the complete and correct application for the previous certificate was submitted; and
6. The applicant demonstrates that the requirements in subsections (F)(3) through (F)(6) of this Section are met.

H. Before issuing a certificate, the Director shall classify the certificate for the purposes of R12-15-705 and R12-15-706 as follows:

1. Type A certificate. The Director shall classify the certificate as a Type A certificate if the applicant meets the criteria in R12-15-720(A)(1) and all of the subdivision's estimated water demand will be met with one or more of the following:
   a. Groundwater served by a proposed municipal provider pursuant to an existing service area right;
   b. Groundwater served by a proposed municipal provider pursuant to a pending service area right, if the proposed municipal provider currently holds or will hold the well permit;
   c. CAP water served by a municipal provider pursuant to the proposed municipal provider's non-declining, long-term municipal and industrial subcontract;
   d. Surface water served by a proposed municipal provider pursuant to the proposed municipal provider's surface water right or claim;
   e. Effluent owned and served by a proposed municipal provider; or
   f. A Type 1 grandfathered right appurtenant to the land on which the groundwater will be used and held by a proposed municipal provider.
2. Type B certificate. The Director shall classify all certificates that do not meet the requirements of subsection (H)(1) of this Section as Type B certificates.

I. The Director shall review an application for a certificate pursuant to the licensing time-frame provisions in R12-15-401.

J. An owner of six or more lots is not required to obtain a certificate if all of the following apply:

1. The lots comprise a subset of a subdivision for which:
   a. A plat was recorded before 1980; or
   b. A certificate was issued before February 7, 1995;
2. No changes were made to the plat since February 7, 1995; and
3. Water service is currently available to each lot.

K. A new owner of all or a portion of a subdivision for which a plat has been recorded is not required to obtain a certificate if all of the following apply:

1. The Director previously issued a Type A certificate for the subdivision pursuant to subsection (H)(1) of this Section or R12-15-707;
2. Water service is currently available to each lot; and
3. There are no material changes to the plat for which the certificate was issued, according to the criteria in R12-15-708.

L. An owner of six or more lots in the Pinal AMA is not required to obtain a certificate if all of the following apply:

1. A plat for the subdivision was recorded before October 1, 2007;
2. There have been no material changes to the plat according to the criteria in R12-15-708, since October 1, 2007;
3. The proposed municipal provider was designated as having an assured water supply when the plat was recorded, but is no longer designated as having an assured water supply; and
4. Water service is currently available to each lot.

M. A person may request a letter stating that the owner is not required to obtain a certificate pursuant to subsection (J), (K), or (L) of this Section by submitting an application on a form prescribed by the Director and attaching evidence that the criteria of subsection (J), (K), or (L) are met. Upon receiving an application pursuant to this subsection, the Director shall:

1. Review the application pursuant to the licensing time-frame provisions in R12-15-401.
2. Determine whether the criteria of subsection (J), (K), or (L) of this Section are met.
3. If the Director determines that the criteria of subsection (J) of this Section are met, issue a letter to the applicant and the Arizona Department of Real Estate stating that the current owner is not required to obtain a certificate.
4. If the Director determines that the criteria of subsection (K) or (L) of this Section are met, issue a letter to the applicant and the Arizona Department of Real Estate stating that the current owner and any future owners are not required to obtain a certificate.

Historical Note

Adopted effective February 7, 1995 (Supp. 95-1). Section repealed; new Section made by final rulemaking at 12 A.A.R. 3475, effective September 12, 2006 (Supp. 06-3). Amended by final rulemaking at 13 A.A.R. 1394, effective October 1, 2007 (Supp. 07-2).

R12-15-705. Assignment of Type A Certificate of Assured Water Supply

A. The certificate holder of a Type A certificate and the assignee may apply for approval of an assignment of the Type A certificate within the time allowed by A.R.S. § 45-579(A). The assignee may file the application if there is no certificate holder. The application shall be submitted on a form prescribed by the Director with the fee required by R12-15-730, and the applicant shall provide the following:
  1. One of the following forms of proof of ownership for each assignee:
    a. A title report, condition of title report, limited search title report, or recorded deed, dated within 90 days of the date the application is submitted to the Director and demonstrating that the assignee is the owner of the land that is the subject of the proposed assignment; or
    b. If the assignee is a potential purchaser, evidence of a purchase agreement;
  2. A current plat of the subdivision;
  3. An estimate of the 100-year water demand for the subdivision, based on the current plat;
  4. Certification by each applicant that:
    a. The proposed municipal provider has not changed and has agreed to continue to serve the subdivision after the assignment; and
    b. All water supplies listed on the current certificate are physically, continuously, and legally available to meet the estimated water demand of the subdivision after the assignment.

B. Each applicant shall sign the application for an assignment of a Type A certificate. If an applicant is not a natural person, the entity's authorized officer, managing member, partner, trust officer, trustee, or other person who performs similar decision-making functions for the applicant shall sign the application. If an applicant submits a letter, signed by the applicant and dated within 90 days of the date the application is submitted, authorizing a representative to submit applications for permits regarding the land included in the certificate, the authorized representative may sign the application on behalf of the applicant.

C. Upon receiving an application for an assignment of a Type A certificate, the Director shall post the notice required by A.R.S. § 45-579(E).

D. If the Director determines that the application meets the criteria of A.R.S. § 45-579(A), the Director shall issue a Type A certificate to each applicant. A Type A certificate issued under this subsection shall retain the issue date, the number of lots, and the estimated water demand shown on the original certificate, except as provided in subsection (E) of this Section. The Director shall determine that the application meets the criteria of A.R.S. § 45-579(A) if all of the following apply:
  1. The application is submitted within the time allowed by A.R.S. § 45-579(A);
  2. The assignee is the owner or a potential purchaser of the portion of the subdivision that is the subject of the assignment;
  3. There have been no material changes to the plat for which the original certificate was issued, according to the criteria in R12-15-708;
  4. Neither the applicant nor a predecessor in interest has impaired the manner in which consistency with management goal requirements were satisfied when the original certificate was issued; and
  5. The applicant makes the certifications required in subsection (A)(4) of this Section.

E. In the case of a partial assignment, the Director shall determine whether changes to the plat are material according to R12-15-708. The Director shall issue a Type A certificate to the assignee for the portion of the subdivision that is the subject of the assignment and for the number of lots and the estimated water demand of the current plat of the portion of the subdivision that is the subject of the assignment. The Director shall issue a Type A certificate to the certificate holder for the portion of the subdivision retained by the certificate holder and for the remainder of the number of lots and the remainder of the estimated water demand. The sum of the number of lots and the sum of the amount of the estimated water demand shown on each certificate shall equal the total number of lots and the total estimated water demand shown on the certificate being assigned.

F. The Director shall review an application for an assignment of a Type A certificate of assured water supply pursuant to the licensing time-frame provisions in R12-15-401.

Historical Note

Adopted effective February 7, 1995 (Supp. 95-1). Amended by final rulemaking at 8 A.A.R. 4390, effective November 22, 2002 (Supp. 02-3). Section repealed; new Section made by final rulemaking at 12 A.A.R. 3475, effective September 12, 2006 (Supp. 06-3).

R12-15-706. Assignment of Type B Certificate of Assured Water Supply

A. The certificate holder of a Type B certificate or a certificate issued before the effective date of this Section that has not been classified pursuant to R12-15-707 and the assignee may apply for approval of an assignment of the certificate to another person within the time allowed by A.R.S. § 45-579(A). The assignee may file the application if there is no certificate holder. The application shall be submitted on a form prescribed by the Director with the fee required by R12-15-730, and the applicant shall provide the following:
  1. One of the following forms of proof of ownership for each assignee:
    a. A title report, condition of title report, limited search title report, or recorded deed, dated within 90 days of the date the application is submitted to the Director and demonstrating that the assignee is the owner of the land that is the subject of the proposed assignment; or
    b. If the assignee is a potential purchaser, evidence of a purchase agreement;
  2. A current plat of the subdivision;
  3. An estimate of the 100-year water demand for the subdivision, based on the current plat;
  4. Evidence that all necessary water rights, permits, licenses, contracts, and easements have been or will be assigned to the assignee of the certificate;
  5. Evidence that the assignee has the financial capability to construct adequate delivery, storage, and treatment works for the subdivision according to the criteria in R12-15-720;
  6. Evidence that all water supplies listed on the current certificate are physically, continuously, and legally available to meet the estimated water demand of the subdivision after the assignment;
  7. Evidence that the proposed municipal provider has not changed and has agreed to serve the subdivision after the assignment;
  8. If the applicant requests that the Director classify the certificate pursuant to subsection (E) of this Section, evidence that the requirements of R12-15-704(H)(1) are satisfied;
  9. Any other information that the Director reasonably deems necessary to determine whether the application meets the criteria of A.R.S. § 45-579.

B. Each applicant shall sign the application for an assignment of a certificate. If an applicant is not a natural person, the entity's authorized officer, managing member, partner, trust officer, trustee, or other person who performs similar decision-making functions for the applicant shall sign the application. If an applicant submits a letter, signed by the applicant and dated within 90 days of the date the application is submitted, authorizing a representative to submit applications for permits regarding the land to be included in the certificate, the authorized representative may sign the application on the applicant's behalf.

C. Upon receiving an application for an assignment, the Director shall post the notice required by A.R.S. § 45-579(E).

D. Except as provided in subsection (E) of this Section, if the Director determines that the application meets the criteria of A.R.S. § 45-579(A), the Director shall issue a Type B certificate to each applicant. A Type B certificate issued under this subsection shall retain the issue date, the number of lots, and the estimated water demand shown on the original certificate, except as provided in subsection (F) of this Section. The Director shall determine that the application meets the criteria of A.R.S. § 45-579(A) if all of the following apply:
  1. The application is submitted within the time allowed by A.R.S. § 45-579(A);
  2. The assignee is the owner or potential purchaser of the portion of the subdivision that is the subject of the assignment;
  3. There have been no material changes to the plat for which the original certificate was issued, according to the criteria in R12-15-708;
  4. The applicant demonstrates the financial capability to construct adequate delivery, storage, and treatment works for the subdivision according to the criteria in R12-15-720;
  5. All necessary water rights, permits, licenses, contracts, and easements have been or will be assigned to the assignee of the certificate;
  6. All water supplies listed on the current certificate are physically, continuously, and legally available to meet the estimated water demand of the subdivision after the assignment;
  7. Neither the applicant nor a predecessor in interest has impaired the manner in which consistency with management goal requirements were satisfied when the original certificate was issued; and
  8. The proposed municipal provider has agreed to serve the subdivision after the assignment.

E. The applicant may include in the application a request to classify the certificate as a Type A certificate. If the Director determines that the request meets the requirements of R12-15-704(H)(1), the Director shall classify the certificate as a Type A certificate.

F. In the case of a partial assignment, the Director shall determine whether changes to the plat are material according to R12-15-708. The Director shall issue a Type B certificate to the assignee for the portion of the subdivision that is the subject of the assignment and for the number of lots and the estimated water demand of the current plat of the portion of the subdivision that is the subject of the assignment. The Director shall issue a Type B certificate to the certificate holder for the portion of the subdivision retained by the certificate holder and for the remainder of the number of lots and the remainder of the estimated water demand. The sum of the number of lots and the sum of the amount of the estimated water demand shown on each certificate shall equal the total number of lots and the total estimated water demand shown on the certificate that is being assigned.

G. The Director shall review an application for an assignment of a Type B certificate pursuant to the licensing time-frame provisions in R12-15-401.

Historical Note

Adopted effective February 7, 1995 (Supp. 95-1). Section repealed; new Section made by final rulemaking at 12 A.A.R. 3475, effective September 12, 2006 (Supp. 06-3).

R12-15-707. Application for Classification of a Type A Certificate

A. A holder of a Type B certificate or a certificate issued before the effective date of this Section may apply to the Director to classify the certificate as a Type A certificate by submitting an application on a form prescribed by the Director with the fee prescribed in R12-15-730 and attaching evidence that the certificate meets the requirements of R12-15-704(H)(1).

B. At least one certificate holder shall sign the application for classification of a certificate as a Type A certificate. If the applicant is not a natural person, the applicant's authorized officer, managing member, partner, trust officer, trustee, or other person who performs similar decision-making functions for the applicant shall sign the application. If the applicant submits a letter, signed by the applicant and dated within 90 days of the date the application is submitted, authorizing a representative to submit applications for permits regarding the land to be included in the certificate, the authorized representative may sign the application on behalf of the applicant.

C. If the applicant demonstrates that the requirements of R12-15-704(H)(1) are met, the Director shall classify the certificate as a Type A certificate and issue a Type A certificate to each certificate holder.

Historical Note

Adopted effective February 7, 1995 (Supp. 95-1). Section repealed; new Section made by final rulemaking at 12 A.A.R. 3475, effective September 12, 2006 (Supp. 06-3).

R-12-15-708. Material Plat Change; Application for Review

A. A certificate or a water report is applicable to the original plat for which the certificate or water report was issued and to a revised plat, unless the plat changes are material according to subsections (C) and (D) of this Section.

B. If a plat is revised after the Director issues a certificate or a water report and the changes to the plat are material according to subsection (C) or (D) of this Section, the holder may:

1. Apply for a new certificate or water report for the revised plat,
2. Use the original plat for which the certificate or water report was issued, or
3. Revise the plat so that any changes are not material according to subsections (C) and (D) of this Section.

C. Changes to the plat for which a certificate or a water report has been issued are material if any of the following apply:
1. The number of lots on the plat has increased by more than:
a. For subdivisions of 6 to 10 lots: one lot;
b. For subdivisions of 11 to 499 lots: 10%, rounding up to the nearest whole number; or
c. For subdivisions of 500 lots or more: 50 lots.
2. The 100-year water demand for the revised plat exceeds the estimated water demand for the certificate, unless all of the following apply:
a. The 100-year water demand for the revised plat does not exceed the estimated water demand for the certificate by more than 10%, rounding to the nearest whole acre-foot, or by more than 25 acre-feet per year, whichever is less;
b. The 100-year water demand is not greater than the supply demonstrated to be physically, continuously, and legally available at the time of issuance of the certificate or water report, and that water supply remains physically, continuously, and legally available; and
c. For a certificate, one of the following applies:
i. The subdivision is enrolled as a member land in the CAGRD;
ii. Groundwater is not included as a source of supply; or
iii. The subdivision is located in the Pinal AMA and the 100-year water demand for the revised plat will not exceed the sum of the amount of the groundwater allowance and the amount of any extinguishment credits pledged to the certificate, including extinguishment credits pledged after the certificate was issued.
3. For a certificate, additional land is included in the plat, unless all of the following apply:
a. The land included in the original plat for which the certificate was issued is located in a master-planned community;
b. The outer boundaries of the master-planned community have not expanded;
c. If the land included in the original plat for which the certificate was issued is enrolled as a member land in the CAGRD, the additional land has also been enrolled in the CAGRD; and
d. A certificate has been issued for the additional land.

D. Changes to a portion of a plat are not material if one of the following applies:
1. The changes to the portion of the plat being reviewed are not material according to subsection (C) of this Section when compared to the equivalent portion of the plat for which the certificate was issued;
2. The changes to the entire revised plat are not material according to subsection (C) of this Section when compared to the entire plat for which the certificate was issued; or
3. For a partial assignment pursuant to R12-15-705 or R12-15-706, the plat for the portion of the subdivision retained by the certificate holder could be configured so that changes to the total number of lots and the estimated water demand for the entire subdivision, including the portion under consideration, are not material according to subsection (C) of this Section. For purposes of this subsection, the Director may require the applicant to submit evidence demonstrating whether changes to the plat are material. However, the Director shall not require the applicant to submit a plat for the retained portion of a subdivision, unless the materiality of changes to the plat cannot be determined with any other evidence.

E. A person may apply for a review of a revised plat to determine whether any changes to the plat are material as follows:
1. The applicant shall submit an application on a form prescribed by the Director with the fee required by R12-15-730 and shall attach the revised plat.
2. The Director shall review the revised plat and the plat for which the certificate or water report was originally issued to determine whether any changes are material according to the criteria in subsections (C) and (D) of this Section.
3. The Director shall issue a letter to the applicant stating whether any changes to the plat are material and identifying which changes, if any, are material. If the Director determines that the changes to the plat are not material, the Director's letter shall state that the certificate or water report is applicable to the revised plat.

Historical Note

Adopted effective February 7, 1995 (Supp. 95-1). Section repealed; new Section made by final rulemaking at 12 A.A.R. 3475, effective September 12, 2006 (Supp. 06-3).

R12-15-709. Certificate of Assured Water Supply; Revocation

A. The Director may revoke a certificate if an assured water supply does not exist.
B. The Director shall not revoke a certificate if any of the residential lots within the plat have been sold.
C. If the Director determines that a certificate should be revoked, the Director shall provide for an administrative hearing, in accordance with A.R.S. Title 41, Chapter 6, Article 10. To determine whether a certificate should be revoked, the Director shall use the standards in place at the time the original application was submitted for the certificate.

Historical Note

Adopted effective February 7, 1995 (Supp. 95-1). Section repealed; new Section made by final rulemaking at 12 A.A.R. 3475, effective September 12, 2006 (Supp. 06-3).

R12-15-710. Designation of Assured Water Supply

A. A municipal provider applying for a designation of assured water supply shall submit an application on a form prescribed by the Director with the fee required by R12-15-730 and provide the following:
1. The applicant's current demand;
2. The applicant's committed demand;
3. The applicant's projected demand for the proposed term of the designation;
4. The proposed term of the designation, which shall not be less than two years;
5. Evidence that the criteria in subsection (E) of this Section are met; and
6. Any other information that the Director determines is necessary to decide whether an assured water supply exists for the municipal provider.

B. An application for a designation shall be signed by:
1. If the applicant is a city or town, the city or town manager or a person employed in an equivalent position. The application shall also include a resolution of the governing body of the city or town, authorizing that person to sign the application; or
2. If the applicant is a private water company, the applicant's authorized officer, managing member, partner, trust officer, trustee, or other person who performs similar decision-making functions for the applicant.

C. The Director shall give public notice of an application for designation in the same manner as provided for certificates in A.R.S. § 45-578.
D. After a complete application is submitted, the Director shall review the application and associated evidence to determine:
1. The annual volume of water physically, continuously, and legally available for at least 100 years;
2. The term of the designation, which shall not be less than two years;
3. The applicant's estimated water demand;
4. The applicant's groundwater allowance; and
5. Whether the applicant has demonstrated compliance with all requirements in subsection (E) of this Section.

E. The Director shall designate the applicant as having an assured water supply if the applicant demonstrates all of the following:
1. Sufficient supplies of water are physically available to meet the applicant's estimated water demand, according to the criteria in R12-15-716;
2. Sufficient supplies of water are continuously available to meet the applicant's estimated water demand, according to the criteria in R12-15-717;
3. Sufficient supplies of water are legally available to meet the applicant's estimated water demand, according to the criteria in R12-15-718;
4. The proposed sources of water are of adequate quality, according to the criteria in R12-15-719;
5. The applicant has the financial capability to construct adequate delivery, storage, and treatment works in a timely manner according to the criteria in R12-15-720;
6. Any proposed groundwater use is consistent with the management plan in effect at the time of the application, according to the criteria in R12-15-721; and
7. Any proposed use of groundwater withdrawn within an AMA is consistent with the management goal, according to the criteria in R12-15-722.

F. The Director shall review an application for a designation of assured water supply pursuant to the licensing time-frame provisions in R12-15-401.

Historical Note

Adopted effective February 7, 1995 (Supp. 95-1). Section repealed; new Section made by final rulemaking at 12 A.A.R. 3475, effective September 12, 2006 (Supp. 06-3).

R12-15-711. Designation of Assured Water Supply; Annual Report Requirements, Review, Modification, Revocation

A. A designated provider shall include in the annual report required by A.R.S. § 45-632 the following information for the preceding calendar year:
1. The designated provider's committed demand;
2. The demand at build-out for customers with which the designated provider has entered into an agreement to serve water, other than committed demand;
3. A report regarding the designated provider's compliance with water quality requirements;
4. The depth-to-static water level of all wells from which the designated provider withdrew water; and
5. Any other information the Director may reasonably require to determine whether the designated provider continues to meet the criteria for a designation of assured water supply.

B. If there is a change of ownership, the subsequent owner of a designated provider shall notify the Director in writing of the change in ownership within 90 days.
C. The Director shall review a designation at least every 15 years following issuance of the designation to determine whether the designation should be modified or revoked. To determine whether the designation should be modified or revoked, the Director shall use the standards in place at the time of review.
D. The Director may modify a designation for good cause, including a merger, division of the designated provider, or a change in ownership of the designated provider.
E. A designated provider may request a modification of the designation at any time pursuant to R12-15-710.
F. The Director may revoke a designation if:
1. After notifying the designated provider and initiating a review of the designated provider's status, the Director determines that the designated provider has less water, according to the criteria in R12-15-710(E), than the amount required for a 100-year supply for the provider's:
a. Current demand,
b. Committed demand, and
c. Projected demand during the next two calendar years;

2. The designated provider fails to construct adequate delivery, storage, and treatment works in a timely manner;
3. ADEQ or another governmental entity with equivalent jurisdiction has determined, after notice and an opportunity for a hearing, that the designated provider is in significant noncompliance with A.A.C. Title 18, Chapter 4 and is not taking action to resolve the noncompliance; or
4. The designated provider has violated its management plan requirements for two or more consecutive calendar years, and one of the following applies:
a. The provider fails to amend its water use plan in a manner that the Director determines will achieve compliance, or
b. The provider fails to sign a stipulated agreement to remedy the violation.

G. If the Director determines that a designation of assured water supply should be revoked, the Director shall provide for an administrative hearing, in accordance with A.R.S. Title 41, Chapter 6, Article 10.

H. If a designated provider's designated status terminates, the provider may apply for re-designation at anytime after termination.

I. Notwithstanding any other provision in this Article, a decision and order of the Director designating a city, town, or private water company as having an assured water supply is not affected by this Article solely because the rule numbers cited in the decision and order may have changed after the effective date of the decision and order.

Historical Note

Adopted effective February 7, 1995 (Supp. 95-1). Section repealed; new Section made by final rulemaking at 12 A.A.R. 3475, effective September 12, 2006 (Supp. 06-3).

R12-15-712. Analysis of Adequate Water Supply

A. A person proposing to develop land outside an AMA that will not be served by a designated provider may apply for an analysis of adequate water supply before applying for a water report. An applicant for an analysis must be the owner of the land that is the subject of the application or have the written consent of the owner. The commissioner of the Arizona State Land Department may apply for an analysis for land owned by the state of Arizona outside an AMA or may consent to the inclusion of such land in an application.

B. An applicant for an analysis shall submit an application on a form prescribed by the Director with the fee required by R12-15-730, and attach the following:
1. A title report, condition of title report, limited search title report, or recorded deed, dated within 90 days of the date the application is submitted to the Director, demonstrating the ownership of the land that is the subject of the application;
2. A description of the development, including:
a. A map of the land uses included in the development,
b. A list of water supplies proposed to be used by the development,
c. A summary of land use types included in the development, and
d. An estimate of the water demand for the land uses included in the development; and
3. Evidence that the applicant has complied with subsection (E) of this Section.

C. An applicant shall sign the application for an analysis. If an applicant is not a natural person, the applicant's authorized officer, managing member, partner, trust officer, trustee, or other person who performs similar decision-making functions for the applicant shall sign the application. If the applicant submits a letter, signed by the applicant and dated within 90 days of the date the application is submitted, authorizing a representative to submit applications for permits regarding the land that is the subject of the water report, the authorized representative may sign the application on the applicant's behalf.

D. After a complete application is submitted, the Director shall determine the estimated water demand of the development.

E. The Director shall issue an analysis if an applicant demonstrates one or more of the following:
1. Sufficient supplies of water are physically available to meet all or part of the estimated water demand of the development for 100 years, according to the criteria in R12-15-716;
2. Sufficient supplies of water are continuously available to meet the estimated water demand of the development for 100 years, according to the criteria in R12-15-717;
3. Sufficient supplies of water are legally available to meet the estimated water demand of the development for 100 years, according to the criteria in R12-15-718;
4. The proposed sources of water are of adequate quality, according to the criteria in R12-15-719.

F. For 10 years after the Director issues an analysis, or a longer period allowed under subsections (H) or (I) of this Section:
1. If groundwater is a source of supply in the analysis and the applicant demonstrates that groundwater is physically available under subsection (E)(1), the Director shall consider that supply of groundwater reserved for the use of the proposed development in subsequent determinations of physical availability pursuant to R12-15-716(B).
2. If an analysis holder applies for a water report for a subdivision located on land included in the analysis, the Director shall presume that a criterion demonstrated in the analysis remains satisfied with respect to the subdivision, unless the Director has received new evidence demonstrating that the criterion is not satisfied. If the Director issues the water report, the Director shall reduce the volume of groundwater reserved pursuant to subsection (F)(1) of this Section by the amount of the estimated water demand for the water report that will be met with groundwater.

G. The Director shall reduce the amount of water considered reserved for use of the development upon request by the analysis holder. If the analysis holder requesting a reduction is not the person to whom the analysis was issued, the Director shall reduce the amount of reserved groundwater only if the person to whom the analysis was issued or that person's designee consents to the request for reduction. The person to whom the analysis was issued shall notify the Director in writing of the person's designee for purposes of this subsection.

H. The analysis holder may apply to the Director for a five-year extension of the time period in subsection (F) of this Section by submitting an application on a form prescribed by the Director no earlier than 36 months before the end of the time period and no later than 30 days before the end of the time period. If an extension is granted, the analysis holder may apply to the Director for an additional five-year extension by submitting an application on a form prescribed by the Director no earlier than 36 months before the end of the extended time period and no later than 30 days before the end of the extended time period. The Director shall extend the time period for no more than two successive five-year periods under this subsection if the analysis holder demonstrates one of the following:
1. The analysis holder has made a substantial capital investment in developing the land included in the analysis.
2. The analysis holder has made material progress in developing the land included in the analysis.
3. Progress in developing the land included in the analysis has been delayed for reasons outside the control of the analysis holder.

I. After the Director grants two five-year extensions pursuant to subsection (H) of this Section, the Director may extend the time period for additional five-year periods if the analysis holder files a timely application pursuant to subsection (H) of this Section and demonstrates one of the criteria in subsections (H)(1), (H)(2), or (H)(3) of this Section.

J. The Director shall review an application for an analysis or an application for an extension pursuant to subsections (H) or (I) of this Section pursuant to the licensing time-frame provisions in R12-15-401.

Historical Note

Adopted effective February 7, 1995 (Supp. 95-1). Section repealed; new Section made by final rulemaking at 12 A.A.R. 3475, effective September 12, 2006 (Supp. 06-3).

R12-15-713. Water Report

A. An application for a water report shall be filed by the current owner of the land that is the subject of the application.

B. An applicant for a water report shall submit an application on a form prescribed by the Director with the fee required by R12-15-730 and provide the following:
1. A title report, condition of title report, limited search title report, or recorded deed, dated within 90 days of the date the application is filed and demonstrating that the applicant is the owner of the land that is the subject of the application;
2. A plat of the subdivision;
3. An estimate of the 100-year water demand for the subdivision;
4. A list of all proposed sources of water that will be used by the subdivision;
5. If the applicant is seeking a finding that the subdivision has an adequate water supply, evidence that the criteria in subsection (E) of this Section are met; and
6. Any other information that the Director reasonably determines is necessary to decide whether an adequate water supply exists for the subdivision.

C. Each applicant shall sign the application for a water report. If an applicant is not a natural person, the applicant's authorized officer, managing member, partner, trust officer, trustee, or other person who performs similar decision-making functions for the applicant shall sign the application. If an applicant submits a letter, signed by the applicant and dated within 90 days of the date the application is submitted, authorizing a representative to submit applications for permits regarding the land to be included in the water report, the authorized representative may sign the application on the applicant's behalf.

D. After a complete application is submitted, the Director shall review the application and associated evidence to determine:
1. The estimated water demand of the subdivision;
2. Whether the applicant has demonstrated all of the requirements in subsection (E) of this Section.

E. The Director shall determine that the subdivision has an adequate water supply if the applicant demonstrates all of the following:
1. Sufficient supplies of water are physically available to meet the estimated water demand of the subdivision, according to the criteria in R12-15-716;
2. Sufficient supplies of water are continuously available to meet the estimated water demand of the subdivision, according to the criteria in R12-15-717;
3. Sufficient supplies of water are legally available to meet the estimated water demand of the subdivision, according to the criteria in R12-15-718;
4. The proposed sources of water will be of adequate quality, according to the criteria in R12-15-719;
5. The applicant has the financial capability to construct adequate delivery, storage, and treatment works for the subdivision according to the criteria in R12-15-720.

F. The Director shall issue a water report to the applicant that states whether the applicant has complied with the requirements in subsection (E) of this Section.

G. The Director shall review an application for a water report pursuant to the licensing time-frame provisions in R12-15-401.

H. The Director may review or modify a water report if the Director receives new evidence regarding the criteria in subsection (E) of this Section. The Director shall not modify a water report pursuant to this subsection if any of the residential lots included in the plat have been sold. To determine whether a water report should be modified pursuant to this subsection, the Director shall use the standards in place at the time the original application was submitted for the water report. If the Director modifies a water report, the Director shall:
1. Provide for an administrative hearing pursuant to A.R.S. Title 41, Chapter 6, Article 10; and
2. Notify the Arizona Department of Real Estate.

I. An owner of land that is the subject of a water report may request a modification of the water report at any time by submitting an application in accordance with subsection (B) of this Section. To determine whether a water report should be modified pursuant to this Section, the Director shall use the standards in place at the time of review.

J. A water report is subject to the provisions of R12-15-708.

Historical Note

Adopted effective February 7, 1995 (Supp. 95-1). Section repealed; new Section made by final rulemaking at 12 A.A.R. 3475, effective September 12, 2006 (Supp. 06-3).

R12-15-714. Designation of Adequate Water Supply

A. A municipal provider applying for a designation of adequate water supply shall submit an application on a form prescribed by the Director with the fee required by R12-15-730 and the

following:
1. The applicant's current demand;
2. The applicant's committed demand;
3. The applicant's projected demand for the proposed term of the designation;
4. The proposed term of the designation, which shall not be less than two years;
5. Evidence that the criteria in subsection (E) of this Section are met; and
6. Any other information that the Director determines is necessary to decide whether an adequate water supply exists for the municipal provider.

B. A city or town, other than a municipal provider, that is applying for a designation shall submit an application on a form prescribed by the Director with the fee required in R12-15-730, and provide the following:
1. The current demand of the applicant's service area;
2. The committed demand of the applicant's service area;
3. The projected demand of the applicant's service area for the proposed term of the designation;
4. The proposed term of the designation, which shall not be less than two years; and
5. Evidence that the requirements in A.R.S. § 45-108(D) are met.

C. An application for a designation shall be signed by:
1. If the applicant is a city or town, the city or town manager or a person employed in an equivalent position. The application shall also include a resolution of the governing body of the city or town, authorizing that person to sign the application; or
2. If the applicant is a private water company, the applicant's authorized officer, managing member, partner, trust officer, trustee, or other person who performs similar decision-making functions for the applicant.

D. After a complete application is submitted, the Director shall review the application and associated evidence to determine:
1. The annual volume of water that is physically, continuously, and legally available for at least 100 years;
2. The term of the designation, which shall not be less than two years;
3. The estimated water demand for the applicant's service area for 100 years; and
4. Whether the applicant has demonstrated compliance with all requirements in subsection (E) or (F) of this Section.

E. The Director shall designate the applicant has having an adequate water supply pursuant to subsection (A) of this Section if the applicant demonstrates all of the following:
1. Sufficient supplies of water are physically available to meet the applicant's estimated water demand, according to the criteria in R12-15-716;
2. Sufficient supplies of water are continuously available to meet the applicant's estimated water demand, according to the criteria in R12-15-717;
3. Sufficient supplies of water are legally available to meet the applicant's estimated water demand, according to the criteria in R12-15-718;
4. The proposed sources of water are of adequate quality, according to the criteria in R12-15-719; and
5. The applicant has the financial capability to construct adequate delivery, storage, and treatment works in a timely manner according to the criteria in R12-15-720.

F. The Director shall issue a designation pursuant to subsection (B) of this Section if the applicant demonstrates that the requirements of A.R.S. § 45-108(D) are met.

G. The Director shall review an application for a designation of adequate water supply pursuant to the licensing time-frame provisions in R12-15-401.

Historical Note

Adopted effective February 7, 1995 (Supp. 95-1). Section repealed; new Section made by final rulemaking at 12 A.A.R. 3475, effective September 12, 2006 (Supp. 06-3).

R12-15-715. Designation of Adequate Water Supply; Annual Report Requirements, Review, Modification, Revocation

A. By March 31 of each calendar year, a designated provider shall submit the following information for the preceding calendar year on a form provided by the Director:
1. The designated provider's committed demand;
2. The demand at build-out for customers with which the designated provider has entered into an agreement to serve water, other than committed demand;
3. A report regarding the designated provider's compliance with water quality requirements;
4. The depth-to static water level of all wells from which the designated provider withdrew water;
5. A report regarding volume of water withdrawn, diverted, or received from each source for delivery to customers;
6. Any other information the Director may reasonably require to determine whether the designated provider continues to meet the criteria for a designation of adequate water supply.

B. If there is a change of ownership, the subsequent owner of a designated provider shall notify the Director in writing of the change in ownership within 90 days.

C. The Director shall review a designation at least every 15 years following issuance of the designation to determine whether the designation should be modified or revoked.

D. The Director may modify a designation for good cause, including a merger, division of the designated provider, or a change in ownership of the designated provider. A designated provider may request a modification of the designation at any time pursuant to R12-15-714. To determine whether the designation should be modified, the Director shall use the standards in place at the time of review.

E. The Director may revoke a designation if:
1. After notifying the designated provider and initiating a review of the designated provider's status, the Director deter mines that the designated provider has less water, according to the criteria in R12-15-714(E), than the amount required for a 100-year supply for the provider's:
a. Current demand,
b. Committed demand, and
c. Projected demand for the next two calendar years;
2. The designated provider fails to construct adequate delivery, storage, and treatment works in a timely manner; or
3. ADEQ or another governmental entity with equivalent jurisdiction has determined, after notice and an opportunity for a hearing, that the designated provider is in significant noncompliance with A.A.C. Title 18, Chapter 4 and is not taking action to resolve the noncompliance.

F. To determine whether the designation should be revoked, the Director shall use the standards in place at the time of review. If the Director determines that a designation of adequate water supply should be revoked, the Director shall provide for an administrative hearing, in accordance with A.R.S. Title 41, Chapter 6, Article 10.

G. If a designated provider's designated status terminates, the provider may apply for re-designation at anytime after termination.

H. Notwithstanding any other provision in this Article, a decision and order of the Director designating a city, town, or private water company as having an assured water supply is not affected by this Article solely because the rule numbers cited in the decision and order may have changed after the effective date of the decision and order.

Historical Head

Adopted effective February 7, 1995 (Supp. 95-1). Section repealed; new Section made by final rulemaking at 12 A.A.R. 3475, effective September 12, 2006 (Supp. 06-3).

R12-15-716. Physical Availability

A. The volume of a proposed source of water that is physically available to an applicant for a determination of assured water supply or a determination of adequate water supply is the amount determined by the Director to be physically available pursuant to subsections (B) through (L) of this Section.

B. If the proposed source is groundwater, the applicant shall submit a hydrologic study, using a method of analysis approved by the Director, that accurately describes the hydrology of the affected area. Except as provided in subsection (D) of this Section, the Director shall determine that the proposed volume of groundwater will be physically available for the proposed use if both of the following apply:
1. The groundwater will be withdrawn as follows:
a. Except as provided in subsection (B)(1)(b) of this Section, from wells owned by the applicant or the proposed municipal provider that are located within the service area of the applicant or the proposed municipal provider or from proposed wells that the Director determines are likely to be constructed for future uses of the applicant or the proposed municipal provider.
b. If the application is for a dry lot development, from wells that the Director determines are likely to be constructed on individual lots.
2. Except as provided in subsection (C) of this Section, the groundwater will be withdrawn from depths that do not exceed the applicable maximum 100-year depth-to-static water level according to the following:

Type and location of development	Maximum 100-year depth-to-static water level
a. Developments in Phoenix, Tucson, or Prescott AMAs, except dry lot developments	1000 feet below land surface
b. Developments in Pinal AMA, except dry lot developments	1100 feet below land surface
c. Developments outside AMAs, except dry lot developments	1200 feet below land surface
d. Dry lot developments	400 feet below land surface

3. The Director shall calculate the projected 100-year depth-to-static water level by adding the following for the area where groundwater withdrawals are proposed to occur:
a. The depth-to-static water level on the date of application.
b. The projected declines caused by existing uses, using the projected decline in the 100-year depth-to-static water level during the 100-year period after the date of application, calculated using records of declines for the maximum period of time for which records are available up to 25 calendar years before the date of application. If evidence is provided to the Director of likely changes in pumpage patterns and aquifer conditions, as opposed to those patterns and conditions occurring historically, the Director may determine projected declines using a model rather than evidence of past declines.
c. The projected decline in the depth-to-static water level during the 100-year period after the date of application, calculated by adding the projected decline from each of the following that are not accounted for in subsection (B)(3)(b) of this Section:
i. The estimated water demand of issued certificates and water reports that will be met with groundwater or stored water recovered outside the area of impact of the stored water, not including the demand of subdivided lots included in abandoned plats;

ii. The estimated water demand of designations that will be met with groundwater or stored water recovered outside the area of impact of the stored water; and
iii. The groundwater reserved for developments for which the Director has issued an analysis pursuant to R12-15-703 or R12-15-712.
d. The projected decline in depth-to-static water level that the Director projects will result from the applicant's proposed use over a 100-year period.

C. The Director shall lower the maximum 100-year depth-to-static water level requirement specified in subsection (B)(2) of this Section for an applicant seeking a determination of adequate water supply if the applicant demonstrates both of the following:
1. Groundwater is available at the lower depth; and
2. The applicant has the financial capability to obtain the groundwater at the lower depth, according to the criteria in R12-15-720.

D. If the proposed source is groundwater that will be withdrawn from a groundwater basin outside an AMA and transported into an AMA, the Director shall determine that the proposed volume of groundwater will be physically available if both of the following apply:
1. The groundwater will be withdrawn from wells owned by the applicant or the proposed municipal provider or from proposed wells that the Director determines are likely to be constructed for the future uses of the applicant or the proposed municipal provider.
2. Withdrawal of the groundwater will comply with any depth-to-static water level criteria, decline rate criteria, and volume limitation criteria prescribed by statute. If there are no applicable depth-to-static water level criteria prescribed by statute, withdrawal of the groundwater shall comply with the depth-to-static water level criteria in subsection (B)(2) of this Section.

E. Subject to subsection (L) of this Section, if the proposed source of water is surface water, other than CAP water, or Colorado River water, the Director shall determine the annual volume of water that is physically available for the proposed use, taking into consideration the priority date of the right or claim, by calculating 120% of the firm yield of the proposed source at the point of diversion as limited by the capacity of the diversion works; except that if the applicant demonstrates that an alternative source of water will be physically available during times of shortage in the proposed surface water supply, the Director shall determine the annual volume of water available by calculating 100% of the median flow of the proposed source at the point of diversion as limited by the capacity of the diversion works. The Director shall determine the firm yield or median flow as follows:
1. By calculating the firm yield or median flow at the point of diversion based on at least 20 calendar years of flow records from the point of diversion, unless 20 calendar years of records are unavailable and the Director determines that a shorter period of record provides information necessary to determine the firm yield or median flow; or
2. By calculating the firm yield or median flow at the point of diversion using a hydrologic model that projects the firm yield or median flow, taking into account at least 20 calendar years of historic river flows, changes in reservoir storage facilities, and projected changes in water demand. The yield available to any applicant may be composed of rights to stored water, direct diversion, or normal flow rights. If the permit for the water right was issued less than five years before the date of application, the Director shall require the applicant to submit evidence, as applicable, in accordance with this subsection.

F. Subject to subsection (L) of this Section, if the proposed source of water is CAP water, the Director shall determine the annual volume of water that is physically available for the proposed use as follows:
1. If the applicant or the proposed municipal provider has a non-declining, long-term municipal and industrial subcontract for CAP water, calculate 100% of the annual amount of water established in the subcontract.
2. If the applicant has a lease for Indian priority CAP water, calculate 100% of the annual amount of water established in the lease.
3. If the applicant has a subcontract for CAP water other than a non-declining, long-term municipal and industrial subcontract or a lease for Indian priority CAP water:
a. If the applicant submits evidence of sufficient backup water supplies, calculate 100% of the annual amount of water established in the subcontract. The applicant may establish backup water supplies by one or more of the following:
i. A drought response plan;
ii. Long-term storage credits;
iii. A contract for water with a multi-county water conservation district; or
iv. Evidence of other backup supplies that are physically, continuously, and legally available.
b. If the applicant does not submit evidence of sufficient backup water supplies pursuant to subsection (F)(3)(a) of this Section, calculate the percentage of the annual amount of water established in the subcontract that reasonably reflects the reliability of the applicant's CAP water supply.

G. Subject to subsection (L) of this Section, if the proposed source of water is Colorado River water, the Director shall determine the annual volume of water that is physically available for the proposed use as follows:
1. If the priority of the contract for Colorado River water provides reliability equal to or better than CAP municipal and industrial water, calculate 100% of the annual amount of water established in the contract.
2. If the contract for Colorado River water provides reliability that is less than CAP municipal and industrial water:
a. If the applicant submits evidence of sufficient backup water supplies, calculate 100% of the annual amount of water in the contract. The applicant may establish backup water supplies by one or more of the following:
i. A drought response plan;
ii. Long-term storage credits;
iii. A contract for water with a multi-county water conservation district; or
iv. Evidence of other backup supplies that are physically, continuously, and legally available.
b. If the applicant does not submit evidence of sufficient backup water supplies pursuant to subsection (G)(2)(a) of this Section, calculate the percentage of the annual amount of water established in the contract that reasonably reflects the reliability of the applicant's Colorado River water supply.

H. Subject to subsection (I) of this Section, if the proposed source of water is effluent, the Director shall determine the annual volume of water that will be physically available by evaluating the current, metered production or the projected production of effluent. The volume of effluent that is physically available shall not include the following:
1. If the effluent will be delivered directly from a wastewater treatment plant, the volume of effluent that exceeds the applicant's estimated water demand that will be met with effluent; and
2. The volume of effluent that does not comply with any applicable water quality requirements for the proposed use of the effluent.

I. If the proposed source of water is stored water to be recovered from recovery wells, the Director shall determine the volume of water that is physically available for the proposed use as follows:
1. If the stored water is represented by long-term storage credits in existence on the date of application, the amount that is physically available is the amount that may be recovered pursuant to the credits in a manner consistent with A.R.S. Title 45, Chapter 3.1, subject to subsection (I)(3) of this Section.
2. If the applicant proposes to use long-term storage credits that do not exist on the date of application or recover stored water on an annual basis pursuant to A.R.S. § 45-851.01, the Director shall evaluate the following in determining whether to include the proposed credits or the water proposed to be stored and recovered annually in the amount of water that is physically available for the applicant's proposed use:
a. The terms of a contract to obtain water to store in a storage facility;
b. The physical, continuous, and legal availability of the water proposed to be stored;
c. The presence of an existing storage facility that will be available for use for the proposed storage;
d. The existence of all required permits of an adequate duration; and
e. Whether recovery of the stored water will comply with subsection (I)(3) of this Section.
3. If the applicant proposes to recover the stored water from recovery wells located outside the area of impact of storage, the stored water will be considered physically available only if sufficient water exists for the withdrawals consistent with both of the following:
a. The maximum 100-year depth-to-static water level requirements established in subsection (B)(2) of this Section; and
b. Any criteria for the withdrawals prescribed in the management plan in effect at the time of the application.

J. If the applicant will obtain the source of water through a water exchange agreement, the Director shall determine that the water is physically available for the proposed use if the applicant submits evidence that the source of water the applicant or the applicant's customers will use will be physically available in accordance with the terms of this Section.

K. In the case of two or more pending, conflicting, complete and correct applications for determinations of assured water supply or determinations of adequate water supply, the Director shall give priority to the application with the earliest priority date. The priority date of an application for a determination of assured water supply or determination of adequate water supply shall be the date that a complete and correct application is filed with the Director. The Director shall consider an application complete and correct if it contains all the information required and the Director verifies that the information is accurate.

L. For a certificate applicant that proposes to use surface water, the Director shall determine that the proposed source is physically available only if the applicant demonstrates one of the following:
1. The land that is the subject of the application is a member land of the CAGRD.
2. The applicant has independently obtained the surface water supply.
3. The proposed municipal provider would satisfy the criteria in R12-15-722 if the municipal provider were subject to those requirements.

Historical Note

Adopted effective February 7, 1995 (Supp. 95-1). Section repealed; new Section made by final rulemaking at 12 A.A.R. 3475, effective September 12, 2006 (Supp. 06-3).

R12-15-717. Continuous Availability

A. The Director shall determine that an applicant will have sufficient supplies of water that will be continuously available for 100 years if the applicant submits sufficient evidence that adequate delivery, storage, and treatment works will be in place in a timely manner to make the water available to the applicant or the applicant's customers for 100 years and the applicant meets any applicable requirements in subsections (B) through (G) of this Section.

B. If the proposed source of water is groundwater, the applicant shall demonstrate that wells of a sufficient capacity will be constructed in a timely manner to serve the proposed uses on a continuous basis for 100 years.

C. If the proposed source of water is surface water other than CAP water or Colorado River water, the applicant shall demonstrate that a continuous supply will exist because of one or more of the following:
1. The projected volume to be diverted from the source is perennial at the point of diversion;
2. Adequate storage facilities will be available to the applicant in a timely manner to store water for use when a volume of surface water is not available at the point of diversion to satisfy the applicant's water demands;
3. The applicant has presented evidence of supplies of other sources of water that the Director has determined will be physically, continuously, and legally available to supplement the applicant's proposed surface water supplies;
4. The applicant or the proposed municipal provider will withdraw surface water from wells of sufficient capacity to meet the applicant's estimated water demand on a continuous basis for 100 years; or

5. The applicant has submitted a drought response plan that the Director has determined will conserve or augment a volume of water equal to the volume of water that is subject to drought.

D. If the proposed source of water is CAP water or Colorado River water, the applicant shall demonstrate that a continuous supply is available because of one or more of the following:
1. Adequate storage facilities will be available to the applicant in a timely manner to store water when a volume of CAP water or Colorado River water is not available to meet the applicant's water demands;
2. The applicant has presented evidence of supplies of other sources of water that the Director has determined will be physically, continuously, and legally available to the applicant to supplement the proposed CAP water or Colorado River water supplies; or
3. The applicant has submitted a drought response plan that the Director has determined will conserve or augment a volume of water equal to the volume subject to drought.

E. If the proposed source of water is effluent, the applicant shall demonstrate that the capability to use the effluent to meet the demands of the proposed use will not be affected by any fluctuations in the supply of the effluent.

F. If the proposed source of water is stored water to be recovered from recovery wells, the applicant shall demonstrate that recovery wells of a sufficient capacity will be constructed in a timely manner to serve the proposed use on a continuous basis for 100 years.

G. If an applicant will obtain the source of water through a water exchange agreement, the applicant shall demonstrate that the source of water the applicant or the applicant's customers will use will be continuously available in accordance with the terms of this Section.

Historical Note

Adopted effective February 7, 1995 (Supp. 95-1). Amended by emergency rulemaking at 11 A.A.R. 2706, effective June 29, 2005 for 180 days (Supp. 05-2). Emergency renewed for 180 days at 12 A.A.R. 144, effective December 23, 2005 (Supp. 05-4). Emergency expired. Section repealed; new Section made by final rulemaking at 12 A.A.R. 3475, effective September 12, 2006 (Supp. 06-3).

R12-15-718. Legal Availability

A. The Director shall determine that an applicant will have sufficient supplies of water that will be legally available for at least 100 years if the applicant submits all of the applicable information required by this Section.

B. If the applicant is an applicant for a certificate or a water report, the applicant shall submit the following, as applicable:
1. A Notice of Intent to Serve agreement between the owner of the land to be included in the subdivision and the proposed municipal provider, stating the proposed municipal provider's intent to serve the subdivision;
2. If the proposed municipal provider is a city or town, evidence indicating that the proposed subdivision is located within the incorporated limits of the city or town or evidence of the legal right of the city or town to serve water to the subdivision outside the city or town's incorporated limits; or
3. If the proposed municipal provider is a private water company, one of the following:
a. Evidence that the proposed municipal provider has a certificate of convenience and necessity approved by the Arizona Corporation Commission and the subdivision is located within the geographic area described in the certificate of convenience and necessity or any other area in which the Arizona Corporation Commission authorizes the private water company to serve water;
b. Evidence that the proposed municipal provider has an order preliminary issued by the Arizona Corporation Commission authorizing the municipal provider to provide water service and the proposed subdivision is located within the area described in the order preliminary; or
c. Evidence that the proposed municipal provider is not a public service corporation regulated by the Arizona Corporation Commission.

C. If the applicant is a private water company applying for a designation, the applicant shall submit evidence that the applicant has a certificate of convenience and necessity approved by the Arizona Corporation Commission, or has been issued an order preliminary by the Arizona Corporation Commission for a certificate of convenience and necessity, authorizing the applicant to serve the proposed use.

D. If a proposed source of water is groundwater to be withdrawn within an AMA, the applicant shall submit evidence that the applicant or the proposed municipal provider has one or more of the following:
1. A service area right;
2. An applicable non-irrigation grandfathered right to withdraw groundwater, in an amount sufficient to serve the proposed use; or
3. A pending notice of intent to establish a new service area and all of the following apply:
a. The notice of intent to establish a new service area identifies the proposed subdivision,
b. The applicant or the proposed municipal provider has obtained a permit for any wells used to establish the service area right,
c. The proposed municipal provider has obtained a water right or recovery well permit to establish the service area right, and
d. The water right is of sufficient volume and duration to meet the estimated water demand of the proposed subdivision until the anticipated date of issuance of a service area right.

E. If a proposed source of water is surface water other than CAP water or Colorado River water:
1. The applicant shall submit evidence that the applicant or the proposed municipal provider has a certificated surface water right, decreed water right, or a pre-1919 claim for the proposed source. If the applicant or the proposed municipal provider does not hold a surface water right or claim, but will receive water pursuant to a water right or claim that is appurtenant to the land that is the subject of the application, the applicant shall submit evidence of the water right or claim and evidence that the water right or claim may neither be legally withheld nor severed and transferred by the right holder or claimant.
2. If the certificated surface water right or decreed water right pre-dates the date of application by at least five years, or the applicant submits a pre-1919 claim, the applicant shall submit one of the following:
a. Evidence that the surface water supply has been used pursuant to the applicable water right or claim within the five years before the date of application;
b. Evidence that a court has determined that the right has not been abandoned; or
c. Evidence that the non-use would not have resulted in an abandonment of the right pursuant to A.R.S. § 45-189.
3. The Director shall determine that the volume of water that is legally available pursuant to a certificated surface water right, a decreed water right, or a pre-1919 claim is equal to the face value of the right or claim. If the right or claim is subsequently adjudicated, the Director shall determine the volume of water that is legally available based on the adjudicated amount of water.

F. Subject to subsections (M) and (N) of this Section, if a proposed source of water is CAP water, the applicant shall submit evidence that the applicant or the proposed municipal provider has entered into a subcontract with a multi-county water conservation district for the proposed volume of CAP water. The Director shall presume that a 50-year long-term, non-declining municipal and industrial subcontract is sufficient evidence of the legal availability of the volume of CAP water specified in the subcontract for 100 calendar years.

G. Subject to subsections (M) and (N) of this Section, if a proposed source of water is Colorado River water, the applicant shall submit evidence of one of the following:
1. The applicant or the proposed municipal provider has a contract with the United States Secretary of the Interior for the proposed supply; or
2. The applicant has obtained an allocation of Colorado River water from an entity to which all of the following apply:
a. The entity holds a contract for Colorado River water with the United States Secretary of the Interior;
b. The entity provides Colorado River water to the proposed municipal provider;
c. The entity has allocated a sufficient volume of the Colorado River water to the subdivision; and
d. The area that the entity may serve, described in the contract with the United States Secretary of the Interior, includes the subdivision.

H. If a proposed source of water is effluent, the applicant shall submit evidence that the applicant or the proposed municipal provider has the legal right to use the effluent.

I. If the applicant will obtain a proposed source of water through a written contract other than a water exchange agreement, a contract between a certificate applicant and the municipal provider proposed to serve the applicant, a contract with the United States Secretary of the Interior for Colorado River water, or a subcontract with a multi-county water conservation district, the applicant shall submit evidence that the person providing the water under the contract has a legal right to the water in accordance with the terms of this Section and that the terms of the contract will ensure that the proposed source of water will be delivered to the applicant or to the proposed subdivision. The Director shall determine the term of years for which the proposed source of water is legally available based on the term of years remaining in the contract. The Director shall determine the quantity of water legally available based on the volume established in the contract.

J. If the applicant will obtain a proposed source of water through a water exchange agreement, the applicant shall submit evidence that the water exchange agreement satisfies the requirements of A.R.S. Title 45, Chapter 4.

K. If the Director can determine the proposed source of water to be physically and continuously available only because of the use of storage facilities by the applicant or by the proposed municipal provider, the applicant shall submit evidence of the applicant's or the proposed municipal provider's legal right to store water in the storage facilities.

L. If the applicant proposes to use long-term storage credits, the applicant shall submit evidence that the applicant or the proposed municipal provider has the legal right to use the credits under A.R.S. Title 45, Chapter 3.1.

M. If a proposed supply of water is Colorado River water or CAP water leased from an Indian community, the applicant shall submit evidence that the water leased has a priority equal to or higher than CAP municipal and industrial water, evidence that the Indian community is expressly authorized by an Act of Congress to lease the water for use off Indian community lands, evidence of the lease, and evidence of one of the following:
1. The proposed water supply is available under the lease for at least 100 years from any time during the year in which the applicant submits the application.
2. The term of the lease has less than 100 years remaining in the year in which the applicant submits the application and a supplemental water supply, together with the leased water, provides a 100-year water supply. The applicant shall demonstrate that the supplemental water supply is physically, continuously, and legally available and, if such supplemental supply is groundwater, that use of the groundwater is consistent with the management goal of the AMA. If the supplemental supply is water recovered through the use of long-term storage credits, the applicant shall also submit the following, as applicable:
a. If the applicant is to use the long-term storage credits before the beginning of the lease term, evidence that the applicant or the proposed municipal provider has obtained a recovery well permit that allows the applicant or the proposed municipal provider to recover water pursuant to the long-term storage credits; or
b. If the long-term storage credits will be accrued in the future, evidence that the applicant or the proposed municipal provider will accrue the long-term storage credits within 20 years after the effective date of the designation, certificate, or water report by storing the water under an issued water storage permit at a permitted storage facility and that no more than 20 years of the applicant's supplemental water supply will be provided by the long-term storage credits.

N. If the Director previously determined that Colorado River water or CAP water leased from an Indian community was legally available to a designated provider for 100 years, the Director shall determine that the designated provider continues to have a legally available supply of water for 100 years for the annual amount of water available under the lease if:
1. The lease has at least 50 years remaining in its term or the lease has at least 40 years remaining in its term and the designated provider submits evidence to the Director of active and ongoing negotiations with the Indian community to renew or re-negotiate the lease; and
2. One of the following applies:
a. No more than 15% of the total water supplies that the designated provider establishes as physically, continuously, and legally available during any year are obtained through leases

with Indian communities;

b. Groundwater will be physically, continuously, and legally available to the designated provider at the end of the lease term to substitute for the leased water for the remainder of the 100-year period, and the projected use of groundwater is consistent with the management goal of the AMA. For purposes of this subsection, the designated provider may demonstrate that the proposed use is consistent with the management goal by entering into a written agreement with the Director under which the designated provider agrees to replace through replenishment or underground storage any groundwater used at the end of the lease term if groundwater use is not consistent with the management goal. The written agreement shall provide that specific performance is the only remedy in the event of default;

c. A non-groundwater source of water will be physically, continuously, and legally available at the end of the lease term to substitute for the leased water for the remainder of the 100-year period; or

d. The designated provider's governing board or council submits a resolution requesting that the designated provider be allowed to increase its projected use of Indian lease water from 15%, as allowed by subsection (N)(2)(a) of this Section, to 20%, and the Director finds that all of the following apply:

i. No more than 20% of the total water supplies that the designated provider establishes as physically, continuously, and legally available during any year are obtained through leases with Indian communities;

ii. No more than 15% of the total water supplies that the designated provider establishes as physically, continuously, and legally available during any year are obtained through any single lease with an Indian community; and

iii. The designated provider does not meet the requirements of subsections (N)(2)(a), (b), or (c) of this Section.

Historical Note

Adopted effective February 7, 1995 (Supp. 95-1). Section repealed; new Section made by final rulemaking at 12 A.A.R. 3475, effective September 12, 2006 (Supp. 06-3).

R12-15-719. Water Quality

A. Except as provided in subsection (B) of this Section, when reviewing an application for a determination of assured water supply or a determination of adequate water supply, the Director shall determine that the water supply is of adequate quality if one of the following applies:

1. The applicant certifies on the application that the applicant or the proposed municipal provider will be regulated by ADEQ, or another governmental entity with equivalent jurisdiction, as a public water system pursuant to A.R.S. § 49-351, et seq., unless ADEQ, or another governmental entity with equivalent jurisdiction, has determined, after notice and an opportunity for a hearing, that the public water system is in significant noncompliance with A.A.C. Title 18, Chapter 4 and is not taking action to resolve the noncompliance; or
2. The applicant has submitted results of a lab analysis demonstrating that the water meets water quality requirements in accordance with A.A.C. Title 18, Chapter 4, or that the water will meet these requirements after treatment that is required by law. The lab analysis shall be based on water withdrawn from a well representative of the well or wells from which water will be withdrawn for the proposed use, conducted in compliance with sample collection and analysis requirements in A.A.C. Title 18, Chapter 4, and completed within 60 days of the date the application is submitted to the Director. If ADEQ waives any of the water quality or sample collection and analysis requirements in A.A.C. Title 18, Chapter 4, the Director shall not require the applicant to meet the waived requirements.

B. If a well or a proposed well from which water will be withdrawn for the proposed use is located within one mile of a WQARF site or Superfund site, the Director shall determine that the water supply is of adequate quality only if the applicant submits a contaminant migration and mitigation analysis, demonstrating that the water supply will continue to meet the requirements in A.A.C. Title 18, Chapter 4 for 100 years. The contaminant migration and mitigation analysis may include the impact of any mitigation or treatment, including mitigation or treatment required pursuant to a consent decree.

Historical Note

Adopted effective February 7, 1995 (Supp. 95-1). Section repealed; new Section made by final rulemaking at 12 A.A.R. 3475, effective September 12, 2006 (Supp. 06-3).

R12-15-720. Financial Capability

A. The Director shall determine that an applicant for a certificate or a water report has the financial capability to construct adequate delivery, storage, and treatment works if the applicant demonstrates one or more of the following:

1. The applicant will submit its final plat to a qualified platting authority;
2. The applicant has constructed adequate delivery, storage, and treatment works, and water service is available to each lot; or
3. The applicant has posted a performance bond with the platting authority for the entire cost of adequate delivery, storage, and treatment works.

B. Upon receiving evidence that a platting authority has established standards for proof of financial capability to construct adequate delivery, storage, and treatment works, pursuant to A.R.S. § 9-463.01(C)(8) or A.R.S. § 11-806.01(G), the Director shall classify the platting authority as a qualified platting authority. The Director shall maintain a list of qualified platting authorities.

C. The Director shall determine that an applicant for a designation has the financial capability to construct adequate delivery, storage, and treatment works if the applicant demonstrates one or more of the following for each of those facilities:

1. The applicant has constructed adequate delivery, storage, and treatment works;
2. The applicant has entered into written agreements requiring a potential developer to construct adequate delivery, storage, and treatment works;
3. If the applicant is a city or town, the applicant has:
   a. Adopted a five year capital improvement plan that provides for the construction, or the commencement of construction, of adequate delivery, storage, and treatment works in a timely manner, and has submitted a certification by the applicant's chief financial officer that finances are available to implement that portion of the five-year plan; or
   b. Submitted evidence demonstrating that financing mechanisms are in place to construct adequate delivery, storage, and treatment works in a timely manner; or
4. If the applicant is a private water company, the applicant has received approval from the Arizona Corporation Commission for financing the construction of adequate delivery, storage, and treatment works.

Historical Note

Adopted effective February 7, 1995 (Supp. 95-1). Section repealed; new Section made by final rulemaking at 12 A.A.R. 3475, effective September 12, 2006 (Supp. 06-3).

R12-15-721. Consistency with Management Plan

A. The Director shall determine whether a designation applicant's projected use of groundwater withdrawn within an active management area is consistent with the management plan as follows:

1. If the applicant is providing water to customers as of the date of application, the applicant's projected water use is consistent with the management plan if either of the following apply:
   a. The applicant is in compliance with its applicable management plan requirements in the most recent calendar year for which data is available before the date of application; or
   b. The applicant has signed a stipulation and consent order that is in effect on the date of the application, or that becomes effective during the time of review of the application, to remedy non-compliance with the management plan requirements and the applicant is in compliance with the terms of the stipulation and consent order.
2. If the applicant has not commenced serving water to customers as of the date of application, the applicant shall submit a water use plan that demonstrates to the Director that compliance with management plan requirements will be achieved through the use of conservation or augmentation measures.
3. If the applicant has a pending request for an administrative review or variance from its management plan requirements, the Director shall not make a finding regarding compliance with this Section until the Director has issued a final decision and order on the request or the request has been withdrawn.

B. The Director shall determine that a certificate applicant's projected use of groundwater withdrawn within an AMA is consistent with the management plan if the applicant submits a water use plan for the subdivision that includes both of the following:

1. Information demonstrating that compliance with management plan requirements will be achieved through conservation or augmentation measures; and
2. All information required to calculate the water requirements for each proposed water use.

C. A certificate applicant for a subdivision of 50 or fewer lots is exempt from the requirements of this rule.

Historical Note

Adopted effective February 7, 1995 (Supp. 95-1). Section repealed; new Section made by final rulemaking at 12 A.A.R. 3475, effective September 12, 2006 (Supp. 06-3).

R12-15-722. Consistency with Management Goal

A. For the Phoenix, Prescott, or Tucson AMAs, the Director shall calculate the volume of groundwater that may be used consistent with the management goal of the AMA in which the proposed use is located for at least 100 years by adding the following:

1. The amount of the groundwater allowance, according to R12-15-724(A), R12-15-726(A), or R12-15-727(A).
2. The amount of any extinguishment credits pledged to the certificate or designation, according to R12-15-724(B), R12-15-726(B), or R12-15-727(B).
3. Any groundwater that is consistent with the achievement of the management goal pursuant to A.R.S. Title 45, Chapter 2.

B. The Director shall determine that a proposed groundwater use in the Phoenix, Prescott, or Tucson AMA is consistent with the management goal of the AMA if the volume calculated in subsection (A) of this Section is equal to or greater than the portion of the applicant's estimated water demand to be met with groundwater.

C. For a certificate in the Pinal AMA, the Director shall calculate the volume of groundwater that may be used consistent with the management goal of the AMA for at least 100 years by adding the following:

1. The amount of the groundwater allowance, according to R12-15-725(A)(1).
2. The amount of any extinguishment credits pledged to the certificate for a grandfathered right that was extinguished on or after October 1, 2007, according to R12-15-725(B).
3. The amount of any extinguishment credits pledged to the certificate for a grandfathered right that was extinguished before October 1, 2007. The Director shall calculate the amount of the extinguishment credits by multiplying the annual amount of the credits by 100.
4. Any groundwater that is consistent with the achievement of the management goal pursuant to A.R.S. Title 45, Chapter 2.

D. For a certificate in the Pinal AMA, the Director shall determine that the proposed groundwater use is consistent with the management goal of the AMA if the volume calculated in subsection (C) of this Section is equal to or greater than the portion of the applicant's estimated water demand to be met with groundwater.

E. For a designation in the Pinal AMA, the Director shall calculate the volume of groundwater that may be used consistent with the management goal of the Pinal AMA on an annual basis by adding the following:

1. The amount of the groundwater allowance, according to R12-15-725(A)(2). If any of the groundwater allowance is not used during a year, the unused groundwater allowance shall not be added to the volume calculated under this subsection for the following year.
2. The amount of any extinguishment credits pledged to the designation for a grandfathered right that was extinguished on or after October 1, 2007, according to R12-15-725(B), divided by 100. Extinguishment credits for a grandfathered right that was extinguished on or after October 1, 2007 may be used in any year.
3. The annual amount of any extinguishment credits pledged to the designation for a grandfathered right that was extinguished before October 1, 2007. The following shall apply if any of the extinguishment credits are not used during a calendar year:

a. If the extinguishment credits were pledged to the designation before October 1, 2007, any extinguishment credits not used during a calendar year shall be added to the volume calculated under this subsection for the following calendar year.
b. If the extinguishment credits are pledged to the designation on or after October 1, 2007, any of the extinguishment credits not used during a calendar year shall not be added to the volume calculated under this subsection for the following calendar year, except that if the extinguishment credits were originally pledged to a certificate before October 1, 2007 and are used to support the municipal provider's designation pursuant to R12-15-723(G)(2), any of the extinguishment credits not used during a calendar year shall be added to the volume calculated under this subsection for the following calendar year.

4. Any groundwater that is consistent with the achievement of the management goal pursuant to A.R.S. Title 45, Chapter 2.

F. For a designation in the Pinal AMA, the Director shall determine that the proposed groundwater use is consistent with the management goal of the Pinal AMA if the annual volume calculated in subsection (E) of this Section is equal to or greater than the portion of the applicant's annual estimated water demand to be met with groundwater.

G. Upon application, the following volumes of groundwater used by an applicant are considered consistent with the management goal:

1. If the Director determines that a surface water supply is physically available under R12-15-716 and the volume of the supply actually available during a calendar year is equal to or less than the drought volume for the supply, the volume of groundwater, other than the groundwater that is accounted for under subsection (A), (C), or (E) of this Section, withdrawn within the AMA that, when combined with the available surface water supply, is equal to or less than the drought volume.
2. Any volume of groundwater withdrawn within a portion of an AMA that is exempt from conservation requirements under A.R.S. Title 45 due to waterlogging. The Director shall review the application of this exclusion on a periodic basis, not to exceed 15 years.
3. Remedial groundwater that is consistent with the management goal according to the requirements of R12-15-729.

H. An applicant for a certificate of assured water supply for a dry lot subdivision of 20 lots or fewer is exempt from the requirements of this Section.

Historical Note

Adopted effective February 7, 1995 (Supp. 95-1). Section repealed; new Section made by final rulemaking at 12 A.A.R. 3475, effective September 12, 2006 (Supp. 06-3). Amended by final rulemaking at 13 A.A.R. 1394, effective October 1, 2007 (Supp. 07-2).

R12-15-723. Extinguishment Credits

A. Except as provided in subsection (D) of this Section, the owner of a grandfathered right may extinguish the right in exchange for extinguishment credits by submitting the following:

1. A notarized statement of extinguishment of a grandfathered right on a form provided by the Director;
2. The grandfathered right number;
3. If the right being extinguished is a type 1 non-irrigation grandfathered right or an irrigation grandfathered right, evidence of ownership of the land to which the grandfathered right is appurtenant;
4. If the grandfathered right is located in the Prescott AMA, evidence that all of the following conditions are met:
   a. The land to which the right is appurtenant has not been and will not be subdivided pursuant to a preliminary plat or a final plat that was approved by a city, town, or county before August 21, 1998; and
   b. The land to which the right is appurtenant is not and will not be the location of a subdivision for which a complete and correct application for a certificate of assured water supply was submitted to the Director before August 21, 1998;
5. If the right being extinguished is an irrigation grandfathered right, evidence that the development of the land to which the right is appurtenant is not completed; and
6. Any additional information the Director may reasonably require to process the extinguishment.

B. The Director shall calculate the amount of extinguishment credits pursuant to R12-15-724(B), R12-15-725(B), R12-15-726(B) or R12-15-727(B). The Director shall notify the owner of the amount of extinguishment credits in writing. If the owner is extinguishing only a portion of the right, the Director shall issue a new certificate of grandfathered right for the remainder of the right.

C. A type 1 non-irrigation grandfathered right or an irrigation grandfathered right may be extinguished in whole or in part. A type 2 non-irrigation grandfathered right may be extinguished only in whole.

D. The following rights may not be extinguished in exchange for extinguishment credits:

1. An irrigation grandfathered right that is appurtenant to land that has been physically developed for a non-irrigation use. The Director shall not consider the land to be physically developed until the development is completed.
2. A type 1 non-irrigation grandfathered right, if the Director determines that the holder is likely to continue to receive groundwater from an undesignated municipal provider for the same use pursuant to the provider's service area right or pursuant to a groundwater withdrawal permit.
3. A type 2 non-irrigation grandfathered right that was issued based on the withdrawal of groundwater for mineral extraction or processing or for the generation of electrical energy.
4. On or after January 1, 2025, any grandfathered right that is in the Phoenix, Prescott, or Tucson AMAs.
5. Any grandfathered right in the Pinal AMA beginning in the first calendar year in which the allocation factor for the extinguishment of a grandfathered right is zero, pursuant to R12-15-725(B)(3) or (4).
6. A type 1 non-irrigation grandfathered right that was requested to be included by a city or town in the Tucson AMA in the determination made under A.R.S. § 45-463(F).

E. The owner of extinguishment credits may pledge the credits to a certificate or to a designation before the certificate or designation is issued by submitting with the application for the certificate or designation a notice of intent to pledge extinguishment credits on a form provided by the Director. The extinguishment credits shall be pledged to the certificate or designation upon issuance of the certificate or designation.

F. The owner of extinguishment credits may pledge the credits to a certificate or to a designation after the certificate or designation is issued by submitting a notice of intent to pledge extinguishment credits on a form provided by the Director. The Director shall notify the owner of the extinguishment credits and the certificate holder or designated provider that the credits have been pledged to the certificate or designation.

G. Extinguishment credits that have not been pledged to a certificate or designation may be conveyed within the same AMA. Extinguishment credits pledged to a certificate or designation shall not be conveyed to another person, except that:

1. If extinguishment credits are pledged to a certificate that is later assigned or reissued, any unused credits are transferred, by operation of this subsection, to the assigned or reissued certificate. If the certificate is partially assigned or reissued, a pro rata share of the unused extinguishment credits is transferred to each assigned or reissued certificate according to the estimated water demand.
2. If extinguishment credits are pledged to a certificate for a subdivision that is later served by a designated provider or a municipal provider that is applying for a designation, any unused extinguishment credits may be used to support the municipal provider's designation as long as the municipal provider serves the subdivision and remains designated. If the municipal provider is no longer serving the subdivision or if the municipal provider loses its designated status, any unused extinguishment credits shall revert, by operation of this subsection, to the certificate to which they were originally pledged.

H. The Director shall review a statement of extinguishment of a grandfathered right and a notice of intent to pledge extinguishment credits pursuant to the licensing time-frame provisions in R12-15-401.

Historical Note

Adopted effective February 7, 1995 (Supp. 95-1). Section repealed; new Section made by final rulemaking at 12 A.A.R. 3475, effective September 12, 2006 (Supp. 06-3). Amended by final rulemaking at 13 A.A.R. 1394, effective October 1, 2007 (Supp. 07-2).

R12-15-724. Phoenix AMA Calculation of Groundwater Allowance and Extinguishment Credits

A. The Director shall calculate the groundwater allowance for a certificate or designation in the Phoenix AMA as follows:

1. If the application is for a certificate, multiply the applicable allocation factor in the table below by the annual estimated water demand for the proposed subdivision.

MANAGEMENT PERIOD	ALLOCATION FACTOR
Third	4
Fourth	2
Fifth	1
After Fifth	0

2. If the application is for a designation and the applicant provided water to its customers prior to February 7, 1995, multiply 7.5 by the total volume of water provided by the applicant to its customers from any source during calendar year 1994, consistent with the municipal conservation requirements established for the applicant pursuant to Section 5-103(A)(1) of the Second Management Plan for the Phoenix AMA.
3. If the application is for a designation and the applicant commenced providing water to its customers on or after February 7, 1995, the applicant's groundwater allowance is zero acre-feet.
4. For each calendar year of a designation, the Director shall calculate the volume of incidental recharge for a designated provider within the Phoenix AMA and add that volume to the designated provider's groundwater allowance. The Director shall calculate the volume of incidental recharge by multiplying the provider's total water use from any source in the previous calendar year by the standard incidental recharge factor of 4%. A designated provider may apply for a variance from the standard incidental recharge factor as provided in A.R.S. § 45-566.01(E)(1). The Director may establish a different incidental recharge factor for the designated provider if the provider demonstrates to the satisfaction of the Director that the ratio of the average annual amount of incidental recharge expected to be attributable to the provider during the management period, to the average amount of water expected to be withdrawn, diverted, or received for delivery by the provider for use within its service area during the management period, is different than 4%.

B. The Director shall calculate the extinguishment credits for the extinguishment of a grandfathered right in the Phoenix AMA as follows:

1. For the extinguishment of a type 2 non-irrigation grandfathered right, multiply the number of acre-feet indicated on the certificate by the difference between 2025 and the calendar year of extinguishment.
2. For the extinguishment of all or part of an irrigation grandfathered right, or all or part of a type 1 non-irrigation grandfathered right, multiply 1.5 acre-feet per acre by the number of irrigation acres associated with the extinguished irrigation grandfathered right or the number of acres to which the extinguished type 1 non-irrigation grandfathered right is appurtenant, and then multiply the product by the difference between 2025 and the calendar year of extinguishment, except that:
   a. If only a portion of an irrigation grandfathered right or a type 1 non-irrigation grandfathered right is extinguished, the Director shall include in the calculation only those acres associated with the portion of the right that is extinguished; and
   b. If an extinguished irrigation grandfathered right has a debit balance in the corresponding flexibility account established under A.R.S. § 45-467, the Director shall subtract the amount of the debit from the amount of the extinguishment.

Historical Note

Adopted effective February 7, 1995 (Supp. 95-1). Section repealed; new Section made by final rulemaking at 12 A.A.R. 3475, effective September 12, 2006 (Supp. 06-3).

R12-15-725. Pinal AMA - Groundwater Allowance and Extinguishment Credits Calculation

A. The Director shall calculate the groundwater allowance for a certificate or designation in the Pinal AMA as follows:

1. If the application is for a certificate, multiply the applicable allocation factor in the table below for the management period in effect on the date of application by the annual estimated water demand for the proposed subdivision.

.

MANAGEMENT PERIOD/DATE OF APPLICATION	ALLOCATION FACTOR
Third	10
Fourth	10
Fifth	5
After Fifth	0

2. If the application is for a designation:
   a. If the applicant was designated as having an assured water supply as of October 1, 2007:
      i. Multiply the applicant's service area population as of October 1, 2007 by 125 gallons per capita per day and multiply the product by 365 days. The service area population shall be determined using the methodology set forth in Section 5-103(D) of the Third Management Plan for the Pinal AMA.
      ii. Convert the number of gallons determined in subsection (A)(2)(a)(i) into acre-feet by dividing the number by 325,851 gallons.
      iii. Determine the number of residential lots within plats that were recorded as of October 1, 2007 but not served water as of that date, and to which the applicant commenced water service by January 1, 2010.
      iv. Multiply the number of lots determined in subsection (A)(2)(a)(iii) of this Section by 0.35 acre-foot per lot.
      v. Add the volume from subsection (A)(2)(a)(ii) of this Section and the volume from subsection (A)(2)(a)(iv) of this Section.
   b. If the applicant provided water to its customers before October 1, 2007 but was not designated as having an assured water supply as of that date, and a complete and correct application for designation is filed before January 1, 2012, multiply the applicant's service area population as of October 1, 2007 by 125 gallons per capita per day and multiply the product by 365 days. The service area population shall be determined using the methodology in Section 5-103(D) of the Third Management Plan for the Pinal AMA.
   c. If the applicant provided water to its customers before October 1, 2007 but was not designated as having an assured water supply as of that date, and a complete and correct application for designation is filed on or after January 1, 2012, the applicant's groundwater allowance is zero acre-feet.
   d. If the applicant commenced providing water to its customers on or after October 1, 2007, the applicant's groundwater allowance is zero acre-feet.
3. For each calendar year of a designation, the Director shall calculate the volume of incidental recharge for a designated provider within the Pinal AMA and add that volume to the designated provider's groundwater allowance. The Director shall calculate the volume of incidental recharge by multiplying the provider's total water use from any source in the previous calendar year by the standard incidental recharge factor of 4%. A designated provider may apply for a variance from the standard incidental recharge factor by submitting a hydrologic study demonstrating, to the satisfaction of the Director, that the ratio of the average annual amount of incidental recharge expected to be attributable to the designated provider during the management period to the average annual amount of water expected to be withdrawn, diverted or received for delivery by the designated provider for use within its service area during the management period is different than 4%. The hydrologic study shall include the amount of water withdrawn, diverted or received for delivery by the designated provider for use within its service area during each of the preceding five years and the amount of incidental recharge that was attributable to the designated provider during each of those years. The Director may establish a different incidental recharge factor for the designated provider upon such demonstration.

B. The Director shall calculate the extinguishment credits for the extinguishment of a grandfathered right in the Pinal AMA as follows:

1. For the extinguishment of a type 2 non-irrigation grandfathered right, multiply the number of acre-feet indicated on the certificate by the applicable allocation factor as determined under subsection (B)(3) or (B)(4) of this Section.
2. For the extinguishment of all or part of an irrigation grandfathered right, or all or part of a type 1 non-irrigation grandfathered right, an amount calculated by multiplying 1.5 acre-feet by the number of irrigation acres associated with the extinguished irrigation grandfathered right or the number of acres to which the extinguished type 1 non-irrigation grandfathered right is appurtenant, and then multiply that product by the applicable allocation factor as determined under subsection (B)(3) or (B)(4) of this Section, except that:
   a. If only a portion of an irrigation grandfathered right or a type 1 non-irrigation grandfathered right is extinguished, the Director shall include in the calculation only those acres associated with the portion of the right that is extinguished; and
   b. If an extinguished irrigation grandfathered right has a debit balance in the corresponding flexibility account established under A.R.S. § 45-467, the Director shall subtract the amount of the debit from the amount of the extinguishment credits.
3. Except as provided in subsection (B)(4) of this Section, in calculating the extinguishment credits for the extinguishment of a grandfathered right under subsection (B)(1) or (B)(2) of this Section, the Director shall use the allocation factor associated with the year in which the grandfathered right is extinguished, as shown in the table below.

	Allocation
Year	Factor
2007	100
2008	100
2009	100
2010	90
2011	88
2012	86
2013	84
2014	82
2015	80
2016	78
2017	76
2018	74
2019	72
2020	70
2021	68
2022	66
2023	64
2024	62
2025	60
2026	58
2027	56
2028	54
2029	52
2030	50
2031	48
2032	46
2033	44
2034	42
2035	40
2036	38
2037	36

2038	34
2039	32
2040	30
2041	28
2042	26
2043	24
2044	22
2045	20
2046	18
2047	16
2048	14
2049	12
2050	10
2051	8
2052	6
2053	4
2054	2
After 2054	0

4. If, before January 1, 2055, there is a moratorium on adding new member lands and member service areas in the Pinal AMA pursuant to A.R.S. § 45-576.06(A), in calculating the extinguishment credits for the extinguishment of a grandfathered right under subsection (B)(1) or (B)(2) of this Section, the Director shall use an allocation factor determined as follows:
   a. If the grandfathered right is extinguished while the moratorium is in effect, the Director shall use the allocation factor associated with the year in which the moratorium first became effective, as shown in the table in subsection (B)(3) of this Section.
   b. If the grandfathered right is extinguished when the moratorium is no longer in effect, the Director shall use the allocation factor associated with the year determined pursuant to this subsection, as shown in the table in subsection (B)(3) of this Section. The Director shall determine the year as follows:
      i. Subtract the year in which the moratorium first became effective from the year in which the moratorium ended.
      ii. Subtract the difference in subsection (B)(4)(b)(i) of this Section from the year in which the grandfathered right was extinguished.

Historical Note

Adopted effective February 7, 1995 (Supp. 95-1). Section repealed; new Section made by final rulemaking at 12 A.A.R. 3475, effective September 12, 2006 (Supp. 06-3). Section repealed; new Section made by final rulemaking at 13 A.A.R. 1394, effective October 1, 2007 (Supp. 07-2).

R12-15-726. Prescott AMA Calculation of Groundwater Allowance and Extinguishment Credits

A. The Director shall calculate the groundwater allowance for a certificate or designation in the Prescott AMA as follows:
1. If the application is for a certificate of assured water supply, the Director shall:
   a. Subtract the year of application from 2025,
   b. Multiply the number determined in subsection (A)(1)(a) by the applicant's annual estimated water demand, and
   c. Divide that product by two. The minimum volume that may be calculated in this subsection is zero acre-feet.
2. If the application is for a designation of assured water supply:
   a. Except as provided in subsections (A)(3) and (A)(5), if the applicant was in existence as of January 12, 1999, and the application is filed before calendar year 2026, the Director shall:
      i. Multiply by 100 the largest volume of groundwater determined by the Director to have been withdrawn by the applicant from within the Prescott AMA for use within the applicant's service area in any calendar year from 1995 through 1998, consistent with the municipal conservation requirements applicable under the second management plan for the Prescott active management area;
      ii. Determine the volume of the applicant's total water demand, from any source, for 1999, consistent with the municipal conservation requirements established for the applicant in the management plan in effect on the date of application;
      iii. Determine the volume of the applicant's total water demand, from any source, for 2014, consistent with the municipal conservation requirements established for the applicant in the management plan in effect on the date of application;
      iv. Subtract the volume calculated in subsection (A)(2)(a)(ii) from the volume calculated in subsection (A)(2)(a)(iii) and then multiply the difference by 26;
      v. Divide the product obtained in subsection (A)(2)(a)(iv) by two;
      vi. If any residential groundwater uses, including residential groundwater uses served by an exempt well, in existence on August 21, 1998, have been replaced by permanent water service from the applicant after August 21, 1998, multiply one-half acre-foot of groundwater by the number of housing units receiving the service and then multiply that product by 100;
      vii. Determine the volume of groundwater withdrawn by the applicant from within the Prescott active management area during the period beginning January 1, 1999, and ending December 31 of the calendar year before the date of the application;
      viii. Multiply the volume of groundwater withdrawn by the applicant from within the Prescott active management area in 1999 by the number of calendar years in the period beginning with 1999 and ending with the calendar year before the date of application;
      ix. Subtract from the volume calculated in subsection (A)(2)(a)(vii) the volume calculated in subsection (A)(2)(a)(viii). The volume calculated in this subsection shall not be less than zero; and
      x. Add the volumes calculated in subsections (A)(2)(a)(i), (A)(2)(a)(v), and (A)(2)(a)(vi), and then subtract from the sum the volume calculated in subsection (A)(2)(a)(ix).
   b. If the applicant did not exist as of January 12, 1999, or the date of application occurs after calendar year 2025, the groundwater allowance is zero acre-feet, except that if any residential groundwater uses, including residential groundwater uses served by an exempt well, in existence on August 21, 1998, have been replaced by permanent water service from the applicant after August 21, 1998, the groundwater allowance is a volume of groundwater computed by multiplying one-half acre-foot of groundwater by the number of housing units receiving the service and multiplying that product by 100.
3. For the purpose of determining the groundwater allowance under subsection (A)(2)(a), at the request of the applicant, the Director shall replace the volume of groundwater calculated in subsection (A)(2)(a)(ii) through (v) with the amount of groundwater necessary for the applicant to serve the residential lots described in subsection (A)(4):
   a. To compute this amount of groundwater, the Director shall:
      i. Determine the average dwelling occupancy within the applicant's service area and multiply that average occupancy by an amount of groundwater, calculated by multiplying 150 gallons per capita per day by 365 days; and
      ii. Multiply the product in subsection (A)(3)(a)(i) by the number of residential lots described in subsection (A)(4), and then multiply that product by 100.
   b. The Director shall not include the amount computed in subsection (A)(3)(a) within the amount of groundwater that the applicant may use under subsection (A)(2)(a) until a final plat for the lots has been recorded.
4. The Director shall include residential lots that will be served by the applicant in the calculation made under subsection (A)(3) if the lots meet all of the following criteria:
   a. A preliminary plat for the lots was submitted to the city, town, or county on or before August 21, 1998, and the final plat is subsequently recorded;
   b. The lots were not being served water on or before August 21, 1998; and
   c. Any one of the following applies:
      i. The lots were included within an application for certificate of assured water supply that was filed before August 21, 1998, the Director determined that the application was complete and correct as of August 21, 1998, and the Director subsequently issued a certificate of assured water supply for the lots.
      ii. A preliminary plat for the lots was approved by a city, town, or county on or before August 21, 1998. At the time the preliminary plat was approved, the subdivider of the lots obtained a written commitment of water service from a municipal provider that was designated as having an assured water supply and the provider demonstrated to the satisfaction of the Director that sufficient water is physically available to serve the lots under the criteria in R12-15-716.
5. For the purpose of determining the groundwater allowance under subsection (A)(2)(a), if the applicant makes the request described in subsection (A)(3), the Director shall replace the volume of groundwater calculated in subsection (A)(2)(a)(viii) with an amount of groundwater calculated as follows. The Director shall:
   a. Determine the number of calendar years in the period beginning with 1999 and ending with the calendar year before the date of application and multiply that number of years by the largest volume of groundwater determined by the Director to have been withdrawn by the applicant from within the Prescott active management area for use within the applicant's service area in any calendar year from 1995 through 1998, consistent with the municipal conservation requirements applicable under the second management plan for the Prescott active management area;
   b. Determine the average dwelling occupancy within the applicant's service area and multiply that average dwelling occupancy by an amount of groundwater calculated by multiplying 150 gallons per capita per day by 365 days;
   c. For each year in the period beginning with 1999 and ending with the calendar year before the date of application, determine the number of the residential lots that meet the criteria in subsection (A)(4) and were served water by the applicant as of July 1 of the relevant year and add the number of these residential lots determined for each year;
   d. Multiply the volume of groundwater calculated in subsection (A)(5)(b) by the number of residential lots in subsection (A)(5)(c); and
   e. Add the volumes of groundwater from subsections (A)(5)(a) and (A)(5)(d).

B. The Director shall calculate the extinguishment credits for extinguishing a grandfathered right in the Prescott AMA as follows:
1. For the extinguishment of a type 2 non-irrigation grandfathered right, multiply the number of acre-feet indicated on the certificate by the difference between 2025 and the calendar year of extinguishment.
2. For the extinguishment of an irrigation grandfathered right or a type 1 non-irrigation grandfathered right:
a. Through December 31, 2010:
i. If the irrigation acres associated with the extinguished right were irrigated for at least four of the six calendar years preceding January 1, 2000, multiply 1.5 acre-feet per acre by the number of irrigation acres associated with the extinguished right or the number of acres to which the extinguished right is appurtenant and multiply that product by 25.
ii. If the irrigation acres associated with the extinguished right were not irrigated for at least four of the six calendar years preceding January 1, 2000, multiply 1.5 acre-feet per acre by the number of irrigation acres associated with the extinguished right or the number of acres to which the extinguished right is appurtenant and multiply the product by the difference between 2025 and the year in which the statement of intent to extinguish is filed.
b. After December 31, 2010, multiply 1.5 acre-feet per acre by the number of irrigation acres associated with the extinguished right or the number of acres to which the extinguished right is appurtenant and multiply the product by the difference between 2025 and the year in which the statement of intent to extinguish is filed.

Historical Note
New Section made by final rulemaking at 12 A.A.R. 3475, effective September 12, 2006 (Supp. 06-3).

R12-15-727. Tucson AMA Calculation of Groundwater Allowance and Extinguishment Credits
A. The Director shall calculate the groundwater allowance for a certificate or designation in the Tucson AMA as follows:
1. If the application is for a certificate, multiply the applicable allocation factor in the table below by the annual estimated water demand for the proposed subdivision.

MANAGEMENT PERIOD	ALLOCATION FACTOR
Third	8
Fourth	4
Fifth	2
After Fifth	0

2. If the application is for a designation and the applicant provided water to its customers before February 7, 1995, multiply 15 by the total volume of water provided by the applicant to its customers from any source during calendar year 1994, consistent with the municipal conservation requirements established for the applicant pursuant to Section 5-103(A)(1) of the Second Management Plan for the Tucson AMA.
3. If the application is for a designation and the applicant commenced providing water to its customers on or after February 7, 1995, the applicant's groundwater allowance is zero acre-feet.
4. For each calendar year of the designation, the Director shall calculate the volume of incidental recharge for a designated provider within the Tucson AMA and add that volume to the designated provider's groundwater allowance. The Director shall calculate the volume of incidental recharge by multiplying the provider's total water use from any source in the previous calendar year by the standard incidental recharge factor of 4%. A designated provider may apply for a variance from the standard incidental recharge factor as provided in A.R.S. § 45-566.01(E)(1). The Director may establish a different incidental recharge factor for the designated provider if the provider demonstrates to the satisfaction of the Director that the ratio of the average annual amount of incidental recharge expected to be attributable to the provider during the management period, to the average amount of water expected to be withdrawn, diverted, or received for delivery by the provider for use within its service area during the management period, is different than 4%.

B. The Director shall calculate the extinguishment credits for the extinguishment of a grandfathered right in the Tucson AMA as follows:
1. For the extinguishment of a type 2 non-irrigation grandfathered right, multiply the number of acre-feet indicated on the certificate by the difference between 2025 and the calendar year of extinguishment.
2. For the extinguishment of all or part of an irrigation grandfathered right, or all or part of a type 1 non-irrigation grandfathered right, multiply 1.5 acre-feet per acre by the number of irrigation acres associated with the extinguished irrigation grandfathered right or the number of acres to which the extinguished type 1 non-irrigation grandfathered right is appurtenant, and then multiply the product by the difference between 2025 and the calendar year of extinguishment, except that:
a. If only a portion of an irrigation grandfathered right or a type 1 non-irrigation grandfathered right is extinguished, the Director shall include in the calculation only those acres associated with the portion of the right that is extinguished; and
b. If an extinguished irrigation grandfathered right has a debit balance in the corresponding flexibility account established under A.R.S. § 45-467, the Director shall subtract the amount of the debit from the amount of the extinguishment.

Historical Note
New Section made by final rulemaking at 12 A.A.R. 3475, effective September 12, 2006 (Supp. 06-3).

R12-15-728. Reserved

R12-15-729. Remedial Groundwater; Consistency with Management Goal
A. Use of remedial groundwater by a municipal provider before January 1, 2025, is deemed consistent with the management goal of the AMA in which the remedial groundwater is withdrawn and is excluded when determining compliance with management goal requirements in this Article if all of the following apply:
1. The Director determines that the remedial groundwater use is consistent with the management goal under subsection (F) or (H) of this Section or the remedial groundwater use is consistent with the management goal under subsection (J) of this Section; and
2. The municipal provider complies with the metering and reporting requirements in subsection (K) of this Section.

B. A municipal provider that is using remedial groundwater or that has agreed in a consent decree or other document approved by ADEQ or the EPA to use remedial groundwater may apply to the Director for a determination that the municipal provider's use of the remedial groundwater is consistent with the management goal of the active management area by submitting an application on a form provided by the Director with the information required in subsection (D) of this Section before January 1, 2010.

C. A municipal provider filing an application under subsection (B) of this Section for remedial groundwater use associated with a treatment plant in operation before June 15, 1999, may request an increase in the project's annual authorized volume at the time the application is filed. The Director shall grant the request and increase the annual authorized volume up to the maximum treatment capacity of the treatment plant if the municipal provider submits evidence that an increase in the annual authorized volume is necessary to further the purpose of the remedial action project and that the increase is not in violation of the consent decree or other document approved by ADEQ or the EPA for the remedial action project.

D. An applicant shall provide the following with an application submitted under subsection (B) of this Section:
1. A document evidencing ADEQ's or EPA's approval of the municipal provider's withdrawal and use of remedial groundwater, such as a remedial action plan, record of decision, or consent decree;
2. The volume of remedial groundwater that will be withdrawn and used annually by the municipal provider and the purpose for which the remedial groundwater will be used;
3. The time period during which the remedial groundwater will be withdrawn and used by the municipal provider;
4. A reference to the annual authorized volume provided in the document submitted pursuant to subsection (D)(1) of this Section or, if the document submitted pursuant to subsection (D)(1) does not specify the annual authorized volume for the project, the annual authorized volume claimed by the municipal provider and a written justification for that volume;
5. If the approved remedial action project is currently operating, the volume of remedial groundwater withdrawn pursuant to the project for each year before the year in which the application is filed;
6. The designated provider or certificate to which the remedial groundwater will be pledged;
7. If the municipal provider is requesting an increase in the annual authorized volume of the project pursuant to subsection (C) of this Section, evidence that the increase is necessary to further the purpose of the remedial action project and that the increase is not in violation of the consent decree or other document approved by ADEQ or the EPA for the project;
8. The name and telephone number of a person the Department may contact regarding the application; and
9. Any other information reasonably required to assist the Director in making the determination under subsection (F) of this Section.

E. After receiving an application under subsection (B) of this Section, the Director shall determine that the application is complete and correct if it contains all the information required in subsection (D) of this Section and the Director verifies that the information is accurate. If the Director determines that the application is complete and correct, the Director shall assign a priority date to the application according to the following:
1. If the Director determines that the application was complete and correct when filed, the priority date of the application is the date the application was filed.
2. If the Director determines that the application was not complete or correct when filed because of minor deficiencies, the Director shall notify the applicant of the deficiencies in writing and give the applicant 30 days to correct the deficiencies. If the applicant submits the necessary information to correct the deficiencies within 30 days after the date of the notice, the priority date of the application is the date the application was filed.
3. If the Director determines that the application was not complete or correct when filed and that the deficiencies are not minor, the Director shall notify the applicant of the deficiencies and give the applicant at least 60 days to submit the necessary information to correct the deficiencies. If the applicant submits the necessary information to correct the deficiencies within the time allowed by the Director, the priority date of the application is the date the applicant submits the necessary information to correct the deficiencies.

F. The Director shall approve a complete and correct application filed under subsection (B) of this Section if the Director determines that the applicant will use remedial groundwater before January 1, 2025. If the Director approves a municipal provider's application, the Director shall calculate the annual amount of remedial groundwater use that is deemed consistent with the management goal of the AMA as follows:
1. The Director shall determine the total annual amount of remedial groundwater use in all AMAs that is deemed to be consistent with the management goal under this subsection and subsections (H) and (I) of this Section for applications with a priority date earlier than the priority date of the municipal provider's application.
2. If the amount determined in subsection (F)(1) of this Section is less than 65,000 acre-feet and the difference between those amounts is equal to or greater than the municipal provider's authorized remedial groundwater use during the year, the amount of remedial groundwater use by the municipal provider that is deemed to be consistent with the management goal during the year is the amount of the municipal provider's authorized remedial groundwater use during the year.
3. If the amount determined in subsection (F)(1) of this Section is less than 65,000 acre-feet and the difference between those amounts is less than the municipal provider's authorized remedial groundwater use during the year, the amount of remedial groundwater use by the municipal provider that is deemed consistent with the management goal during the year is the amount of the municipal provider's authorized remedial groundwater use during the year up to the difference between the amount determined in subsection (F)(1) and 65,000 acre-feet, plus a percentage of the municipal provider's authorized remedial groundwater use during the year that exceeds the difference. The percentage is 50 percent for calendar years 2000 through 2009, 25 percent for calendar years 2010 through 2019, and 10 percent for calendar years 2020 through 2024.

4. If the amount determined in subsection (F)(1) of this Section is equal to or greater than 65,000 acre-feet, the amount of remedial groundwater use by the municipal provider that is deemed consistent with the management goal during the year is a percentage of the municipal provider's authorized remedial groundwater use during the year. The percentage is 50 percent for calendar years 2000 through 2009, 25 percent for calendar years 2010 through 2019, and 10 percent for calendar years 2020 through 2024.

G. If the Director determines that remedial groundwater use by a municipal provider is consistent with the management goal of the active management area under subsection (F) of this Section, the determination shall apply to remedial groundwater used by the municipal provider between the priority date of the application and January 1, 2025.

H. If, before the effective date of this Section, a municipal provider filed an application with the Director requesting that the Director determine that the provider's use of remedial groundwater pursuant to an approved remedial action project is consistent with the management goal of the active management area under Laws 1997, Ch. 287, § 52, as amended by Laws 1999, Ch. 295, § 50, the following shall apply:

1. If the Director approved the application before the effective date of this Section and determined the annual amount of remedial groundwater use by the applicant that will be considered consistent with the management goal, the Director's determination shall apply after the effective date of this Section and the Director shall include the annual amount of remedial groundwater use determined by the Director to be consistent with the management goal in the total amount of remedial groundwater determined in subsection (F)(1) of this Section.
2. If the Director did not approve the application before the effective date of this Section, the Director shall process the application under subsections (E) and (F) of this Section. If the Director approves the application, the Director's determination shall apply to remedial groundwater withdrawn and used by the municipal provider pursuant to the approved remedial action project from the priority date of the application until January 1, 2025.

I. A municipal provider that is using remedial groundwater that has been determined by the Director to be consistent with the management goal under subsection (F) or (H) of this Section may apply to the Director for an increase in the annual authorized volume of the approved remedial action project as follows:

1. The applicant shall submit an application on a form provided by the Director.
2. The Director shall determine that the application is complete and correct if it contains all of the required information and the Director verifies that the information is accurate.
3. If the Director determines that an application filed under this subsection is complete and correct, the Director shall assign a priority date to the application using the criteria in subsection (E) of this Section.
4. The Director shall approve the application if the municipal provider submits information that demonstrates one of the following:
   a. The annual authorized volume of the approved remedial action project has been increased in a consent decree or other document approved by ADEQ or the EPA; or
   b. An increase is necessary to further the purpose of the approved remedial action project, and the increase is not in violation of the consent decree or other document approved by ADEQ or the EPA for the project.
5. If the Director approves the application, the Director shall determine the additional annual amount of remedial groundwater use by the municipal provider that is deemed consistent with the management goal of the active management area, using the criteria in subsections (F) and (G) of this Section. The Director shall include the annual amount of remedial groundwater use determined by the Director to be consistent with the management goal under this subsection in the total amount of remedial groundwater determined in subsection (F)(1) of this Section.

J. Until January 1, 2025, use of remedial groundwater by a municipal provider during a year is deemed consistent with the management goal of the AMA in which the remedial groundwater was withdrawn without approval of the Director under subsection (F) or (H) of this Section if:

1. The total annual amount of remedial groundwater withdrawn from all wells pursuant to the approved remedial action project does not exceed 250 acre-feet; and
2. If remedial groundwater withdrawals pursuant to the approved remedial action project commenced before June 15, 1999, the municipal provider notified the Director in writing of the volume and duration of the anticipated withdrawals on or before August 15, 1999. If remedial groundwater withdrawals pursuant to the approved remedial action project commenced on or after June 15, 1999, the municipal provider gave written notice of the volume and duration of the anticipated withdrawals on or before August 15, 1999, or before the date the withdrawals commenced, whichever is later. If the municipal provider gives notice after the effective date of this Section, the municipal provider shall include or attach all of the following:
   a. A copy of a document evidencing ADEQ's or EPA's approval of the municipal provider's withdrawal and use of remedial groundwater, such as a remedial action plan, record of decision, or consent decree;
   b. The volume of remedial groundwater that will be withdrawn and used annually by the municipal provider and the purpose for which the remedial groundwater will be used;
   c. The time period during which the remedial groundwater will be withdrawn and used by the municipal provider;
   d. If the approved remedial action project is currently operating, the volume of remedial groundwater withdrawn pursuant to the project for each year before the year in which the application is filed;
   e. The designated provider or certificate of assured water supply to which the remedial groundwater will be pledged; and
   f. The name and telephone number of a person the Department may contact regarding the exemption.

K. A municipal provider withdrawing remedial groundwater that has been determined to be consistent with the management goal under subsection (F) or (H) of this Section or that is consistent with the management goal under subsection (J) of this Section shall meter the remedial groundwater withdrawals separately from groundwater withdrawn pursuant to another groundwater withdrawal authority. The municipal provider shall include in its annual reports, filed under A.R.S. § 45-632, the amount of remedial groundwater withdrawn during the reporting year that is consistent with the management goal under this Section and the purposes for which the remedial groundwater was used.

Historical Note

New Section made by final rulemaking at 12 A.A.R. 3475, effective September 12, 2006 (Supp. 06-3).

R12-15-730. Assured and Adequate Water Supply Fees

A. With respect to an application listed in subsection (B) of this Section, the Director shall accept or take action on the application only upon payment of the applicable fee as listed.

B. An applicant shall pay the following fees, as applicable:

APPLICATION	FEE ($)
1. Certificate	3000.00 for the first 20 lots; 3.00 for each additional lot; maximum 5000.00
2. Assignment of certificate issued after effective date of this Section	None
3. Reissuance of certificate issued after effective date of this Section, pursuant to R12-15-704(G)	None
4. Assignment of certificate issued before effective date of this Section, with or without request for classification as Type A certificate	250.00 for the first 20 lots; 0.50 for each additional lot; maximum 1000.00
5. Reissuance of certificate issued before effective date of this Section, pursuant to R12-15-704(G)	250.00 for the first 20 lots; 0.50 for each additional lot; maximum 1000.00
6. Classification as Type A, for certificate issued before the effective date of this Section (not included in assignment application)	250.00 for the first 20 lots; 0.50 for each additional lot; maximum 1000.00
7. Material plat change review	250.00
8. Designation or modification of designation that includes evaluation of physical, legal, and continuous availability or consistency with management goal	1000.00 for the first 1000 acre-feet; 0.50 for each additional acre-foot; maximum 10,000.00
9. Modification of designation that does not include evaluation of physical, legal, and continuous availability or consistency with management goal	500.00
10. Water report	900.00 for the first 20 lots; 2.00 for each additional lot; maximum 2000.00
11. Analysis	7500.00
12. Physical availability determination	5000.00

Historical Note

New Section made by final rulemaking at 12 A.A.R. 3475, effective September 12, 2006 (Supp. 06-3).

ARTICLE 8. WELL CONSTRUCTION AND LICENSING OF WELL DRILLERS

R12-15-801. Definitions

In addition to the definitions set forth in A.R.S. §§ 45-101, 45-402, and 45-591 and in R12-15-202, the following words and phrases in this Article shall have the following meanings, unless the context otherwise requires:

1. "Annular space" means the space between the outer well casing and the borehole wall. An annular space also means the space between an inner well casing and outer well casing.
2. "Aquifer" means an underground formation capable of yielding or transmitting usable quantities of water.
3. "Artesian aquifer" means an aquifer which is overlain by a confining formation and which contains groundwater under sufficient pressure for the water to rise above the top of the aquifer.
4. "Artesian well" means a well that penetrates an artesian aquifer.
5. "Bentonite" means a colloidal clay composed mainly of sodium montmorillonite, a hydrated aluminum silicate.
6. "Cap" means a tamper-resistant, watertight steel plate of at least one-quarter inch thickness on the top of all inside and outside casings of a well.
7. "Casing" means the tubing or pipe installed in the borehole during or after drilling to support the sides of the well and prevent caving.
8. "Confining formation" means the relatively impermeable geologic unit immediately overlying an artesian aquifer.
9. "Consolidated formation" means a naturally occurring geologic unit through or into which a well is drilled, having a composition, density, and thickness which will provide a natural hydrologic barrier.
10. "Department" means the Arizona Department of Water Resources.
11. "Director" means the Director of the Arizona Department of Water Resources.
12. "Drilling card" means a card which is issued by the Director to the well drilling contractor or single well licensee designated in the notice of intent or permit, authorizing the well drilling

contractor or licensee to drill the specific well or wells in the specific location as noticed or permitted.
13. "Exploration well" means a well drilled in search of geophysical, mineralogical or geotechnical data.
14. "Flowing artesian well" means an artesian well in which the pressure is sufficient to cause the water to rise above the land surface.
15. "Grout" or "cement grout" means cement mixed with no more than 50% sand by volume, and containing no more than six gallons of water per 94 pound sack of cement.
16. "Mineralized water" means any groundwater containing over 3000 milligrams per liter (mg/l) of total dissolved solids or containing any of the following chemical constituents above the indicated concentrations:
Constituent Concentration (mg/l)
Arsenic 0.05
Barium 1.0
Cadmium 0.01
Chromium (total) 0.05
Fluoride 4.0
Lead 0.05
Mercury 0.002
Nitrate (as N) 10.0
Selenium 0.01
Silver 0.05
17. "Monitor well" means a well designed and drilled for the purpose of monitoring water quality within a specific depth interval.
18. "Open well" means a well which is not equipped with either a cap or a pump.
19. "Perforations" means a series of openings in a casing, made either before or after installation of the casing, to permit the entrance of water into the well.
20. "Piezometer well" means a well that is designed and drilled for the purpose of monitoring water levels within a specific depth interval.
21 "Pitless adaptor" means a commercially manufactured watertight unit or device designed for attachment to a steel well casing which permits discharge from the well below the land surface and allows access into the well casing while preventing contaminants from entering the well.
22. "Polluted water" means water whose chemical, physical, biological, or radiological integrity has been degraded through the artificial or natural infusion of chemicals, radionuclides, heat, biological organisms, or mineralogical or other extraneous matter.
23. "Pressure grouting" means a process by which a grout is confined within the borehole or casing of a well by the use of retaining plugs, packers, or a displacing fluid by which sufficient pressure is applied to drive the grout into and within the annular space or interval to be grouted.
24. "Qualifying party" means a partner, officer, or employee of a well drilling contractor, who has significant supervisory responsibilities and who has been designated to take the licensing examination for that well drilling contractor.
25. "Single well license" means a license issued to a person which allows the drilling or modification of a single exempt well on land owned by that person.
26 "Vadose zone well" means a well constructed in the interval between the land surface and the top of the static water level.
27. "Vault" means a tamper-resistant watertight structure used to complete a well below the land surface.
28. "Well abandonment" means the modification of the structure of a well by filling or sealing the borehole so that water may not be withdrawn or obtained from the well.
29. "Well drilling" means the construction or repair of a well, or the modification, except for abandonment, of a well, regardless of whether compensation is involved, including any deepening or additional perforating, any addition of casing or change to existing casing construction, and any other change in well construction not normally associated with well maintenance, pump replacement, or pump repair.
30. "Well drilling contractor" means an individual, public or private corporation, partnership, firm, association, or any other public or private organization or enterprise that holds a well driller's license pursuant to A.R.S. § 45-595(B).

Historical Note
Adopted effective March 5, 1984 (Supp. 84-2). Amended effective June 18, 1990 (Supp. 90-2).

R12-15-802. Scope of Article
This Article shall apply to man-made openings in the earth through which water may be withdrawn or obtained from beneath the surface of the earth, including all water wells, monitor wells and piezometer wells. It shall also apply to geothermal wells to the extent provided by A.R.S. § 45-591.01, and all exploration wells and grounding or cathodic protection holes greater than 100 feet in depth. However, this Article shall not apply to the following:
1. Man-made openings in the earth not commonly considered to be wells, such as construction and mining blast holes, underground mines and mine shafts, open pit mines, tunnels, septic tank systems, caissons, basements, and natural gas storage cavities.
2. Injection wells and vadose zone wells which are subject to regulation by the Arizona Department of Environmental Quality.
3. Oil, gas, and helium wells drilled pursuant to the provisions of A.R.S. Title 27.
4. Drilled boreholes in the earth less than 100 feet in depth which are made for purposes other than withdrawing or encountering groundwater, such as exploration wells and grounding or cathodic protection holes; except that in the event that groundwater is encountered in the drilling of a borehole, this Article shall apply.

Historical Note
Adopted effective March 5, 1984 (Supp. 84-2). Amended effective June 18, 1990 (Supp. 90-2).

R12-15-803. Well Drilling and Abandonment Requirements; Licensing and Supervision Requirements
A. A person shall not drill or abandon a well, or cause a well to be drilled or abandoned, in a manner which is not in compliance with A.R.S. Title 45, Chapter 2, Article 10, and the rules adopted thereunder.
B. A person, other than a single well licensee or a bona fide employee of a well drilling contractor, shall not engage in well drilling or abandonment without first securing a well drilling license in accordance with R12-15-804, R12-15-805 and R12-15-806.
C. A qualifying party of a well drilling contractor shall provide direct and personal supervision of the contractor's employees to ensure that all wells are constructed and abandoned in accordance with this Article.

Historical Note
Adopted effective March 5, 1984 (Supp. 84-2). Section 12-15-803 amended and the text of former Section R12-15-804 renumbered to subsections (B) and (C) and amended effective June 18, 1990 (Supp. 90-2).

R12-15-804. Application for well drilling license
A. An applicant for a well drilling license shall submit a verified application of a form prescribed and furnished by the Director which contains the following information:
1. A designation of the classification of license sought by the applicant.
2. If the applicant is an individual, the individual's name, address and telephone number.
3. If the applicant is a partnership, the names, addresses, and telephone numbers of all partners, with a designation of any limited partners.
4. If the applicant is a corporation, association or other organization, the names, addresses and telephone numbers of the directors and of the president, vice president, secretary and treasurer, or the names, addresses and telephone numbers of the functional equivalent of such officers.
5. The address or location of the applicant's place of business, the mailing address if it is different from the applicant's place of business, and if applicant is a corporation, the state in which it is incorporated.
6. The name, address and telephone number of each qualifying party, the qualifying party's relationship to the applicant, and a detailed history of each qualifying party's supervisory responsibilities and well drilling experience, including previous employers, job descriptions, duties and types of equipment utilized.
7. The names, addresses and telephone numbers of three persons not members of each qualifying party's immediate family, who can attest to each qualifying party's good character and reputation, experience in well drilling, and qualifications for licensing.
8. Such additional information relevant to the applicant's or qualifying party's experience and qualifications in well drilling as the Director may require.
B. An applicant shall notify the Director in writing of any change in the information contained in the application within 30 days after such change.
C. The Director shall not issue a license under this Article if the applicant or a qualifying party lacks good character and reputation.
D. Prior to the issuance of a license, a qualifying party shall demonstrate three years of experience, dealing specifically with the type of drilling for which the applicant is applying for a license. This experience requirement may be reduced if the Director finds that the qualifying party has clearly and convincingly demonstrated a high degree of understanding and knowledge of well drilling techniques for the type of drilling for which the applicant is applying for a license. In no case, however, shall the practical experience requirement be less than two years.

Historical Note
Adopted effective March 5, 1984 (Supp. 84-2). Former Section R12-15-804 renumbered to R12-15-803(B) and (C), new Section R12-15-804 adopted effective June 18, 1990 (Supp. 90-2).

R12-15-805. Examination for Well Drilling License
A. The Director shall offer an examination for a well drilling license no less than six times yearly. The examination shall be administered to those eligible applicants whose applications were submitted at least 20 days prior to the date of the examination. The examination shall consist of a section on legal requirements, a section on general knowledge and one or more of six specialized sections. The section on legal requirements shall test the qualifying party's knowledge of A.R.S. Title 45, Chapter 2, Article 10, and the rules adopted thereunder. The section on general knowledge shall test the qualifying party's knowledge of general hydrologic concepts, principles, and practices in the well construction industry, and shall test knowledge of groundwater protection, pollution, water quality and public health effects. The specialized sections shall test the qualifying party's knowledge in the following classifications:
1. Cable tool drilling in rock and unconsolidated material.
2. Air rotary drilling in rock and unconsolidated material.
3. Mud rotary drilling in rock and unconsolidated material.
4. Reverse rotary drilling in rock and unconsolidated material.
5. Jetting and driving wells in unconsolidated material.
6. Boring and augering in unconsolidated material.
B. Only the qualifying party, department personnel, and persons having the express permission of the Director shall be permitted in the examination room while the examination is in progress.

The qualifying party shall not bring books or notes into the examination room, or communicate by any means whatsoever while the examination is in progress without the express permission of the presiding examiner. The qualifying party shall not leave the examination room while the examination is in progress without first obtaining the permission of the presiding examiner. The Director may disqualify an applicant for violation of this subsection.

C. To obtain a well drilling license, a qualifying party of the applicant shall pass the section on legal requirements, the section on general knowledge, and one or more specialized sections. Each section of the examination shall be graded separately. The passing grade on each section shall be 70 percent.

D. No person may take the examination more than twice during any 12 months.

E. The Director may exempt a qualifying party from taking the section on general knowledge, and one or more of the specialized sections, if the qualifying party provides proof of passing an equivalent examination given by the National Ground Water Association.

Historical Note

Adopted effective March 5, 1984 (Supp. 84-2). Section repealed, new Section adopted effective June 18, 1990 (Supp. 90-2). Amended by final rulemaking at 13 A.A.R. 3022, effective October 6, 2007 (Supp. 07-3).

R12-15-806. License Fee; Issuance and Term of Licenses; Renewal; Display of License

A. The fee for a well driller's license shall be fifty dollars. No additional fee shall be charged for amendments to licenses pursuant to subsection (B).

B. Upon submittal of the license fee and satisfactory completion of an examination, the Director shall issue the applicant a well drilling license. The license shall be numbered and shall state the specialized classifications of drilling activities for which the applicant is qualified and licensed. The applicant shall be licensed in only those classifications for which the qualifying party has passed the specialized sections of the examination. If the qualifying party subsequently passes other specialized sections, the applicant's license shall be amended.

C. A well drilling contractor shall notify the Director in writing within 30 days of the date on which the well drilling contractor no longer has a qualifying party for one or more of its specialized drilling classifications. Upon such notification, the Director may revoke or suspend part or all of the well drilling license of the well drilling contractor and require a new qualifying party to take and pass the examination.

D. A well drilling license shall expire each year on June 30th, unless renewed pursuant to subsection (E).

E. A person may renew a well drilling license by submitting an application for renewal on forms prescribed and furnished by the Director. The renewal fee shall be ten dollars. If the application and renewal fee are postmarked on or before June 30, the well drilling contractor may operate as a licensee until actual issuance of the renewal license. A license which has expired may be reactivated and renewed within one year of its expiration by filing the required application and 20 dollars. If a license has been expired for one or more years for failure to renew, the well drilling contractor shall apply for a new license and repeat the examination.

F. A well drilling contractor shall prominently display the well drilling license number on all well drilling rigs owned or operated by the contractor in this state. Good quality paint or commercial decal numbers shall be used in placing each identification number on the drilling rig. The license number shall not be inscribed in crayon, chalk, pencil, or other temporary markings.

Historical Note

Adopted effective March 5. 1984 (Supp. 84-2). Amended effective June 18, 1990 (Supp. 90-2).

R12-15-807. Single Well License

A. An applicant for a single well license pursuant to A.R.S. § 45-595(D) shall submit a verified application on forms prescribed and furnished by the Director, which shall include:

1. The name and address of the applicant.
2. The location of the well and whether the applicant owns the land.
3. The type of drill rig to be used and the owner of the rig.
4. The proposed design of the well or method of abandonment.
5. The names of any people who will be assisting the applicant in the drilling or abandonment of the well, and whether the applicant will compensate them for their efforts.
6. The applicant's experience, if any, in well drilling or abandonment.
7. Such other information as the Director may require relevant to the applicant's experience and qualifications in well drilling or abandonment.

B. The Director shall offer the single well examination no less than six times yearly and shall administer the examination to those eligible applicants whose applications were submitted at least 20 days prior to the date of the examination.

C. The single well examination shall be of a form prescribed and furnished by the Director and shall test the applicant's knowledge of abandonment techniques, or those minimum well construction requirements and drilling techniques applicable to the proposed design of the well. The passing grade on the sections of the examination dealing with construction requirements and drilling techniques, respectively, shall be 70 percent.

D. Rule R12-15-805 relating to testing procedures shall be fully applicable.

E. Applicants who twice fail the examination shall wait a minimum of 90 days before re-testing.

F. Upon passing the examination, the applicant shall be issued a single well license, authorizing the applicant to drill or abandon one exempt well at the location specified in the application. The license shall be valid for a period of one year from issuance.

Historical Note

Adopted effective March 5, 1984 (Supp. 84-2). Amended effective June 18, 1990 (Supp. 90-2).

R12-15-808. Revocation of License

The Director may revoke, suspend, or place on probationary status a well drilling license issued pursuant to R12-15-806, or a single well license, for good cause, including:

1. Intentionally making a misstatement of fact on any filing with the Department.
2. Violating any provision of A.R.S. Title 45, Chapter 2, Article 10, and the rules promulgated thereunder, or aiding and abetting in such a violation.

Historical Note

Adopted effective March 5, 1984 (Supp. 84-2). Amended effective June 18, 1990 (Supp. 90-2). Section number corrected (Supp. 93-1).

R12-15-809. Notice of Intention to Drill

A notice of intention to drill required to be filed pursuant to A.R.S. § 45-596 shall be signed by the owner or lessee of the property upon which the well is to be drilled.

Historical Note

Adopted effective March 5, 1984 (Supp. 84-2).

R12-15-810. Authorization to Drill

A. A well drilling contractor or single well licensee may commence drilling a well only if the well drilling contractor or licensee has possession of a drilling card at the well site issued by the Director in the name of the well drilling contractor or licensee, authorizing the drilling of the specific well in the specific location.

B. In extraordinary situations not requiring a permit but only a notice of intention to drill, the Director may grant a request by telephone for emergency authorization of commencement of drilling prior to the actual receipt by the well driller of the drilling card. Within seventy-two hours after such a request is granted, the well driller shall file a written statement indicating the nature and reasons for the request, and the date, time and Department employee granting the request, and the well owner shall file a notice of intent to drill if such a notice has not previously been filed.

Historical Note

Adopted effective March 5, 1984 (Supp. 84-2). Amended effective June 18, 1990 (Supp. 90-2). Amended to correct typographical error under A.A.C. R1-1-109 (Supp. 01-2). Amended by final rulemaking at 13 A.A.R. 3022, effective October 6, 2007 (Supp. 07-3).

R12-15-811. Minimum Well Construction Requirements

A. Well casing

1. Casing shall be of a sufficient strength and wall thickness to hold the borehole open and survive any necessary grouting. A person shall use only steel or thermoplastic casing in the construction of a well, unless the person has received a variance from the Director pursuant to R12-15-820. The well casing or an extension of the casing shall extend a minimum of one foot above ground level. When installing a pitless adaptor, the casing may be terminated below ground level for aesthetic reasons or freeze protection purposes. Casing made of, or which has been exposed to, hazardous or potentially harmful materials, such as asbestos, shall not be used.
2. All well casing joints or overlaps shall be made watertight to prevent the degradation of the water supply by the migration of inferior quality water. Except as provided in subsection (H) of this rule, any openings in the casing that will be above the water level in the well, such as bar holes, cracks or perforations, shall be completely plugged or sealed.
3. Thermoplastic casing shall be installed only in an over sized drillhole without driving. Thermoplastic casing shall conform with American Society for Testing and Materials Standard Specification F480-89 (1989), which is incorporated herein by reference and is on file with the Office of the Secretary of State. Rivets or screws used in the casing joints shall not penetrate the inside of the casing.
4. Steel casing shall be new or in like-new condition, free from pits or breaks, and shall conform with American Society for Testing and Materials Standard Specification A53-89a (1989), A139-89b (1989) or A312/A312M-89a (1989), whichever is applicable, all of which are incorporated herein by reference and are on file with the Office of the Secretary of State.
5. Copies of The American Society for Testing and Materials standard specifications referred to in subsections (3) and (4) above may be obtained with these rules at the Office of the Secretary of State of the State of Arizona, State Capitol, West Wing, Phoenix, Arizona 85007; from the Department of Water Resources, 3550 N. Central Avenue, Phoenix, AZ 85012; and from the American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohocken, PA 19428-2959. This rule does not include any later amendments or editions of those standard specifications.

B. Surface seal

1. Except as provided in subsections (2) and (4) of this subsection, and R12-15-817(B)(1), all wells shall be constructed with a surface seal as herein provided. The seal shall consist of steel casing, one foot of which shall extend above ground level, and cement grout placed in one continuous application from the bottom of the zone to be grouted to the land surface. If a pitless adaptor is utilized, the cement grout may terminate at the bottom of the pitless adaptor. The minimum length of the steel casing shall be 20 feet. The minimum annular space between the casing and the borehole for placement of grout shall be one and one-half inches. Curing additives, such as calcium chloride, shall not exceed ten percent of the total volume of grout. Bentonite as an additive shall not exceed five percent of the total volume. The minimum length of the surface seal shall be 20 feet. Any annular space between the outer casing and an inner casing shall be completely sealed to prevent contamination of the well.
2. All hand-dug wells shall be constructed with a watertight curbing extending, at a minimum, from one foot above the natural ground level to the static water level, or into the confining formation if the aquifer is artesian. The curbing shall consist of poured cement grout or casing surrounded by cement grout. Concrete block with cement grout and rock with cement

grout may also be used. The poured cement grout shall not be less than six inches thick. If casing is to be used, the minimum annular space between the casing and the borehole shall be three inches. Hand-dug wells shall be sealed at the surface with a watertight, tamper-resistant cover to prevent contaminants from entering the well.

3. All wells constructed by jetting or driving shall have cement grout placed in the annular space to a minimum depth of six feet. The minimum annular space between the casing and the borehole for placement of the grout shall be one and one-half inches.
4. All horizontal wells, to prevent leakage, shall be constructed with a surface seal consisting of steel casing and cement grout extending a minimum of ten feet into the land surface.

C. Access port. Every well with casing four inches in diameter or larger shall be equipped with a functional watertight access port with a minimum diameter of one-half inch so that the water level or pressure head in the well can be monitored at all times.

D. Gravel packed wells

1. If a gravel pack has been installed, the annular space between the outer casing and the inner casing shall be sealed, either by welding a cap at the top or by filling with cement grout from the bottom of the outer casing to the surface.
2. If a gravel tube is installed, it shall be sealed with a cap.

E. Vents. All vents installed in the well casing shall open downward and be screened to prevent the entrance of foreign material.

F. Removal of drilling materials

1. In constructing a water well, the well driller shall take all reasonable precautions to protect the producing aquifer from contamination by drilling materials. Upon completion of the well, the well driller shall remove all foreign substances and materials introduced into the aquifer or aquifers during well construction. For purposes of this subsection, "substances and materials" means all drilling fluids, filter cake, lost circulation materials, and any other organic or inorganic substances.
2. Materials known to present a health hazard, such as chrome-based mud thinners, asbestos products, and petroleum-based fluids, shall not be used as construction, seal or fill materials or drilling fluids.
3. Drilling fluids and cuttings shall be contained in a manner which prevents discharge into any surface water.

G. Repair of existing wells

1. If, in the repair of a well, the old casing is withdrawn, the well shall be recased in conformance with these rules.
2. If an inner casing is installed to prevent leakage of undesirable water into a well, the annular space between the casings shall be completely sealed by packers, casing swedging, pressure grouting or other methods which will prevent the movement of water between the casings.

H. Monitor wells

1. A monitor well may be screened up to ten feet above the highest seasonal static water level of record for the purpose of monitoring contaminants.
2. A monitor well shall be identified as such on the vault cover or at the top of the steel casing. Identification information shall include the well registration number.

I. Completion at the surface. In areas of traffic or public rights-of-way, wells may be constructed below the land surface in a vault. All other requirements in this Article shall apply.

Historical Note

Adopted effective March 5, 1984 (Supp. 84-2). Amended effective June 18, 1990 (Supp. 90-2). The reference to R12-14-817(B)(1) in subsection (B)(1) corrected to read R12-15-817(B)(1) (Supp. 93-1). Amended by final rulemaking at 11 A.A.R. 5395, effective February 4, 2006 (Supp. 05-4).

R12-15-812. Special Aquifer Conditions

A. Artesian wells

1. The well casing shall extend into the confining formation immediately overlying the artesian aquifer and shall be grouted from a minimum of ten feet into the confining formation to the land surface to prevent surface leakage into and subsurface leakage from the artesian aquifer.
2. If leaks occur adjacent to the well or around the well casing, within 30 days the well shall be completed with the seals, packers, or casing and grouting necessary to eliminate such leakage or the well shall be abandoned according to R12-15-816.
3. If the well flows at land surface, the well shall be equipped with a control valve, or suitable alternative means of completely controlling the flow, which must be available for inspection at the well site at all times.

B. Mineralized or polluted water. In all water-bearing geologic units containing mineralized or polluted water as indicated by available data, the borehole shall be cased and grouted so that contamination of the overlying or underlying groundwater zones will not occur.

Historical Note

Adopted effective March 5, 1984 (Supp. 84-2). Amended effective June 18, 1990 (Supp. 90-2).

R12-15-813. Unattended Wells

All wells, when unattended during well drilling, shall be securely covered for safety purposes and to prevent the introduction of foreign substances into the well.

Historical Note

Adopted effective March 5, 1984 (Supp. 84-2). Section number corrected (Supp. 93-1).

R12-15-814. Disinfection of Wells

A well drilling contractor shall disinfect any well from which the water to be withdrawn is intended to be utilized for human consumption or culinary purposes without prior treatment before removing the drill rig from the well site in accordance with the requirements contained in Engineering Bulletin No. 8, "Disinfection of Water Systems", issued by the Arizona Department of Health Services in August 1978, and Engineering Bulletin No. 10, "Guidelines for the Construction of Water Systems", issued by the Arizona Department of Health Services in May 1978, both of which are incorporated by reference and are on file with the Office of the Secretary of State. Copies of the Engineering Bulletins referred to above may be obtained with these rules at the Office of the Secretary of State of the State of Arizona, State Capitol, West Wing, Phoenix, Arizona 85007, and from the Department of Water Resources, 3550 N. Central Avenue, Phoenix, AZ 85012. This rule does not include any later amendments or editions of those Bulletins.

Historical Note

Adopted effective March 5, 1984 (Supp. 84-2). Amended effective June 18, 1990 (Supp. 90-2). Amended by final rulemaking at 11 A.A.R. 5395, effective February 4, 2006 (Supp. 05-4).

R12-15-815. Removal of Drill Rig from Well Site

The drilling rig shall not be removed from the well site unless the well is in one of the following conditions:

1. Constructed in full conformance with R12-15-811 and R12-15-812 and either sealed with a cap or equipped with a pump.
2. Abandoned in accordance with R12-15-816.

Historical Note

Adopted effective March 5, 1984 (Supp. 84-2). Amended effective June 18, 1990 (Supp. 90-2).

R12-15-816. Abandonment

A. Well abandonment shall be performed only by a licensed well drilling contractor or single well licensee.

B. Except as provided in subsection (F) of this Section, the owner of a well shall file a notice of intent to abandon the well prior to abandonment, on a form prescribed and furnished by the Director, which shall include:

1. The name and mailing address of the person filing the notice.
2. The legal description of the land upon which the well proposed to be abandoned is located and the name and mailing address of the owner of the land.
3. The legal description of the location of the well on the land.
4. The depth, diameter and type of casing of the well.
5. The well registration number.
6. The materials and methods to be used to abandon the well.
7. When abandonment is to begin.
8. The name and well drilling license number of the well drilling contractor or single well licensee who is to abandon the well.
9. The reason for the abandonment.
10. Such other information as the Director may require.

C. The Director shall, upon receipt of a proper notice of intent to abandon, mail a well abandonment authorization card to the designated well drilling contractor or single well licensee.

D. Except as described in subsection (F) of this Section, a well drilling contractor or single well licensee may commence abandoning a well only if the driller has possession of an abandonment card at the well site, issued by the Director in the name of the driller, authorizing the abandonment of that specific well or wells in that specific location.

E. Within 30 days after a well is abandoned pursuant to this Section, the well drilling contractor or single well licensee shall file with the Director a Well Abandonment Completion Report on a form prescribed and furnished by the Director which shall include the date the abandonment of the well was completed and such other information as the Director may require.

F. In the course of drilling a new well, the well may be abandoned without first filing a notice of intent to abandon and without an abandonment card. If the well is abandoned pursuant to this subsection without first filing a notice of intent to abandon and without an abandonment card, the well drilling contractor or single well licensee shall provide the following information in the Well Abandonment Completion Report:

1. The legal description of the land upon which the well was abandoned and the name and mailing address of the owner of the land.
2. The legal description of the location of the well on the land.
3. The depth, diameter and type of casing of the well prior to abandonment.
4. The well registration number.
5. The materials and methods used to abandon the well.
6. The name and well drilling license number of the well drilling contractor or single well licensee who abandoned the well.
7. The date of completion of the abandonment of the well.
8. The reason for the abandonment.
9. Such other information as the Director may require.

G. The abandonment of a well shall be accomplished through filling or sealing the well so as to prevent the well, including the annular space outside the casing, from being a channel allowing the vertical movement of water.

H. A well drilling contractor or single well licensee shall construct a surface seal for a well that does not penetrate an aquifer, as follows:

1. If the casing is removed from the top 20 feet of the well, a cement grout plug shall be set extending from two feet below the land surface to a minimum of 20 feet below the land surface, and the well shall be backfilled above the top of the cement grout plug to the original land surface.
2. If the casing is not removed from the top 20 feet of the well, a cement grout plug shall be set extending from the top of the casing to a minimum of 20 feet below the land surface and the annular space outside the casing shall be filled with cement from the land surface to a minimum of 20 feet below the land surface.

I. In addition to the surface seal required in subsection (H):
1. A well penetrating a single aquifer system with no vertical flow components shall be filled with cement grout, concrete, bentonite drilling muds, clean sand with bentonite, or cuttings from the well.
2. A well penetrating a single or multiple aquifer system with vertical flow components shall be sealed with cement grout or a column of bentonite drilling mud of sufficient volume, density, and viscosity to prevent fluid communication between aquifers.

J. Materials containing organic or toxic matter shall not be used in the abandonment of a well.

K. The owner or operator of the well shall notify the Director in writing no later than 30 days after abandonment has been completed. The notification shall include the well owner's name, the location of the well, and the method of abandonment.

Historical Note

Adopted effective March 5, 1984 (Supp. 84-2). Amended effective June 18, 1990 (Supp. 90-2). Amended by final rulemaking at 13 A.A.R. 3022, effective October 6, 2007 (Supp. 07-3).

R12-15-817. Exploration Wells

A. Notification. Prior to drilling one or more exploration wells, the well owner, lessee, or exploration firm shall file a notice of intention to drill on forms provided by the Director. If the notice of intention to drill is filed for the project as a whole, the drilling card shall be issued for the project as a whole.

B. Construction and abandonment.
1. If an exploration well which is to be left open for re-entry at a later date encounters groundwater, it shall be cased and capped in accordance with R12-15-811, R12-15-812, and R12-15-822. The minimal length of surface seal shall be either 20 feet, or five feet into the first encountered consolidated formation, whichever is less. If no groundwater is encountered, the well shall be cased, grouted and capped in such a manner so as to prevent contamination of the well bore from the surface.
2. Exploration wells not left open for re-entry shall be abandoned in accordance with R12-15-816.

C. Completion report. Within 30 days of project completion, the well owner, lessee, or exploration firm shall submit a project completion report on forms provided by the Director. The report shall include:
1. The exact number of wells drilled.
2. The depth to water encountered or detected, with reference to specific wells.
3. The abandonment method utilized, or construction details if completed for re-entry.
4. Any other information which the Director may require.

Historical Note

Adopted effective March 5, 1984 (Supp. 84-2). Amended effective June 18, 1990 (Supp. 90-2).

R12-15-818. Well Location

Except for monitor wells and piezometer wells, no well shall be drilled within 100 feet of any septic tank system, sewage disposal area, landfill, hazardous waste facility, storage area of hazardous materials or petroleum storage areas and tanks, unless authorized in writing by the Director.

Historical Note

Adopted effective March 5, 1984 (Supp. 84-2). Amended effective June 18, 1990 (Supp. 90-2).

R12-15-819. Use of Well as Disposal Site

No well may be used as a storage or disposal site for sewage, toxic industrial waste, or other materials that may pollute the groundwater, except as authorized by the Arizona Department of Environmental Quality.

Historical Note

Adopted effective March 5, 1984 (Supp. 84-2). Amended effective June 18, 1990 (Supp. 90-2).

R12-15-820. Request for Variance

A. If extraordinary or unusual conditions exist, a well drilling contractor or owner may request a variance from the provisions of this Article.

B. The request for variance shall be in writing and shall set forth the location of the well site, the reasons for the request, and the recommended requirements to be applied. The Director may approve the request only if the well drilling contractor or owner has clearly demonstrated that the variance will not adversely affect other water users or the local aquifers.

C. A variance shall not be effective until the well drilling contractor or owner receives from the Director a written approval of the variance and a new drilling card stamped "variance issued."

Historical Note

Adopted effective March 5, 1984 (Supp. 84-2). Amended effective June 18, 1990 (Supp. 90-2).

R12-15-821. Special Requirements

If the Director determines that the literal application of the minimum well construction requirements contained in this Article would not adequately protect the aquifer or other water users, the Director may require that further additional measures be taken, such as increasing the length of the surface seal or increasing the well's minimum distance from a potential source of contamination.

Historical Note

Adopted effective March 5, 1984 (Supp. 84-2). Amended effective June 18, 1990 (Supp. 90-2).

R12-15-822. Capping of Open Wells

A. The owner of an open well shall either install a cap on the well or abandon the well in accordance with R12-15-816. Within five days after capping the well, the owner of the well shall file with the Department a notice of well capping on a form approved by the Director which shall include the following information:
1. The name and address of the well owner.
2. The name and address of the person installing the cap.
3. The well registration number.
4. The legal description of the location of the well.
5. The date the well was capped.
6. The method of capping.
7. The type and diameter of casing.

B. If no casing exists in an open well, or if the integrity of the existing casing is insufficient to allow installation of a cap, the well owner shall install a surface seal in accordance with R12-15-811(B) prior to capping.

C. The owner of a well on which a cap is installed shall make the cap tamper resistant by welding the cap to the top of the casing by the electric arc method of welding, except that the owner of a well may make the cap tamper resistant by securing the cap to the top of the casing with a lock during temporary periods of well maintenance, modification or repair, not to exceed 30 days, or at any time if the well is a monitor well or piezometer well.

Historical Note

Adopted as an emergency effective March 2, 1989, pursuant to A.R.S. § 41-1026, valid for only 90 days (Supp. 89-1). Emergency expired. Readopted without change as an emergency effective June 2, 1989, pursuant to A.R.S. § 41-1026, valid for only 90 days (Supp. 89-2). Emergency expired. Readopted without change as an emergency effective September 5, 1989, pursuant to A.R.S. § 41-1026, valid for only 90 days (Supp. 89-3). Emergency expired. Readopted without change as an emergency effective December 1, 1989, pursuant to A.R.S. § 41-1026, valid for only 90 days (Supp. 89-4). Emergency expired. Readopted without change as an emergency effective March 23, 1990, pursuant to A.R.S. § 41-1026, valid for only 90 days (Supp. 90-1). Permanent rule adopted with changes effective June 18, 1990
(Supp. 90-2). Amended by final rulemaking at 13 A.A.R. 3022, effective October 6, 2007 (Supp. 07-3).

R12-15-823. Reserved

through

R12-15-849. Reserved

R12-15-850. Evaluation of Notices of Intention to Drill; Notification of Registered Site Locations; Vertical Cross-Contamination Evaluation

A. The Director shall, upon receipt of a complete and correct notice of intention to drill form required under A.R.S. § 45-596, or upon receipt of an application for a permit under A.R.S. § 45-597 through 45-599, identify whether the proposed well will be drilled within a groundwater basin or subbasin in which there exists a site listed on the registry established under A.R.S. § 49-287.01(D). If the proposed well is situated within such a groundwater basin or subbasin, the Director shall notify the applicant and the authorized well drilling contractor in writing of the existence of the site and shall enclose a map indicating the boundaries of all listed sites within the groundwater basin or subbasin. The notification letter shall include the name, address, and telephone number of a Department contact person, along with a reference to the provision in R12-15-851 that requires the applicant to notify the Department in advance of the date drilling of the well will commence. The Department shall also specify in the notification letter whether the applicant is subject to the requirements of R12-15-851.

B. The Director shall, upon receipt of a complete and correct notice of intention to drill form required under A.R.S. § 45-596, or upon receipt of an application for a permit under A.R.S. § 45-597 through 45-599, identify whether the proposed well will be drilled within an area where existing or anticipated future groundwater contamination presents a risk of vertical cross-contamination, as defined in A.R.S. § 49-281(15). If the Director determines that the proposed well will be drilled in such an area, and if the Director finds that the requirements of R12-15-811 are insufficient to prevent the risk of vertical cross-contamination, the Director shall establish site-specific requirements pursuant to R12-15-812 and R12-15-821.

Historical Note

New Section adopted by final rulemaking at 6 A.A.R. 469, effective January 3, 2000 (Supp. 00-1).

R12-15-851. Notification of Well Drilling Commencement

A well owner who has been issued a drilling card for a notice of intent to drill authorizing the drilling of a well located within a site listed on the registry established under A.R.S. § 49-287.01, shall provide written notice to the Director indicating the date drilling will commence. The well owner shall coordinate with the contracted well driller to ensure that the Department receives proper notification under this Section. This notification shall consist of a letter or facsimile transmission received by the Department at least 2 business days before drilling commences at the well site. The Department shall use notification letters required by R12-15-850(A) to inform well owners whether they are subject to the requirements of this Section.

Historical Note

New Section adopted by final rulemaking at 6 A.A.R. 469, effective January 3, 2000 (Supp. 00-1).

R12-15-852. Notice of Well Inspection; Opportunity to Comment

A. At least 30 days before the beginning of a well inspection under A.R.S. § 45-605(A), the Director shall notify in writing all potentially affected well owners of record within a community involvement area established under A.R.S. § 49-289.02 or within other areas that the Director has selected for inspection of wells that may be contributing to vertical cross-contamination. The notices shall include a map of the community involvement area, remedial site, or a subsection of either, that the Department intends to inspect, indicating the location of affected wells of record. The notice shall indicate the approximate date the inspection will start, the approximate duration of the inspection, an access agreement defining what specific activities will occur during a well inspection, and the name, address, and telephone number of a Department contact person.

B. Once the Director has given notice of a well inspection under A.R.S. § 45-605(A), potentially affected well owners have 30 days from the date the letter is postmarked to comment on the proposed inspection. The Director, upon receiving a written request, may extend the comment period for a maximum of 30 additional days.

Historical Note

New Section adopted by final rulemaking at 6 A.A.R. 469, effective January 3, 2000 (Supp. 00-1).

ARTICLE 9. WATER MEASUREMENT

R12-15-901. Definitions

In addition to the definitions set forth in A.R.S. §§ 45-101 and 45-402, the following words and phrases shall have the following meanings, unless the context otherwise requires:

1. "Approved measuring device" means an instrument, approved by the Director pursuant to R12-15-903 or R12-15-909(A) which measures the volume or flow rate of water withdrawn, delivered, received, transported, recharged, stored, recovered, or used, and which measurements, when used with an approved measuring method, allow for accurate computation of a volume of water.
2. "Approved measuring method" means a procedure, approved by the Director in R12-15-903 or R12-15-909(A), which, when used with an approved measuring device, will accurately calculate a volume of water.
3. "Flow rate" or "discharge" means the volume of water, including any sediment or other solids that may be dissolved or mixed with it, which passes through a particular reference section in a unit of time.
4. "Measured system" means a system through which water passes for the purpose of withdrawal, delivery, receipt, transportation, recharge, storage, replenishment, recovery or use.
5. "Responsible party" means an irrigation district or a person required by A.R.S. Title 45 or by a permit, rule, or order issued pursuant to A.R.S. Title 45, to use a measuring device or method approved by the Director.

Historical Note

Adopted effective December 27, 1982 (Supp. 82-6). Amended effective June 15, 1995 (Supp. 95-2). Amended to correct typographical error under A.A.C. R1-1-109 (Supp. 01-2).

R12-15-902. Installation of Approved Measuring Devices

A. A responsible party shall install an approved measuring device to monitor the volume of water withdrawn, delivered, transported, recharged, stored, replenished, recovered, and used.

B. A responsible party shall install and use a sufficient number of approved measuring devices to allow for the separate monitoring and reporting of the volume of water passing through the measured system pursuant to the following categories of rights:

1. Irrigation grandfathered rights,
2. Non-irrigation grandfathered rights,
3. Service area rights,
4. Groundwater withdrawal permits, and
5. Recovery well permits or water storage permits.

This subsection does not require separate measuring devices for rights within each category unless otherwise required by A.R.S. Title 45, a permit, rule, or order pursuant to that Title.

C. An approved measuring device which measures groundwater withdrawals shall be installed as close to the wellhead as is practical, consistent with the manufacturer's instructions. An approved measuring device which measures another point in the measured system shall be installed as close as is practical to the point of delivery, receipt, transportation, recharge, storage, replenishment, recovery, or use which the device is intended to measure, consistent with the manufacturer's instructions.

Historical Note

Adopted effective December 27, 1982 (Supp. 82-6). Amended effective June 15, 1995 (Supp. 95-2). Amended to correct typographical error under A.A.C. R1-1-109 (Supp. 01-2).

R12-15-903. Approved Water Measuring Devices and Methods

A. Any measuring device is approved by the Director if it is installed, maintained, and used in accordance with the manufacturer's recommendations, and if it meets the accuracy requirements set forth in R12-15-905(A).

B. An approved measuring device shall be used with an approved measuring method set forth in R12-15-903(C) or an alternative measuring method approved by the Director as provided in R12-15-909(A).

C. The following water measuring methods are approved by the Director:

1. Totalizing measuring method: This method requires an approved measuring device which continuously records the volume of water passing through the measured system;
2. Electrical consumption measuring method: This method requires measurements of either pipeflow rates or open-channel flow rates used in combination with electrical energy records;
3. Natural gas consumption measuring method: This method requires measurements of either pipe flow rates or open channel flow rates used in combination with natural gas energy records;
4. Hour meter measuring method: This method requires measurements of either pipe flow rates or open-channel flow rates used in combination with hour meter readings;
5. Elapsed time of flow method: This method requires measurements of flow rates used in combination with elapsed time of the flow. This method may be used only by a responsible party who receives water from an open channel or by a person or entity who delivers water in an open channel to one or more grandfathered rightholders or permit holders, if it is not possible to use the electrical or gas consumption measurement methods or hour meter measuring method.

Historical Note

Adopted effective December 27, 1982 (Supp. 82-6). Amended effective June 15, 1995 (Supp. 95-2).

R12-15-904. Water Measuring Method Reporting Requirements

A. A responsible party using one of the water measuring methods described in R12-15-903 shall file, with the annual report required by A.R.S. Title 45 and on a form prescribed by the Director, the following information, unless that information has not changed from that submitted in the annual report filed in the previous calendar year.

1. The approved measuring method used;
2. The type of approved measuring device used;
3. The make, model, and size of the approved measuring device used.

B. Except as provided in R12-15-904(B)(5) and R12-15-909(B) and (D), a responsible party shall file with the annual report the information required in subsection (A) of this Section and the following information on a form prescribed by the Director:

1. Totalizing measuring method:
   a. The initial totalizing meter reading for the reporting year taken prior to the first use of the measured system during the reporting year;
   b. The end totalizing meter reading for the year taken subsequently to the last use of the measured system during the reporting year;
   c. The units in which the water is measured;
   d. Whether the power meter serves uses other than the pump motor or engine;
   e. An estimate of the amount of any water passing through the measured system during measuring device malfunctions;
   f. If the well is in operation for more than a 30-day period, the results of a minimum of two flow-rate measurements per reporting year taken under normal system operating conditions. The responsible party shall not submit the results of the flow-rate measurements with the annual report unless a meter malfunction continues longer than 72 hours during the reporting year;
   g. The installation or overhaul date of the totalizing meter; and
   h. The name of the energy company supplying energy to the responsible party's measured system, its power account number, meter number, total energy consumption for the year, and the type of energy unit.
2. Electrical consumption measuring method:
   a. The results of a minimum of two flow-rate measurements per reporting year taken at least 30 days apart and under normal system operating conditions or, if the measured system is used during a single period of 30 days or less during the year, the result of one flow-rate measurement taken during that single period in that year under normal system operating conditions;
   b. The dates of the measurements;
   c. The discharges in gallons per minute;
   d. The time, in seconds, of ten cycles of the electric meter disk, power indicator pulse, or an alternative measurement, provided that the alternative means of measurement is approved in advance by the Director;
   e. The inside diameter of the discharge pipe;
   f. The multiplier (Kr) and disk constant (Kh) of the electric meter; and
   g. The name of the energy company supplying energy to the responsible party's measured system, its power account number, meter number, total energy consumption for the year, and the type of energy unit.
3. Natural gas consumption measuring method:

a. The results of a minimum of two flow-rate measurements per reporting year taken at least 30 days apart and under normal system operating conditions or, if the measured system is used during a single period of 30 days or less during the year, the result of one flow-rate measurement taken during that single period in that year under normal system operating conditions;
b. The dates of the measurements;
c. The discharges in gallons per minute;
d. The amounts of gas per second in cubic feet indicated by the gas meter;
e. The billing factors (F);
f. The inside diameter of the discharge pipe; and
g. The name of the energy company supplying energy to the responsible party's measured system, its power account number, meter number, total energy consumption for the year, and the type of energy unit.

4. Hour meter measuring method:
a. The results of a minimum of two flow-rate measurements per reporting year taken at least 30 days apart and under normal system operating conditions or, if the measured system is used during a single period of 30 days or less during the year, the result of one flow-rate measurement taken during that single period in that year under normal system operating conditions;
b. The dates of the measurements;
c. The discharges in gallons per minute;
d. The initial hour meter reading for the reporting year taken prior to the first use of the measured system during the reporting year;
e. The end hour meter reading taken subsequently to the last use of the measured system during the reporting year;
f. Whether the energy meter serves uses other than the pump motor or engine;
g. The installation or overhaul date of the hour meter; and
h. The name of the energy company supplying energy to the responsible party's measured system, its power account number, meter number, total energy consumption for the year, and the type of energy unit.

5. Elapsed time of flow measuring method: A responsible party using this measuring method shall not be required to submit the following information with the annual report but instead shall record and retain it for three years after the reporting year.
a. The responsible party or agent shall measure and record an initial flow rate taken at the start of flow for each delivery of water;
b. If the flow rate continues for more than eight hours, a subsequent measured flow-rate measurement shall be taken. If any subsequently measured flow-rate differs by more than 10% from the initial flow rate, and the delivery is not adjusted to conform with the initial flow rate, the responsible party or agent shall record the subsequent flow rate;
c. The time the flow begins and the time the flow ends for each delivery of water; and
d. The dates of the measurements.

C. A responsible party or person or entity who uses an approved measuring method or an approved alternative water measurement method shall save the records required by subsections (A) and (B) of this Section for three years after the reporting year.

Historical Note

Adopted effective December 27, 1982 (Supp. 82-6). Former Section R12-15-904 renumbered to R12-15-905, new Section adopted effective June 15, 1995 (Supp. 95-2). Amended by final rulemaking at 11 A.A.R. 5395, effective February 4, 2006 (Supp. 05-4).

R12-15-905. Accuracy of Approved Measuring Devices

A. A responsible party shall install, maintain, and use an approved measuring device and method in a manner which will ensure that its measurement error does not exceed 10% of the actual flow rate.

B. All measured systems shall be installed or constructed and thereafter maintained so as to allow the Director, using another measuring device, to check readily the accuracy of the measuring device utilized by the responsible party.

Historical Note

Adopted effective December 27, 1982 (Supp. 82-6). Former Section R12-15-905 renumbered to R15-15-906, new Section R12-15-905 renumbered from R12-15-904 and amended effective June 15, 1995 (Supp. 95-2).

R12-15-906. Repair and Replacement of Approved Measuring Devices

If an approved measuring device fails to perform its designated function for more than 72 hours, the responsible party shall notify the Director of the failure, in writing, within seven calendar days after the discovery of the failure of the device. The reason for such failure shall be stated, as well as the estimated date of return to service of the device. If the malfunction is discovered by the Director and the malfunction does not appear to be the result of an attempt to render the device inaccurate, the Director shall notify the responsible party of the malfunction. The responsible party shall return the measuring device to full service within 30 days of either original notice by the responsible party to the Director or by the Director to the responsible party, unless repair or replacement service or parts are not available. In such case, the responsible party shall notify the Director of the delay within seven days and the reasons for it. The responsible party shall take corrective action in such cases as soon as practical. In all cases, the responsible party shall notify the Director within seven days when the measuring device is returned to full service and shall submit on a form prescribed by the Director estimates of the volume of water, if any, passing through the measured system during the period the measuring device was out of service and a description of the method used to calculate the estimates.

Historical Note

Section R12-15-906 renumbered from R12-15-905 and amended effective June 15, 1995 (Supp. 95-2).

R12-15-907. Calculation of Irrigation Water Deliveries

If one or more irrigation grandfathered rights receive water by a common distribution system where water is measured with an approved device or method at the point of delivery to the common distribution system, but not at a point of delivery to each irrigation grandfathered right, each irrigation grandfathered rightholder or agent shall report the water used by either of the following methods:

1. Estimate the amount of water used based on a pro rata share of the acres irrigated, or
2. Estimate the amount of water used based on a combination of the pro rata share of the acres irrigated and the consumptive use of each crop grown.

Historical Note

Adopted effective June 15, 1995 (Supp. 95-2).

R12-15-908. Measurement of Water by One Person on Behalf of Another

A responsible party shall be liable for any fines, penalties, or other sanctions resulting from the installation, monitoring, use, or accuracy of any measuring device, method, or recordkeeping, notwithstanding that the installation, monitoring, use, or recordkeeping may have been done by an agent of the responsible party.

Historical Note

Adopted effective June 15, 1995 (Supp. 95-2).

R12-15-909. Alternative Water Measuring Devices, Methods, and Reporting

A. A responsible party may use an alternative water measuring device or method that differs from those described in R12-15-903 provided the device or method is approved in advance by the Director. The Director shall approve an alternative water measuring device or method if the device meets the requirements of R12-15-905. The Director may require from the responsible party such information as may be necessary to demonstrate that the alternative device or method meets the requirements of R12-15-905.

B. Responsible parties may substitute equivalent information for the information required on the annual report form or use reporting formats that differ from that required in R12-15-904, provided the substituted information or format is approved in advance by the Director.

C. Responsible parties may use estimation methods that differ from those described in R12-15-907 provided they are approved in advance by the Director.

D. A municipal provider is exempted from the reporting requirements under R12-15-904 and the provisions under R12-15-906 pertaining to notification to the Director of measuring device malfunctions regarding metered service connections, unless required to report by A.R.S. Title 45 or by a permit, rule, or order issued pursuant to A.R.S. Title 45.

E. Municipal providers and irrigation districts may notify the Director of measuring device malfunctions at the time of filing the annual report and in a manner that differs from the requirements of R12-15-906, provided the municipal provider or irrigation district implements a schedule of regular maintenance of measuring devices, repairs or replaces malfunctioning measuring devices within seven days of discovery of the malfunction, and the alternative notification is approved in advance by the Director.

Historical Note

Adopted effective June 15, 1995 (Supp. 95-2).

ARTICLE 10. REPORTING REQUIREMENTS FOR ANNUAL REPORTS, ANNUAL ACCOUNTS, OPERATING FLEXIBILITY ACCOUNTS, AND CONVEYANCES OF GROUNDWATER RIGHTS

R12-15-1001. Definitions

In addition to the definitions in A.R.S. §§ 45-101 and 45-402, the following words and phrases in this Article have the following meanings, unless the context otherwise requires:

1. "Annual account" means an accounting of water required to be filed pursuant to A.R.S. § 45-468.
2. "Annual report" means an annual report of water withdrawn, delivered, received, transported, recharged, stored, recovered, replenished or used as required by A.R.S. §§ 45-437, 45-467, 45-632, 45-875.01, 45-876.01, 45-877.01, 45-878.01 or 45-1004.
3. "Central Arizona project water" means Colorado River water delivered through the facilities of the central Arizona project, and surface water from any other source conserved and developed by dams and reservoirs in the central Arizona project and lawfully delivered by the United States or a multi-county conservation district.
4. "Decreed or appropriative surface water" means surface water which is delivered or used pursuant to a decreed or appropriative water right, except any such water which is included in central Arizona project water.
5. "Farm" means an area of irrigated land under the same ownership as defined in A.R.S. § 45-402, including the area of land described in a certificate of irrigation grandfathered right, as well as contiguous land that the owner is legally entitled to irrigate only with decreed or appropriative surface water.
6. "Maximum annual groundwater allotment" means the quantity of water in acre-feet obtained by multiplying the number of water duty acres for a farm by the current irrigation water duty

for the farm unit.
7. "Normal flow" means water delivered or used pursuant to a right to appropriate an unstored, natural flow of surface water.
8. "Operating flexibility account" means an accounting of water use pursuant to an irrigation grandfathered right as provided in A.R.S. § 45-467.
9. "Responsible party" means a person required by law to file an annual account or annual report.
10. "Spillwater" means surface water, other than Colorado River water, released for beneficial use from storage, diversion, or distribution facilities to avoid spilling that would otherwise occur due to uncontrolled surface water inflows that exceed facility capacity and to which one of the following applies:
    a. The water is released from the facility under written criteria for releasing water to avoid spilling that have been approved in writing by the Director.
    b. The water is released from the facility because an unreasonable risk exists that the storage capacity of the facility will be exceeded within the next 30 days because the facility is near capacity and either the inflow to the facility or the forecast runoff into the facility is equal to or greater than the quantity of water ordered from the facility.
    c. The water is released from the facility because an unreasonable risk exists that the storage capacity of the facility will be exceeded more than 30 days in the future because the forecast runoff into the facility exceeds current unused storage capacity and projected water demand during the forecast period, provided that the Director has made a written finding before the release that the forecast is reasonable.
11. "Surface water right acre" means land to which the owner is legally entitled to apply decreed or appropriative surface water.
12. "Tailwater" means water which, after having been applied to a farm for irrigation purposes,
    a. Is subsequently used for the irrigation of a different farm, without having entered the distribution system of a city, town, private water company or irrigation district, or
    b. Is delivered to an irrigation district in accordance with R12-15-1010. Such water, once having entered the distribution system of the irrigation district, loses its characterization as tailwater.
13. "Water deliverer" means a city, town, private water company or irrigation district delivering a combination of groundwater and any other type of water for irrigation purposes.

Historical Note

Adopted effective December 27, 1982 (Supp. 82-6). Section R12-15-1001 renumbered to R12-15-1003, new Section R12-15-1001 adopted effective December 12, 1990 (Supp. 90-4). Amended to correct typographical error under A.A.C. R1-1-109 (Supp. 01-2). Amended by final rulemaking at 11 A.A.R. 5395, effective February 4, 2006 (Supp. 05-4).

R12-15-1002. Form of Annual Account or Annual Report

A. A person filing an annual account or an annual report shall do so on a form prescribed by the Director, unless the person has requested and received the Director's prior written approval to use an alternative form.

B. A person may file both an annual account and an annual report in one document. A person required to file an annual account shall designate in the annual account whether the annual account is being filed also as an annual report.

Historical Note

Adopted effective December 12, 1990 (Supp. 90-4).

R12-15-1003. Accuracy of Annual Reports

The quantity of water a responsible party reports in an annual report as having been withdrawn, delivered, received, transported, recharged, replenished, stored, recovered, or used during a year shall not deviate from the quantity of water actually withdrawn, delivered, received, transported, recharged, replenished, stored, recovered, or used by the responsible party during the year unless both of the following apply:
1. The deviation is 10 percent or less.
2. The deviation is not the result of an intentional act of misrepresentation by the responsible party.

Historical Note

Section R12-15-1003 renumbered from R12-15-1001 effective December 12, 1990 (Supp. 90-4). Amended by final rulemaking at 11 A.A.R. 5395, effective February 4, 2006 (Supp. 05-4).

R12-15-1004. Annual Reports Filed on Behalf of a Responsible Party

A. A responsible party is liable for any fines, penalties, or other sanctions resulting from or attributable to the filing or content of an annual report filed on behalf of the responsible party by an irrigation district pursuant to A.R.S. § 45-632, or by another person in a form acceptable to the Director.

B. If a responsible party has not filed an annual report for a calendar year, and the Department receives an annual report for that calendar year purportedly filed on behalf of the responsible party by an irrigation district pursuant to A.R.S. § 45-632, or by another person in a form acceptable to the Director, there is a rebuttable presumption that the annual report was filed with the responsible party's knowledge, consent, and authorization.

Historical Note

Adopted effective December 12, 1990 (Supp. 90-4). Amended to correct typographical error under A.A.C. R1-1-109 (Supp. 01-2). Amended by final rulemaking at 11 A.A.R. 5395, effective February 4, 2006 (Supp. 05-4).

R12-15-1005. Management Plan Monitoring and Reporting Requirements

A responsible party who is required by a provision of a management plan to comply with monitoring and reporting requirements shall comply with such requirements and shall include all such information in an annual account or annual report.

Historical Note

Adopted effective December 12, 1990 (Supp. 90-4).

R12-15-1006. Reporting Requirements for Holders of Recovery Well Permits

A responsible party recovering water during a year pursuant to a recovery well permit shall include in the annual report required by A.R.S. § 45-875.01 the names of any persons, other than non-irrigation customers of cities, towns, private water companies and irrigation districts, to whom the responsible party delivered the recovered water during the year, the quantity of recovered water delivered to each person named, and the uses to which the recovered water was applied. If the recovered water included commingled groundwater, decreed or appropriative surface water other than spillwater, central Arizona project water, effluent or spillwater, the responsible party shall include in the annual report an estimate of the quantity of each type of water delivered to each person named in the annual report or put to a specific use by the responsible party.

Historical Note

Adopted effective December 12, 1990 (Supp. 90-4). Amended by final rulemaking at 11 A.A.R. 5395, effective February 4, 2006 (Supp. 05-4).

R12-15-1007. Reporting Requirements for Annual Account

A person required to file an annual account pursuant to A.R.S. § 45-468 shall account for water provided to the following classes of users:
1. Cities and towns,
2. Private water companies,
3. Irrigation districts,
4. Dairies,
5. Metal mining facilities,
6. Cattle feed lots,
7. Turf-related facilities,
8. Sand and gravel facilities,
9. Electrical power generation facilities,
10. Other industrial users.

Historical Note

Adopted effective December 12, 1990 (Supp. 90-4).

R12-15-1008. Information Required to Maintain an Operating Flexibility Account

A. A responsible party who withdraws, receives, or uses groundwater during a calendar year pursuant to an irrigation grandfathered right, including any in lieu water received pursuant to a groundwater savings facility permit issued pursuant to A.R.S. § 45-812.01, shall include the following information for the calendar year in an annual report filed pursuant to A.R.S. § 45-467 or 45-632:
1. The quantity of groundwater withdrawn from each well.
2. The quantity of groundwater withdrawn and delivered to another person for irrigation purposes.
3. The quantity of groundwater received from a city, town, private water company, or irrigation district, including any in lieu water received pursuant to a groundwater savings facility permit issued pursuant to A.R.S. § 45-812.01.
4. The quantity of groundwater received from a person other than a city, town, private water company, or irrigation district, including any in lieu water received pursuant to a groundwater savings facility permit issued pursuant to A.R.S. § 45-812.01.
5. The quantity of effluent received.
6. The quantity of decreed or appropriative surface water received, other than normal flow and spillwater.
7. The quantity of normal flow received.
8. The quantity of spillwater received.
9. The quantity of tailwater used.
10. The quantity of tailwater delivered in accordance with the provisions of R12-15-1010(A), and the farm or irrigation district to which the tailwater was delivered.
11. The quantity of central Arizona project water received.
12. The quantity of any surface water received and not accounted for pursuant to subsections (6) through (11) of this subsection.
13. The number of surface water right acres in the farm to which the irrigation grandfathered right is appurtenant.
14. The quantity of water used for the legal irrigation of acres in the farm to which irrigation grandfathered rights are not appurtenant. If the responsible party omits this information, the Director shall presume that the total amount of water received or used for the irrigation of the farm was applied to acres to which irrigation grandfathered rights are appurtenant.

15. Any other information the Director may reasonably require to accomplish the management goals of the applicable active management area.

B. A water deliverer shall include the following information for an accounting period in an annual account filed pursuant to A.R.S. § 45-468:
1. The quantity of groundwater delivered to each farm, including any in lieu water delivered pursuant to a groundwater savings facility permit issued pursuant to A.R.S. § 45-812.01.
2. The quantity of normal flow delivered to each farm.
3. The quantity of spillwater delivered to each farm.
4. The quantity of decreed or appropriative surface water, other than normal flow and spillwater, delivered to each farm.
5. The quantity of central Arizona project water delivered to each farm.
6. The quantity of decreed or appropriative surface water, other than normal flow and spillwater, delivered for use within the service area of the water deliverer, including all farm and non-farm deliveries.
7. The number of surface water right acres within the service area of the water deliverer.
8. The quantity of effluent delivered to each farm.
9. Any other information the Director may reasonably require to accomplish the purposes of A.R.S. § 45-468.

Historical Note
Adopted effective December 12, 1990 (Supp. 90-4). Amended by final rulemaking at 11 A.A.R. 5395, effective February 4, 2006 (Supp. 05-4).

R12-15-1009. Credits to Operating Flexibility Account

A. Except as provided in subsection (B) of this Section and in R12-15-1010, if the total amount of water from all sources other than spillwater used by a farm for irrigation purposes in a calendar year is less than the farm's maximum annual groundwater allotment for the year, the Director shall register the difference as a credit to the farm's operating flexibility account.

B. If a farm is within the service area of a water deliverer, the Director shall reduce the credit as calculated pursuant to subsection (A) of this Section by an amount equal to the difference between the farm's pro rata share of the total quantity of decreed or appropriative surface water, other than normal flow or spillwater, delivered by the water deliverer during the year for use within its service area, and the quantity of water actually received by the farm during the year. The Director shall determine the farm's pro rata share by dividing the number of surface water right acres in the farm that are within the service area of the water deliverer by the total number of surface water right acres within the service area of the water deliverer, and multiplying the quotient by the total quantity of decreed or appropriative surface water, other than normal flow or spillwater, delivered by the water deliverer during the year for use within its service area.

Historical Note
Adopted effective December 12, 1990 (Supp. 90-4). Amended by final rulemaking at 11 A.A.R. 5395, effective February 4, 2006 (Supp. 05-4).

R12-15-1010. Operating Flexibility Account; Tailwater

A. When calculating credits or debits to a farm's operating flexibility account for a year, the Director shall exclude from the total amount of water used on the farm during that year the amount of any tailwater that originated on the farm and that was delivered from the farm to another farm or to an irrigation district for irrigation purposes during the year if all of the following apply:
1. Prior to January 1 of the year in which the deliveries of tailwater take place, the Director approves a written plan to measure and record the tailwater deliveries. The plan shall include:
a. The installation and use of a totalizing water measuring device that will record tailwater deliveries with no greater than a 10 percent margin of error.
b. Procedures for keeping accurate records of the tailwater deliveries.
c. A description of how the tailwater will be delivered.
d. An identification of the farm or irrigation district to which the tailwater will be delivered.
2. The person has measured, recorded, and delivered the tailwater in accordance with the plan approved under subsection (A)(1) of this Section.
3. The tailwater was delivered directly from the farm on which it originated to:
a. A specified farm that used the tailwater for the legal irrigation of irrigation acres or surface water right acres on that farm, or
b. A specified irrigation district that delivered the tailwater for the legal irrigation of irrigation acres or surface water right acres within that district.

B. A person who delivers tailwater in accordance with subsection (A) of this Section, and a person who directly receives and uses the tailwater pursuant to subsection (A)(3)(a) of this Section, shall account for and report the tailwater as if it were comprised of a mixture of groundwater, decreed and appropriative surface water other than normal flow, central Arizona project water, spillwater, other surface water, and effluent, as applicable, in the same proportions as those types of water comprise the total amount of water other than normal flow received or withdrawn for irrigation use during the calendar year on the farm on which the tailwater originated.

C. A person who uses tailwater that has not been delivered and accounted for as provided in subsections (A) and (B) of this Section may credit against the person's use of groundwater in a calendar year the amount of the tailwater used during the calendar year if the use of such tailwater would cause a debit to be incurred. The credit shall be applied only against the person's operating flexibility account debits that otherwise would have been incurred that year and shall not be used to discharge debits from prior years or accumulate credits for future years. For purposes of calculating credits to the person's operating flexibility account, the Director shall treat tailwater as groundwater, unless reported otherwise according to its source.

D. An irrigation district that receives tailwater pursuant to subsection (A)(3)(b) shall account for the water in the same manner as other water in the district's distribution system.

Historical Note
Adopted effective December 12, 1990 (Supp. 90-4). Amended by final rulemaking at 11 A.A.R. 5395, effective February 4, 2006 (Supp. 05-4).

R12-15-1011. Statement of Operating Flexibility Account

A. The Director shall annually issue to each owner or user of an irrigation grandfathered right for which a current annual report has been filed a statement of the operating flexibility account setting forth the status of the operating flexibility account for the farm, based on the information submitted in the annual report filed for the right.

B. Upon a motion or on the initiative of the Director, the Director may amend a statement of operating flexibility account at any time to correct clerical mistakes or to adjust the balance of the account based on information submitted in an amended or late annual report. The Director shall give written notice of any amendments made pursuant to this subsection to the person to whom the statement of operating flexibility account was issued.

Historical Note
Adopted effective December 12, 1990 (Supp. 90-4). Amended by final rulemaking at 11 A.A.R. 5395, effective February 4, 2006 (Supp. 05-4).

R12-15-1012. Rule of Construction

Nothing in A.A.C. R12-15-1001 through R12-15-1011 shall be construed to determine the legality of any water use for which an accounting is required under these rules.

Historical Note
Adopted effective December 12, 1990 (Supp. 90-4).

R12-15-1013. Retention of Records for Annual Accounts and Annual Reports

The responsible party shall keep and maintain, for at least three calendar years following the filing of an annual account or an annual report, all records which may be necessary to verify the information and data contained therein.

Historical Note
Adopted effective December 12, 1990 (Supp. 90-4).

R12-15-1014. Late Filing or Payment of Fees; Extension Penalties

A. An annual account, an annual report, or a request for extension pursuant to subsection (E) of this rule shall be deemed to be filed at the time a complete annual account, a complete annual report or a request for extension is hand-delivered to any Department office, or at the time the envelope in which it is mailed is postmarked.

B. Except as provided in subsection (C) of this Section, groundwater withdrawal fees and long-term storage credit recovery fees are deemed paid at the time the fees are hand-delivered to any Department office, or at the time the envelope in which they are mailed is postmarked.

C. If any groundwater withdrawal fees or long-term storage credit recovery fees are paid with a negotiable instrument that is not honored and paid upon the Department's initial demand, the fees are deemed paid at the time the Department actually receives the fees in cash or when the negotiable instrument is honored and paid to the Department.

D. If an annual account or an annual report filed on or before the date required by the applicable statute is found by the Director to be incomplete, the Director shall notify the responsible party of the inadequacies and allow the responsible party 30 days from the date of the notice to provide the missing information in a form prescribed by the Director. If the responsible party does not provide the missing information within 30 days from the date of the notice, late penalties under A.R.S. §§ 45-437, 45-632, 45-875.01, 45-876.01, 45-877.01, 45-878.01 or 45-1004 shall begin to accrue on the 31st day following the date of the notice. The Director shall not recommend to a court, pursuant to A.R.S. §§ 45-634, 45-635, 45-881.01, 45-882.01, 45-1062 or 45-1063, that civil penalties be imposed through the first 30 days following the date of the notice. However, if the inadequacy included the failure to pay all groundwater withdrawal fees due or all long-term storage credit recovery fees due, late penalties under A.R.S. §§ 45-614 or 45-874.01 shall begin to accrue on April 1, except as provided in subsection (E) of this Section.

E. A responsible party required to file an annual account or annual report for a year may request a 30-day extension of the first day of accrual of the late penalties under A.R.S. §§ 45-437, 45-614, 45-632, 45-874.01, 45-875.01, 45-876.01, 45-877.01, 45-878.01 or 45-1004 and of the civil penalties that the Director may recommend that a court impose pursuant to A.R.S. §§ 45-634, 45-635, 45-881.01, 45-882.01, 45-1062 or 45-1063. The request shall be filed no later than the date the annual account or annual report is required to be filed under the applicable statute. The Director shall grant a request for a 30-day extension if good cause is shown. If the Director grants the request, the late penalties and civil penalties shall begin to accrue on the first day after the 30-day extension period, except that if the Director finds that the person making the request presented false or misleading information to the Director and the Director relied on that information in granting the request, the late penalties and civil penalties shall begin to accrue as if the request was not granted. The Director shall not grant an extension to a responsible party who was granted an extension in the preceding calendar year and who subsequently failed to file a complete annual account or annual report and pay all groundwater withdrawal fees and all long-term storage credit recovery fees due within the 30-day extension period.

Historical Note
Adopted effective December 12, 1990 (Supp. 90-4). Amended by final rulemaking at 11 A.A.R. 5395, effective February 4, 2006 (Supp. 05-4).

R12-15-1015. Reporting Requirements for Conveyances of Grandfathered Rights and Groundwater Withdrawal Permits

A. A person who is required by A.R.S. § 45-482 to notify the Director of a conveyance of a grandfathered right shall file a notice of conveyance, on a form prescribed by the Director, within 30 days of the conveyance. All parties to the conveyance may use a single form for the required notice. Except provided in subsection (B) of this rule, the notice of conveyance shall include an accounting of the amount of water withdrawn or received pursuant to that grandfathered right from January 1 to the date of conveyance for that calendar year.

B. If the person to whom a grandfathered right is conveyed is unable, because of extraordinary circumstances and good cause shown, to perform the accounting otherwise required by subsection (A) of this rule, the Director may waive the requirement for that person.

C. If a person, including a person who is granted a waiver pursuant to subsection (B) of this rule, fails to include the required accounting in a timely filed notice of conveyance pursuant to subsection (A) of this rule, the Director shall determine the amount of groundwater withdrawn or received pursuant to the grandfathered right from January 1 to the date of conveyance for that calendar year. Such a person shall bear the burden, in any subsequent administrative or judicial proceeding, of establishing by clear and convincing evidence that the Director's determination was incorrect.
D. A person requesting the Director's approval of a proposed conveyance of a groundwater withdrawal permit pursuant to A.R.S. § 45-520(B) shall include with such request the quantity of groundwater withdrawn pursuant to the groundwater withdrawal permit for that calendar year and all other information required to be submitted pursuant to A.R.S. § 45-632.

Historical Note
Adopted effective December 12, 1990 (Supp. 90-4).

R12-15-1016. Spillwater Reporting by Water Deliverers
A water deliverer that delivers spillwater during a year shall include the following information in the annual account or annual report submitted by the water deliverer for that year:
1. The total quantity of spillwater delivered for non-irrigation uses during the year.
2. The total quantity of spillwater delivered for irrigation uses during the year.
3. Any other information the Director may reasonably require to determine whether the water qualifies as spillwater under R12-15-1001(10).

Historical Note
New Section made by final rulemaking at 11 A.A.R. 5395, effective February 4, 2006 (Supp. 05-4).

R12-15-1017. Maintenance and Filing of Annual Reports Required by A.R.S. § 45-343
A community water system required to file an annual report under A.R.S. § 45-343 shall maintain the report on a calendar year basis and shall file the report with the Director no later than June 1 of each year for the preceding calendar year.

Historical Note
New Section made by final rulemaking at 11 A.A.R. 5395, effective February 4, 2006 (Supp. 05-4).

ARTICLE 11. INSPECTIONS AND AUDITS

R12-15-1101. Inspections
A. For the purpose of this rule, "inspection" means an entry by the Director at reasonable times onto private or public property for any of the following purposes:
1. To obtain factual data or access to records required to be kept under A.R.S. §§ 45-632, 45-879.01, or 45-1004.
2. To inspect a well or another facility for the withdrawal, transportation, use, measurement, or recharge of groundwater under A.R.S. § 45-633.
3. To inspect a facility that is used for the purpose of water storage, stored water recovery, or stored water use under A.R.S. § 45-880.01(A).
4. To inspect a body of water under A.R.S. § 45-135 or to ascertain compliance with A.R.S. Title 45, Chapter 1, Article 3.
5. To inspect or to obtain factual data or access to records pursuant to any Section of A.R.S. Title 45 that requires the Director to adopt rules for conducting inspections, examining records, and obtaining warrants.
6. To inspect facilities used for the withdrawal, diversion, or use of water pursuant to a water exchange under A.R.S. § 45-1061.

B. Not less than seven days prior to an inspection, the Director shall mail notice of the inspection by first class letter to the owner, manager or occupant of the property. The notice shall include the statutory authorization and purpose for the inspection. The notice shall specify a date and time certain or a seven-day period within which the inspection may take place. If a request is made before the seven-day period, the Director shall schedule the inspection for a time certain within the seven-day period to allow an opportunity for a representative of the property to be present at the inspection. The notice shall include the name and telephone number of a Department employee who may be contacted to arrange such an appointment.
C. Whenever practical, Department employees shall minimize disruptions to on-going operations caused by an inspection.
D. If the property is controlled or secured against entry at the time specified in the notice of inspection but consent to the inspection was not denied, the Director shall give a second notice in the manner prescribed in subsection (B) before seeking a search warrant or its equivalent. The second notice shall request that a representative of the property be present at the inspection to accompany Department personnel.
E. If the Director gives notice of an inspection and is not permitted to conduct an inspection, the Director may apply for and obtain a search warrant or its equivalent.
F. Notice of inspection shall not be required under subsections (B) and (D) of this rule if the Director reasonably believes that notice would frustrate the enforcement of A.R.S. Title 45, or where entry is sought for the sole purpose of inspecting water measuring devices required pursuant to A.R.S. § 45-604.
G. The Director shall mail a copy of the report of the inspection either to the person to whom the notice of inspection was directed, or to the owner, manager or occupant of the property if no notice of inspection was given. The report shall include the date of the inspection and a short summary of the findings. If no notice was given, the report shall include an explanation of the reason for determining that notice would not be given, unless providing the explanation would frustrate enforcement of A.R.S. Title 45. An aggrieved person may file with the Director written comments on the report within 30 days after the report is mailed.
H. The owner, manager or occupant of the property may waive the provisions for notice contained in this rule.
I. The Director shall comply with the requirements of A.R.S. § 41-1009 when conducting inspections under this Section.

Historical Note
Adopted effective August 31, 1992 (Supp. 92-3). Amended effective July 22, 1994 (Supp. 94-3). Amended by final rulemaking at 11 A.A.R. 5395, effective February 4, 2006 (Supp. 05-4).

R12-15-1102. Audits
A. For the purpose of this rule, "representative" means
1. An officer or director of a corporation subject to the audit,
2. A general partner of a partnership subject to the audit, or
3. A person who appears at an audit and produces a signed authorization to act on behalf of the person subject to the audit.

B. This rule applies to audits conducted pursuant to A.R.S. §§ 45-633(C), 45-880.01, and any other Section of A.R.S. Title 45 that authorizes the Director to require a person to appear at the Director's office and produce records and information and that also requires the Director to adopt rules for conducting inspections, examining records, and obtaining warrants.
C. No less than 20 days prior to an audit, the Director shall mail notice of the audit by first class letter to the person that is the subject of the audit. The notice shall state the date, time and place of the audit. The notice shall specify the records or information which the person must produce. The notice shall also include the statutory authorization and purpose for the audit and the name and telephone number of a Department employee who may be contacted for further information. The audit shall be held at the Department's offices, unless the Director grants a request to have the audit conducted at a different location.
D. The person subject to the audit or a representative shall appear at the scheduled time and shall produce the records and information specified in the notice. The person subject to the audit or a representative may make one request to reschedule the audit, which the Department shall grant if practicable.
E. The Director shall mail a copy of the report of the audit to the person subject to the audit. An aggrieved person may file with the Director written comments on the report within 30 days after the report is mailed.
F. The person subject to the audit may waive the provisions for notice contained in this rule.

Historical Note
Adopted effective August 31, 1992 (Supp. 92-3). Amended effective July 22, 1994 (Supp. 94-3).

ARTICLE 12. DAM SAFETY PROCEDURES

R12-15-1201. Applicability
A. This Article applies to any artificial barrier meeting the specifications of A.R.S. § 45-1201(1) as interpreted by R12-15-1204. This Article applies to an application for the construction of a dam and reservoir; an application to reconstruct, repair, alter, enlarge, breach, or remove an existing dam and reservoir, including a breached or damaged dam; operation and maintenance of an existing dam and reservoir; and enforcement. A structure identified in R12-15-1203 is exempt from this Article.
B. This Article is applicable to any dam regardless of hazard potential classification, with the following exceptions:
1. R12-15-1208, R12-15-1209, R12-15-1213, R12-15-1221, R12-15-1225, and R12-15-1226 apply only to a dam classified as a high or significant hazard potential dam.
2. R12-15-1210 applies only to a dam classified as a low hazard potential dam. A low hazard potential dam is exempt from R12-15-1208, R12-15-1209, R12-15-1211, R12-15-1213, R12-15-1221, R12-15-1225, and R12-15-1226.
3. R12-15-1211 applies only to a dam classified as a very low hazard potential dam. A very low hazard potential dam is exempt from R12-15-1208, R12-15-1209, R12-15-1210, R12-15-1212, R12-15-1213, R12-15-1215, R12-15-1216, R12-15-1221, R12-15-1225, and R12-15-1226.
4. R12-15-1216(B) applies only to an embankment dam.

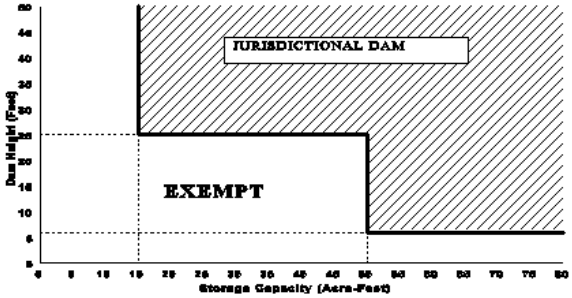
Historical Note
Adopted effective November 2, 1978 (Supp. 78-6). Former Section R12-15-01 renumbered without change as Section R12-15-1201 effective October 8, 1982 (Supp. 82-5). Section repealed; new Section adopted by final rulemaking at 6 A.A.R. 2558, effective June 12, 2000 (Supp. 00-2).

R12-15-1202. Definitions
In addition to the definitions provided in A.R.S. § 45-1201, the following definitions are applicable to this Article:
1. "Alteration or repair of an existing dam or appurtenant structure" means to make different from the originally approved construction drawings and specifications or current condition without changing the height or storage capacity of the dam or reservoir, except for ordinary repairs and general maintenance as prescribed in R12-15-1217.
2. "Appurtenant structure" means any structure that is contiguous and essential to the safe operation of the dam including embankments, saddle dikes, outlet works and controls, diversion ditches, spillway and controls, access structures, bridges, and related housing at a dam.
3. "Classification of dams" means the placement of dams into categories based upon an evaluation of the size and hazard potential, regardless of the condition of the dam.
4. "Concrete dam" means any dam constructed of concrete, including arch, gravity, arch-gravity, slab and buttress, and multiple arch dams. A dam that only has a concrete facing is not a concrete dam.
5. "Construction" means any activity performed by the owner or someone employed by the owner that is related to the construction, reconstruction, repair, enlargement, removal, or

alteration of any dam, unless the context indicates otherwise. Construction is performed after approval of an application and before issuance of a license.
6. "Dam failure inundation map" means a map depicting the maximum area downstream from a dam that would be flooded in the event of the worst condition failure of the dam.
7. "Department" means the Arizona Department of Water Resources.
8. "Director" means the Director of the Arizona Department of Water Resources or the Director's designee.
9. "Embankment dam" means a dam that is constructed of earth or rock material.
10. "Emergency spillway" means a spillway designed to safely pass the inflow design flood routed through the reservoir. If the flow is controlled by gates, it is a controlled spillway. If the flow is not controlled by gates, it is an uncontrolled spillway.
11. "Engineer" means a Professional Engineer registered and licensed in accordance with A.R.S. Title 32, Chapter 1, with proficiency in engineering and knowledge of dam technology.
12. "Enlargement to an existing dam or appurtenant structure" means any alteration, modification, or repair that increases the vertical height of a dam or the storage capacity of the reservoir.
13. "Flashboards" mean timber, concrete, or steel sections placed on the crest of a spillway to raise the retention water level that may be quickly removed at time of flood either by a tripping device or by designed failure of the flashboards or their supports.
14. "Flood control dam" means a dam that uses all of its reservoir storage capacity for temporary impoundment of flood waters and collection of sediment or debris.
15. "Hazard potential" means the probable incremental adverse consequences that result from the release of water or stored contents due to failure or improper operation of a dam or appurtenances.
16. "Hazard potential classification" means a system that categorizes dams according to the degree of probable incremental adverse consequences of failure or improper operation of a dam or appurtenances. The hazard potential classification does not reflect the current condition of the dam with regard to safety, structural integrity, or flood routing capacity.
17. "Height" means the vertical distance from the lowest elevation of the outside limit of the barrier at its intersection with the natural ground surface to the spillway crest elevation. For the purpose of determining jurisdictional status, the lowest elevation of the outside limit of the barrier may be the outlet pipe invert elevation if the outlet is constructed below natural ground.
18. "Impound" means to cause water or a liquid to be confined within a reservoir and held with no discharge.
19. "Incremental adverse consequences" means under the same loading conditions, the additional adverse consequences such as economic, intangible, lifeline, or human losses, that would occur due to the failure or improper operation of the dam over those that would have occurred without failure or improper operation of the dam.
20. "Inflow design flood" or "IDF" means the reservoir flood inflow magnitude selected on the basis of size and hazard potential classification for emergency spillway design requirements of a dam.
21. "Intangible losses" means incremental adverse consequences to property that are not economic in nature, including property related to social, cultural, unique, or resource-based values, including the loss of irreplaceable and unique historic and cultural features; long-lasting pollution of land or water; or long-lasting or permanent changes to the ecology, including fish and endangered species habitat identified and evaluated by a public natural resource management or protection agency.
22. "Jurisdictional dam" means a barrier that meets the definition of a dam prescribed in A.R.S. § 45-1201 that is not exempted by R12-15-1203 over which the Department of Water Resources exercises jurisdiction.
23. "Levee" means an embankment of earth, concrete, or other material used to prevent a watercourse from spreading laterally or overflowing its banks. A levee is not used to impound water.
24. "License" means license of final approval issued by the Director upon completion or enlargement of a dam under A.R.S. § 45-1209.
25. "Lifeline losses" mean disruption of essential services such as water, power, gas, telephone, or emergency medical services.
26. "Liquid-borne material" means mine tailings or other milled ore products transported in a slurry to a storage impoundment.
27. "Maximum credible earthquake" means the most severe earthquake that is believed to be possible at a point on the basis of geologic and seismological evidence.
28. "Maximum water surface" means the maximum elevation of the reservoir water level attained during routing of the inflow design flood.
29. "Natural ground surface" means the undisturbed ground surface before excavation or filling, or the undisturbed bed of the stream or river.
30. "Outlet works" means a closed conduit under or through a dam or through an abutment for the controlled discharge of the contents normally impounded by a dam and reservoir. The outlet works include the inlet and outlet structures appurtenant to the conduit. Outlet works may be controlled or uncontrolled.
31. "Probable" means likely to occur, reasonably expected, and realistic.
32. "Probable maximum flood" or "PMF" means the flood runoff expected from the most severe combination of critical meteorologic and hydrologic conditions that are reasonably possible in the region, including rain and snow where applicable. 1/2 PMF is that flood represented by the flood hydrograph with ordinates equal to 1/2 the corresponding ordinates of the PMF hydrograph.
33. "Probable maximum precipitation" means the greatest depth of precipitation for a given duration that is theoretically physically possible over a particular size storm area at a particular geographical location at a particular time of year.
34. "Reservoir" means any basin that contains or is capable of containing water or other liquids impounded by a dam.
35. "Residual freeboard" means the vertical distance between the highest water surface elevation during the inflow design flood and the lowest point at the top of the dam.
36. "Restricted storage" means a condition placed on a license by the Director to reduce the storage level of a reservoir because of a safety deficiency.
37. "Saddle dike or saddle dam" means any dam constructed in a topographically low area on the perimeter of a reservoir, required to contain the reservoir at the highest water surface elevation.
38. "Safe" means that a dam has sufficient structural integrity and flood routing capacity to make failure of the dam unlikely.
39. "Safe storage level" means the maximum reservoir water surface elevation at which the Director determines it is safe to impound water or other liquids in the reservoir.
40. "Safety deficiency" means a condition at a dam that impairs or adversely affects the safe operation of the dam.
41. "Safety inspection" means an investigation by an engineer or a person under the direction of an engineer to assess the safety of a dam and determine the safe storage level for a reservoir, which includes review of design reports, construction documents, and previous safety inspection reports of the dam, spillways, outlet facilities, seepage control and measurement systems, and permanent monument or monitoring installations.
42. "Spillway crest" means the highest elevation of the floor of the spillway along a centerline profile through the spillway.
43. "Storage capacity" means the maximum volume of water, sediment, or debris that can be impounded in the reservoir with no discharge of water, including the situation where an uncontrolled outlet becomes plugged. The storage capacity is reached when the water level is at the crest of the emergency spillway, or at the top of permanently mounted emergency spillway gates in the closed position. Storage capacity excludes dead storage below the natural ground surface.
44. "Surcharge storage" means the additional water storage volume between the emergency spillway crest or closed gates, and the top of the dam.
45. "Total freeboard" means the vertical distance between the emergency spillway crest and the top of the dam.
46. "Unsafe" means that safety deficiencies in a dam or spillway could result in failure of the dam with subsequent loss of human life or significant property damage.

Historical Note

Adopted effective November 2, 1978 (Supp. 78-6). Former Section R12-15-02 renumbered without change as Section R12-15-1202 effective October 8, 1982 (Supp. 82-5). Section repealed; new Section adopted by final rulemaking at 6 A.A.R. 2558, effective June 12, 2000 (Supp. 00-2). Amended to correct typographical error under A.A.C. R1-1-109 (Supp. 01-2).



R12-15-1203. Exempt Structures

The following structures are exempt from regulation by the Department:
1. Any artificial barrier identified as exempt on Table 1 and defined as follows:
   a. Less than 6 feet in height, regardless of storage capacity.
   b. Between 6 and 25 feet in height with a storage capacity of less than 50 acre-feet.
   c. Greater than 25 feet in height with 15 acre-feet or less of storage capacity.
2. A dam owned by the federal government. A dam designed by the federal government for any non-federal entity or person that will subsequently be owned or operated by a person or entity defined as an owner in A.R.S. § 45-1201 is subject to jurisdiction, beginning with design and construction of the dam.
3. A dam owned or operated by an agency or instrumentality of the federal government, if a dam safety program at least as stringent as this Article is applicable to and enforced against the agency or instrumentality.
4. A transportation structure such as a highway, road, or railroad fill that exists solely for transportation purposes. A transportation structure designed, constructed, or modified with the intention of impounding water on an intermittent or permanent basis and meeting the definition of dam in A.R.S. § 45-1201 is subject to jurisdiction.
5. A levee constructed adjacent to or along a watercourse, primarily to control floodwater.
6. A self-supporting concrete or steel water storage tank.
7. An impoundment for the purpose of storing liquid-borne material.
8. A release-contained barrier as defined by A.R.S. § 45-1201(5).

Historical Note

Adopted effective November 2, 1978 (Supp. 78-6). Former Section R12-15-03 renumbered without change as Section R12-15-1203 effective October 8, 1982 (Supp. 82-5). Section repealed; new Section adopted by final rulemaking at 6 A.A.R. 2558, effective June 12, 2000 (Supp. 00-2).

Table 1. Exempt Structures

Historical Note
New Table adopted by final rulemaking at 6 A.A.R. 2558, effective June 12, 2000 (Supp. 00-2).

R12-15-1204. Provision for Guidelines
The Department may develop and adopt substantive policy statements that serve as dam safety guidelines to aid a dam owner or engineer in complying with this Article. The Department recommends that dam owners and engineers consult design guidelines published by agencies of the federal government, including the U.S. Bureau of Reclamation, the U.S. Army Corps of Engineers, the Natural Resources Conservation Service, and the Federal Energy Regulatory Commission, for the design of concrete, roller compacted concrete, stone masonry, timber, inflatable rubber, and mechanically-stabilized earth dams. The Director may require that other criteria be used or revise any of the specific criteria for the purpose of dam safety. An owner shall obtain advance approval by the Director of design criteria.

Historical Note
Adopted effective November 2, 1978 (Supp. 78-6). Former Section R12-15-04 renumbered without change as Section R12-15-1204 effective October 8, 1982 (Supp. 82-5). Section repealed; new Section adopted by final rulemaking at 6 A.A.R. 2558, effective June 12, 2000 (Supp. 00-2).

R12-15-1205. General Responsibilities
A. Each owner is responsible for the safe design, operation, and maintenance of a dam. The owner shall operate, maintain, and regularly inspect a dam so that it does not constitute a danger to human life or property. The owner of a high or significant hazard potential dam shall provide timely warning to the Department and all other persons listed in the emergency action plan of problems at the dam. The owner shall develop and maintain effective emergency action plans and coordinate those plans with local officials as prescribed in R12-15-1221.
B. The owner shall conduct frequent observation of the dam, as prescribed in the emergency action plan and as follows:
1. The owner shall increase the frequency of observation when the reservoir is full, during heavy rains or flooding, and following an earthquake.
2. The owner shall report to the Director any condition that threatens the safety of the dam as prescribed in R12-15-1224(A). The owner shall make the report as soon as possible, but not later than 12 hours after discovery of the conditions.
3. If dam failure appears imminent, the owner shall notify the county sheriff or other emergency official immediately.
4. The owner is responsible for the safety of the dam and shall take action to lower the reservoir if it appears that the dam has weakened or is in danger of failing.
C. The owner of a dam shall install, maintain, and monitor instrumentation to evaluate the performance of the dam. The Director shall require site-specific instrumentation that the Director deems necessary for monitoring the safety of the dam when failure may endanger human life and property. Conditions that may require monitoring include land subsidence, earth fissures, embankment cracking, phreatic surface, seepage, and embankment movements.
D. The owner shall perform timely maintenance and ordinary repair of a dam. The owner shall implement an annual plan to inspect the dam and accomplish the maintenance and ordinary repairs necessary to protect human life and property.
E. If a change of ownership of a dam occurs, the new owner shall notify the Department within 15 days after the date of the transaction and provide the mailing address and telephone number where the new owner can be contacted. Within 90 days after the date of the transaction, the new owner shall provide the name and telephone number of the individual or individuals who are responsible for operating and maintaining the dam.

Historical Note
Adopted effective November 2, 1978 (Supp. 78-6). Former Section R12-15-05 renumbered without change as Section R12-15-1205 effective October 8, 1982 (Supp. 82-5). Section repealed; new Section adopted by final rulemaking at 6 A.A.R. 2558, effective June 12, 2000 (Supp. 00-2).

R12-15-1206. Classification of Dams
A. Size Classification. Dams are classified by size as small, intermediate, or large. Size is determined with reference to Table 2. An owner or engineer shall determine size by storage capacity or height, whichever results in the larger size.
B. Hazard Potential Classification
1. The Department shall base hazard potential classification on an evaluation of the probable present and future incremental adverse consequences that would result from the release of water or stored contents due to failure or improper operation of the dam or appurtenances, regardless of the condition of the dam. The evaluation shall include land use zoning and development projected for the affected area over the 10 year period following classification of the dam. The Department considers all of the following factors in hazard potential classification: probable loss of human life, economic and lifeline losses, and intangible losses identified and evaluated by a public resource management or protection agency.
a. The Department bases the probable incremental loss of human life determination primarily on the number of permanent structures for human habitation that would be impacted in the event of failure or improper operation of a dam. The Department considers loss of human life unlikely if:
i. Persons are only temporarily in the potential inundation area;
ii. There are no residences or overnight campsites; and
iii. The owner has control of access to the potential inundation area and provides an emergency action plan with a process for warning in the event of a dam failure or improper operation of a dam.
b. The Department bases the probable economic, lifeline, and intangible loss determinations on the property losses, interruptions of services, and intangible losses that would be likely to result from failure or improper operation of a dam.
2. The 4 hazard potential classification levels are very low, low, significant, and high, listed in order of increasing probable adverse incremental consequences, as prescribed in Table 3. The Director shall classify intangible losses by considering the common or unique nature of features or habitats and temporary or permanent nature of changes.
a. Very Low Hazard Potential. Failure or improper operation of a dam would be unlikely to result in loss of human life and would produce no lifeline losses and very low economic and intangible losses. Losses would be limited to the 100 year floodplain or property owned or controlled by the dam owner under long-term lease. The Department considers loss of life unlikely because there are no residences or overnight camp sites.
b. Low Hazard Potential. Failure or improper operation of a dam would be unlikely to result in loss of human life, but would produce low economic and intangible losses, and result in no disruption of lifeline services that require more than cosmetic repair. Property losses would be limited to rural or agricultural property, including equipment, and isolated buildings.
c. Significant Hazard Potential. Failure or improper operation of a dam would be unlikely to result in loss of human life but may cause significant or high economic loss, intangible damage requiring major mitigation, and disruption or impact on lifeline facilities. Property losses would occur in a predominantly rural or agricultural area with a transient population but significant infrastructure.
d. High Hazard Potential. Failure or improper operation of a dam would be likely to cause loss of human life because of residential, commercial, or industrial development. Intangible losses may be major and potentially impossible to mitigate, critical lifeline services may be significantly disrupted, and property losses may be extensive.
3. An applicant shall demonstrate the hazard potential classification of a dam before filing an application to construct. The Department shall review the applicant's demonstration early in the design process at pre-application meetings prescribed in R12-15-1207(D).
4. The Department shall review the hazard potential classification of each dam during each subsequent dam safety inspection and revise the classification in accordance with current conditions.

Historical Note
Adopted effective November 2, 1978 (Supp. 78-6). Former Section R12-15-06 renumbered without change as Section R12-15-1206 effective October 8, 1982 (Supp. 82-5). Section repealed; new Section adopted by final rulemaking at 6 A.A.R. 2558, effective June 12, 2000 (Supp. 00-2).

Exhibit A. Repealed

Historical Note
Exhibit repealed by final rulemaking at 6 A.A.R. 2558, effective June 12, 2000; a Historical Note for Exhibit A did not exist before this date (Supp. 00-2).

Table 2. Size Classification

Category	Storage Capacity (acre-feet)	Height (feet)
Small	50 to 1,000	25 to 40
Intermediate	greater than 1,000 and not exceeding 50,000	higher than 40 and not exceeding 100

Large	greater than 50,000	higher than 100

Historical Note
New Table adopted by final rulemaking at 6 A.A.R. 2558, effective June 12, 2000 (Supp. 00-2).

Table 3. Downstream Hazard Potential Classification

Hazard Potential Classification	Probable Loss of Human Life	Probable Economic, Lifeline, and Intangible Losses
Very Low	None expected	Economic and lifeline losses limited to owner's property or 100-year floodplain. Very low intangible losses identified.
Low	None expected	Low
Significant	None expected	Low to high
High	Probable - One or more expected	Low to high (not necessary for this classification)

Historical Note
New Table adopted by final rulemaking at 6 A.A.R. 2558, effective June 12, 2000 (Supp. 00-2).

R12-15-1207. Application Process

A. An applicant shall obtain written approval from the Director before constructing, reconstructing, repairing, enlarging, removing, altering, or breaching a dam. Application requirements differ according to the hazard potential of the dam.
   1. To construct, reconstruct, repair, enlarge, or alter a high or significant hazard potential dam, the applicant shall comply with R12-15-1208.
   2. To breach or remove a high or significant hazard potential dam, the applicant shall comply with R12-15-1209.
   3. To construct, reconstruct, repair, enlarge, alter, breach, or remove a low hazard potential dam, the applicant shall comply with R12-15-1210.
   4. To construct, reconstruct, repair, enlarge, alter, breach, or remove a very low hazard potential dam, the applicant shall comply with R12-15-1211.

B. An application shall not be filed with the Director under the following circumstances:
   1. The dam is exempt under R12-15-1203;
   2. A dam owner starts repairs to an existing dam that are necessary to safeguard human life or property and the Director is notified without delay;
   3. The owner performs general maintenance or ordinary repairs as prescribed in R12-15-1217(A) or (B); or
   4. Breach, removal, or reduction of a very low hazard dam as prescribed in R12-15-1211(C).

C. An applicant is not required to comply with a requirement in this Article if the Director finds that, considering the site characteristics and the proposed design, the requirement is unduly burdensome or expensive and is not necessary to protect human life or property. The Director shall consider the size, hazard potential classification, physical site conditions, and applicability of a requirement to a proposed dam. The Director shall state in writing the reason or reasons the applicant is not required to comply with a requirement.

D. An applicant shall schedule pre-application conferences with the Department to discuss the requirements of this Article and to resolve issues essential to the design of a dam while the design is in preliminary stages. The Director shall view the dam site during the pre-application process. The following are examples of issues for pre-application conferences: the hazard potential classification, the approximate inflow design flood, the basic design concepts, and any requirements that may be found by the Director to be unduly burdensome or expensive and not necessary to protect human life or safety. In addition, the applicant may submit preliminary design calculations to the Department for review and comment. The Department shall comment as soon as practicable, depending on the size of the submittal and the current workload.

E. The Department shall review applications as follows:
   1. Applications will be received by appointment. During this meeting the Department shall make a brief review of the application to determine that the application contains each of the items required by R12-15-1208, R12-15-1209, R12-15-1210, or R12-15-1211.
   2. Following receipt of an application submitted under R12-15-1208, R12-15-1209, R12-15-1210, or R12-15-1211, the Director shall complete an administrative review as prescribed in R12-15-401(1) and notify the applicant in writing whether the application is administratively complete. If the application is not administratively complete, the notification shall include a list of additional information that is required to complete the application.
   3. After finding the application submitted under R12-15-1208, R12-15-1209, R12-15-1210, or R12-15-1211 administratively complete, the Director shall complete a substantive review as prescribed in R12-15-401(3) and notify the applicant in writing of the Director's approval or disapproval. If during this review period, the Director determines that there are defects in the application that would impact human life and property, a written notice of the defects shall be sent to the applicant.
   4. An applicant may request in writing that the Director expedite the review of an application by employing an expert consultant on a contract basis under A.R.S. § 45-104(D). The Director shall establish on-call contracts with expert consultants to facilitate the process of expediting review. The Director may retain a consultant to review all or a portion of the application as necessary to expedite the process in response to an owner's request or to comply with time-frame rules. Before conducting the review, the consultant shall provide the Director and the applicant with a proposed time schedule and cost estimate. If the applicant agrees to the consultant's proposal for an expedited review of an application and the Director employs the consultant, the applicant shall pay to the Department the cost of the consultant's services in addition to the application fees. The Director retains the authority to review and approve, disapprove, or modify the findings and recommendations of the consultant.
   5. The Director shall not approve an application in less than 10 days from the date of receipt.
   6. If the Director disapproves the application, the Director shall provide the applicant with a statement of the Director's objections.
   7. If the Director approves an application, the applicant shall submit in triplicate revised drawings and specifications that incorporate any required changes.
      a. The Director shall return to the applicant 1 set of final construction drawings and specifications with the Department's approval stamp to be retained onsite during construction;
      b. The Director shall retain for permanent state record 1 set of final construction drawings and specifications with the Department's approval stamp; and
      c. The Director shall retain for use by the Department during construction the 3rd set of final construction drawings and specifications with the Department's approval stamp.
   8. The Director shall impose conditions and limitations that the Director deems necessary to safeguard human life and property. Examples of the conditions of approval include but are not limited to:
      a. The applicant shall not cover the foundation or abutment with the material of the dam until the Department has been given notice and a reasonable time to inspect and approve them.
      b. The applicant shall start construction within 1 year from the date of approval.
      c. The applicant shall maintain a safe storage level for an existing dam being reconstructed, repaired, enlarged, altered, or breached.

F. An approval to construct a new dam or repair, enlarge, alter, breach, or remove an existing dam is valid for 1 year.
   1. If construction does not begin within 1 year, the approval is void.
   2. Upon written request and good cause shown by the owner, the time for commencing construction may be extended. An applicant shall not start construction before the Director reviews the application for changes and grants approval.

Historical Note
New Section adopted by final rulemaking at 6 A.A.R. 2558, effective June 12, 2000 (Supp. 00-2).

R12-15-1208. Application to Construct, Reconstruct, Repair, Enlarge, or Alter a High or Significant Hazard Potential Dam

A. An application package to construct, reconstruct, repair, enlarge, or alter a high or significant hazard potential dam shall include the following prepared by or under the supervision of an engineer as defined in R12-15-1202(11).
   1. A completed application filed in duplicate on forms provided by the Director.
   2. A design information summary or checklist of items prepared in duplicate on forms provided by the Director.
   3. An initial application fee based on the total estimated project cost and computed in accordance with A.R.S. § 45-1204 and R12-15-151(B)(11).
   4. A detailed estimate of project costs. Project costs are all costs associated with construction of the dam and appurtenant works including preliminary investigations and surveys, engineering design, supervision of construction, and any other engineering costs.
   5. Two complete sets of construction drawings as prescribed in R12-15-1215(1).
   6. Two complete sets of construction specifications as prescribed in R12-15-1215(2).
   7. An engineering design report that includes information needed to evaluate all aspects of the design of the dam and appurtenances, including references with page numbers to support any assumptions used in the design, as prescribed in R12-15-1215(3). The engineering design report shall recommend a safe storage level for existing dams being reconstructed, repaired, enlarged, or altered.
   8. A construction quality assurance plan describing all aspects of construction supervision.
   9. A description of the use for the impounded or diverted water, proof of a right to appropriate, and a permit to store water as prescribed in A.R.S. §§ 45-152 and 45-161.
   10. A long-term budget plan and evidence of financing, prepared using customary accounting principles, that demonstrate that the applicant has the financial capability to construct, operate, and maintain the dam in a safe manner. If the applicant does not have evidence that can be verified by an independent audit of the financial capability to construct, operate, and maintain the dam in a safe manner, the Director may require a performance bond for the entire cost of the proposed construction work.

B. The following may be submitted with the application or during construction.
   1. An emergency action plan as prescribed in R12-15-1221.
   2. An operation and maintenance plan to accomplish the annual maintenance.
   3. An instrumentation plan regarding instruments that evaluate the performance of the dam.

Historical Note
New Section adopted by final rulemaking at 6 A.A.R. 2558, effective June 12, 2000 (Supp. 00-2).

R12-15-1209. Application to Breach or Remove a High or Significant Hazard Potential Dam

A. An applicant shall excavate the dam down to the level of the natural ground at the maximum section. Upon approval of the Director, additional breaches may be made. This provision shall not

be construed to require more than total removal of the dam regardless of the flood magnitude. The breach or breaches shall be of sufficient width to pass the greater of:
1. The 100 year flood at a depth of less than 5 feet, or
2. The 100 year flood at a normal flood depth of not more than 2 feet at a distance of 2,000 feet downstream of the dam.

B. The sides of each breach shall be excavated to a slope ratio that is stable and not steeper than 1 horizontal to 1 vertical.

C. Each breach shall be designed to prevent silt that has previously been deposited on the reservoir bottom and the excavated material from the breach from washing downstream.

D. Before breaching the dam, the reservoir shall be emptied in a controlled manner that will not endanger lives or damage downstream property. The applicant shall obtain approval from the Director for the method of breaching or removal.

E. An application package to breach or remove a high or significant hazard potential dam shall include the following prepared by or under the supervision of an engineer as defined in R12-15-1202(11).
1. The construction drawing or drawings for the breach or removal of a dam, including the location, dimensions, and lowest elevation of each breach.
2. A long-term budget plan and evidence of financing, prepared using customary accounting principles, that demonstrate that the applicant has the financial capability to breach or remove the dam in a safe manner. If the applicant does not have evidence that can be verified by an independent audit of the financial capability to breach or remove the dam in a safe manner, the Director may require a performance bond for the entire cost of the proposed construction work.
3. A construction quality assurance plan describing all aspects of construction supervision.

F. Reduction of a high or significant downstream hazard potential dam to nonjurisdictional size may be approved by letter under the following circumstances:
1. The owner shall submit a completed application form and construction drawings for the reduction and the appropriate specifications, prepared by or under the supervision of an engineer as defined in R12-15-1202(11).
2. The construction drawings and specifications shall contain sufficient detail to enable a contractor to bid on and complete the project.
3. The plans shall comply with all requirements of this Section except that the breach is not required to be to natural ground.
4. Upon completion of an alteration to nonjurisdictional size, the engineer shall file as constructed drawings and specifications with the Department.

Historical Note

New Section adopted by final rulemaking at 6 A.A.R. 2558, effective June 12, 2000 (Supp. 00-2).

R12-15-1210. Application to Construct, Reconstruct, Repair, Enlarge, Alter, Breach, or Remove a Low Hazard Potential Dam

A. An application package to construct, reconstruct, repair, enlarge, or alter a low hazard potential dam shall include the following prepared by or under the supervision of an engineer as defined in R12-15-1202(11).
1. A completed application filed in duplicate on forms provided by the Director.
2. An initial application fee based on the total estimated project cost, computed in accordance with A.R.S. § 45-1204 and R12-15-151(B)(11).
3. A detailed estimate of project costs. Project costs are all costs associated with construction of the dam and appurtenant works, including preliminary investigations and surveys, engineering design, supervision of construction, and any other engineering costs.
4. The seal and signature of the responsible engineer in accordance with A.A.C. R4-30-304.
5. A statement by the responsible engineer that classifies the dam as low hazard in accordance with R12-15-1206(B). The responsible engineer shall submit a map of the area that would be inundated by failure or improper operation of the dam. The responsible engineer shall demonstrate that failure or improper operation of the dam would be unlikely to result in:
   a. Loss of human life. The demonstration may be based on an emergency action plan for persons who may be in the area of inundation;
   b. Significant incremental adverse consequences; or
   c. Significant intangible losses, as defined in R12-15-1202(21) and identified and evaluated by a public natural resource management or protection agency.
6. Two complete sets of construction drawings as prescribed by R12-15-1215(1).
7. Two complete sets of construction specifications as prescribed by R12-15-1215(2).
8. An engineering design report that includes information needed to evaluate all aspects of the design of the dam and appurtenances, including references with page numbers to support any assumptions used in the design, as prescribed in R12-15-1215(3).
9. A description of the use for the impounded or diverted water, proof of a right to appropriate, and a permit to store water as prescribed in A.R.S. §§ 45-152 and 45-161.
10. A construction quality assurance plan clearly describing all aspects of construction supervision.
11. A long-term budget plan and evidence of financing, prepared using customary accounting principles, that demonstrate that the applicant has the financial capability to construct, operate, and maintain the dam in a safe manner. If the applicant does not have evidence that can be verified by an independent audit of the financial capability to construct, operate, and maintain the dam in a safe manner, the Director may require a performance bond for the entire cost of the proposed construction work.

B. An application package for the breach or removal of a low hazard potential dam shall include the following.
1. A completed application filed in duplicate on forms provided by the Director that contains the following information:
   a. The name and address of the owner of the dam or the agent of the owner.
   b. A description of the proposed removal.
   c. The proposed time for beginning and completing the removal.
2. An initial application fee based on the total estimated project cost and computed in accordance with A.R.S. § 45-1204 and R12-15-151(B)(11).
3. A statement by the responsible engineer demonstrating both of the following:
   a. That the dam will be excavated to the level of natural ground at the maximum section; and
   b. That the breach or breaches will be of sufficient width to pass the greater of:
      i. The 100 year flood at a depth of less than 5 feet, or
      ii. The 100 year flood at a normal flood depth of not more than 2 feet at a distance of 2,000 feet downstream of the dam.
      iii. Subsection (b) shall not be construed to require more than a total removal of the dam regardless of flood magnitude.
   c. That the sides of the breach will be excavated to a slope ratio that is stable and not steeper than 1 horizontal to 1 vertical.
4. A detailed estimate of project costs. Project costs are all costs associated with the removal of the dam and appurtenant works, including preliminary investigations and surveys, engineering design, supervision of removal, and any other engineering costs.

C. An applicant intending to reduce a low hazard potential dam to nonjurisdictional size shall submit a written notice to the Director at least no less than 60 days before the date that construction begins.

D. Within 45 days after receipt of a complete application package as prescribed by subsection (A) or (B), the Director shall either:
1. Determine that the dam falls within the low hazard potential classification; or
2. Issue a written notice that the dam does not fall within the low hazard potential classification.

E. The Director's determination that the proposed dam does not fall within the low hazard classification is an appealable agency action and subject to administrative and judicial review under A.R.S. Title 41, Chapter 6, Article 10.

F. Upon completion of construction, the owner shall notify the Department in writing. The owner shall not use the dam or reservoir before issuance of a license unless the Director issues written approval.

G. Within 90 days after completing construction, reconstruction, repair, enlargement, or alteration of a low hazard potential dam, the owner shall file the following.
1. An affidavit showing the actual cost of construction, reconstruction, repair, enlargement, or alteration of the dam. The owner shall submit a detailed accounting of the costs, including all engineering costs.
2. An additional fee or refund request computed in accordance with A.R.S. § 45-1209 and R12-15-151(B)(11), based on the actual cost of construction, reconstruction, repair, enlargement, or alteration.
3. A brief completion report summarizing the salient features of the project, including a description of the causes for any changes or deviations from the approved application package prepared by the engineer who supervised the construction, in accordance with A.R.S. Title 32, Chapter 1. The engineer shall indicate:
   a. That the dam has been designed and constructed in compliance with basic principles of dam construction currently being practiced in the industry;
   b. That the dam as constructed has structural integrity and flood routing capacity consistent with its hazard potential classification; and
   c. That the as constructed drawings and the report accurately represent the construction of the dam.
4. As constructed drawings prepared and sealed by the engineer who supervised the construction. The owner and the engineer shall maintain a record of the drawings.

H. Upon receiving the Director's written approval, the owner may operate the dam and appurtenant works. Within 30 days after receipt of the information in subsection (G), the Director shall issue to the owner either a license or a notice that the dam and appurtenant works shall not be operated because the dam and appurtenant works do not qualify as low hazard or were not built according to the submitted design. The license shall include conditions of operation, including:
1. The safe storage level of the reservoir;
2. A requirement that the dam be operated and maintained so that it does not constitute a danger to human life and property;
3. A requirement that the conditions resulting in the low hazard classification be maintained throughout the life of the dam; and
4. A requirement that the owner demonstrate in writing the low hazard classification in the manner prescribed by subsection (A)(5) every 5 years.

I. Within 90 days after completing removal of a low hazard potential dam, the owner shall file the following. The Director shall remove the dam from jurisdiction upon approval of the submittal.
1. An affidavit showing the actual cost of removal of the dam. The owner shall submit a detailed accounting of the costs, including all engineering costs.
2. An additional fee or refund request computed in accordance with A.R.S. § 45-1209 and R12-15-151(B)(11) based on the actual cost of removal.
3. A brief completion report, including a description of the causes for any changes or deviations from the approved application package prepared by the engineer who supervised the construction, in accordance with A.R.S. Title 32, Chapter 1. The engineer shall certify that the as removed drawings and the report accurately represent the actual removal of the dam.
4. As-removed drawings prepared and sealed by the engineer who supervised the removal. The owner and the engineer shall maintain a record of the drawings.

J. An owner shall immediately commence repairs necessary to safeguard human life and property and prevent failure and improper operation of a low hazard potential dam. The owner shall notify the Department as soon as reasonably possible and in all cases within 10 days of commencing the required repairs.

Historical Note

New Section adopted by final rulemaking at 6 A.A.R. 2558, effective June 12, 2000 (Supp. 00-2). Amended by final rulemaking at 13 A.A.R. 3022, effective October 6, 2007 (Supp. 07-3).

R12-15-1211. Application to Construct, Reconstruct, Repair, Enlarge, Alter, Breach, or Remove a Very Low Hazard Potential Dam

A. An application package to construct, reconstruct, repair, enlarge, or alter a very low hazard potential dam shall include the following prepared by an engineer or a person under the supervision

of an engineer as defined in R12-15-1202(11).

1. A completed application filed in duplicate on forms provided by the Director that contains the following information:
   a. The name and address of the owner of the dam or the agent of the owner.
   b. The location, type, size, and height of the proposed dam and appurtenant works.
   c. The storage capacity of the reservoir associated with the proposed dam.
   d. The proposed time for beginning and completing construction.
   e. A description of the use for the impounded or diverted water and proof of a right to impound that water.
2. The means, plans, and specifications by which the stream or body of water is to be dammed, by-passed, or controlled during construction.
3. Maps, drawings, and specifications of the proposed dam.
4. An initial application fee based on the total estimated project cost and computed in accordance with A.R.S. § 45-1204 and R12-15-151(B)(11).
5. A detailed estimate of project costs. Project costs are all costs associated with construction of the dam and appurtenant works, including preliminary investigations and surveys, engineering design, supervision of construction, and any other engineering costs.
6. A statement by the responsible engineer that classifies the dam as very low hazard in accordance with R12-15-1206(B). The responsible engineer shall submit a map of the area that would be inundated by failure or improper operation of the dam. The responsible engineer shall demonstrate that failure or improper operation would be unlikely to result in:
   a. Loss of human life. The demonstration may be based on an emergency action plan for persons who may be in the area of inundation;
   b. Significant incremental adverse consequences; or
   c. Significant intangible losses, as defined in R12-15-1202(21) and identified and evaluated by a public natural resource management protection agency, because the dam has a size classification of either small or intermediate under R12-15-1206(A) and any release would be limited to the 100 year floodplain or property owned or controlled by the dam owner under long-term lease.
7. The seal and signature of the responsible engineer in accordance with A.R.S. Title 32, Chapter 1.
8. The drawings required by subsection (A)(3) shall include a plan view and maximum section of the dam; the outlet works; and the spillway plan, profile, and cross section.
9. The specifications required by subsection (A)(3) shall include the construction materials, testing criteria, and installation techniques.

B. The Director may make other requirements for drawings and specifications for the proposed repair or alteration of a very low hazard potential dam. In determining other requirements, the Director shall consider the size and extent of the repair or alteration, the portions of the dam that will be repaired or altered, and whether the requirements elicit a description of the proposed construction work that is adequate to allow the Director to evaluate the repair or alteration.

C. An owner intending to breach, remove, or reduce a very low hazard potential dam to nonjurisdictional size shall submit written notice to the Director at least 60 days before the date that construction begins.

D. After receipt of a complete application package as prescribed by subsection (A), the Director shall either:

1. Determine that the dam falls within the very low hazard classification and approve the application in writing; or
2. Issue a written notice that the dam does not fall within the very low hazard classification.

E. The Director's determination that the proposed dam does not fall within the very low hazard classification is an appealable agency action and subject to administrative and judicial review under A.R.S. Title 41, Chapter 6, Article 10.

F. Upon completion of construction, the owner shall notify the Department in writing. The owner shall not use the dam and reservoir before receipt of a license unless the Director issues written approval.

G. Within 90 days after completion of the construction, reconstruction, repair, enlargement, or alteration of a very low hazard potential dam, the owner shall file the following:

1. An affidavit showing the actual cost of construction, reconstruction, repair, enlargement, or alteration of the dam. The owner shall submit a detailed accounting of the costs, including all engineering costs.
2. An additional fee or refund request computed in accordance with A.R.S. § 45-1209 and R12-15-151(B)(11) based on the actual cost of construction, reconstruction, repair, enlargement, or alteration.
3. A brief completion report summarizing the salient features of the project, including a description of the causes for any changes or deviations from the approved application package prepared by the engineer who supervised the construction in accordance with A.R.S. Title 32, Chapter 1. The report shall include:
   a. That the dam has been designed and constructed in compliance with basic principles of dam construction currently being practiced in the industry;
   b. That the dam as constructed has structural integrity and flood routing capacity consistent with its hazard potential classification; and
   c. That the as constructed drawings and the report accurately represent the construction of the dam.
4. As constructed drawings prepared by the engineer who supervised the construction. The owner and the engineer shall maintain a record of the drawings.

H. Within 30 days after receipt of the information in subsection (G), the Director shall issue to the owner either a license or a notice that the dam and appurtenant works shall not be operated because the dam and appurtenant works do not qualify as very low hazard or were not built according to the submitted design. Upon receiving the Director's written approval, the owner may operate the dam and appurtenant works. The license shall include conditions of operation, including:

1. The safe storage level of the reservoir;
2. A requirement that the conditions resulting in the very low hazard classification be maintained throughout the life of the dam; and
3. A requirement that the owner demonstrate in writing the very low hazard classification in the manner prescribed by subsection (A)(6) every 5 years.

I. An owner shall immediately commence repairs necessary to safeguard human life and property and prevent failure or improper operation of a very low hazard potential dam. The owner shall notify the Department as soon as reasonably possible and in all cases within 10 days of commencing the required repairs.

J. The Department may periodically inspect construction to confirm that it is proceeding according to the approved design and that proper construction quality assurance is being exercised by the owner's engineer. The owner, or the owner's engineer under the direction of the owner, shall remedy any unsatisfactory condition using the contractor.

K. The owner shall provide the Department access to the dam site for purposes of inspecting all phases of construction, including the foundation, embankment and concrete placement, inspection and test records, and mechanical installations.

Historical Note

New Section adopted by final rulemaking at 6 A.A.R. 2558, effective June 12, 2000 (Supp. 00-2).

R12-15-1212. Construction of a High, Significant, or Low Hazard Potential Dam

A. Before commencement of construction activities, the owner shall invite to a pre-construction conference all involved regulatory agencies, the prime contractor, and all subcontractors. At this meeting the Department shall identify, to the extent possible, the key construction stages at which an inspection will be made. At least 48 hours before each key construction stage identified for inspection, the owner or the owner's engineer shall provide notice to the Department.

B. The owner and the owner's engineer shall oversee construction of a new dam or reconstruction, repair, enlargement, alteration, breach, or removal of an existing dam. Failure to perform the work in accordance with the construction drawings and specifications approved by the Director renders the approval revocable. The owner's engineer shall exercise professional judgment independent of the contractor.

C. A professional engineer with proficiency in engineering and knowledge of dam technology shall supervise or direct the supervision of construction in accordance with the construction quality assurance plan.

D. The owner's engineer shall submit summary reports of construction activities and test results according to a schedule approved by the Department.

E. The owner shall immediately report to the Department any condition encountered during construction that requires a deviation from the approved plans and specifications.

F. The owner shall promptly submit a written request for approval of any necessary change and sufficient information to justify the proposed change. The owner shall not commence construction without the written approval of the Director unless the change is a minor change. A minor change is a change that complies with the requirements of this Article and provides equal or better safety performance.

G. Upon completion of construction, the owner shall notify the Department in writing. The Department shall make a final inspection. The owner shall correct any deficiencies noted during the inspection.

Historical Note

New Section adopted by final rulemaking at 6 A.A.R. 2558, effective June 12, 2000 (Supp. 00-2).

R12-15-1213. Completion Documents for a Significant or High Hazard Potential Dam

Within 90 days after completion of the construction or removal work for a significant or high hazard potential dam and final inspection by the Department, the owner shall file the following.

1. An affidavit showing the actual cost of the construction. The owner shall submit a detailed accounting of the costs, including all engineering costs.
2. An additional fee or refund request based on the actual cost of the construction, computed in accordance with A.R.S. § 45-1209 and R12-15-151(B)(11).
3. One set of full sized as constructed drawings prepared and sealed by the engineer who supervised the construction. If changes were made during construction, the owner shall file supplemental drawings showing the dam and appurtenances as actually constructed.
4. Construction records, including grouting, materials testing, and locations and baseline readings for permanent bench marks and instrumentation, initial surveys, and readings.
5. Photographs of construction from exposure of the foundation to completion of construction.
6. A brief completion report summarizing the salient features of the project, including a description of the causes for any changes or deviations from the approved drawings and specifications that were made during the construction phase.
7. A schedule for filling the reservoir, specifying fill rates, water level elevations to be held for observation, and a schedule for inspecting and monitoring the dam. The owner shall monitor the dam monthly during the first filling.
8. An operating manual for the dam and its appurtenant structures. The operating manual shall include a process for safety inspections prescribed in R12-15-1219. The operating manual shall include schedules for surveillance activities and baseline information for any installed instrumentation as follows:
   a. The frequency of monitoring;
   b. The data recording format;
   c. A graphical presentation of data; and
   d. The person who will perform the work.

Historical Note

New Section adopted by final rulemaking at 6 A.A.R. 2558, effective June 12, 2000 (Supp. 00-2).

R12-15-1214. Licensing

A. Upon review and approval of the documents filed under R12-15-1213 and finding that the construction at the dam has been completed in accordance with the approved plans and specifications and finding that the dam is safe, the Director shall issue a license. The license shall specify the safe storage level for the reservoir and shall specify conditions for the safe operation of the dam. The dam and reservoir shall not be used before issuance of a license unless the Director issues written approval. Procedures for issuance of a license for low and very low hazard potential dams are prescribed in R12-15-1210(H) and R12-15-1211(H), respectively.

B. A new license shall be issued in the following instances:

1. Upon change of ownership of a dam.
2. Upon change of the safe storage level.
3. Upon expiration of time to appeal a notice issued under R12-15-1223(B).
4. Upon expiration of time to appeal an order issued by the Director under R12-15-1223(D).
5. Upon expiration of time to appeal an order of a court.

Historical Note

New Section adopted by final rulemaking at 6 A.A.R. 2558, effective June 12, 2000 (Supp. 00-2).

R12-15-1215. Construction Drawings, Construction Specifications, and Engineering Design Report for a High, Significant, or Low Hazard Potential Dam

The owner and engineer are responsible for complete and adequate design of a dam and for including in the application all aspects of the design pertaining to the safety of the dam.

1. Construction Drawing Requirements. The construction drawings required by R12-15-1208(5), R12-15-1209(E)(1), and R12-15-1210(A)(6) shall include the following:
   a. The seal and signature of the responsible engineer in accordance with A.A.C. R4-30-304.
   b. One or more topographic maps of the dam, spillway, outlet works, and reservoir on a scale large enough to accurately locate the dam and appurtenances, indicate cut and fill lines, and show the property lines and ownership status of the land. Contour intervals shall be compatible with the height and size of the dam and its appurtenances and shall show design and construction details.
   c. A reservoir area and capacity curve that reflect area in acres and capacity in acre-feet in relation to depth of water and elevation in the reservoir. The construction drawings shall show the spillway invert and top of dam elevations. The construction drawings shall also show the reservoir volume and space functional allocations. The construction drawings may include alternate scales as required for the owner's use.
   d. Spillway and outlet works rating curves and tables at a scale or scales that allow determination of discharge rate in cubic feet per second at both low and high flows as measured by depth of water passing over the spillway control section.
   e. A location map showing the dam footprint and all exploration drill holes, test pits, trenches, adits, borrow areas, and bench marks with elevations, reference points, and permanent ties. This map shall use the same vertical and horizontal control as the topographic map.
   f. Geologic information including 1 or more geologic maps, profile along the centerline, and other pertinent cross sections of the dam site, spillway or spillways, and appurtenant structures, aggregate and material sources, and reservoir area at 1 or more scales compatible with the site and geologic complexity, showing logs of exploration drill holes, test pits, trenches, and adits.
   g. One or more plans of the dam to delineate design and construction details.
   h. Foundation profile along the dam centerline at a true scale where the vertical scale is equal to the horizontal scale, showing the existing ground and proposed finished grade at cut and fill elevations, including anticipated geologic formations. The foundation profile shall include any proposed grout and drain holes.
   i. Profile and a sufficient number of cross sections of the dam to delineate design and construction details. The drawings shall illustrate and show dimensions of camber, details of the top, core zone, interior filters and drains, and other zone details. The profile of the dam may be drawn to different horizontal and vertical scales if required for detail. A maximum section of the dam shall be drawn to a true scale, where the vertical scale is equal to the horizontal scale. The outlet conduit may be shown on the maximum section if this is typical of the proposed construction.
   j. One or more dam foundation plans showing excavation grades and cut slopes with any proposed foundation preparation, grout and drain holes, and foundation dewatering requirements.
   k. Plan, profile, and details of the outlet works, including the intake structure, the gate system, conduit, trashrack, conduit filter diaphragm, conduit concrete encasement, and the downstream outlet structure. The drawings shall include all connection and structural design details.
   l. Plan, profile, control section, and cross sections of the spillway, including details of any foundation preparation, grouting, or concrete work that is planned. A complex control structure, a concrete chute, or an energy dissipating device for a terminal structure shall include both hydraulic and structural design details.
   m. Hydrologic data, drainage area and flood routing, and diversion criteria.
2. Construction Specification Requirements. The construction specifications required by R12-15-1208(6) and R12-15-1210(A)(7) shall include the following:
   a. The seal and signature of the responsible engineer in accordance with A.A.C. R4-30-304.
   b. The statement that the construction drawings and specifications shall not be materially changed without the prior written approval of the Director.
   c. A detailed description of the work to be performed and a statement of the requirements for the various types of materials and installation techniques that will enter into the permanent construction.
   d. The statement that construction shall not be considered complete until the Director has approved the construction in writing.
   e. The statement that the owner's engineer shall control the quality of construction.
   f. The following construction information:
      i. All earth and rock material descriptions, placement criteria, and construction requirements for all elements of the dam and related structures.
      ii. All concrete, grout, and shotcrete material and mix descriptions, placement and consolidation criteria, temperature controls, and construction requirements for all elements of the dam and related structures.
      iii. Material criteria and material testing, cleaning, and treatment. If foundation or curtain grouting is required, the specifications shall describe the type of grout, grouting method, special equipment necessary, recording during grouting, and foundation monitoring to avoid disturbance from grouting.
      iv. All materials testing that will be performed by the contractor for pre-qualification of materials, including special performance testing, such as water pressure tests in conduits. The Director shall accept materials that are pre-tested successfully and constructed in-place in accordance with specifications.
      v. A plan for control or diversion of surface water during construction. The design engineer may determine frequency of storm runoff to be controlled during construction, commensurate with the risk of economic loss during construction.
      vi. Criteria for blast monitoring and acceptable blast vibration levels, including particle velocities for the dam and other critical appurtenances. Monitoring equipment and monitoring locations shall be specified.
      vii. Instrumentation material descriptions, placement criteria, and construction requirements and a statement that instrumentation shall be installed by experienced speciality subcontractors.
3. Engineering Design Report Requirements. The engineering design report required by R12-15-1208(7) and R12-15-1210(A)(8) shall include the following:
   a. The seal and signature of the responsible engineer in accordance with A.A.C. R4-30-304.
   b. The classification under R12-15-1206 of the proposed dam, or for the proposed enlargement of an existing dam or reservoir.
   c. Hydrologic considerations, including calculations and a summary table of data used in determining the required emergency spillway capacity and freeboard, and design of any diversion or detention structures. The design report shall include input and output listings on both hard copy and computer diskette.
   d. Hydraulic characteristics, engineering data, and calculations used in determining the capacities of the outlet works and emergency spillway. The design report shall include input and output listings on both hard copy and computer diskette.
   e. Geotechnical investigation and testing of the dam site and reservoir basin. Results and analysis of subsurface investigations, including logs of test borings and geologic cross sections.
   f. Guidelines and criteria for blasting to be used by the contractor in preparing the blasting plan.
   g. Details of the plan for control or diversion of surface water during construction.
   h. Details of the dewatering plan for subsurface water during construction.
   i. Testing results of earth and rock materials, including the location of test pits and the logs of these pits.
   j. Discussion and design of the foundation blanket grouting, grout curtain, and grout cap based on foundation stability and seepage considerations.
   k. Calculations and basic assumptions on loads and limiting stresses for reinforced concrete design. The design report shall include input and output listings on both hard copy and computer diskette.
   l. A discussion and stability analysis of the dam including appropriate seismic loading, safety factors, and embankment zone strength characteristics. Analyses shall include both short-term and long-term loading on upstream and downstream slopes. The design report shall include input and output listings on both hard copy and computer diskette.
   m. A discussion of seismicity of the project area and activity of faults in the vicinity. The design report shall use both deterministic and statistical methods and identify the appropriate seismic coefficient for use in analyses.
   n. Discussion and design of the cutoff trench based on seepage and other considerations.
   o. Permeability characteristics of foundation and dam embankment materials, including calculations for seepage quantities through the dam, the foundation, and anticipated in the internal drain system. The design report shall include input and output listings on both hard copy and computer diskette. The design report shall include copies of any flow nets used.
   p. Discussion and design of internal drainage based on seepage quantity calculations. The design report shall include instrumentation necessary to monitor the drainage system and filter design calculations for protection against piping of foundation and embankment.
   q. Erosion protection against waves and rainfall runoff for both the upstream and downstream slopes, as appropriate.
   r. Discussion and design of foundation treatment to compensate for geological weakness in the dam foundation and abutment areas and in the spillway foundation area.
   s. Post-construction vertical and horizontal movement systems.
   t. Discussion of foundation conditions including the potential for subsidence, fissures, dispersive soils, collapsible soils, and sink holes.

Historical Note

New Section adopted by final rulemaking at 6 A.A.R. 2558, effective June 12, 2000 (Supp. 00-2).

R12-15-1216. Design of a High, Significant, or Low Hazard Potential Dam

A. General Requirements.

1. Emergency Spillway Requirements. An applicant shall:
   a. Construct each spillway in a manner that avoids flooding in excess of the flooding that would have occurred in the same location under the same conditions before construction. The owner of a dam shall demonstrate that a spillway discharge would not result in incremental adverse consequences. In determining whether a spillway discharge of a dam would result in incremental adverse consequences, the Director shall evaluate whether the owner has taken any or all of the following actions: issuing public notice to downstream property owners, complying with flood insurance requirements, adopting emergency action plans, conducting mock flood drills, acquiring flow easements or other acquisitions of real property, or other actions appropriate to safeguard the dam site and flood channel.
   b. Include a control structure to avoid head cutting and lowering of the spillway crest for spillways excavated in soils or soft rock. In the alternative, the design may provide evidence acceptable to the Director that erosion during the inflow design flood will not result in a sudden release of the reservoir.
   c. Provide each spillway and channel with a minimum width of 10 feet and suitable armor to prevent erosion during the discharge resulting from the inflow design flood.
   d. Ensure that downstream spillway channel flows do not encroach on the dam unless suitable erosion protection is constructed.
   e. Ensure that each spillway, in combination with outlets, is able to safely pass the peak discharge flow rate, as calculated on the basis of the inflow design flood.
   f. Not construct bridges or fences across a spillway unless the construction is approved in writing by the Director. The Director's approval may include conditions regarding the design and operation of the spillway and fencing, based on safety concerns.
   g. Not use a pipe or culvert as an emergency spillway unless the Director approves the use following review of the dam design and site characteristics.
2. Inflow Design Flood Requirements
   a. Unless directed otherwise in writing by the Director, the inflow design flood requirements for determining the spillway minimum capacity are stated in Table 4.
   b. As an alternative to the requirements prescribed in Table 4, the Director may accept an inflow design flood determined by an incremental damage assessment study, based on the relative safety of the alternatives.
   c. The Director may accept site-specific probable maximum precipitation studies in determination of the inflow design flood.
   d. An applicant shall ensure that the total freeboard is the largest of the following:
      i. The sum of the inflow design flood maximum water depth above the spillway crest plus wave run up.
      ii. The sum of the inflow design flood maximum water depth above the spillway crest plus 3 feet.
      iii. A minimum of 5 feet.
3. Outlet Works Requirements. An applicant shall ensure that a dam has a low level outlet works that:
   a. Is capable of draining the reservoir to the sediment pool level. A low level outlet works for a high or significant hazard potential dam shall be a minimum of 36 inches in diameter. A low level outlet works for a low hazard potential dam shall be a minimum of 18 inches in diameter.
   b. For a high or significant hazard potential dam, has the capacity to evacuate 90% of the storage capacity of the reservoir within 30 days, excluding reservoir inflows.
   c. Has a filter diaphragm or other current practice measures to reduce the potential for piping along the conduit.
   d. Has accessible outlet controls when the spillway is in use.
   e. Has an emergency manual override system or can be operated manually.
   f. Is constructed of materials appropriate for loading condition, seismic forces, thermal expansion, cavitation, corrosion, and potential abrasion. The applicant shall not use corrugated metal pipes or other thin-walled pipes except as a form for a cast-in-place concrete conduit. The applicant shall construct outlet conduits of cast-in-place reinforced concrete. The applicant shall design each outlet to maintain water tightness. The applicant shall construct each outlet to prevent the occurrence of piping adjacent to the outlet.
   g. Has an operating or guard gate on the upstream end of any gated outlet.
   h. Has an outlet conduit near the base of 1 of the abutments on native bedrock or other competent material. The applicant shall support the entire length of the conduit on foundation materials of uniform density and consistency to prevent adverse differential settlement.
   i. Has an upstream valve or gate capable of controlling the discharge through all ranges of flow on any gated outlet conduit.
   j. Has a trashrack designed for a minimum of 25% of the reservoir head to which it would be subjected if completely clogged at the upstream end of the outlet.
   k. Has an air vent pipe just downstream of the control gate. The applicant shall include a blow-off valve at or near the downstream toe of the dam for an outlet conduit that is connected directly to a distribution system.
   l. Has an outlet conduit designed for internal pressure equal to the full reservoir head and for superimposed embankment loads, acting separately.
4. Dam Site And Reservoir Area Requirements
   a. An applicant shall demonstrate that reservoir storage during the inflow design flood will not result in incremental adverse consequences and that the design will not result in the inundation or wave damage of properties within the reservoir, except marina-type structures, during the inflow design flood. In determining whether a discharge will result in incremental adverse consequences, the Director shall evaluate whether the owner has taken any or all of the following actions: issuing public notice to upstream affected property owners, complying with flood insurance requirements, adopting emergency action plans, conducting mock flood drills, acquiring flood easements or other acquisitions of real property, or other actions appropriate to safeguard the dam site and reservoir. Permanent habitations are not allowed within the reservoir below the spillway elevation.
   b. The applicant shall clear the reservoir storage area of logs and debris.
   c. The applicant shall place borrow areas a safe distance from the upstream toe and the downstream toe of the dam to prevent a piping failure of the dam.
   d. The applicant shall keep the top of the dam and appurtenant structures accessible by equipment and vehicles for emergency operations and maintenance.
5. Geotechnical Requirements
   a. The applicant shall provide an evaluation of the static stability of the foundation, dam, and slopes of the reservoir rim and demonstrate that sufficient material is available to construct the dam as designed.
   b. The applicant shall not construct a dam on active faults, collapsible soils, dispersive soils, sink holes, or fissures, unless the applicant demonstrates that the dam can safely withstand the anticipated offset or other unsafe effects on the dam.
6. Seismic Requirements
   a. The applicant shall submit a review of the seismic or earthquake history of the area around the dam within a radius of 100 miles to establish the relationship of the site to known faults and epicenters. The review shall include any known earthquakes and the epicenter locations and magnitudes of the earthquakes.
   b. The applicant shall identify the location of active or potentially active faults that have experienced Holocene or Late Pleistocene displacement within a radius of 100 miles of the site.
   c. For a high or significant hazard potential dam, the applicant shall design the dam to withstand the maximum credible earthquake.
   d. For a low hazard potential dam, the applicant shall use probabilistic or deterministic methods to determine the design earthquake. The magnitude of the design earthquake shall vary with the size of the dam, site condition, and specific location.

B. Embankment Dam Requirements.
1. Geotechnical Requirements. Table 5 states minimum factors of safety for embankment stability under various loading conditions. For an embankment dam an applicant shall provide a written analysis of minimum factors of safety for stability.
   a. The analysis of minimum factors of safety shall include the effects of anisotropy on the phreatic surface position by using a ratio of horizontal permeability to vertical permeability of at least 10. The Director may require ratios of up to 100 if the material types and construction techniques will cause excessive stratification.
   b. The applicant shall use tests modeling the conditions being analyzed to determine the strengths used in the stability analysis. The stability analysis shall include total and effective stress strengths appropriate for the different material zones and conditions analyzed. The stability analysis shall use undrained strengths or strength parameters for all saturated materials.
   c. The applicant shall perform an analysis of the upstream slope stability for a partial pool with steady seepage considering the reservoir level that provides the lowest factor of safety.
   d. A stability analysis is not required for low hazard potential dams if the owner or the owner's engineer demonstrates that conservative slopes and competent materials are included in the design.
2. Seismic Requirements
   a. The applicant shall determine the seismic characteristics of the site as prescribed in subsection (A)(6).
   b. The applicant shall determine the liquefaction susceptibility of the embankment, foundation, and abutments. The applicant shall use standard penetration testing, cone penetration testing, shear wave velocity measurements, or a combination of these methods to make this determination. The applicant shall compute the minimum factor of safety against liquefaction at specific points and make a determination of whether the overall site is subject to liquefaction.
   c. The applicant shall determine the safety of the dam under seismic loading using a pseudo static stability analysis, computing the minimum factor of safety if the embankment, foundation or abutment is not subject to liquefaction and has a maximum peak acceleration of 0.2g or less, or a maximum peak acceleration of 0.35g or less, and consists of clay on a clay or bedrock foundation. The applicant shall use in the pseudo static stability analysis a pseudo static coefficient that is at least 60% of the maximum peak bedrock acceleration at the site.
   d. The applicant shall compute a minimum factor of safety against overtopping due to deformation and settlement in each of the following cases. The minimum factor of safety against overtopping can be no less than 2.5, determined by dividing the total pre-earthquake freeboard by the estimated vertical settlement in feet. The applicant shall determine the total vertical settlement by adding the settlement values of the upstream and downstream slopes.
      i. The minimum factor of safety in a pseudo static analysis is less than 1.0;
      ii. An embankment, foundation, or abutment is not subject to liquefaction, has a maximum peak acceleration of more than 0.2g or a maximum peak acceleration of more than 0.35g and consists of clay on a clay or bedrock foundation; or
      iii. The embankment, foundation or abutment is subject to liquefaction.
   e. The applicant shall perform a liquefaction analysis to establish approximate boundaries of liquefiable zones and physical characteristics of the soil following liquefaction for an embankment, foundation, or abutment subject to liquefaction. The applicant shall perform an analysis of the potential for flow liquefaction.
   f. Other, more sophisticated analytical procedures may be required by the Director for sites with high seismicity or low strength embankment or foundation soils.
3. Miscellaneous Design Requirements
   a. The design of any significant or high hazard potential dam shall provide seepage collection and prevent internal erosion or piping due to embankment cracking or other causes.
   b. The Director shall review the filter and permeability design for a chimney drain, drain blanket, toe drain, or outlet conduit filter diaphragms on the basis of unique site characteristics.
      i. The minimum thickness of an internal drain is 3 feet.
      ii. The minimum width of a chimney drain is 6 feet.
      iii. The applicant shall filter match an internal drain to its adjacent material.
      iv. The applicant shall design internal drains with sufficient capacity for the expected drainage without the use of drainpipes using only natural granular materials.
   c. The use of a geosynthetic is not permitted in a design if it serves as the sole defense against dam failure. The use of geotextiles and geonets as a filter or drain material or a

geomembrane liner is permitted only in a location that is easily accessible for repair or if its excavation cannot create an unsafe condition at the dam. A geosynthetic liner is allowed under special conditions and in specific situations if it is subject to monitoring and redundant safety controls. The Director may impose conditions, including monitoring appropriate to the hazard classification, inspection, and necessary repairs, each performed every 5 years.

d. The applicant shall use armoring on any upstream slope of an embankment dam that impounds water for more than 30 days at a time. If the applicant uses rock riprap, it shall be well-graded, durable, sized to withstand wave action, and placed on a well-graded pervious sand and gravel bedding or geotextile with filtering capacity appropriate for the site.

e. The applicant shall protect the downstream slopes and groins of an embankment dam from erosion.

f. The minimum width of the top of an embankment dam is equal to the structural height of the dam divided by 5 plus an additional 5 feet. The required minimum width for any embankment dam is 12 feet. The maximum width for any embankment dam is 25 feet.

Historical Note

New Section adopted by final rulemaking at 6 A.A.R. 2558, effective June 12, 2000 (Supp. 00-2).

Table 4. Inflow Design Flood

Dam Hazard Class	Dam Size Classification	IDF Magnitude
Very Low	All Sizes	100-year
Low	All Sizes	0.25 PMF
Significant	Small	0.25 PMF
	Intermediate	0.5 PMF
	Large	0.5 PMF
High*	All Sizes	*

* For a high hazard potential dam, the applicant shall design the dam to withstand an inflow design flood that varies from .5 PMF to the full PMF, with size increasing based on persons at risk and potential for downstream damage. The applicant shall consider foreseeable future conditions.

Historical Note

New Table adopted by final rulemaking at 6 A.A.R. 2558, effective June 12, 2000 (Supp. 00-2).

Table 5. Minimum Factors of Safety for Stability1

Embankment Loading Condition	Minimum Factor of Safety
End of construction case - upstream and downstream slopes	1.3
End of construction case for embankments greater than 50 feet in height on weak foundations	1.4
Steady state seepage - upstream (critical partial pool) and downstream slope (full pool)	1.5
Instantaneous drawdown - upstream slope	1.2

1 Not applicable to an embankment on a clay shale foundation.

Historical Note

New Table adopted by final rulemaking at 6 A.A.R. 2558, effective June 12, 2000 (Supp. 00-2).

R12-15-1217. Maintenance and Repair; Emergency Actions

A. An owner shall perform general maintenance and ordinary repairs that do not impair the safety of the dam. General maintenance and ordinary repair activities listed under this subsection do not require prior approval of the Director. These repair activities include:
1. Removing brush or tall weeds.
2. Cutting trees and removing slash from the embankment or spillway. Small stumps may be removed provided no excavation into the embankment occurs.
3. Exterminating rodents by trapping or other methods. Rodent damage may be repaired provided it does not involve excavation that extends more than 2 feet into the embankment and replacement materials are compacted as they are placed.
4. Repairing erosion gullies less than 2 feet deep on the embankment or in the spillway.
5. Grading the surface on the top of the dam embankment or spillway to eliminate potholes and provide proper drainage, provided the freeboard is not reduced.
6. Placing additional riprap and bedding on the upstream slope, or in the spillway in areas that have sustained minor damage and restoring the original riprap protection where the damage has not yet resulted in erosion and weakening of the dam.
7. Painting, caulking, or lubricating metal structures.
8. Patching or caulking spalled or cracked concrete to prevent deterioration.
9. Removing debris, rock, or earth from outlet conduits or spillway channels and basins.
10. Patching to prevent deterioration within outlet works.
11. Replacing worn or damaged parts on outlet valves or controls to restore them to original condition or its equivalent.
12. Repairing or replacing fences intended to keep traffic or livestock off the dam or spillway.

B. General maintenance and ordinary repair that may impair or adversely effect safety, such as excavation into or near the toe of the dam, construction of new appurtenant structures for the dam, and repair of damage that has already significantly weakened the dam shall be performed in accordance with this Article. The Director may approve maintenance performed according to a standard detail or method of repair on file with the Department upon submittal of a letter. The Director shall determine whether general maintenance and ordinary repair activities not listed in subsection (A) will impair safety.

C. Emergency actions not impairing the safety of the dam may be taken before guidance can be provided by an engineer and do not require prior approval of the Director. Emergency actions do not excuse an owner's responsibility to promptly undertake a permanent solution. Emergency actions include:
1. Stockpiling materials such as riprap, earth fill, sand, sandbags, and plastic sheeting.
2. Lowering the reservoir level by making releases through the outlet or a gated spillway, by pumping, or by siphoning.
3. Armoring eroded areas by placing sandbags, riprap, plastic sheeting, or other available material.
4. Plugging leakage entrances on the upstream slope.
5. Increasing freeboard by placing sandbags or temporary earth fill on the dam.
6. Diverting flood waters to prevent them from entering the reservoir basin.
7. Constructing training berms to control flood waters.
8. Placing sandbag ring dikes or reverse filter materials around boils at the downstream toe to provide back pressure.
9. Removing obstructions from outlet or spillway flow areas.

D. Emergency actions impairing the safety of the dam require prior approval of the Director. An owner shall not lower the water level by excavating the spillway or embankment unless failure is imminent.

E. For all high and significant hazard potential dams, the emergency action plan shall be implemented with any emergency actions taken at the dam.

F. The owner shall notify the Director immediately of any emergency condition that exists and any emergency action taken.

Historical Note

New Section adopted by final rulemaking at 6 A.A.R. 2558, effective June 12, 2000 (Supp. 00-2).

R12-15-1218. Safe Storage Level

The Director has the authority to determine the safe storage level for the reservoir behind each dam, including the storage level of an existing dam while it is being repaired, enlarged, altered, breached, or removed. The elevation of the safe storage level is stated on the license. The owner shall not store water in excess of the level determined by the Director to be safe. The owner shall not place flashboards or other devices in the emergency spillway without approval of an alteration of the dam in accordance with this Article.

Historical Note

New Section adopted by final rulemaking at 6 A.A.R. 2558, effective June 12, 2000 (Supp. 00-2).

R12-15-1219. Safety Inspections

A. Except as provided in subsection (E), the Director shall conduct a dam safety inspection annually or more frequently for each high hazard potential dam, triennially for each significant hazard potential dam, and once every 5 years for each low and very low hazard potential dam.

B. An engineer is considered qualified to provide information to the Director regarding the safe storage level of a reservoir if the engineer:
1. Meets the criteria in R12-15-1202(11);
2. Has 3 years of experience in the field of dam safety; and
3. Has actual experience in conducting dam safety inspections.

C. A dam safety inspection includes:
1. Review of previous inspections, reports, and drawings;
2. Inspection of the dam, spillways, outlet facilities, seepage control, and measurement systems;
3. Inspection of any permanent monument or monitoring installations;
4. Assessment of all parts of the dam that are related to the dam's safety; and
5. A recommendation regarding the safe storage level of the reservoir.

D. The engineer shall submit a safety inspection report that describes the findings and lists actions that will improve the safety of the dam. The report shall include the engineer's recommendation of the safe storage level. The engineer shall use a report form approved by the Director.
E. Inspections by the Owner
1. An owner may provide to the Director, at the owner's expense, a safety inspection report that complies with the requirements of subsections (B), (C), and (D) in place of an inspection by the Department. The owner's engineer shall notify the Director and submit a written summary of the engineer's qualifications at least 14 days before the scheduled safety inspection.
2. The Director may refuse to accept an inspection that does not conform to this Article.
F. Inspections by the Department
1. The Director may enter at reasonable times upon private or public property and the owner shall permit such entry, where a dam is located, including a dam under construction, reconstruction, repair, enlargement, alteration, breach, or removal, for any of the following purposes:
a. To enforce the conditions of approval of the construction drawings and specifications related to an application for construction, reconstruction, repair, enlargement, alteration, breach, or removal.
b. To inspect a dam that is subject to this Article.
c. To investigate or assemble data to aid review and study of the design and construction of dams, reservoirs, and appurtenances or make watershed investigations to facilitate decisions on public safety to fulfill the duties of A.R.S. § 45-1214.
d. To ascertain compliance with this Article and A.R.S. Title 45, Chapter 6.
2. Upon receipt of a complaint that a dam is endangering people or property:
a. The Director shall inspect the dam unless there is substantial cause to believe the complaint is without merit.
b. If the complainant files a complaint in writing and deposits with the Director sufficient funds to cover the costs of the inspection, the Director shall make an inspection.
c. The Director shall provide a written report of the inspection to the complainant and the dam owner.
d. If an unsafe condition is found, the Director shall cause it to be corrected and return the deposit to the complainant. If the complaint was without merit the deposit shall be paid into the general fund.
3. The Director may employ qualified on-call consultants to conduct inspections.
4. Inspections under subsection (A) shall comply with the requirements of A.R.S. § 41-1009.

Historical Note
New Section adopted by final rulemaking at 6 A.A.R. 2558, effective June 12, 2000 (Supp. 00-2).

R12-15-1220. Existing Dams
A. The requirements of this Article apply to existing dams, except as provided in subsections (B) and (C).
B. If the Director has determined that an existing dam is in a safe condition, the owner is not required to comply with R12-15-1216 unless the Director determines that it is cost effective to upgrade the dam to comply with the requirements of R12-15-1216 at the time a major alteration or major repair is planned. In determining whether it is cost effective to upgrade a dam, the Director shall consider:
1. The hazard potential classification of the dam;
2. Whether the cost of the upgrade would exceed 25% of the total cost of the major alteration or major repair; and
3. Whether there is a more cost effective alternative that would provide an equivalent increase in safety.
C. If the Director has determined that a dam is in an unsafe condition, the owner shall comply with the requirements in R12-15-1216. The owner is not required to comply with a requirement in this Article if the Director finds that, considering the site characteristics and the proposed design, the requirement is unduly burdensome or expensive and is not necessary to protect human life or property. The Director shall consider the size, hazard potential classification, physical site conditions, and applicability of a requirement to the dam. The Director shall state in writing the reason or reasons the owner is not required to comply with a requirement.
D. The owner shall ensure that installation of utilities beneath or through an existing dam is accomplished by open cuts or jacking and boring methods.

Historical Note
New Section adopted by final rulemaking at 6 A.A.R. 2558, effective June 12, 2000 (Supp. 00-2).

R12-15-1221. Emergency Action Plans
A. Each owner of a high or significant hazard potential dam shall prepare, maintain, and exercise a written emergency action plan for immediate defensive action to prevent failure of the dam and minimize any threat to downstream development. The emergency action plan shall contain a:
1. Notification chart showing the priority for notification in an emergency situation. The owner shall notify local emergency response agencies, affected downstream populations, county emergency management agencies, and affected flood control districts;
2. Description of the demand reservoir and scope of the emergency action plan;
3. Delineation of potentially unsafe conditions, evaluation procedures, and triggering events that require the initiation of partial or full emergency notification procedures, based on the urgency of the situation;
4. Delineation of areas of responsibility of the owner and other parties. The emergency action plan shall clearly identify individuals responsible for notifications and declaring an emergency;
5. Specific notification procedure for each emergency situation anticipated;
6. Description of emergency supplies and resources, equipment access to the site, and alternative means of communication. The emergency action plan shall also identify specific preparedness activities required, such as annual full or partial mock exercises and updates of the emergency action plan; and
7. Map showing the area that would be subject to flooding due to spillway flows and dam failures.
B. The owner shall use the Director's model emergency action plan, which is available at no cost, or an equivalent model, for guidance in preparing the emergency action plan.
C. The owner shall submit a copy of the proposed emergency action plan for review by the Arizona Division of Emergency Management and all local emergency coordinators involved in the plan. The owner shall incorporate appropriate recommendations generated by the reviews and submit the revised emergency action plan to the Department.
D. The owner shall review and update the emergency action plan annually or more frequently to incorporate changes such as new personnel, changing roles of emergency agencies, emergency response resources, conditions of the dam, and information learned from mock exercises. The owner shall send updated portions of the plan to persons and agencies holding copies of the plan within 15 days after preparation of an update.

Historical Note
New Section adopted by final rulemaking at 6 A.A.R. 2558, effective June 12, 2000 (Supp. 00-2).

R12-15-1222. Right of Review
A. An applicant or owner aggrieved by a decision of the Director regarding the determination of hazard classification, jurisdictional status, or the Director's application of this Article may seek review of an appealable agency action under A.R.S. Title 41, Chapter 6, Article 10.
B. An applicant or owner aggrieved by a decision of the Director that requires the exercise of professional engineering judgment or discretion or the assessment of risk to human life or property, such as the adequacy of an applicant's project documentation, dam design, safe storage level, requirements for existing dams, or maintenance, may seek review by a board of review under A.R.S. §§ 45-1210 and 45-1211.
C. The following actions are not subject to review:
1. Emergency measures taken under A.R.S. §§ 45-1212 or 45-1221.
2. Agency decisions made under A.R.S. §§ 41-1009(E) or (F).
3. Agency actions made exempt from review by law.

Historical Note
New Section adopted by final rulemaking at 6 A.A.R. 2558, effective June 12, 2000 (Supp. 00-2).

R12-15-1223. Enforcement Authority
A. The Department may exercise its discretion to take action necessary to prevent danger to human life or property. The Director may take any legal action that is proper and necessary for the enforcement of this Chapter.
B. If the Director has cause to believe that a dam is unsafe or a person is violating or has violated a provision of this Article or A.R.S. Title 45, Chapter 6, Article 1, the Director may issue a notice directing the owner to remedy the safety deficiency or correct the violation. The owner may appeal a notice issued under this subsection as an appealable agency action in accordance with A.R.S. Title 41, Chapter 6, Article 10. If the owner does not appeal within 30 days after the date on the notice, the notice becomes final and may be incorporated as a condition of any license based on the duration of the requirement.
C. If the Director has cause to believe that a dam is unsafe or a person is violating or has violated a provision of this Article or A.R.S. Title 45, Chapter 6, Article 1, the Director may proceed under A.R.S. § 45-1221 to initiate a contested case under A.R.S. Title 41, Chapter 6, Article 10 by requesting an administrative hearing.
D. Following a written decision by an administrative law judge, the Director shall issue a decision and order accepting, rejecting, or modifying the administrative law judge's decision. Upon expiration of time to appeal, the decision and order becomes final and may be incorporated as a condition of any license based on the duration of the requirement.
E. If the Director has cause to believe that a dam is unsafe or a person is violating or has violated a provision of this Article or A.R.S. Title 45, Chapter 6, Article 1 the Director may commence an action in a court of appropriate jurisdiction if:
1. The violation is an emergency requiring appropriate steps to be taken without delay; or
2. The Director has cause to believe that use of the administrative procedure would be ineffective or that delay would ensue and a deterioration in the safety of the dam would occur.
F. If the Director commences an action it shall be brought in a court of appropriate jurisdiction in which:
1. The cause or some part of the cause arose; or
2. The owner or person complained of has his or her place of business; or
3. The owner or person complained of resides.
G. A person determined to be in violation of this Article; A.R.S. Title 45, Chapter 6; a license; or order may be assessed a civil penalty not exceeding $1,000 per day of violation. The Director may offer evidence relating to the amount of the penalty in accordance with A.R.S. § 45-1222.
H. A violation of A.R.S. Title 45, Chapter 6, Article 1 regarding Supervision of Dams, Reservoirs, and Projects is a class 2 misdemeanor, in accordance with A.R.S. § 45-1216.

Historical Note

New Section adopted by final rulemaking at 6 A.A.R. 2558, effective June 12, 2000 (Supp. 00-2).

R12-15-1224. Emergency Procedures

A. The owner of a dam shall immediately notify the Department and responsible authorities in adjacent and downstream communities, including emergency management authorities, of a condition that may threaten the safety of the dam. The owner shall take necessary actions to protect human life and property, including action required under an emergency action plan or order issued under this Article.
   1. A condition that may threaten the safety of a dam includes:
      a. Sliding of upstream or downstream slopes or abutments contiguous to the dam;
      b. Sudden subsidence of the top of the dam;
      c. Longitudinal or transverse cracking of the top of the dam;
      d. Unusual release of water from the downstream slope or face of the dam;
      e. Other unusual conditions at the downstream slope of the dam;
      f. Significant landslides in the reservoir area;
      g. Increasing volume of seepage;
      h. Cloudy seepage or recent deposits of soil at seepage exit points;
      i. Sudden cracking or displacement of concrete in a concrete or masonry dam spillway or outlet works;
      j. Loss of freeboard or dam cross section due to storm wave erosion;
      k. Flood waters overtopping an embankment dam; or
      l. Spillway backcutting that threatens evacuation of the reservoir.
   2. In case of an emergency, the owner shall telephone the Arizona Department of Public Safety's emergency numbers at (800) 411-2336 or (602) 223-2000.

B. The Director shall issue an emergency approval to repair, alter, or remove an existing dam if the Director finds that immediate remedial action is necessary to alleviate an imminent threat to human life or property.
   1. The emergency approval shall be provided in writing on a form developed for this purpose.
   2. The emergency approval may contain conditions the Director determines are appropriate to protect human life or property.
   3. The emergency approval is effective immediately for 30 days after notice is issued unless extended in writing by the Director. The Director shall also send notice to the county flood control district of the county in which the dam is located, all municipalities within 5 miles downstream of the dam, and any additional persons identified in the emergency action plan.
   4. The Director may institute legal or administrative proceedings that the Director deems appropriate for violations of the emergency approval or conditions of the emergency approval.

Historical Note

New Section adopted by final rulemaking at 6 A.A.R. 2558, effective June 12, 2000 (Supp. 00-2).

R12-15-1225. Emergency Repairs

A. The Director shall use monies from the dam repair fund, established under A.R.S. § 45-1212.01 to employ any remedial measure necessary to protect human life and property resulting from a condition that threatens the safety of a dam if the dam owner is unable or unwilling to take action and there is not sufficient time to issue and enforce an order.

B. The deputy director may authorize an expenditure not to exceed $10,000 from the dam repair fund for remedial measures under A.R.S. § 45-1212. The expenditure of any additional funds shall be approved by the Director.

C. The Director shall hold a lien against all property of the owner in accordance with A.R.S. § 45-1212.

Historical Note

New Section adopted by final rulemaking at 6 A.A.R. 2558, effective June 12, 2000 (Supp. 00-2).

R12-15-1226. Non-Emergency Repairs; Loans and Grants

A. If the Director determines that a dam represents a threat to human life and property but is not in an emergency condition, the Director may use the dam repair fund, established under A.R.S. § 45-1212.01, as prescribed in this Article to defray the costs of repair.

B. Monies from the dam repair fund may be used for loans and grants to owners as provided in A.R.S. §§ 45-1218 and 45-1219.

C. To qualify for a loan or grant from the dam repair fund, a dam shall be classified as unsafe by the Director.

D. The Director may authorize grant funds for all or part of the cost of engineering studies or construction needed to mitigate the threat to human life and property created by a dam.
   1. The Director and the grantee shall execute a financial assistance agreement that includes terms of financial assistance, the work progress, and payment schedule.
   2. The Director shall disburse grant funds in accordance with the financial assistance agreement.
   3. The Director shall establish a priority ranking for grants based on factors including the potential for failure of a dam, the number of lives at risk, and the capability of the owner to pay a portion of the costs.

E. The Director may loan funds for engineering studies or for all or part of construction as prescribed in A.R.S. § 45-1218.
   1. The Director and the dam owner shall execute a loan repayment agreement. The loan repayment agreement shall be delivered to and held by the Department.
   2. The Director shall establish a priority ranking for loans based on factors including the potential for failure of a dam, the number of human lives at risk, and the capability of the owner to pay a portion of the costs.

Historical Note

New Section adopted by final rulemaking at 6 A.A.R. 2558, effective June 12, 2000 (Supp. 00-2).

ARTICLE 13. WELL SPACING REQUIREMENTS; REPLACEMENT WELLS IN APPROXIMATELY THE SAME LOCATION

R12-15-1301. Definitions

In addition to the definitions in A.R.S. §§ 45-101, 45-402, and 45-591, the following words and phrases in this Article shall have the following meanings, unless the context otherwise requires:
   1. "Abandoned well" means a well for which a well abandonment completion report has been filed pursuant to R12-15-816(E) or for which a notification of abandonment has been filed pursuant to R12-15-816(K).
   2. "Additional drawdown" means a lowering in the water levels surrounding a well that is the result of the operation of the well and that is not attributable to existing regional rates of decline or existing impacts from other wells.
   3. "Applicant" means any of the following:
      a. A person who has filed an application for a permit to construct a new well or a replacement well in a new location under A.R.S. § 45-599;
      b. A person who has filed an application for a recovery well permit under A.R.S. § 45-834.01 for a new well as defined in A.R.S. § 45-591 or, except as provided in A.R.S. § 45-834.01 (B)(2) or (3), an existing well as defined in A.R.S. § 45-591;
      c. A person who has filed an application for approval to use a well to withdraw groundwater for transportation to an active management area under A.R.S. § 45-559; or
      d. A person, other than a city, town, private water company, or irrigation district, who has filed an application for a water exchange permit under A.R.S. § 45-1041.
   4. "ADEQ" means the Arizona Department of Environmental Quality.
   5. "Contaminated groundwater" means groundwater that has been contaminated by a release of a hazardous substance, as defined in A.R.S. § 49-201, or a pollutant, as defined in A.R.S. § 49-201.
   6. "DOD" means the United States Department of Defense.
   7. "EPA" means the United States Environmental Protection Agency.
   8. "LCR plateau groundwater transporter" means a person transporting groundwater from the Little Colorado River plateau groundwater basin to another groundwater basin pursuant to A.R.S. § 45-544(B)(1).
   9. "Notice of water exchange participant" means a person, other than a city, town, private water company, or irrigation district, named as a participant in a water exchange in a notice of water exchange filed under A.R.S. § 45-1051.
   10. "Original well" means the well replaced by a replacement well in approximately the same location, except that if the replacement well is the latest in a succession of two or more wells drilled as replacement wells in approximately the same location under R12-15-1308 or temporary rule R12-15-840 adopted by the director on March 11, 1983, "original well" means the well replaced by the first replacement well in approximately the same location.
   11. "Remedial action site" means any of the following:
      a. The site of a remedial action undertaken pursuant to the comprehensive environmental response, compensation, and liability act ("CERCLA") of 1980, as amended, 42 U.S.C. 9601, et seq., commonly known as a "superfund" site;
      b. The site of a corrective action undertaken pursuant to A.R.S. Title 49, Chapter 6, commonly known as a leaking underground storage tank ("LUST") site;
      c. The site of a voluntary remediation action undertaken pursuant to A.R.S. Title 49, Chapter 1, Article 5;
      d. The site of a remedial action undertaken pursuant to A.R.S. Title 49, Chapter 2, Article 5, commonly known as a water quality assurance revolving fund ("WQARF") site;
      e. The site of a remedial action undertaken pursuant to the Resource Conservation and Recovery Act ("RCRA"), 42 U.S.C. 6901, et seq.; or
      f. The site of remedial action undertaken pursuant to the Department of Defense Environmental Restoration Program, 10 U.S.C. 2701, et seq., commonly known as a "Department of Defense site" or a "DOD site."
   12. "Replacement well" means a well drilled for the purpose of replacing another well.
   13. "Replacement well in a new location" means a replacement well that does not qualify as a replacement well in approximately the same location under R12-15-1308.
   14. "Replacement well in approximately the same location" means a replacement well that qualifies as a replacement well in approximately the same location under R12-15-1308.
   15. "Well" has the meaning prescribed in A.R.S. § 45-402. An abandoned well is not a well.
   16. "Well of record" means, with respect to an applicant, an LCR plateau groundwater transporter, or a notice of water exchange participant, any well or proposed well not owned by the applicant, LCR plateau groundwater transporter, or notice of water exchange participant, or proposed to be drilled by the applicant, LCR plateau groundwater transporter, or notice of water exchange participant, to which any of the following apply:
      a. The well is an existing well as defined in A.R.S. § 45-591 and the owner or operator has registered the well with the Department, unless the current well information on file with the Department identifies the sole purpose or purposes of the well as one or more of the following:

i. Cathodic protection;
ii. Use as a sump pump or heat pump;
iii. Air sparging;
iv. Injection of liquids or gasses into the aquifer or vadose zone, including injection wells that are part of an underground storage facility permitted under A.R.S. Title 45, Chapter 3.1;
v. Monitoring water levels or water quality, including a piezometer well;
vi. Obtaining geophysical, mineralogical, or geotechnical data;
vii. Grounding;
viii. Soil vapor extraction;
ix. Electrical energy generation pursuant to a temporary permit for electrical energy generation issued under A.R.S. § 45-517;
x. Dewatering pursuant to a dewatering permit issued under A.R.S. § 45-513 or a temporary dewatering permit issued under A.R.S. § 45-518;
xi. Drainage pursuant to a drainage water withdrawal permit issued under A.R.S. § 45-519; or
xii. Hydrologic testing pursuant to a hydrologic testing permit issued under A.R.S. § 45-519.01.

b. The well is a new well as defined in A.R.S. § 45-591 for which a notice of intention to drill was not filed pursuant to A.R.S. § 45-596 and for which a permit was not issued pursuant to A.R.S. §§ 45-599 or 45-834.01, and the owner or operator has registered the well with the Department, unless the current well information on file with the Department identifies the sole purpose or purposes of the well as one or more of the purposes in subsection (16)(a)(i) through (xii) of this Section;

c. A filing has been made for the well pursuant to A.R.S. § 45-596(A) or (B), unless any of the following apply:
i. The filing has expired pursuant to A.R.S. § 45-596(E);
ii. The filing identifies the sole purpose or purposes of the well as one or more of the purposes in subsection (16)(a)(i) through (xii) of this Section; or
iii. The well is an exempt well and the director is prohibited by A.R.S. § 45-454(D)(4) from considering impacts on the well when determining whether to approve or reject a permit application filed under A.R.S. § 45-599.

d. An application for a permit to drill the well has been received by the Department pursuant to A.R.S. § 45-599, unless the application has been rejected after exhaustion of all administrative and judicial appeals or the permit issued pursuant to the application has been revoked or has expired according to its terms or for failure to complete the well in a timely manner pursuant to A.R.S. § 45-599(G);

e. An application for a permit pursuant to A.R.S. §§ 45-514 or 45-516 has been received by the Department pursuant to A.R.S. § 45-521, unless the application has been rejected after exhaustion of all administrative and judicial appeals or the permit issued pursuant to the application has been revoked or has expired according to its terms or for failure to complete the well before expiration of the drilling authority; or

f. An application for a permit to drill a recovery well has been received by the Department pursuant to A.R.S. § 45-834.01, unless the application has been rejected after exhaustion of all administrative and judicial appeals or the permit issued pursuant to the application has been revoked or has expired according to its terms or for failure to complete the well in a timely manner pursuant to A.R.S. § 45-834.01(F).

Historical Note

New Section made by final rulemaking at 12 A.A.R. 2193, effective August 7, 2006 (Supp. 06-2).

R12-15-1302. Well Spacing Requirements - Applications to Construct New Wells or Replacement Wells in New Locations Under A.R.S. § 45-599

A. The director shall not approve an application for a permit to construct a new well or a replacement well in a new location under A.R.S. § 45-599 if the director determines that the withdrawals from the proposed well or wells will cause unreasonably increasing damage to surrounding land or other water users from the concentration of wells under subsection (B) of this Section.

B. The director shall determine that the withdrawals from the proposed well or wells will cause unreasonably increasing damage to surrounding land or other water users from the concentration of wells if any of the following apply:

1. Except as provided in subsection (D) of this Section, the director determines that the probable impact of the withdrawals from the proposed well or wells on any well of record in existence as of the date of receipt of the application will exceed 10 feet of additional drawdown after the first five years of operation of the proposed well or wells. To assist the director in making a determination under this subsection, the applicant may submit a hydrological study delineating those areas surrounding the proposed well or wells in which the projected impacts on water levels will exceed 10 feet of additional drawdown after the first five years of operation of the proposed well or wells. The director may require the applicant to submit such a hydrological study if the director determines that the study will assist the director in making a determination under this subsection;
2. The director determines that the proposed well or wells will be located in an area of known land subsidence and the withdrawals from the proposed well or wells will likely cause unreasonably increasing damage from additional regional land subsidence. To assist the director in making a determination under this subsection, the applicant may submit a hydrological study, which may include a geophysical evaluation, demonstrating the impact of the withdrawals from the proposed well or wells on regional land subsidence. The director may require the applicant to submit such a hydrological study if the director determines that the study will assist the director in making a determination under this subsection; or
3. Except as provided in subsection (E) of this Section, the director determines, after consulting with ADEQ, that withdrawals from the proposed well or wells will likely cause the migration of contaminated groundwater from a remedial action site to a well of record in existence as of the date of the receipt of the application, resulting in a degradation of the quality of the water withdrawn from the well of record so that the water will no longer be usable for the purpose for which it is currently being used without additional treatment, and that the damage to the owner of the well of record will not be prevented or adequately mitigated through the implementation of a program regulated under Title 49 of the Arizona Revised Statutes, or a program regulated by EPA or DOD. To assist the director in making a determination under this subsection, the applicant may submit a hydrological study demonstrating whether the withdrawals from the proposed well or wells will have the effect described in this subsection. The director may require the applicant to submit such a hydrological study if the director determines that the study will assist the director in making a determination under this subsection.

C. In making a determination under subsection (B)(1), (B)(2), or (B)(3) of this Section, if the proposed well is a replacement well in a new location, the director shall take into account the collective effects of reducing or terminating withdrawals from the well being replaced combined with the proposed withdrawals from the replacement well if the applicant submits a hydrological study demonstrating those collective effects to the satisfaction of the director.

D. If the director determines under subsection (B)(1) of this Section that the probable impact of the withdrawals from the proposed well or wells on one or more wells of record in existence as of the date of receipt of the application will exceed 10 feet of additional drawdown after the first five years of operation of the proposed well or wells, the director shall notify the applicant in writing of the location of the wells of record and the names and addresses of the owners of the wells as shown in the Department's well registry. The director shall not determine that the withdrawals from the proposed well or wells will cause unreasonably increasing damage to surrounding land or other water users from the concentration of wells under subsection (B)(1) of this Section if within 60 days after the date on the notice, or a longer time period approved by the director, the applicant submits one of the following for each well of record identified in the notice:

1. A signed and notarized consent form from the owner of the well of record consenting to the withdrawals from the proposed well or wells. The applicant shall use the consent form furnished by the director; or
2. Evidence satisfactory to the director that the address of the owner of the well of record as shown in the Department's well registry records is inaccurate and that the applicant made a reasonable attempt to locate the current owner of the well of record but was unable to do so.

E. If the director determines that withdrawals from the proposed well or wells will have the effect described in subsection (B)(3) of this Section on one or more wells of record in existence as of the date of receipt of the application, the director shall notify the applicant in writing of the location of the wells of record and the names and addresses of the owners of the wells as shown in the Department's well registry. The director shall not determine that the withdrawals from the proposed well or wells will cause unreasonably increasing damage to surrounding land or other water users from the concentration of wells under subsection (B)(3) of this Section if within 60 days after the date on the notice, or a longer time period approved by the director, the applicant submits one of the following for each well of record identified in the notice:

1. A signed and notarized consent form from the owner of the well of record consenting to the withdrawals from the proposed well or wells. The applicant shall use the consent form furnished by the director; or
2. Evidence satisfactory to the director that the address of the owner of the well of record as shown in the Department's well registry records is inaccurate and that the applicant made a reasonable attempt to locate the current owner of the well of record but was unable to do so.

F. At any time before a final determination under this Section, the applicant may:

1. Amend the application to change the location of the proposed well or wells or the amount of groundwater to be withdrawn from the proposed well or wells to lessen the degree of impact on wells of record or regional land subsidence; or
2. Agree to construct or operate the proposed well or wells in a manner that lessens the degree of impact on wells of record or regional land subsidence. The director shall indicate in the well permit that compliance with the agreement is a condition of the well permit.

Historical Note

New Section made by final rulemaking at 12 A.A.R. 2193, effective August 7, 2006 (Supp. 06-2).

R12-15-1303. Well Spacing Requirements - Applications for Recovery Well Permits Under A.R.S. § 45-834.01

A. The director shall not approve an application for a recovery well permit under A.R.S. § 45-834.01 that is filed for a new well as defined in A.R.S. § 45-591 or, except as provided in A.R.S. § 45-834.01(B)(2) or (3), for an existing well as defined in A.R.S. § 45-591, if the director determines that the recovery of stored water from the proposed well or wells will cause unreasonably increasing damage to surrounding land or other water users from the concentration of wells under subsection (B) of this Section.

B. The director shall determine that the recovery of stored water from the proposed well or wells will cause unreasonably increasing damage to surrounding land or other water users from the concentration of wells if any of the following apply:

1. Except as provided in subsection (D) of this Section, the director determines that the probable impact of the recovery of stored water from the proposed well or wells on any well of record in existence as of the date of receipt of the application will exceed 10 feet of additional drawdown after the first five years of the recovery of stored water from the proposed well or wells. To assist the director in making a determination under this subsection, the applicant shall submit with the application a hydrological study delineating those areas surrounding the proposed well or wells in which the projected impacts on water levels will exceed 10 feet of additional drawdown after the first five years of the recovery of stored water from the proposed well or wells;
2. The director determines that the proposed recovery well or wells will be located in an area of known land subsidence and the recovery of stored water from the proposed well or wells will likely cause unreasonably increasing damage from additional regional land subsidence. To assist the director in making a determination under this subsection, the applicant may submit a hydrological study, which may include a geophysical evaluation, demonstrating the impact of the recovery of stored water from the proposed recovery well or wells on regional land subsidence. The director may require the applicant to submit such a hydrological study if the director determines that the study will assist the director in making a determination under this subsection; or

3. Except as provided in subsection (E) of this Section, the director determines, after consulting with ADEQ, that the recovery of stored water from the proposed well or wells will likely cause the migration of contaminated groundwater from a remedial action site to a well of record in existence as of the date of receipt of the application, resulting in a degradation of the quality of the water withdrawn from the well of record so that the water will no longer be usable for the purpose for which it is currently being used without additional treatment, and that the damage to the owner of the well of record will not be prevented or adequately mitigated through the implementation of a program regulated under Title 49 of the Arizona Revised Statutes, or a program regulated by EPA or DOD. To assist the director in making a determination under this subsection, the applicant may submit a hydrological study demonstrating whether the recovery of stored water from the proposed well or wells will have the effect described in this subsection. The director may require the applicant to submit such a hydrological study if the director determines that the study will assist the director in making a determination under this subsection.

C. In making a determination under subsection (B)(1), (B)(2), or (B)(3) of this Section:
1. If the proposed recovery well is a replacement well in a new location, the director shall take into account the collective effects of reducing or terminating withdrawals from the well being replaced combined with the proposed recovery of stored water from the replacement well if the applicant submits a hydrological study demonstrating those collective effects to the satisfaction of the director.
2. If the proposed recovery well will be located within the area of impact, as defined in A.R.S. § 45-802.01, of an underground storage facility and the applicant will account for all of the water recovered from the well as water stored at the facility, the director shall take into account the effects of water storage at the facility on the proposed recovery of stored water from the recovery well if the applicant submits a hydrological study demonstrating those effects to the satisfaction of the director.

D. If the director determines under subsection (B)(1) of this Section that the probable impact of the recovery of stored water from the proposed recovery well or wells on any well of record in existence as of the date of receipt of the application will exceed 10 feet of additional drawdown after the first five years of operation of the proposed well or wells, the director shall notify the applicant in writing of the location of the wells of record and the names and addresses of the owners of the wells as shown in the Department's well registry. The director shall not determine that the recovery of stored water from the proposed recovery well or wells will cause unreasonably increasing damage to surrounding land or other water users from the concentration of wells under subsection (B)(1) of this Section if within 60 days after the date on the notice, or a longer time period approved by the director, the applicant submits one of the following for each well of record identified in the notice:
1. A signed and notarized consent form from the owner of the well of record consenting to the recovery of stored water from the proposed recovery well or wells. The applicant shall use the consent form furnished by the director; or
2. Evidence satisfactory to the director that the address of the owner of the well of record as shown in the Department's well registry records is inaccurate and that the applicant made a reasonable attempt to locate the current owner of the well of record but was unable to do so.

E. If the director determines that the recovery of stored water from the proposed recovery well or wells will have the effect described in subsection (B)(3) of this Section on one or more wells of record in existence as of the date of receipt of the application, the director shall notify the applicant in writing of the location of the wells of record and the names and addresses of the owners of the wells as shown in the Department's well registry. The director shall not determine that the recovery of stored water from the proposed recovery well or wells will cause unreasonably increasing damage to surrounding land or other water users from the concentration of wells under subsection (B)(3) of this Section if within 60 days after the date on the notice, or a longer time period approved by the director, the applicant submits one of the following for each well of record identified in the notice:
1. A signed and notarized consent form from the owner of the well of record consenting to the recovery of stored water from the proposed recovery well or wells. The applicant shall use the consent form furnished by the director; or
2. Evidence satisfactory to the director that the address of the owner of the well of record as shown in the Department's well registry records is inaccurate and that the applicant made a reasonable attempt to locate the current owner of the well of record but was unable to do so.

F. At any time before a final determination under this Section, the applicant may:
1. Amend the application to change the location of the proposed recovery well or wells or the amount of stored water to be recovered from the proposed recovery well or wells to lessen the degree of impact on wells of record or regional land subsidence; or
2. Agree to construct or operate the proposed recovery well or wells in a manner that lessens the degree of impact on wells of record or regional land subsidence. The director shall indicate in the recovery well permit that compliance with the agreement is a condition of the recovery well permit.

New Section made by final rulemaking at 12 A.A.R. 2193, effective August 7, 2006 (Supp. 06-2).

R12-15-1304. Well Spacing Requirements - Wells Withdrawing Groundwater From the Little Colorado River Plateau Groundwater Basin for Transportation to Another Groundwater Basin Under A.R.S. § 45-544(B)(1)

A. An LCR plateau groundwater transporter may not withdraw groundwater from a well or wells drilled in the Little Colorado river plateau groundwater basin after January 1, 1991, except a replacement well in approximately the same location or a well drilled after that date pursuant to a notice of intention to drill filed on or before that date, for transportation away from the basin pursuant to A.R.S. § 45-544(B)(1) if the director determines that the withdrawals for that purpose will cause unreasonably increasing damage to surrounding land or other water users from the concentration of wells under subsection (B) of this Section.

B. The director shall determine that the withdrawals of groundwater from the well or wells will cause unreasonably increasing damage to surrounding land or other water users from the concentration of wells if any of the following apply:
1. Except as provided in subsection (D) of this Section, the director determines that the probable impact of the withdrawals of groundwater from the well or wells on any well of record in existence when the withdrawals commenced or are proposed to commence will exceed 10 feet of additional drawdown after the first five years of the withdrawals. To assist the director in making a determination under this subsection, the LCR plateau groundwater transporter may submit to the director a hydrological study delineating those areas surrounding the LCR plateau groundwater transporter's well or wells in which the projected impacts on water levels will exceed 10 feet of additional drawdown after the first five years of the withdrawals. The director may require the LCR plateau groundwater transporter to submit such a hydrological study if the director determines that the study will assist the director in making a determination under this subsection;
2. The director determines that the well or wells from which the groundwater is withdrawn are located in an area of known land subsidence and the withdrawals of groundwater will likely cause unreasonably increasing damage from additional regional land subsidence. To assist the director in making a determination under this subsection, the LCR plateau groundwater transporter may submit to the director a hydrological study, which may include a geophysical evaluation, demonstrating the impact of the withdrawals on regional land subsidence. The director may require the LCR plateau groundwater transporter to submit such a hydrological study if the director determines that the study will assist the director in making a determination under this subsection; or
3. Except as provided in subsection (E) of this Section, the director determines, after consulting with ADEQ, that the withdrawals of groundwater from the well or wells will likely cause the migration of contaminated groundwater from a remedial action site to a well of record in existence when the groundwater withdrawals commenced or are proposed to commence, resulting in a degradation of the quality of the water withdrawn from the well of record so that the water will no longer be usable for the purpose for which it is currently being used without additional treatment, and that the damage to the owner of the well of record will not be prevented or adequately mitigated through the implementation of a program regulated under Title 49 of the Arizona Revised Statutes, or a program regulated by EPA or DOD. To assist the director in making a determination under this subsection, the LCR plateau groundwater transporter may submit to the director a hydrological study demonstrating whether the withdrawals of groundwater will have the effect described in this subsection. The director may require the LCR plateau groundwater transporter to submit such a hydrological study if the director determines that the study will assist the director in making a determination under this subsection.

C. In making a determination under subsection (B)(1), (B)(2), or (B)(3) of this Section, if a well from which the groundwater is withdrawn is a replacement well in a new location, the director shall take into account the collective effects of reducing or terminating withdrawals from the well being replaced combined with the withdrawals from the replacement well if the LCR plateau groundwater transporter submits a hydrological study demonstrating those collective effects to the satisfaction of the director.

D. If the director determines under subsection (B)(1) of this Section that the probable impact of the withdrawals of groundwater from the well or wells on any well of record in existence when the withdrawals commenced or are proposed to commence will exceed 10 feet of additional drawdown after the first five years of the withdrawals, the director shall notify the LCR plateau groundwater transporter in writing of the location of the wells of record and the names and addresses of the owners of the wells as shown in the Department's well registry. The director shall not determine that the withdrawals will
cause unreasonably increasing damage to surrounding land or other water users from the concentration of wells under subsection (B)(1) of this Section if within 60 days after the date on the notice, or a longer time period approved by the director, the LCR plateau groundwater transporter submits one of the following for each well of record identified in the notice:
1. A signed and notarized consent form from the owner of the well of record consenting to the withdrawals. The LCR plateau groundwater transporter shall use the consent form furnished by the director; or
2. Evidence satisfactory to the director that the address of the owner of the well of record as shown in the Department's well registry records is inaccurate and that the LCR plateau groundwater transporter made a reasonable attempt to locate the current owner of the well of record but was unable to do so.

E. If the director determines that the withdrawals of groundwater from the well or wells will have the effect described in subsection (B)(3) of this Section on one or more wells of record in existence when the groundwater withdrawals commenced or are proposed to commence, the director shall notify the LCR plateau groundwater transporter in writing of the location of the wells of record and the names and addresses of the owners of the wells as shown in the Department's well registry. The director shall not determine that the withdrawals will cause unreasonably increasing damage to surrounding land or other water users from the concentration of wells under subsection (B)(3) of this Section if within 60 days after the date on the notice, or a longer time period approved by the director, the LCR plateau groundwater transporter submits one of the following for each well of record identified in the notice:
1. A signed and notarized consent form from the owner of the well of record consenting to the withdrawals. The LCR plateau groundwater transporter shall use the consent form furnished by the director; or
2. Evidence satisfactory to the director that the address of the owner of the well of record as shown in the Department's well registry records is inaccurate and that the LCR plateau groundwater transporter made a reasonable attempt to locate the current owner of the well of record but was unable to do so.

F. At any time before a final determination under this Section, the LCR plateau groundwater transporter may agree to construct or operate the well or wells in a manner that lessens the degree of impact on wells of record or regional land subsidence. Compliance with the agreement is a condition for the use of the well or wells to withdraw groundwater for transportation away from the basin pursuant to A.R.S. § 45-544(B)(1).

Historical Note

New Section made by final rulemaking at 12 A.A.R. 2193, effective August 7, 2006 (Supp. 06-2).

R12-15-1305. Well Spacing Requirements - Applications to Use a Well to Withdraw Groundwater for Transportation to an Active Management Area Under A.R.S. § 45-559

A. The director shall not approve an application to use a well or wells constructed after September 21, 1991, to withdraw groundwater for transportation to an active management area under A.R.S. § 45-559 if the director determines that the withdrawals for that purpose will cause unreasonably increasing damage to surrounding land or other water users from the concentration of wells under subsection (B) of this Section.

B. The director shall determine that the withdrawals of groundwater will cause unreasonably increasing damage to surrounding land or other water users from the concentration of wells if any of the following apply:
1. Except as provided in subsection (C) of this Section, the director determines that the probable impact of the groundwater withdrawals on any well of record in existence as of the date of receipt of the application will exceed 10 feet of additional drawdown after the first five years of the withdrawals. To assist the director in making a determination under this subsection, the applicant may submit a hydrological study delineating those areas surrounding the proposed well or wells in which the projected impacts of the groundwater withdrawals on water levels will exceed 10 feet of additional drawdown after the first five years of the withdrawals. The director may require the applicant to submit such a hydrological study if the director determines that the study will assist the director in making a determination under this subsection;
2. The director determines that the proposed well or wells will be located in an area of known land subsidence and the groundwater withdrawals will likely cause unreasonably increasing damage from additional regional land subsidence. To assist the director in making a determination under this subsection, the applicant may submit a hydrological study, which may include a geophysical evaluation, demonstrating the impact of the groundwater withdrawals on regional land subsidence. The director may require the applicant to submit such a hydrological study if the director determines that the study will assist the director in making a determination under this subsection; or
3. Except as provided in subsection (D) of this Section, the director determines, after consulting with ADEQ, that the groundwater withdrawals will likely cause the migration of contaminated groundwater from a remedial action site to a well of record in existence as of the date of receipt of the application, resulting in a degradation of the quality of the water withdrawn from the well of record so that the water will no longer be usable for the purpose for which it is currently being used without additional treatment, and that the damage to the owner of the well of record will not be prevented or adequately mitigated through the implementation of a program regulated under Title 49 of the Arizona Revised Statutes, or a program regulated by EPA or DOD. To assist the director in making a determination under this subsection, the applicant may submit a hydrological study demonstrating whether the groundwater withdrawals will have the effect described in this subsection. The director may require the applicant to submit such a hydrological study if the director determines that the study will assist the director in making a determination under this subsection.

C. If the director determines under subsection (B)(1) of this Section that the probable impact of the groundwater withdrawals on any well of record in existence as of the date of receipt of the application will exceed 10 feet of additional drawdown after the first five years of the withdrawals, the director shall notify the applicant in writing of the location of the wells of record and the names and addresses of the owners of the wells as shown in the Department's well registry. The director shall not determine that the groundwater withdrawals will cause unreasonably increasing damage to surrounding land or other water users from the concentration of wells under subsection (B)(1) of this Section if within 60 days after the date on the notice, or a longer time period approved by the director, the applicant submits one of the following for each well of record identified in the notice:
1. A signed and notarized consent form from the owner of the well of record consenting to the withdrawals. The applicant shall use the consent form furnished by the director; or
2. Evidence satisfactory to the director that the address of the owner of the well of record as shown in the Department's well registry records is inaccurate and that the applicant made a reasonable attempt to locate the current owner of the well of record but was unable to do so.

D. If the director determines that the groundwater withdrawals will have the effect described in subsection (B)(3) of this Section on one or more wells of record in existence as of the date of receipt of the application, the director shall notify the applicant in writing of the location of the wells of record and the names and addresses of the owners of the wells as shown in the Department's well registry. The director shall not determine that the groundwater withdrawals will cause unreasonably increasing damage to surrounding land or other water users from the concentration of wells under subsection (B)(3) of this Section if within 60 days after the date on the notice, or a longer time period approved by the director, the applicant submits one of the following for each well of record identified in the notice:
1. A signed and notarized consent form from the owner of the well of record consenting to the withdrawals. The applicant shall use the consent form furnished by the director; or
2. Evidence satisfactory to the director that the address of the owner of the well of record as shown in the Department's well registry records is inaccurate and that the applicant made a reasonable attempt to locate the current owner of the well of record but was unable to do so.

E. At any time before a final determination under this Section, the applicant may:
1. Amend the application to change the location of the proposed well or wells or the amount of groundwater to be withdrawn from the proposed well or wells to lessen the degree of impact on wells of record or regional land subsidence; or
2. Agree to construct or operate the proposed well or wells in a manner that lessens the degree of impact on wells of record or regional land subsidence. The director shall indicate in the permit that compliance with the agreement is a condition of the permit to use the well or wells to withdraw groundwater for transportation to an active management area under A.R.S. § 45-559.

Historical Note
New Section made by final rulemaking at 12 A.A.R. 2193, effective August 7, 2006 (Supp. 06-2).

R12-15-1306. Well Spacing Requirements - Applications for Water Exchange Permits Under A.R.S. § 45-1041

A. The director shall not approve an application for a water exchange permit filed under A.R.S. § 45-1041 by a person other than a city, town, private water company or irrigation district if the director determines that any new or increased pumping by the applicant from a well or wells within an active management area pursuant to the water exchange will cause unreasonably increasing damage to surrounding land or other water users under subsection (B) of this Section.

B. The director shall determine that new or increased pumping by the applicant from a well or wells within an active management area will cause unreasonably increasing damage to surrounding land or other water users if any of the following apply:
1. Except as provided in subsection (C) of this Section, the director determines that the probable impact of the new or increased pumping on any well of record in existence as of the date of receipt of the application will exceed 10 feet of additional drawdown after the first five years of the pumping. To assist the director in making a determination under this subsection, the applicant may submit a hydrological study delineating those areas surrounding the proposed well or wells in which the projected impacts of the new or increased pumping on water levels will exceed 10 feet of additional drawdown after the first five years of the pumping. The director may require the applicant to submit such a hydrological study if the director determines that the study will assist the director in making a determination under this subsection;
2. The director determines that the new or increased pumping will occur in an area of known land subsidence and the pumping will likely cause unreasonably increasing damage from additional regional land subsidence. To assist the director in making a determination under this subsection, the applicant may submit a hydrological study, which may include a geophysical evaluation, demonstrating the impact of the new or increased pumping on regional land subsidence. The director may require the applicant to submit such a hydrological study if the director determines that the study will assist the director in making a determination under this subsection; or
3. Except as provided in subsection (D) of this Section, the director determines, after consulting with ADEQ, that the new or increased pumping will likely cause the migration of contaminated groundwater from a remedial action site to a well of record in existence as of the date of receipt of the application, resulting in a degradation of the quality of the water withdrawn from the well of record so that the water will no longer be usable for the purpose for which it is currently being used without additional treatment, and that the damage to the owner of the well of record will not be prevented or adequately mitigated through the implementation of a program regulated under Title 49 of the Arizona Revised Statutes, or a program regulated by EPA or DOD. To assist the director in making a determination under this subsection, the applicant may submit with the application a hydrological study demonstrating whether the new or increased pumping will have the effect described in this subsection. If the applicant does not submit such a hydrological study with the application, the director may require the applicant to submit the study if the director determines that the study will assist the director in making a determination under this subsection.

C. If the director determines under subsection (B)(1) of this Section that the probable impact of the new or increased pumping on any well of record in existence as of the date of receipt of the application will exceed 10 feet of additional drawdown after the first five years of the pumping, the director shall notify the applicant in writing of the location of the wells of record and the names and addresses of the owners of the wells as shown in the Department's well registry. The director shall not determine that the new or increased pumping will cause unreasonably increasing damage to surrounding land or other water users under subsection (B)(1) of this Section if within 60 days after the date on the notice, or a longer time period approved by the director, the applicant submits one of the following for each well of record identified in the notice:
1. A signed and notarized consent form from the owner of the well of record consenting to the new or increased pumping. The applicant shall use the consent form furnished by the director; or
2. Evidence satisfactory to the director that the address of the owner of the well of record as shown in the Department's well registry records is inaccurate and that the applicant made a reasonable attempt to locate the current owner of the well of record but was unable to do so.

D. If the director determines that the new or increased pumping will have the effect described in subsection (B)(3) of this Section on one or more wells of record in existence as of the date of receipt of the application, the director shall notify the applicant in writing of the location of the wells of record and the names and addresses of the owners of the wells as shown in the Department's well registry. The director shall not determine that the new or increased pumping will cause unreasonably increasing damage to surrounding land or other water users from the concentration of wells under subsection (B)(3) of this Section if within 60 days after the date on the notice, or a longer time period approved by the director, the applicant submits one of the following for each well of record identified in the notice:
1. A signed and notarized consent form from the owner of the well of record consenting to the new or increased pumping. The applicant shall use the consent form furnished by the director; or
2. Evidence satisfactory to the director that the address of the owner of the well of record as shown in the Department's well registry records is inaccurate and that the applicant made a reasonable attempt to locate the current owner of the well of record but was unable to do so.

E. At any time before a final determination under this Section, the applicant may:
1. Amend the application to change the location of the proposed well or wells or the amount of the new or increase pumping to lessen the degree of impact on wells of record or regional land subsidence; or
2. Agree to construct or operate the proposed well or wells in a manner that lessens the degree of impact on wells of record or regional land subsidence. The director shall indicate in the water exchange permit that compliance with the agreement is a condition of the water exchange permit.

Historical Note
New Section made by final rulemaking at 12 A.A.R. 2193, effective August 7, 2006 (Supp. 06-2).

R12-15-1307. Well Spacing Requirements - Notices of Water Exchange Under A.R.S. § 45-1051

A. A notice of water exchange participant may not participate in a water exchange for which a notice is filed under A.R.S. § 45-1051 if the director determines that any new or increased pumping by the person from a well or wells within an active management area pursuant to the water exchange will cause unreasonably increasing damage to surrounding land or other water users under subsection (B) of this Section.

B. The director shall determine that new or increased pumping from the well or wells in an active management area will cause unreasonably increasing damage to surrounding land or other water users if any of the following apply:
1. Except as provided in subsection (C) of this Section, the director determines that the probable impact of the new or increased pumping on any well of record in existence when the pumping commenced or is proposed to commence will exceed 10 feet of additional drawdown after the first five years of the pumping. To assist the director in making a determination under this subsection, the notice of water exchange participant may submit to the director a hydrological study delineating those areas surrounding the notice of water exchange

participant's well or wells in which the projected impacts of the new or increased pumping on water levels will exceed 10 feet of additional drawdown after the first five years of the pumping. The director may require the notice of water exchange participant to submit such a hydrological study if the director determines that the study will assist the director in making a determination under this subsection;

2. The director determines that the new or increased pumping is in an area of known land subsidence and the pumping will likely cause unreasonably increasing damage from additional regional land subsidence. To assist the director in making a determination under this subsection, the notice of water exchange participant may submit to the director a hydrological study, which may include a geophysical evaluation, demonstrating the impact of the pumping on regional land subsidence. The director may require the notice of water exchange participant to submit such a hydrological study if the director determines that the study will assist the director in making a determination under this subsection; or
3. Except as provided in subsection (D) of this Section, the director determines, after consulting with ADEQ, that the new or increased pumping will likely cause the migration of contaminated groundwater from a remedial action site to a well of record in existence when the pumping commenced or is proposed to commence, resulting in a degradation of the quality of the water withdrawn from the well of record so that the water will no longer be usable for the purpose for which it is currently being used without additional treatment, and that the damage to the owner of the well of record will not be prevented or adequately mitigated through the implementation of a program regulated under Title 49 of the Arizona Revised Statutes, or a program regulated by EPA or DOD. To assist the director in making a determination under this subsection, the notice of water exchange participant may submit to the director a hydrological study demonstrating whether the new or increased pumping will have the effect described in this subsection. The director may require the notice of water exchange participant to submit such a study if the director determines that the study will assist the director in making a determination under this subsection.

C. If the director determines under subsection (B)(1) of this Section that the probable impact of the new or increased pumping on any well of record in existence when the pumping commenced or is proposed to commence will exceed 10 feet of additional drawdown after the first five years of the pumping, the director shall notify the notice of water exchange participant in writing of the location of the wells of record and the names and addresses of the owners of the wells as shown in the Department's well registry. The director shall not determine that the new or increased pumping will cause unreasonably increasing damage to surrounding land or other water users from the concentration of wells under subsection (B)(1) of this Section if within 60 days after the date on the notice, or a longer time period approved by the director, the notice of water exchange participant submits one of the following for each well of record identified in the notice:

1. A signed and notarized consent form from the owner of the well of record consenting to the new or increased pumping. The notice of water exchange participant shall use the consent form furnished by the director; or
2. Evidence satisfactory to the director that the address of the owner of the well of record as shown in the Department's well registry records is inaccurate and that the notice of water exchange participant made a reasonable attempt to locate the current owner of the well of record but was unable to do so.

D. If the director determines that the new or increased pumping will have the effect described in subsection (B)(3) of this Section on one or more wells of record in existence when the pumping commenced or is proposed to commence, the director shall notify the notice of water exchange participant in writing of the location of the wells of record and the names and addresses of the owners of the wells as shown in the Department's well registry. The director shall not determine that the new or increased pumping will cause unreasonably increasing damage to surrounding land or other water users from the concentration of wells under subsection (B)(3) of this Section if within 60 days after the date on the notice, or a longer time period approved by the director, the notice of water exchange participant submits one of the following for each well of record identified in the notice:

1. A signed and notarized consent form from the owner of the well of record consenting to the new or increased pumping. The notice of water exchange participant shall use the consent form furnished by the director; or
2. Evidence satisfactory to the director that the address of the owner of the well of record as shown in the Department's well registry records is inaccurate and that the notice of water exchange participant made a reasonable attempt to locate the current owner of the well of record but was unable to do so.

E. At any time before a final determination under this Section, the notice of water exchange participant may agree to construct or operate the well or wells in a manner that lessens the degree of impact on wells of record or regional land subsidence. Compliance with the agreement is a condition for the use of the well to pump water for the water exchange.

Historical Note

New Section made by final rulemaking at 12 A.A.R. 2193, effective August 7, 2006 (Supp. 06-2).

R12-15-1308. Replacement Wells in Approximately the Same Location

A. For purposes of A.R.S. §§ 45-544, 45-596, and 45-597, a replacement well in approximately the same location is a proposed well to which all of the following apply:

1. The proposed well will be located no greater than 660 feet from the original well, and the location of the original well can be determined at the time the notice of intention to drill the proposed well is filed;
2. Except as provided in subsections (A)(3) and (A)(4) of this Section, the proposed well will not annually withdraw an amount of water in excess of the maximum annual capacity of the original well. The director shall determine the maximum annual capacity of the original well by multiplying the maximum pump capacity of the original well in gallons per minute by 525,600, and then converting the result into acre-feet by dividing the result by 325,851 gallons. The director shall presume that the maximum pump capacity of the original well is the maximum pump capacity of the well in gallons per minute as shown in the Department's well registry records, except that:
   a. If the director has reason to believe that the maximum pump capacity as shown in the Department's well registry records is inaccurate, or if the applicant submits evidence demonstrating that the maximum pump capacity as shown in the Department's well registry records is inaccurate, the director shall determine the maximum pump capacity by considering all available evidence, including the depth and diameter of the well and any evidence submitted by the applicant; or
   b. If the Department's well registry records do not show the maximum pump capacity of the original well, the director shall not approve the proposed well as a replacement well in approximately the same location unless the applicant demonstrates to the director's satisfaction the maximum pump capacity of the original well;
3. If a well permit was issued for the original well under A.R.S. § 45-599, the proposed well will not annually withdraw an amount of groundwater in excess of the maximum annual volume set forth in the well permit;
4. If a recovery well permit was issued for the well to be replaced pursuant to A.R.S. § 45-834.01(B) and the permit sets forth a maximum annual volume of stored water that may be recovered from the well, the proposed well will not annually recover an amount of stored water in excess of the maximum annual volume set forth in the recovery well permit;
5. If the well to be replaced has been physically abandoned in accordance with R12-15-816, a notice of intention to drill the proposed well is filed no later than 90 days after the well to be replaced was physically abandoned; and
6. If the proposed well will be used to withdraw groundwater from the Little Colorado river plateau groundwater basin for transportation away from the basin pursuant to A.R.S. § 45-544(B)(1), one of the following applies:
   a. The original well was drilled on or before January 1, 1991, or was drilled after that date pursuant to a notice of intention to drill that was on file with the Department on that date; or
   b. The director previously determined that the withdrawal of groundwater from the original well for transportation away from the Little Colorado river plateau groundwater basin complies with R12-15-1304.

B. After a replacement well in approximately the same location is drilled, the replacement well may be operated in conjunction with the original well and any other wells that replaced the original well if the total annual withdrawals from all wells do not exceed the maximum amount allowed under subsection (A)(2), (A)(3), or (A)(4) of this Section, whichever applies.

C. A proposed well may be drilled as a replacement well in approximately the same location for more than one original well if the criteria in subsections (A)(1), (A)(5), and (A)(6) of this Section are met with respect to each original well and if the total annual withdrawals from the proposed well will not exceed the combined maximum annual amounts allowed for each original well under subsections (A)(2), (A)(3), or (A)(4) of this Section, whichever apply.

D. The director may include conditions in the approval of the notice of intention to drill the replacement well to ensure that the drilling and operation of the replacement well meets the requirements of this Section.

Historical Note

New Section made by final rulemaking at 12 A.A.R. 2193, effective August 7, 2006 (Supp. 06-2).

XII. GLOSSARY

TITLE VII

RULES GOVERNING
DESIGN AND OPERATON OF DAMS
[As Restated October, 1993]

SUBTITLE I. GENERAL PROVISIONS

Section 701.1. PURPOSE.

A. Provide for the comprehensive regulation and supervision of dams for the protection of the health, safety, welfare, and property of the citizens of Arkansas.

B. Assure proper planning, design, construction, maintenance, monitoring and supervision of dams, including such preventive measures as are necessary to provide an adequate margin of safety.

Section 701.2. AUTHORITY.

Rules governing design and operation of dams within the State of Arkansas are promulgated under authority of Subchapter 2 of Chapter 22 of title 15 of the Arkansas Code of 1987.

Section 701.3. SCOPE OF REGULATIONS.

All dams within the State of Arkansas, except those owned by the United State Government or those exempted by Section 701.4, must have a valid construction and operation permit issued under the provisions of this title.

Section 701.4. EXEMPTIONS.

Dams meeting either of the following criteria are not subject to rules contained in this title, unless Section 701.5 of this title is successfully invoked.

A. Dams with height less than 25 feet.

B. Dams with normal storage less than 50 acre-feet.

C. Dams with crest elevations below the ordinary high water mark of the stream at that location.

Section 701.5. PETITION BY AFFECTED PERSONS.

Persons who believe themselves or their property to be endangered by failure of a dam which is below the size requirements specified in Section 701.4 may file a petition requesting that the Commission require permitting and compliance with dam safety regulations for that dam.

A. Commission Investigation. Upon receipt of such petition, the Executive Director shall immediately begin an investigation of the petitioner's allegations.

B. Public Hearing. As a part of the Commission's investigation, a Public Hearing shall be held within the county in which the dam is located. Notice of the hearing shall be published in a manner consistent with Section 702.8.

C. Commission Order. Upon consideration of staff findings and testimony received, the Commission shall issue an order either approving or denying the petitioner's request.

Section 701.6. DUTIES, OBLIGATIONS, AND LIABILITIES OF DAM OWNERS.

Nothing in these rules shall be construed to relieve an owner or operator of a dam or reservoir of the legal duties, obligations, or liabilities incident to ownership or operation.

Section 701.7. NO LIABILITY BY COMMISSION, EMPLOYEES, OR AGENTS.
No action shall be brought against the State or the Commission or its employees or agents for the recovery of damages caused by the partial or total failure of any dam or reservoir or through the operation of any dam or reservoir upon the grounds that the aforementioned parties are liable by virtue of any of the following:

A. The approval of the dam or reservoir, or approval of flood-handling plans during construction;

B. The issuance or enforcement of orders relative to maintenance and operation of the dam or reservoir;

C. Inspection, control and regulation of the dam or reservoir;

D. Measures taken to protect against failure during an emergency.

Section 701.8. EXCEPTIONS.
The Commission may grant exceptions to requirements contained within this title. Any variance from these rules must be supported by written approval of the Commission's Executive Director setting forth the reason for its granting and the limits placed thereon.

SUBTITLE II. PERMITS FOR DAMS

Section 702.1. CONSTRUCTION PERMIT.
A permit issued by the Commission is required prior to construction of any dam not exempted under Sections 701.3 or 701.4 of this title.

Section 702.2. OPERATION PERMIT.

A. Before water is deliberately impounded by closing drain gates on a newly constructed dam, an operation permit must be issued by the Commission. An operation permit will be issued by the Chief Engineer upon completion of final inspection and receipt of the Certificate of Substantial Compliance by the owner's engineer. (See Section 706.6).

B. An operation permit is required for all existing dams not exempted under Sections 701.3 or 701.4 of this title.

Section 702.3. TRANSFER OF PERMIT.
Within six (6) months after change of ownership of a permitted dam, the new owner shall notify the Commission. The Commission shall issue a dam permit in the name of the new owner.

Section 702.4. WATER PLAN COMPLIANCE.
Filing of an application to permit a proposed dam also serves as filing for Water Plan Compliance Certification as described in Section 602.5 of the Commission's rules. The water plan compliance process may run concurrently with the dam permit review.

Section 702.5. APPLICATION.
Applicants for dam permits must provide all applicable information requested on the form supplied by the Commission.

Section 702.6. COMMISSION REVIEW.

Upon receipt of application for dam permit, the Commission staff will review data presented to determine compliance with State law, Commission rules, and accepted engineering practices. If necessary, the staff may request additional data to insure compliance.

Section 702.7. PUBLIC NOTICE.
Upon completion of Commission review, the Executive Director will cause a Public Notice to be published two times, one week apart. The Public Notice will be placed in a newspaper having general circulation in the county in which the dam is/will be located. Information in the public notice will include: the owner's name and address, the dam's location and pertinent physical data describing the dam. In addition, the Public Notice will request that questions, comments and objections to the dam's permitting and/or requests for public hearing be forwarded in writing to the Commission for action within twenty (20) days after the second publication.

Section 702.8. PUBLIC HEARING.
If requested, the Executive Director shall cause a Public Hearing to be conducted within the county in which the dam is/will be located. Said hearing will be for the purpose of describing the proposed actions and taking testimony regarding the public view of the proposal. The Executive Director shall cause publication of a public notice describing the time, place and purpose of the Public Hearing. Copies of the public notice shall be furnished to the owner(s), complainant(s) and adjacent landowners (if known). Publication shall be in a newspaper having general circulation in the county in which the dam is/will be located. Notice shall be published twice, one week apart.

Section 702.9. COMMISSION ACTION.
A. If no Public Hearing is requested as a result of the Public Notice, the Executive Director will either approve or deny the permit request.
B. If a Public Hearing is requested as a result of the Public Notice, the Executive Director will approve or deny the permit request based upon the evidence presented.
C. Prior to issuance of the permit, a Water Plan Compliance Certification must be obtained as prescribed in Title VI of the Commission's rules, if applicable.

SUBTITLE III. FEES

Section 703.1. ESTIMATED APPLICATION REVIEW FEES.
Any application for permitting a proposed dam after March 24, 1993, shall be accompanied by a check for one percent (1%) of the estimated construction cost of the dam or $100.00, whichever is greater, except that no application review fee shall exceed $1000.00.

Section 703.2. FINAL COST REPORT.
The owner shall provide to the Commission a report of actual construction costs within forty-five (45) days after completion of construction.

Section 703.3. FINAL APPLICATION REVIEW FEES.
A. If the estimated application review fee exceeds the fee based on actual construction cost, an amount equal to the difference will be refunded.

B. If the fee based on construction cost exceeds the estimated application review fee, an amount equal to the difference will be paid to the Commission.

Section 703.4. ANNUAL PERMIT FEE.
The annual permit fee shall be computed as specified in Ark. Code Ann. §15-22-219, as may be amended from time to time.

Excerpt from Ark. Code Ann. §15-22-219:

> *Any person obtaining a permit under the provisions of §15-22-210 shall, in consideration therefor, pay to the Commission a fee equal to twelve cents (12¢ per acre-foot of water which the dam involved is designed to impound, but not less than twenty-five dollars ($25.00), nor more than ten thousand dollars ($10,000.00). The permit shall provide that the same fee shall be paid by that person to the Commission each year thereafter during which the dam is maintained, on or before the anniversary date of the issuance of the permit.*

The volume "the dam involved is designed to impound" is defined as the billing volume. (See Subtitle XII, GLOSSARY)

SUBTITLE IV. ENFORCEMENT

Section 704.1. NOTICE OF NON-EMERGENCY DEFICIENCY.
Upon discovery of a deficiency, which does not immediately threaten the dam's safety, the Chief Engineer will issue a letter specifying actions necessary to remedy the problem and requesting a schedule for implementing the required actions. Based on mutual agreement a consent order will be issued which will embody the agreed upon actions and timetable.

Section 704.2. PUBLIC HEARINGS.
In the event remedial measures for non-emergency deficiencies cannot be accomplished through the means of consent orders, the Executive Director shall cause a Public Hearing to be conducted to present the staff's proposed order and accept testimony. The hearing shall be conducted in the county in which the dam is located. Public notice of the hearing shall be provided in a manner consistent with Section 702.8 of this title.

Section 704.3. COMMISSION ORDERS.
After review of findings of the Public Hearing, the Commission may issue orders compelling specified actions.

Section 704.4. PENALTIES.
Non-compliance with commission rules or disregard of Commission orders may result in fines of up to $10,000. In general, penalties will be set by doubling the costs incurred by the Commission.

Section 704.5. EMERGENCY REMEDIAL ORDERS.
Upon discovery of a condition which renders a dam subject to rapid failure, the Executive Director may issue an Emergency Remedial Order describing actions which must be taken to protect life and property.

Failure to comply with these orders may result in penalties under Section 704.4.

Section 704.6. APPEALS.
Actions by the Commission may be appealed as described in Subtitle V of Title I, *rules of Organization and General Operation of the Arkansas Soil and Water Conservation Commission.*

SUBTITLE V. DESIGN CRITERIA

Section 705.1. GENERAL STANDARDS.
All dams must be designed in accordance with currently accepted engineering practices. Acceptable guidelines include those published and recommended by the U.S. Army Corps of Engineers; U.S. Department of Agriculture, Soil Conservation Service; U.S. Department of Interior, bureau of Reclamation; and Federal Energy Regulatory Commission.

Section 705.2. REGISTERED PROFESSIONAL ENGINEER.
Preparation of all plans and specifications, and the construction, enlargement alteration, repair or removal of dams subject to Commission review shall be under the supervision of an engineer registered in this state.

Section 705.3. SIZE CLASSIFICATION CRITERIA.
Size classification is based on the more stringent of two categories, either height of dam or maximum storage, and shall be in accordance with Table 1 of this section.

Table 1

SIZE CLASSIFICATION

SIZE	MAXIMUM STORAGE (ACRE-FEET)	HEIGHT (FEET)
Small	50 to 1000	25 to 40
Intermediate	• 1000 And < 50,000	•40 and < 100
Large	• 50,000	• 100

Section 705.4. HAZARD CLASSIFICATION CRITERIA.
All dams will be classified or reclassified as required to assure appropriate safety considerations. Hazard classification shall be based on the more stringent of either potential loss of human life or economic loss in accordance with Table 2 of this section. If doubt exists concerning classification, the more hazardous category must be selected.

NOTE: The hazard classification does not indicate the physical condition of a dam.

Table 2

HAZARD CLASSIFICATION

CATEGORY	LOSS OF HUMAN LIFE	ECONOMIC LOSS
Low	No	Minimal (No significant structures; pastures, woodland, or largely undeveloped land); less than $100,000.
Significant	No	Appreciable (Significant structures, industrial, or commercial development, or cropland); $100,000 to $500,000.
High	Yes	Excessive (Extensive public, industrial, commercial, or agricultural development); over $500,000.

NOTE: Loss of human life is based upon presence of habitable structures.

Section 705.5. SPILLWAY DESIGN FLOOD (SDF) FOR DAMS. The size and hazard classifications are combined to determine the hydrologic criteria for dams.

A. The minimum acceptable spillway design floods (SDFs) for dams are shown in Table 3.

B. The minimum hydrologic criteria may be reduced if properly prepared dam breach analyses show that dam failure during the SDF would cause an increase in flood level of one foot or less at, and downstream of, the first habitable structure or financially significant development.

Table 3

SPILLWAY DESIGN FLOOD FOR DAMS

HAZARD CLASSIFICATION		SIZE	SPILLWAY DESIGN FLOOD
Low		Small	.25 PMF
		Intermediate	.25 to .50 PMF
	*	Large	.50 to .75 PMF
Significant		Small	.25 to .50 PMF
		Intermediate	.50 to PMF
		Large	PMF
High		Small	.50 PMF to PMF
		Intermediate	PMF
		Large	PMF

NOTE: Where ranges are given in this table, the spillway design flood shall be determined by straight line interpolation, based upon the effective height of dam or maximum storage, whichever computed SDF is greater.

*SDF shall be extrapolated at the same rate of change as an intermediate size dam to a maximum of .75 PMF.

Section 705.6. DOWNSTREAM RELEASES.
Each dam constructed after the effective date of these regulations shall be equipped with a release port(s) designed to release a flow of water for instream and downstream riparian uses.

A. Minimum release quantities shall be sufficient to maintain existing instream and offstream uses and shall be defined after consideration of the best available low flow information.

B. Minimum release ports must be designed to operate without manual intervention.

Section 705.7. RESERVOIR DRAIN CONDUIT.
All proposed dams must include a permanent facility for draining the reservoir.

A. Such conduit shall have a minimum diameter of twelve (12) inches for watershed areas less than one square mile and eighteen (18) inches for watershed greater than one square mile. Such

conduits must be capable of lowering the surface of the reservoir at a rate not less than two (2) inches per day (at normal pool) while inflow to the reservoir is twice the annual average daily flow.

B. Operating equipment for the drain facility must be accessible from above the maximum design water surface, unless inlet design is such that the conduit is flowing at capacity at a lower elevation.

Section 705.8. STRUCTURAL CRITERIA.

As a minimum, the design must address the following:

A. Slope stability under all probable loading conditions.

B. Stability against sliding and overturning.

C. Adequacy of foundation for imposed loads.

D. Adequacy of energy dissipating devices at discharge points.

E. Adequacy of channels and conduits for expected flows.

F. Protection of embankments and other earth slopes from erosion.

G. Stability against seismic forces for all "High or Significant Hazard" dams in Seismic Zones 2 and 3. (See Figure 1.)

SUBTITLE VI. CONSTRUCTION REQUIREMENTS

Section 706.1. PLANS AND SPECIFICATIONS.

Written approval of plans and specifications must be obtained from the Chief Engineer prior to start of construction.

Section 706.2. CONSTRUCTION INSPECTIONS.

An agent of the design registered professional engineer must be on site during construction to ensure that techniques and materials used comply with plans and specifications.

Section 706.3. CONSTRUCTION RECORDS.

The applicant (or applicant's engineer) must retain construction records throughout the life of the dam. As a minimum, the records must include:

A. Daily log of construction activities.

B. Record of personnel and equipment on site.

C. Documentation of soil tests such as standard proctor, in-place density, and moisture.

D. Documentation of concrete cylinder tests.

E. Copies of all engineering change orders and field change notes.

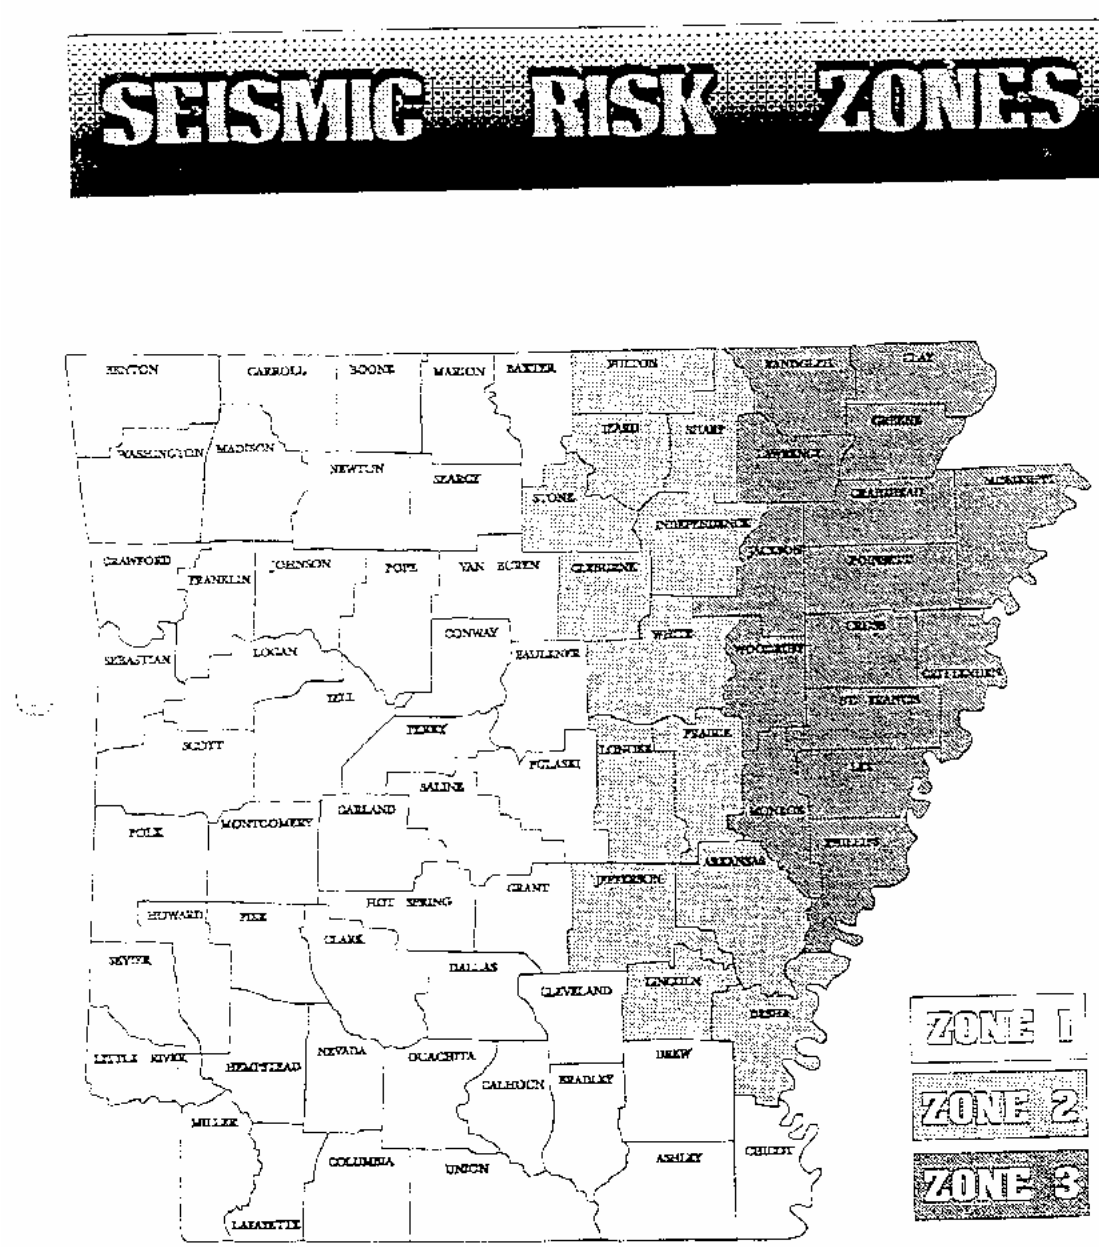

FIGURE 1

Section 706.4. EROSION PROTECTION

During construction, adequate measures must be taken to prevent excessive erosion and off site sedimentation. Suitable techniques include: temporary vegetation, mulching, staked straw bales, filter fences, and chemical stabilization. Other techniques may be sued is approved by the Chief Engineer.

Section 706.5. FINAL INSPECTION.
Upon substantial completion of construction, the owner must notify the Commission and schedule a final inspection of the work.

Section 706.6. ENGINEER'S CERTIFICATION.
Upon completion of construction, the project engineer shall file with the Commission a certificate of substantial compliance with approved plans and specifications.

Section 706.7. RECORD DRAWINGS.
Within sixty (60) days after completion of construction, the owner, or his engineer, shall submit to the Chief Engineer a complete set of record drawings of the project for filing as a permanent record with the Commission.

Section 706.8. PERMANENT REFERENCE MARKS.
Two or more permanent reference marks shall be established for future use near but not on the dam. Accurate longitude, latitude and elevation shall be shown on the record drawings. Elevations shall be referenced to the National Geodetic Vertical Datum of 1929.

SUBTITLE VII. EVALUATIONS OF EXISTING DAMS

Section 707.1. TYPES OF EVALUATIONS.

A. Spillway Design Flood. Existing dams will be evaluated periodically to determine if development of downstream areas warrants change in hazard classification and review of spillway design flood (SDF). Overtopping during the SDF may be allowed if properly prepared analyses demonstrate that: (1) overtopping will have a return interval greater than 25 years; and (2) the dam will withstand the projected overtopping without failure.

B. Structural. A complete evaluation of the structural integrity may include the following: geotechnical investigation, structural stability, seismic resistance, horizontal and vertical alignments, structural concrete reliability, erosion controls, inlet and outlet works, stilling basins, seepage, and others.

C. Operation and Maintenance. Evaluation of an existing structure shall include, but not be limited to: visual inspections and evaluations of potential problems such as leakage, seepage, cracks, slides, settlement, spillway blockages, conduit controls and other operational and maintenance deficiencies which could lead to failure of the dam. There may be sufficient evidence for a finding that an existing dam is inadequate.

Section 707.2. DEFICIENCIES.
Dams not meeting minimum acceptable standards (See Subtitle V and VIII) are deemed inadequate and therefore subject to necessary action under Subtitle IV.

Section 707.3. INTERIM ALTERNATIVES.

When the Commission considers the permanent upgrading or removal of an inadequate dam, the dam owner may request the Commission to consider interim alternatives including, but not limited to, temporary repairs, reservoir dewatering, insurance coverage, and downstream warning/evacuation plans. Consideration shall be given to the time required to overcome economic, physical and legal restraints to upgrading, the prospect of permanent repair, current use of the facility, degree of risk, and public welfare.

Section 707.4. VARIANCE.
Upon request by the owner of an existing dam which does not meet the minimum acceptable standards stated in Subtitles V and VIII of this title, the Chief engineer may authorize a variance from these criteria. The Chief Engineer's decision shall consider: (a) consequences of dam failure, (b) the owner's proposal for reduction of hazards, (c) barriers to upgrading of the structure, and (d) other pertinent factors.

SUBTITLE VIII. OPERATION AND MAINTENANCE

Section 708.1. COMPLIANCE WITH APPROVED DOCUMENTS.
Operation and maintenance must be performed in accord with documents filed by the owner or owner's engineer in obtaining the dam permit.

Section 708.2. EROSION PROTECTION.
Maintenance of adequate means to protect embankments, abutments, crests, and earthen channels from erosion is required.

Section 708.3. WOODY VEGETATION PROHIBITED: EMBANKMENT DAMS.
Growth of woody vegetation is not permitted on the spillway, crest, upstream or downstream embankments, and within twenty (20) feet of the downstream toe or groin of the dam.

A. Remediation: Trees with roots likely to extend to the crest of the dam shall be removed. Trees whose roots are unlikely to extend to the crest may remain if erosion control vegetation can be maintained and inspections can be accomplished. Trees larger than six (6) inches in diameter which are to be removed from embankments, must be removed together with roots larger than two inches. The resulting voids shall be repaired with compacted soil similar to the remaining embankment material. Smaller trees and brush, and those not on embankments may be cut and/or treated with herbicide.

B. Time for compliance: New growth must be removed before it shades out desirable vegetation generally on a two-year cycle. Where extensive tree and brush growth were established prior to adoption of these rules, a compliance schedule of up to five years may be approved provided that: (a) No evidence of significant immediate hazard is detected; (b) The compliance schedule includes a reasonable estimate for costs, and a rational procedure for accumulating necessary funds; (c) Vegetation is not so dense that effective inspections are impossible; and (d) Appropriate annual efforts are scheduled. The long-term schedule may be cancelled if evidence of immediate hazards is discovered in subsequent inspections.

Section 708.4. WOODY VEGETATION PROHIBITED; CONCRETE OR MASONRY DAMS.

No grass, vines, brush, trees or other vegetation is permitted to grow in cracks or joint of concrete or masonry structures.

A. Remediation: Vegetation shall be removed by manual, mechanical or chemical means or a combination thereof. Open cracks or joints shall be repaired by approved means.

C. Time for compliance: In the absence of conditions indicating immediate hazards, a schedule resulting in complete compliance within six months may be approved.

Section 708.5. OPERATION OF GATES AND CONTROLS.
All gates, valves and controls, must be maintained in operational condition. Operation of each such item must be tested at least annually, and such tests must be documented in the owner's permanent records. However, tests may be waived by the Chief Engineer if the design of drainage facilities and/or their condition is such that reclosing the drain would be impossible until the reservoir was substantially emptied.

Section 708.6. REPAIRS AND MODIFICATIONS.
Written approval by the Chief Engineer is required before repairs or modifications to a dam or appurtenances may be undertaken. Plans and specifications prepared by a registered professional engineer may be required for major actions.

Section 708.7. RECORDS.
Documentation of all owner's inspections, and repairs or modifications to the dam or appurtenances must be retained by the owner.

SUBTITLE IX. INSPECTION

Section 709.1. OWNER INSPECTIONS.
At least once per year and after each major storm event, the owner (or owner's agent) of all permitted dams must perform a visual inspection of the dam. Results of such inspections must be summarized on forms supplied by the Commission and mailed to the Commission office within 10 days of inspection. Commission staff may provide training or assistance in performing or interpreting inspections. Any deterioration of the dam or appurtenances must be reported to the Commission, and remedial measures undertaken after approval by the Chief Engineer.

Section 709.2. COMMISSION INSPECTIONS.
Commission personnel will periodically perform inspections of each permitted dam. Commission inspections are of three types: Maintenance and Operation; Dam Safety Evaluation; and Emergency. The frequency of inspections and evaluations will vary according to the hazard rating, size and condition of the dam. Emergency inspections will be performed when conditions warrant.

Section 709.3. ACCESS.
The owner or owner's agent must provide Commission personnel access to the dam during reasonable working hours for Commission inspections. Access during emergency conditions must be available to Commission personnel.

Section 709.4. ASSISTANCE BY OWNER.

The owner or owner's agent may be requested to provide limited assistance to Commission personnel in performing inspections. Requested assistance may include:

A. Operating gates, valves, and other controls.

B. Cutting excessive vegetation in preparation for inspections.

SUBTITLE X. EMERGENCY ACTION PLANS

Section 710.1. EMERGENCY ACTION PLANS REQUIRED.
An emergency action plan (EAP) must be prepared by the owner for all permitted high hazard dams.

Section 710.2. APPROVAL OF EMERGENCY ACTION PLANS REQUIRED.
Written approval of the Chief Engineer must be obtained for all EAPs.

Section 710.3. CONTENTS OF EMERGENCY ACTION PLANS.
Site conditions will dictate exact contents of specific EAPs. Guidelines for preparation of EAPs are available from the Commission.

Section 710.4. ANNUAL EXERCISES AND DRILLS.
Implementation of EAPs must include at least one tabletop exercise per year and one test drill every three years. The Commission's Chief Engineer must be notified at least one week in advance of either procedure.

SUBTITLE XI. REMOVAL OF DAMS

Section 711.1. APPROVAL OF PLANS REQUIRED.
Prior to removal, a plan for removal and revegetation must be approved by the Chief Engineer.

Section 711.2. NOTICE TO DOWNSTREAM LANDOWNERS.
Downstream landowners must be notified of the proposed action if any measure of flood protection would be lost due to the removal of the dam.

Section 711.3. RIGHTS OF OTHER LANDOWNERS.
Downstream landowners and those adjacent to the reservoir have the right to notice of projected changes in streamflow patterns or reservoir levels, but do not have the right to continued benefits at the dam owner's expense, unless the dam owner is contractually bound to provide such benefits.

Section 711.4. PROCEDURE FOR BREACHING.
The procedure for breaching must adequately guard against downstream flooding, erosion, and sedimentation.

Section 711.5. RESTORATION OF ORIGINAL STREAM CHANNEL.
Dimensions of the final cut through the dam must be defined in the plan and must be of sufficient size to prevent impounding water when streamflow equals the 100-year flood.

Section 711.6. EROSION PROTECTION.
The plan must provide for establishment of vegetation or other erosion protection measures sufficient to guard against deposition of excessive sediment off site.

SUBTITLE XII. GLOSSARY

Unless clearly indicated by context, the following words and terms, when used in this title, shall have meanings as defined below:

A. Billing volume - Normal storage designed to contain sediment accumulation over the life of the dam.
B. Chief Engineer - The Deputy Director/Chief Engineer of the Arkansas Soil and Water Conservation Commission.
C. Commission - The Arkansas Natural Resources Commission.
D. Construction costs - Estimated or actual material and labor costs, including excavation, embankment placement, spillways, gates, valves, and conduits. Shall not include costs of: land, reservoir clearing, engineering, water treatment facilities, or other costs not directly related to construction of the dam.
E. Dam - Any barrier, including one for flood detention, designed to impound liquid volumes. This shall not include highway, railroad or other roadway embankments, including low water crossings that may temporarily detain floodwater, levees designed to prevent inundation by floodwater, or closed dikes to temporarily impound liquids in the event of emergencies and those barriers not exempt by Sections 701.3 or 701.4 of this title.
F. Effective crest of the dam - The elevation of the lowest pint on the crest of the dam excluding spillways.
G. Executive Director - The Executive Director of the Arkansas Natural Resources Commission.
H. Height of dam - The vertical distance from the effective crest of the dam to the lowest elevation on the downstream toe of the dam.
I. Maximum storage - The volume of the impoundment created by the dam at the effective crest of the dam.
J. Minimum release - Daily quantity of water which must be released to preserve downstream riparian rights, permitted non-riparian rights or to meet instream water needs including, but not limited to those of fish and wildlife.
K. Normal storage - The volume of the impoundment created by the dam at the lowest uncontrolled spillway crest.
L. PMF (probable maximum flood) - The maximum runoff condition resulting from the most severe combination of hydrologic and meteorologic conditions that are reasonably possible for a given watershed. The PMF is the maximum runoff computed from the spatial and temporal distribution of the PMP over the watershed.
M. PMP (probable maximum precipitation) - The greatest theoretical depth of precipitation (rainfall equivalent) for a given duration that is physically possible over a given size storm area at a particular geographical location at a certain time of the year.
N. Spillway design flood (SDF) - The largest flood the spillway must pass without overtopping a dam.

E.5. California

HYDROLOGIC ANALYSIS WITHIN CALIFORNIA'S DAM SAFETY PROGRAM

By Emil R. Calzascia[1] and James A. Fitzpatrick[2]

Introduction

The topography and climate of California are extremely diverse, ranging from low elevations at the coast to the high altitudes of the Sierras, from less than 3 inches of annual rainfall in the southeast desert basins to over 120 inches on the extreme north coast. Drainage basins for dams vary in size from portions of an acre to thousands of square miles. Stream gages are sparse in most areas and are essentially nonexistent in the undeveloped areas. Accurate estimation of rare flood flows from recorded data is especially difficult due to the lack of basic site-specific flow data from which the flood producing potential of a drainage basin can be predicted. However, estimates of rare floods must be developed for all damsites to be used in evaluation of spillway capacities. To this end, precipitation records are employed in lieu of actual flow data. A method was developed by California's Division of Safety of Dams (DSOD) to estimate flood hydrographs for ungaged or poorly gaged watersheds for use in spillway evaluation.

Outline of Method

DSOD requires that all dams within its jurisdiction be capable of adequately passing a selected design flood. A method has been devised by DSOD to determine the hydrologic adequacy of any spillway in California on a rational and consistent basis (DSOD, 1981).

The procedure can be divided into eight parts:

1. Assessment of the potential downstream hazard
2. Determination of appropriate storm return period
3. Development of precipitation
4. Development of synthetic unit hydrograph parameters
5. Development of loss rate parameters
6. Computation of the flood hydrograph
7. Routing of the flood hydrograph through the reservoir
8. Evaluation of the spillway adequacy

The following discussion will, elaborate on the basic concepts underlying these procedures, but will not present detailed design formulas or criteria.

---

[1]Senior Engineer, California Department of Water Resources, Division of Safety of Dams, P.O. Box 942836, Sacramento, California 94236-0001

[2] Principal Engineer, California Department of Water Resources, Division of Safety of Dams

Hazard Assessment

The hazard classification of any given dam is determined with respect to the dam's size and to the potential downstream damage due to failure of the structure. The classification is selected from a rating system that considers (1) reservoir capacity, (2) dam height, (3) estimated number of people that would be placed in peril and need to be evacuated in anticipation of dam failure, and (4) potential downstream property damage. Each factor is categorized as low, moderate, high or extreme. The method produces a composite numerical rating termed the Total Class Weight (TCW). The form, shown in Figure 1, is used as an aid to determine the TCW. With this system, small remote dams generally have a TCW of 2, while large urban dams might have a TCW of 36. The capacity of the reservoir and height of the dam are clearly defined. Estimated evacuation and potential downstream damage are uncertain and require an investigation of the potentially flooded area. This investigation includes estimating the population at risk, the possible loss of life, the physical property damage, the social consequences and the environmental impact. Through application to the many dams under its jurisdiction, DSOD has developed a coherent and uniform approach to conducting the damage investigations so that consistent total class weights are found.

DSOD does not allow the use of Economic Risk Analysis in the selection of a design flood for spillway evaluation. It is felt that the above procedure adequately addresses the issue of risk.

DAMAGE POTENTIAL CLASSIFICATION FOR

FLOOD ESTIMATE AND SPILLWAY ANALYSIS

Name of Dam _____ Type of Dam _____Dam No. _____

County _____ Located on _____

	Damage Potential Rating			
	Extreme	High	Moderate	Low
Capacity _____ AF	100,000 & Over	1,000-99,999	100-999	15-99
(circle weight)	6	4	2	0
Height _____ Ft.	150 & Over	100-149	50-99	6-49
(circle weight)	6	4	2	0
Estimated Evacuation _____	1,000 & Over	100-999	1-99	None
(circle weight)	12	8	4	0
Potential D/S Damage	High	Moderate	Low	None
(circle weight)	12	8	4	0

Total Class Weight _____

Figure 1

Precipitation

It is prudent to a allow a continuous range of design floods corresponding to the developed Total Class Weights. The minimum allowable design event required is a 1000 year storm which corresponds with a TCW of 4. The maximum event is a storm derived from the Probable Maximum Precipitation and is equated with a TCW of 30. The design event is interpolated between these limits at the computed TCW. Typically, probable maximum precipitation storms are required only for dams that impound 1000 acre-feet or more, are at least 50 feet high, would require an estimated evacuation of at least 1000 people, and have a damage potential of $25,000,000 or greater. However, most dams require a design storm falling between the 1000 year event and the probable maximum event. Figure 2 presents a histogram of TCW (as determined by DSOD) for all jurisdictional dams within California. As can be seen, less than 8 percent of all dams require a PMF.

If the TCW is 30 or greater, the design storm is the probable maximum precipitation (PMP) as determined by Hydrometeorological Report No. 36 (U.S. Weather Bureau, 1961) or Hydrometeorological Report No. 49 (National Weather Service, 1977), depending on geographical location. The estimated rainfall is determined directly for these reports.

If the TCW is less than 30, a statistical frequency estimate of the rainfall is chosen. It is assumed that extreme precipitation follows a Pearson Type III probability distribution, with a general skew of 1.3 for northern California and 1.5 for southern California.

The equation for precipitation is:

$$P_{ij} = M_i + k_j * S_i$$
$$= (1.0 + k_j * CV_i) * M_i$$

where:

P_{ij} = extreme precipitation value
M_i = average of extreme values
S_i = standard deviation
k_j = frequency factor
CV_i = coefficient of variation

where:

subscript $_i$ denotes the event duration
subscript $_j$ denotes the return period

The appropriate coefficient of variation for the drainage basin is obtained from Bulletin 195 (DWR, 1976). This publication is a statistical compilation of observed rainfall data for both long-term and short-term durations from measuring stations throughout California. The mean rainfall values for various time durations are found from Bulletin 195 or from other available rainfall records for stations in the vicinity of the given basin. These means combined with the proper number of standard deviations give the precipitation estimates.

The number of standard deviations (k,) required for a 1000 year storm is 4.96 for northern California and 5.23 for southern California. The equivalent number of standard deviations for the PMP is obtained from a generalized contour plot relating this upper limit to geographical location. Using a nonlinear proration between these two points (k_{1000},TCW_{1000} and k_{PMP},TCW_{PMP}), the k**,** for the given TCW is obtained. The corresponding return period is computed from the probability distribution.

The rainfall depth-duration values are estimated either by the PMP procedures or the above described statistical method. After adjustment for watershed area, the results are plotted on log-log scales and smoothed if necessary to obtain the depth-duration curve.

Unit Hydrograph

Where no known reliable hydrographs exist, recourse is made to the computation of a synthetic unit hydrograph by Clark's method (Clark, 1945). Clark's unitgraph parameters are obtained from a generalized study of observed rainfall and runoff events, which related these parameters to drainage basin characteristics by regression analysis (DWR, 1971). The study is applicable to the State of California except that area south of the Tehachapi Mountain Divide and the area east of the Sierra Nevada Divide. The study was limited to drainage basins approximately 30 square miles or less in area, in recognition that approximately 80 percent of the dams under jurisdiction of the Division of Safety of Dams have drainage areas of less than this size. Most of the damsites for large reservoirs have been exploited in California, and dams that will be constructed in the future will, for the most part, be smaller in size and have relatively small drainage areas. Future dams with large drainage basins will require special investigation.

The regression equations from the generalized study relate the drainage basin characteristics of

stream length, area, elevation, and ground cover to the time of concentration (t_c) and Clark's storage coefficient (R) for development of a basin-specific unit hydrograph. The study also presents guidelines for estimating loss rate parameters.

For coastal basins south of the Tehachapi Mountains, the unitgraph and loss rate parameters are obtained by the procedure given in the U. S. Army Corps of Engineers report entitled "Generalized Standard Project Rainflood Criteria-Southern California Coastal Streams", (Hydrologic Engineering Center, 1967).

Guidelines for southeastern California have been developed in a study (Mayer, 1987) similar to that for northern California. The region is subdivided into three subareas, with regression equations presented to develop unit hydrograph and loss rate parameters.

Flood Hydrograph

The flood hydrograph is developed using the computer program HEC-1 (Hydrologic Engineering Center, 1981). The program obtains the flood hydrograph by convolution of the effective rainfall increments with Clark's unitgraph.

Rainfall increments are determined from the depth-duration curve at specified time intervals and are then arranged into a storm pattern which places the maximum value at the center of the storm duration with successively smaller values placed alternately on each side (approximating a bell-shaped distribution). In general, the total precipitation duration is taken to be 72 hours. If routing will not significantly affect the peak outflow, a shorter storm (e.g., 24 hours) can be considered since the peak inflow will be about the same in either case.

It is assumed that antecedent storms have saturated the drainage basin so that loss rates are fairly low. For each time interval, the losses from rainfall due to surface retention and infiltration are estimated by the exponential loss rate function within HEC-1. These losses are deducted from the distributed precipitation to produce excess rainfall values for each time interval. The general criteria is that the percent runoff should not be less than 70 when the mean annual precipitation (MAP) at the basin is greater than 25 inches and should not be less than 60 when the MAP is 25 inches or less.

If applicable, allowances for snowmelt, base flow in the basin, runoff from prior storms, import of water etc., are added to the storm runoff hydrograph to obtain the design flood hydrograph for the watershed.

Flood Routing Through Reservoir

The design flood hydrograph is routed through the reservoir and spillway(s) to obtain the time-history of storage elevation, spillway discharge, tailwater elevation, etc. that describe passage of the flood through the reservoir. This is essentially a process of accounting for volumes of inflow, storage, and outflow throughout the duration of the flood. It is usually assumed that the reservoir is full at the beginning of the design flood. If there are several reservoirs in the watershed, the reservoir routing is repeated from the uppermost to the most downstream reservoir, in turn.

Evaluating Spillway Capacity

New embankment dams must pass the spillway design flood with a minimum of 1.5 feet of residual freeboard above the maximum reservoir flood stage. Additional freeboard is required for severe wave conditions from wind effects. Residual freeboard requirements for new concrete dams are based on the ability of the abutments and foundation to resist damage from overpour. Existing embankment dams must pass the spillway design flood without overtopping.

Refinements and Future Enhancements

It is the policy of DSOD to continually refine the developed methodology as new data becomes available and as the state-of-the-art advances. A reevaluation of the coefficients of variation, skew factors, and the appropriate probability distribution for precipitation is presently underway.

STATUTES AND REGULATIONS

PERTAINING TO

SUPERVISION OF

DAMS AND RESERVOIRS

FOREWARD

Since August 14, 1929, the State of California has supervised dams to prevent failure, to safeguard life, and to protect property. The legislation was a result of the failure of St. Francis Dam in March of 1928. Legislation enacted in 1965 revised the Statutes to include off-stream storage reservoirs as a result of the failure of Baldwin Hills Reservoir in December 1963.

Dams and reservoirs are defined in the California Water Code Sections 6002, 6003, and 6004. Certain exemptions are included in Sections 6004 and 6025. All dams under these definitions are subject to State supervision unless they are owned and operated by the United States. A careful reading of all the California Water Code sections and the California Code of Regulations sections included herein is strongly recommended for those who are regulated by these provisions. The schedule of fees is periodically adjusted in accordance with Section 6307 of the Water Code. The current fee structure is listed on the Division website under “Fees.”

This document contains Parts 1 and 2 of Division 3, Dams and Reservoirs, of the California Water Code (Statutes), Chapter 1 of Division 2, Title 23 Waters, of the California Code of Regulations (Regulations adopted by the Department of Water Resources), and an outline of Current Practices of the Department in Supervision of Dams and Reservoirs.

NOTICE

This compendium of laws governing dams and reservoirs has been compiled by the Department of Water Resources, Division of Safety of Dams, for convenient reference only and is not represented to be the official version of the statutes or the regulations. Notes, text, and history of repealed sections are not included in this reprint.

Chapter 1. Definitions

6000. Unless the context otherwise requires, the definitions in this chapter govern the construction of this part.

6002. “Dam” means any artificial barrier, together with appurtenant works, which does or may impound or divert water, and which either (a) is or will be 25 feet or more in height from the natural bed of the stream or watercourse at the downstream toe of the barrier, as determined by the department, or from the lowest elevation of the outside limit of the barrier, as determined by the department, if it is not across a stream channel or watercourse, to the maximum possible water storage elevation or (b) has or will have an impounding capacity of 50 acre-feet or more.

6003. Any such barrier which is or will be not in excess of 6 feet in height, regardless of storage capacity, or which has or will have a storage capacity not in excess of 15 acre-feet, regardless of height, shall not be considered a dam.

6004. a) No obstruction in a canal used to raise or lower water therein or divert water therefrom, no levee, including but not limited to a levee on the bed of a natural lake the primary purpose of which levee is to control floodwaters, no railroad fill or structure, and no road or highway fill or structure, no circular tank constructed of steel or concrete, or both, no tank elevated above the ground, and no barrier which is not across a stream channel, watercourse, or natural drainage area and which has the principal purpose of impounding water for agricultural use shall be considered a dam.

b) No obstruction in the channel of astream or watercourse which is 15 feet or less in height from the lowest elevation of the obstruction and which has the single purpose of spreading water within the bed of the stream or watercourse upstream from the obstruction for percolation underground shall be considered a dam.

c) The levee of an island adjacent to tidal waters in the Sacramento-San Joaquin Delta, as defined in Section 12220, even when used to impound water, shall not be considered a dam and the impoundment shall not be considered a reservoir if the maximum possible water storage elevation of the impounded water does not

exceed four feet above mean sea level, as established by the United Stated Geological Survey 1929 datum.

d) No noncircular tank, constructed of steel or concrete, or both, that is constructed in a county of the third class by a public agency, under the supervision of a civil engineer registered in the state, that does not exceed 75 acre-feet in capacity or 30 feet in height, and no barrier that is not across a stream channel, watercourse, or natural drainage area and that has the principal use as a sewage sludge drying facility shall be considered a dam.

6004.5. "Reservoir" means any reservoir which contains or will contain the water impounded by a dam.

6005. "Owner" includes any of the following who own, control, operate, maintain, manage, or propose to construct a dam or reservoir:

(a) The State and its departments, institutions, agencies, and political subdivisions.

(b) Every municipal or quasi-municipal corporation.

(c) Every public utility.

(d) Every district.

(e) Every person.

(f) The duly authorized agents, lessees, or trustees of any of the foregoing.

(g) Receivers or trustees appointed by any court for any of the foregoing.

"Owner" does not include the United States.

6006. "Alterations", "repairs", or either of them, mean only such alterations or repairs as may affect the safety of the dam or reservoir.

6007. "Enlargement" means any change in or addition to an existing dam or reservoir, which raises or may raise the water storage elevation of the water impounded by the dam or reservoir.

6008. Water storage elevation means that elevation of water surface which could be obtained by the existing dam or reservoir, as previously operated, were there no outflow and were the reservoir full of water.

Chapter 2. General Provisions

6025. It is the intent of the Legislature by this part to provide for the regulation and supervision of dams and reservoirs exclusively by the State.

6025.5 a) Notwithstanding any other provision, subject to subdivision (b), the requirements for state regulation and supervision of safety of dams, as contained in this division, shall not be applicable to waste water treatment and storage ponds constructed as a part of a waste water control facility.

b) This section applies to those ponds specified in subdivision (a) only after the governing body of the city, county, district, or other agency which operates the waste water control facility adopts a resolution which (1) finds that the ponds have been constructed and operated to standards adequate to protect life and property, and (2) provides that the city, county, district, or other agency shall supervise and regulate the design, construction, operation, enlargement, replacement, and removal of the ponds after the effective date of the resolution.

c) This section applies only to ponds specified in subdivision (a) which (1) have a maximum height of 15 feet or less and a maximum storage capacity of 1,500 acre-feet or less, (2) have been designed by, and constructed under the supervision of, a registered civil engineer, and (3) are not across a stream channel or watercourse.

6025.6 a) An owner of a structure defined as a dam pursuant to Section 6002, but excluded from that definition pursuant to subdivision (d) of Section 6004 or otherwise exempted from the requirements of this chapter pursuant to Section 6025.5, shall comply with the requirements of Section 8589.5 of the Government Code and shall employ a civil engineer who is registered in the state to supervise the structure for the protection of life and property for the full operating life of the structure.

b) (1) The civil engineer supervising a dam pursuant to subdivision (a) shall take into consideration, in determining whether or not a dam constitutes, or would constitute, a danger to life or property, the possibility that the dam might be endangered by seepage, earth movement, or other conditions that exist, or might occur, in any area in the vicinity of the dam.

(2) If the civil engineer determines that a dam under his or her supervision constitutes, or would constitute, a danger to life

or property, the civil engineer shall notify the owner of the dam and recommend appropriate action.

c) The owner shall submit to the department the name, business address, and telephone number of each supervising civil engineer.

d) The department shall submit the information provided pursuant to subdivision (c) to the Office of Emergency Services on or before January 1, 1995, and on or before each January 1 thereafter. Any change in the information shall be submitted to the department on or before July 1 of each year.

6026. No city or county has authority, by ordinance enacted by the legislative body thereof or adopted by the people under the initiative power, or otherwise, to regulate, supervise, or provide for the regulation or supervision of any dams or reservoirs in this state, or the construction, maintenance, or operation thereof, nor to limit the size of any dam or reservoir or the amount of water which may be stored therein. This part shall not prevent a city or county from adopting ordinances regulating, supervising, or providing for the regulation or supervision of dams and reservoirs that (a) are not within the state's jurisdiction, or (b) are not subject to regulation by another public agency or body.

6027. Whenever supervision of safety of design or construction of a proposed or existing dam or reservoir is exercised by the United States or any of its agencies pursuant to a jurisdiction superior to that of the state, and the requirements made under authority of such jurisdiction are so contradictory with requirements made by the department under this part that a compliance cannot be made which will meet both federal and state requirements, then the state requirements shall be modified by the department sufficiently to make possible compliance with both federal and state requirements.

6028. No action shall be brought against the state or the department or its agents or employees for the recovery of damages caused by the partial or total failure of any dam or reservoir or through the operation of any dam or reservoir upon the ground that such defendant is liable by virtue of any of the following:

(a) The approval of the dam or reservoir.

(b) The issuance or enforcement of orders relative to maintenance or operation of the dam or reservoir.

(c) Control and regulation of the dam or reservoir.

(d) Measures taken to protect against failure during an emergency.

6029. Nothing in this part shall be construed to relieve an owner or operator of a dam or reservoir of the legal duties, obligations, or liabilities incident to the ownership or operation of the dam or reservoir.

6030. The findings and orders of the department and the certificate of approval of any dam or reservoir issued by the department are final and conclusive and binding upon all state agencies, regulatory or otherwise, as to the safety of design, construction, maintenance, and operation of any dam or reservoir.

6031. Nothing in this part shall be construed to deprive any owner of such recourse to the courts as he may be entitled to under the laws of this State.

Chapter 3. Administrative Provisions

6052. The department shall employ such clerical, engineering, and other assistants as are necessary for carrying on the work of dam and reservoir supervision in accordance with this part.

6053. The department may employ consultants.

6054. When the safety and technical considerations pertaining to a certificate of approval, dam, reservoir, or plans and specifications require it, or when requested in writing to do so by the owner, the department shall appoint a consulting board of two or more consultants to report to the department on the safety features involved.

6055. The cost and expense of a consulting board if appointed on the request of an owner shall be paid by the owner.

6056. The department shall retain a board of three consultants who shall make an independent report to the director upon the issuance, modification, or renewal of any certificate of approval for any dam owned by the department.

Chapter 4. Powers of the Department

Article 1. Powers in General

6075. The department, under the police power of the state, shall supervise the construction, enlargement, alteration, repair, maintenance, operation, and removal of dams and reservoirs for the protection of life and property as provided in this part.

6076. All dams and reservoirs in the state are under the jurisdiction of the department.

6077. It is unlawful to construct, enlarge, repair, alter, remove, maintain, or operate any dam or reservoir except upon approval of the department as provided in this part.

6078. The department shall adopt and revise from time to time such rules and regulations and issue such general orders as may be necessary for carrying out, but not inconsistent with, the provisions of this part.

6079. In carrying out the provisions of this part the department may cooperate with the United States or any of its agencies.

6080. In making any investigations or inspections required or authorized by this part the department or its representatives may enter upon private property as may be necessary.

6081. In determining whether or not a dam or reservoir or proposed dam or reservoir constitutes or would constitute a danger to life or property, the department shall take into consideration the possibility that the dam or reservoir might be endangered by seepage, earth movement, or other conditions which exist or which might occur in any area in the vicinity of the dam or reservoir. Whenever the department deems that any such condition endangers a dam or reservoir, it shall order the owner to take such action as the department determines to be necessary to remove the resultant danger to life and property.

Article 2. Maintenance and Operation

6100. Supervision over the maintenance and operation of dams and reservoirs insofar as necessary to safeguard life and property from injury by reason of the failure thereof is vested in the department.

6101. The department may require owners to keep records of, and to report on, maintenance, operation, staffing, and engineering and geologic investigations and shall issue such rules and regulations and orders as necessary to secure maintenance and operation and to require staffing and engineering and geologic investigations which will safeguard life and property. In addition, the owner of a dam or reservoir or his agent shall fully and promptly advise the department of any sudden or unprecedented flood or unusual or alarming circumstance or occurrence affecting the dam or reservoir.

6102. The department, from time to time, shall make inspections of dams and reservoirs at state expense for the purpose of determining their safety but shall require owners to perform at their expense such work as necessary to disclose information sufficient to enable the department to determine conditions of dams and reservoirs in regard to their safety and to perform at their expense other work necessary to secure maintenance and operation which will safeguard life and property.

Article 3. Emergency Work

6110. The department shall immediately employ any remedial means necessary to protect life and property if either:

(a) The condition of any dam or reservoir is so dangerous to the safety of life or property as not to permit time for the issuance and enforcement of an order relative to maintenance or operation.

(b) Passing or imminent floods threaten the safety of any dam or reservoir.

6111. In applying the remedial means provided for in this article, the department may in emergency do any of the following:

(a) Lower the water level by releasing water from the reservoir.

(b) Completely empty the reservoir.

(c) Take such other steps as may be essential to safeguard life and property.

6112. The department shall continue in full charge and control of such dam or reservoir, or both, and its appurtenances until they are rendered safe or the emergency occasioning the action has ceased.

6113. The cost and expenses of the remedial means provided in this article, including cost of any work done to render a dam or reservoir of its appurtenances safe, shall be recoverable by the state from the owner by action brought by the department in the superior court of the county wherein the dam or reservoir or any part thereof is situated.

Article 4. Investigations and Studies

6120. For the purpose of enabling it to make decisions as compatible with economy and public safety as possible the department

shall make or cause to be made such investigations and shall gather or cause to be gathered such data as may be needed for a proper review and study of the various features of the design and construction of dams, reservoirs, and appurtenances.

6121. The department shall also make or cause to be made such watershed investigations and studies as may facilitate its decisions.

Article 5. Action and Procedure To Restrain Violations

6150. The department may commence an action or proceeding under this article, either by mandamus or injunction, for the purpose of stopping or preventing violations or threatened violations.

6151. An action or proceeding under this article may be commenced whenever any owner or any person acting as a director, officer, agent, or employee of any owner, or any contractor or agent or employee of such contractor is:

(a) Failing or omitting or about to fail or omit to do anything required of him by this part or by any approval, order, rule, regulation, or requirement of the department under the authority of this part; or

(b) Doing or permitting anything or about to do or permit anything to be done in violation of or contrary to this part or any approval, order, rule, regulation, or requirement of the department under this part.

6152. Any action or proceeding under this article shall be commenced in the superior court in and for the county in which (a) the cause or some part thereof arose, (b) the owner or person complained of has its principal place of business or (c) the person complained of resides.

6153. Any action or proceeding under this article shall be brought by petition in the superior court, alleging the violation or threatened violation complained of, and praying for appropriate relief by way of mandamus or injunction.

6154. The court shall specify a time, not exceeding 20 days after the service of the copy of the petition, within which the owner or person complained of shall answer the petition, and in the meantime the owner or person may be restrained.

6155. In case of default in answer or after answer the court shall immediately inquire into the facts and circumstances of the case.

6156. The court may join such parties as it deems necessary or proper in order to make its judgment, order, or writ effective.

6157. The final judgment in such action or proceeding shall either dismiss the action or proceeding or direct that the writ of mandamus or injunction issue or be made permanent as prayed for in the petition, or in such modified or other form as will afford appropriate relief.

Chapter 5. Applications

Article 1. New Dams and Reservoirs or Enlargements of Dams and Reservoirs

6200. Construction of any new dam or reservoir or the enlargement of any dam or reservoir shall not be commenced until the owner has applied for and obtained from the department written approval of plans and specifications.

6201. A separate application for each dam or reservoir shall be filed with the department upon forms to be provided by it, except that only one application need be filed for a dam and the reservoir which will contain the water impounded by the dam.

6202. The application shall give the following information:

(a) The name and address of the owner.

(b) The location, type, size, and height of the proposed dam or reservoir and appurtenant works.

(c) The storage capacity of the reservoir.

(d) Such other pertinent information as the department requires.

(e) As accurately as may be readily obtained,the area of the drainage basin, rainfall and streamflow records and floodflow records and estimates.

6203. The department may also require the following:

(a) Data concerning subsoil and foundation conditions and the materials entering into construction of the dam or reservoir.

(b) Investigations of, and reports on, subsurface conditions, involving such matters as exploratory pits, trenches and adits, drilling, coring, geophysical surveys, tests to determine leakage rates, and physical tests to measure in place the properties and behavior of foundation materials at the dam or reservoir site.

(c) Investigations of, and reports on, the geology of the dam or reservoir site and its vicinity, possible geologic hazards, availability and quality of construction materials, and other pertinent features.

(d) Such other appropriate information as may be necessary in a given instance.

6204. In instances wherein the physical conditions involved and the size of the dam or reservoir are such as to render the above requirements as to drainage areas, rainfall, streamflow, floodflow, and drilling or prospecting of site unnecessary, the department may waive the requirements.

6205. The application shall set forth the purpose for which the impounded or diverted water is to be used.

6206. The application shall be accompanied by maps and plans and specifications of such character and size and setting forth such pertinent details and dimensions as the department requires.

The maps and plans and specifications shall be a part of the application.

Article 2. Repairs, Alterations or Removals

6225. Before commencing the repair, alteration, or removal of a dam or reservoir, including the alteration or removal of a dam or reservoir so that it no longer constitutes a dam or reservoir as defined in this part, the owner shall secure the written approval of the department, except as provided in this article.

6226. The application shall give such pertinent information or data concerning the dam or reservoir, or both, as may be required by the department and such information as to other matters appropriate to a thorough consideration of the safety of such a change as may be required by the department.

6227. The application shall state the proposed time of commencement and of completion of construction.

6228. The application shall give the name and address of applicant, shall adequately detail, with appropriate references to the existing dam or reservoir, the changes which it is proposed to effect, and shall be accompanied by maps and plans and specifications which shall be a part of the application and which shall be of such character and size and set forth such pertinent details and dimensions as the department may require. The department may waive any of the requirements of this section if found by it unnecessary.

6229. In case of an emergency where repairs are necessary to safeguard life and property, repairs may be started immediately, but the department shall be notified at once of proposed repairs and of work under way.

6230. The proposed repairs and work shall be made to conform to such orders as the department issues.

Article 3. Dams Constructed Prior to August 14, 1929

6250. Unless application for approval of the dam has heretofore been made, every owner of a dam completed prior to August 14, 1929 shall, immediately after the effective date of this part, file an application for the approval of such dam.

6251. A separate application shall be made for each dam and shall be filed with the department upon forms to be supplied by it and shall supply such appropriate information concerning the dam as the department requires.

6252. The department shall give notice to file to owners who have failed to do so as required by this article, and a failure to file within 30 days after such notice shall be punishable as provided in this part.

6253. The notice provided for in this article may be given by registered mail and a return receipt signed by the owner shall constitute prima facie evidence of service.

Article 4. Approval of Applications

6260. Upon receipt of any application other than an application provided for in Article 3 of this chapter the department shall give its consideration thereto and shall approve or disapprove the same within the time provided in this article.

6261. A defective application made in a bona fide attempt to conform to the law and rules and regulations of the department shall not be rejected but notice of defect shall be sent to the applicant by ordinary and registered mail.

6262. If within 30 days of the date of mailing the notice the applicant does not file an amended and perfected application, the application shall be rejected and canceled unless for good cause shown the department allows the applicant further time.

6263. No application shall be approved in less than 10 days from its receipt but all applications shall be approved or disapproved as soon as practicable after the receipt of all data and information found necessary by the department.

6264. Approvals may be granted under terms, conditions, and limitations necessary to safeguard life and property.

6265. Actual construction shall be commenced within one year after date of approval, otherwise the approval becomes void.

6266. The department may, upon written application and for good cause shown, extend the time for commencing construction.

6267. Notice shall be given to the department at least 10 days before construction is to be commenced and such other notices shall be given to the department as it may require.

Chapter 6. Fees

6300. (a) The application for a new dam or reservoir or enlargement shall set forth the estimated cost, as defined in this article, of the dam or reservoir or enlargement and shall be accompanied by a filing fee based upon the estimated cost and according to the following schedule:

(1) For the first three hundred thousand dollars ($300,000), a fee of 3 percent of the estimated cost.

(2) For the next seven hundred thousand dollars ($700,000), a fee of 2 percent.

(3) For the next one million dollars ($1,000,000) a fee of 1 ½ percent.

(4) For the next one million dollars ($1,000,000), a fee of 1 ¼ percent.

(5) For the next two million dollars ($2,000,000), a fee of 1 percent.

(6) For the next two million dollars ($2,000,000), a fee of three-fourths of 1 percent.

(7) For all costs in excess of seven million dollars ($7,000,000), a fee of one-half of 1 percent.

(b) In no case, however, shall the minimum fee be less than three hundred dollars ($300).

6301. One filing fee only shall be collected for an enlargement to be effected by flashboards, sandbags, earthen levees, gates, or other works, devices, or obstructions which are, from time to time, to be removed and replaced or opened and shut and thereby operated so as to vary the surface elevation of the impounded water.

6302. For the purposes of this part, the estimated cost of the dam or reservoir or enlargement involved shall include the following:

(a) The cost of all labor and materials entering into the construction of the dam and appurtenant works or reservoir.

(b) The cost of preliminary investigations and surveys.

(c) The cost of the construction plant properly chargeable to the cost of the dam or reservoir.

(d) Any and all other items entering directly into the cost of the dam or reservoir.

6303. The costs of right-of-way, detached powerhouses, electrical generating machinery, and roads and railroads affording access to the dam or reservoir shall not be included among the items used in the determination of cost.

6304. An application shall not be considered by the department until the filing fee is received.

6305. In the event the actual cost exceeds the estimated cost by more than 15 percent, a further fee shall be required by the department before final approval and shall be 115 percent of the amount by which the original fee is less than it would have been had the cost it was based upon been the same as the actual cost. No further fee shall be required, however if such fee is to be computed at less than twenty dollars ($20).

6306. Applications for dams found by the department to have been less than 90 percent constructed on August 14, 1929, shall be accompanied by fees as much
less than provided for dams commenced after that date as the percentage of construction found by the department to have been completed on that date.

6307. (a) (1) The department shall adopt, by regulation, a schedule of fees to cover the department's costs in carrying out the supervision of dam safety.

(2) The revenue generated by the fees imposed under this section shall be adjusted periodically for cost-of-living increases. If the director determines that the revenue collected during the preceding fiscal year was greater or less than the cost to operate the program, the director shall adjust the fees to compensate for the overcollection or undercollection of revenue. The department shall provide a schedule of fees to the Legislature and to every dam owner that has a permit or has applied for a permit, when any adjustment is made to the fees under this section.

(b) (1) An annual fee shall be paid on or before January 31, 2004, July 1, 2004, and on or before July 1 of each succeeding year, based upon a fixed rate and height of the dam, including all enlargements thereto, substantially completed by or in operation on June 30, 2003, and on June 30 of each succeeding year. The fees collected on December 31, 2003, will be credited toward the fees due January 31, 2004. The annual fee shall be four hundred dollars ($400) per dam, plus one hundred ten dollars ($110) per foot of height. This fee shall be periodically adjusted, as described in subdivision (a).

(2) A penalty plus interest, as set forth in Section 6428 of the Water Code, shall be imposed for fees received after July 1 in any year, except that for the year 2003, the penalty plus interest shall be imposed for any fees received after January 31, 2004.

(c) For the purposes of this section, “height of the dam” means the vertical distance, to the nearest foot, from the natural bed of the stream or watercourse at the downstream toe of the barrier, as determined by the department, or from the lowest elevation of the outside limit of the barrier, as determined by the department, if it is not across a stream channel or watercourse, to the maximum possible water storage elevation.

(d) Notwithstanding subdivision (b), the department shall limit the total annual fee per dam to not more than seventy-five ($75) if both of the following apply:

(1) The dam has a storage capacity of not more than 100 acre-feet.

(2) The governing body of a private school or the governing board of a public school certifies that the dam is used as a subject of study by its students.

(e)(1) Notwithstanding subdivision (b), the department shall limit the total annual fee for dams or reservoirs located on farms or ranch properties to one hundred fifty dollars ($150) per dam, and sixteen dollars ($16) per foot of height.

(2) For purposes of this subdivision, “farm” has the same meaning as defined in Section 52262 of the Food and Agricultural Code.

(f)(1) Privately owned dams with less than 100 acre-feet of storage capacity shall be assessed an annual fee in accordance with paragraph (1) of subdivision (e).

(2) As used in this subdivision, “privately owned” does not include dams owned by municipalities, water districts or companies, irrigation districts, private, investor owned or publicly owned utilities, or public agencies.

6308. All fees, penalties, interest, fines, or charges collected by the department under this division shall be deposited in the Dam Safety Fund, which is hereby established in the State Treasury. The money in that fund shall be available to the department, upon appropriation by the Legislature, for the administration of the dam safety program.

6309. The fees provided for in this chapter shall be required of any “owner”, as defined in Section 6005.

Chapter 7. Inspection and Approval

Article 1. New or Enlarged Dams and Reservoir

6350. Immediately upon completion of a new dam or reservoir or enlargement of a dam or reservoir, the owner shall give a notice of completion to the department and as soon thereafter as possible shall file with the department supplementary drawings or descriptive matter showing or describing the dam or reservoir as actually constructed, including the following:

(a) A record of all grout holes and grouting.

(b) A record of permanent location points and bench marks.

(c) A record of tests of concrete or other material used in the construction of the dam or reservoir.

(d) Any other items which may be of permanent value and have a bearing on the safety and permanency of the dam or reservoir.

6351. In connection with the enlargement of a dam or reservoir, the supplementary drawings and descriptive matter need apply only to the new work.

6352. As soon as possible after giving notice of completion, the owner shall file an affidavit with the department stating the actual cost of the dam or reservoir in such detail as the department requires to determine whether a further fee is due. In the event the owner of a new or enlarged dam or reservoir, because of loss of records, recent change of ownership, or other causes beyond his control, is unable to report the actual cost of construction or enlargement, he shall file an affidavit to this effect, stating the reasons therefore, within 30 days after receiving a written request therefore from the department. The department shall then make its own appraisal of the cost of construction or enlargement and determine what further fee, if any, is required. Upon making a determination that a further fee is required, the department shall notify the owner by certified mail of the amount of such fee within 15 days and shall notify the owner that he may appear within 60 days thereafter before an authorized representative of the department to protest the amount of the fee, in whole or in part, determined by the department to be required, and the sufficiency of the appraisal upon which such determination was based.

6354. As soon as practicable the completed dam or reservoir shall be inspected by the department.

6355. A certificate of approval shall be issued upon a finding that the dam or reservoir is safe to impound water within the limitations prescribed in the certificate. Upon written request by an owner for a certificate of approval, the department shall issue the certificate if it finds that the dam or reservoir is safe to impound water within the limitations prescribed in the certificate. Pending issuance of a certificate of approval by the department, the owner of the dam or reservoir shall not, through action or inaction, cause the dam or reservoir to impound water.

Article 1.5. Certificates of Approval

6357. Each certificate of approval issued by the department under this part may contain such terms and conditions as the department may prescribe.

6357.1 The department may revoke any certificate of approval whenever it determines that the dam or reservoir constitutes a danger to life and property. Whenever it deems such action necessary to safeguard life and property, the department may also amend the terms and conditions of any such certificate by issuing a new certificate containing the revised terms and conditions.

6357.2 The owner of a dam or reservoir for which a certificate of approval has been issued shall not, through action or inaction, cause the dam or reservoir to impound water after the certificate terminates unless a new certificate is issued for the dam or reservoir. A new certificate shall be issued upon a finding by the department that the dam or reservoir is safe to impound water within the limits prescribed in the certificate.

6357.3 With respect to each certificate of approval or written consent for use of a dam which has been issued by the department or a predecessor of the department and which is in effect prior to the effective date of this article, the department shall, within one year from such effective date, issue a new certificate of approval, which shall supersede the previous certificate or written consent for use, or shall revoke the existing certificate or written consent for use if it finds that the dam or reservoir is not safe to impound water.

6357.4 Before any certificate of approval is revoked by the department, the department shall hold a hearing. Written notice of the time and place of the hearing shall be mailed, at least 20 days prior to the date set for the hearing, to the holder of the certificate. Any interested persons may appear at the hearing and

present their views and objections to the proposed action. Any petition for a writ of mandate to inquire into the validity of action of the department revoking a certificate of approval shall be commenced within 30 days after service of notice of the revocation on the holder of the certificate.

Article 2. Repaired or Altered Dams and Reservoirs

6360. Immediately upon completion of the repair or alteration of any dam or reservoir, the owner shall give notice of completion to the department and as soon thereafter as possible shall file with it supplementary drawings or descriptive matter showing or describing the dam or reservoir as actually repaired or altered together with such maps, data, records, and information pertaining to the dam or reservoir as repaired or altered as the department requires.

6362. As soon as practicable the dam or reservoir as repaired or altered shall be inspected by the department.

6363. A certificate of approval shall be issued upon a finding that the dam or reservoir is safe to impound water within the limitations prescribed in the certificate. Pending issuance of a new certificate of approval, the owner of the dam or reservoir shall not, through action or inaction, cause the dam or reservoir to impound water beyond the limitations prescribed in the existing certificate.

6364. The certificate of approval shall supersede any previous certificate of approval issued for the dam or reservoir so repaired or altered.

Article 3. Removal of Dams and Reservoirs

6370. Upon completion of the removal of a dam or reservoir such evidence as to the manner in which the work was performed and as to the conditions obtaining after the removal as the department requires shall be filed with the department.

6371. This evidence shall show that a sufficient portion of the dam has been removed to permit the safe passage of floods down the watercourse across which the dam was located.

6372. Before final approval of the removal of a dam or reservoir is issued, the department shall inspect the work and determine that all danger to life and property has been eliminated.

Article 4. Dams Completed Prior to August 14, 1929

6380. The department shall make inspections at State expense of all dams in the State completed prior to August 14, 1929.

6381. The department shall require owners to perform at their expense such work or tests as necessary to disclose information sufficient to enable the department to determine whether to issue certificates of approval or to issue orders directing further work at the owners' expense necessary to safeguard life and property.

6382. If, upon inspection or upon completion to the satisfaction of the department of all work that may be ordered, the department finds that the dam is safe to the full extent for which use is or will be made, a certificate of approval shall be issued.

Article 5. Complaints as to Unsafe Conditions

6390. Upon receipt of a written complaint alleging that the person or property of the complainant is endangered by the construction, maintenance, or operation of any dam or reservoir the department shall cause an inspection to be made unless the data, records, and inspection reports on file with it are found adequate to enable a determination whether or not the complaint is meritorious.

6391. If the complainant insists upon an inspection and deposits with the department a sum estimated by it to be sufficient to cover costs of an inspection, the department shall cause an inspection to be made despite its finding as to the sufficiency of its records to determine the alleged danger.

6392. If it is found that an unsafe condition exists, the department shall take such action as is necessary to render or cause the condition to be rendered safe and any money deposited to secure an inspection shall be returned.

6393. If, after an inspection is made on account of a complaint, the complaint is found by the department to have been without merit, any money deposited therefore shall be payable into the State Treasury.

Article 6. Inspection During Progress of Work

6400. During the construction, enlargement, repair, alteration, or removal of any dam or reservoir the department shall make continuous or periodical inspections at state expense for the purpose

of securing conformity with the approved plans and specifications but shall require the owner to perform at his expense such work or tests as necessary to disclose information sufficient to enable the department to determine that conformity with the approved plans and specifications is being secured.

6401. If, after any inspections, investigations, or examinations, or at any time as the work progresses, or at any time prior to issuance of a certificate of approval it is found by the department that amendments, modifications, or changes are necessary to insure safety, the department may order the owner to revise the plans and specifications.

6402. If conditions are revealed which will not permit the construction of a safe dam or reservoir the approval may be revoked.

6403. In the event that conditions imposed may be waived or made less burdensome without sacrificing a proper margin of safety, the department may authorize an owner to revise the plans and specifications accordingly.

6404. If at any time during construction, enlargement, repair, or alterations of any dam or reservoir the department finds that the work is not being done in accordance with the provisions of the approval and the approved plans and specifications or in accordance with the approval and revised plans and specifications, it shall give a written notice and order by registered mail or by personal service to the owner.

6405. The notice and order shall state the particulars in which the approval and approved plans and specifications or the approval and approved plans and specifications as revised are not being or have not been complied with shall order the immediate compliance with the approval and approved plans and specifications or with the approval and approved revised plans and specifications as the case may be.

6406. The department may order that no further work be done until such compliance has been effected and approved by the department.

6407. A failure to comply with the approval and approved plans and specifications as originally approved or as revised shall render the approval subject to
revocation by the department, if compliance is not made in accordance therewith after notice and order from the department as provided in this article.

Chapter 8. Offenses and Punishment

6425. Every person who violates any of the provisions of this part or of any approval, order, rule, regulation, or requirement of the department is guilty of a misdemeanor and punishable by a fine of not more than two thousand dollars ($2,000) or by imprisonment in the county jail not exceeding six months, or both. In the event of a continuing violation each day that the violation continues constitutes a separate and distinct offense.

6426. Any person who willfully obstructs, hinders, or prevents the department or its agents or employees from performing the duties imposed by this part or who willfully resists the exercise of the control and supervision conferred by this part upon the department or its agents or employees is guilty of a misdemeanor and punishable as provided in this article.

6427. Any owner or any person acting as a director, officer, agent, or employee of an owner, or any contractor or agent or employee of a contractor who engages in the construction, enlargement, repair, alteration, maintenance, or removal of any dam or reservoir, who knowingly does work or permits work to be executed on the dam or reservoir without an approval or in violation of or contrary to any approval as provided for in this part, or any inspector, agent, or employee of the department who has knowledge of such work being done and who fails to immediately notify the department thereof is guilty of a misdemeanor and punishable as provided in this article.

6428. Any owner who fails to pay any annual fee or any part of any annual fee required to be paid pursuant to Section 6307 within the time required shall pay a penalty of 10 percent of the annual fee or part of the annual fee, plus interest at the rate of one-half of 1 percent per month, or fraction thereof, from the date on which the annual fee or the part of the annual fee became due and payable to the state until the date of payment.

Chapter 9. Dams Under Construction Prior to August 14, 1929

6450. Any dam which the department finds was not 90 percent constructed on August 14, 1929 shall be subject to the same provisions as a dam commenced after that date.

6451. Construction work on such a dam may proceed, if an application for approval thereof is filed, until an order from the department is received approving the dam or specifying how its construction must be made or altered to render it safe. After

receipt of an order directing the construction of such a dam, work thereafter must be in accordance with the order.

6452. Dams found to be 90 percent or more constructed on August 14, 1929, shall be subject to the same supervision as dams which were completed prior to that date.

Chapter 10. Dams and Reservoirs Under State Supervision Through1965 Revisions of Part 1

Article 1. Dams and Reservoirs Completed Before 1965 Revisions

6455. Every owner of a dam or reservoir that falls within the definition of a dam or reservoir in this part by virtue of the amendment of Section 6002 or the addition of Section 6004.5 at the 1965 Regular Session of the Legislature and that was completed prior to September 17, 1965, shall immediately file an application with the department for the approval of such dam or reservoir; provided that this Chapter 10 shall not apply to any reservoir which contains the water impounded by a dam for which a certificate of approval is in effect on September 17, 1965.

6456. A separate application shall be made for each dam or reservoir and shall be filed with the department upon forms to be supplied by it and shall include or be accompanied by such appropriate information concerning the dam or reservoir as the department requires.

6457. The department shall give notice to file an application to owners of such dams or reservoirs who have failed to do so as required by this article, and a failure to file within 30 days after such notice shall be punishable as provided in this part.

6458. The notice provided for in this article may be given by registered or certified mail and a return receipt signed by the owner shall constitute prima facie evidence of service.

6459. The department shall make inspections of such dams or reservoirs at state expense.

6460. The department shall require owners of such dams or reservoirs to perform at their expense such work or tests as necessary to disclose information sufficient to enable the department to determine whether to issue certificates of approval or to issue orders directing further work at the owner’s expense necessary to safeguard life and property. For this purpose, the department may

require an owner to lower the water level of, or to empty, the reservoir.

6461. If, upon inspection or upon completion to the satisfaction of the department of all work that may be ordered, the department finds that the dam or reservoir is safe to impound water, a certificate of approval shall be issued. The owner of the dam or reservoir shall not, through action or inaction, cause the dam or reservoir to impound water following receipt by the owner of a written notice from the department that a certificate will not be issued because the dam or reservoir will not safely impound water. Before such notice is given by the department, the department shall hold a hearing. Written notice of the time and place of the hearing shall be mailed, at least 20 days prior to the date set for the hearing, to the owner of the dam or reservoir. Any interested persons may appear at the hearing and present their views and objections to the proposed action. Any petition for a writ of mandate to inquire into the validity of the action of the department shall be commenced within 30 days after receipt by the owner of a written notice from the department that a certificate of approval will not be issued.

Article 2. Dams and Reservoirs Under Construction Before 1965 Revisions

6465. Any dam or reservoir that falls within the definition of a dam or reservoir in this part by virtue of the amendment of Section 6002 or the addition of Section 6004.5 at the 1965 Regular Session of the Legislature and which the department finds was under construction and not 90 percent constructed on September 17, 1965, shall, except as provided in Section 6466, be subject to the same provisions in this part as a dam or reservoir commenced after that date. Every owner of such a dam or reservoir shall file an application with the department for the department's written approval of the plans and specifications of the dam or reservoir. Where an application for approval of the plans and specifications for a dam is pending before the department on September 17, 1965, such application shall be deemed to also constitute an application for approval of the plans and specifications of the reservoir which will contain the water impounded by the dam.

6466. Construction work on such a dam or reservoir may proceed, provided an application for approval of the plans and specifications therefore is filed, until a certificate of approval is received by the owner from the department approving the dam or reservoir or an order is received by the owner from the department specifying how the construction must be performed to render the dam or reservoir safe. After receipt of an order specifying how construction of a dam or

reservoir must be performed, work thereafter must be in accordance with the order.

6467. Such dams or reservoirs as are 90 percent or more constructed on September 17, 1965, shall be subject to the same supervision as dams or reservoirs which were completed prior thereto.

Article 3. Fees for Dams or Reservoirs Under Construction Before 1965 Revisions

6470. The owners of completed dams or reservoirs and dams or reservoirs that are 90 percent or more constructed that are made subject to the provisions of this part by the amendment of Section 6002 or the addition of Section 6004.5 at the 1965 Regular Session of the Legislature shall not be required to pay a fee in relation to applications filed with the department for approval of their dams or reservoirs. Applications for the approval of dams or reservoirs that are made subject to this part by said amendment or addition that are found by the department to have been less than 90 percent constructed on September 17, 1965, shall be accompanied by fees as much less than provided for dams or reservoirs commenced after that date as the percentage of construction found by the department to have been completed on that date.

PART 2. FISHWAYS OVER DAMS

6500. Whenever an application for approval of plans and specifications for a new dam, or for the enlargement of any dam, in any stream in this State, is filed pursuant to Part 1 of this division, a copy of the application shall be filed with the Fish and Game Commission as required by the Fish and Game Code.

6501. The provisions for the installation of fishways over or around dams and for the protection and preservation of fish in streams obstructed by dams are contained in Chapter 3 (commencing with Section 5900), Part 1, Division 6 of the Fish and Game Code.

CALIFORNIA CODE OF REGULATIONS

Title 23. Waters

Division 2. Department of Water Resources

Chapter 1. Dams and Reservoirs

Article 1. General Provisions

301. Definitions.

As used in this subchapter, the terms “dam”, “reservoir”, “owner”, “alteration”, enlargement”, and “water storage elevation” shall have the meanings given in Sections 6002 and 6004.5 through 6008 of the Water Code.

NOTE: Authority cited: Section 6078, Water Code. Reference: Sections 6002-6008, Water Code.

302. Purpose and Effect of Regulations.

The regulations in this subchapter are not intended to limit the authority of the department to act under the police power of the state to the extent authorized by law, when necessary to protect life and property from a dam or reservoir which constitutes, or which may constitute a danger to life and property, and they shall not be interpreted as depriving the department of such authority.

NOTE: Authority cited: Section 6078, Water Code. Reference: Sections 6075, 6081, and 6110, Water Code.

303. Evidence of Water Rights.

(a) The department will not issue a written approval to commence construction or enlargement of a dam or reservoir until the applicant or owner demonstrates evidence of adequate water rights in accordance with the requirements of this section.

(b) The applicant or owner shall provide the department with either:

(1) A copy of an entitlement to the use of water issued by the State Water Resources Control Board pursuant to Division 2, Part 2 (commencing with Section 1200) of the Water Code; or

(2) If the right to divert or use water does not depend on an entitlement identified in subsection (1) above, a statement of the legal basis of the right.

(c) The applicant or owner shall also provide the department with either:

(1) Evidence that a statement of water diversion and use has been filed with the State Water Resources Control Board pursuant to Division 3, Part 1, Chapter 5 (commencing with Section 5100) of the Water Code, or

(2) A statement either establishing that a statement of water diversion and use is not legally required, or showing good cause for not filing one.

(d) The department shall obtain a written statement from the staff of the State Water Resources Control Board stating whether the water right is adequate for the proposed dam and reservoir.

(e) If a right to divert or use water is based upon a claim of riparian rights, or rights to appropriate water established prior to 1914, and such claim is disputed by the State Water Resources Control Board, the department shall not withhold approval to commence construction solely upon the basis of such a dispute, provided that it is satisfied with the evidence of a water right provided pursuant to subsection (b) above.

(f) In the event that the State Water Resources Control Board has initiated proceedings to determine whether to authorize use of water, and no decision has been issued, written approval to commence construction or enlargement shall not be withheld pursuant to this section after the 120th day following either the date that the matter is submitted to the Board for decision after hearing or, if no hearing is held, the date on which the protest period closes.

NOTE: Authority cited: Section 6078, Water Code. Reference: Sections 1052, 6075, 6202(d), 6205, and 6264, Water Code.

304. Civil Engineering Plans and Specifications.

Plans and specifications which are submitted to the department shall be prepared by, or under the direction of, a civil engineer who is registered pursuant to California law and authenticated by him as provided in the Business and Professions Code, or be prepared by such other person as may be permitted under the provisions of said code to prepare such plans and specifications, in which case satisfactory evidence of such other person's right to

so act shall be submitted to the department when the plans and specifications are submitted.

NOTE: Authority cited: Section 6078, Water Code. Reference: Section 6206 Water Code; and Sections 6371, 6374-6375, Business and Professions Code.

305. Civil Engineering Supervision of Construction.

The work of construction, enlargement, repair, alteration or removal of a dam or reservoir shall be under the responsible charge of a civil engineer who is registered pursuant to California law or of such other person as may be permitted under the provisions of the Business and Professions Code to assume responsible charge of such work.

NOTE: Authority cited: Section 6078, Water Code. Reference: Section 6206, Water Code; Sections 6731, 6374-6375, Business and Professions Code.

Article 2. Applications for Construction, Enlargement, Repair, Alteration, Removal of Dams or Reservoirs

310. Applications for Construction or Enlargement.

(a) This section shall apply to applications for the department's approval of plans and specifications for the construction or enlargement of dams and reservoirs.

(b) Applications for construction or enlargement of a dam and reservoir shall be made on printed forms provided by the department. The department shall also provide written instructions for completing the application.

(c) The amount of information required will depend on factors such as the size of the proposed dam and reservoir, potential hazards, hydrology of the watershed, complexity of the site and proximity to active faults.

(d) Plans, maps, specifications and other information required for an application shall be provided in sufficient clarity and detail to be readily interpreted and studied, and to permit an adequate evaluation of the safety of the proposed work.

(e) The department may require the filing of any information, in addition to that specified in this section which, in its opinion, it considers necessary to determine the safety of the dam and reservoir.

(f) In addition to the information required by the Water Code Sections 6201-6206, and subsections (b)-(e), an application shall also include the following:

(1) Evidence of water rights, as required by Section 303.

(2) Information necessary to enable the department to comply with the requirements of the California Environmental Quality Act (Public Resources Code Sections 21000-21174). This information shall be either:

(a) A copy of the environmental impact report (EIR) or negative declaration prepared by a lead agency, or evidence that a lead agency is preparing or will prepare environmental documentation, or

(b) Data and information necessary for the department to act as a lead agency to prepare environmental documentation, where it is required by law to do so.

(3) Where the department acts as a responsible agency, the lead agency's EIR or negative declaration must be submitted to the State Clearinghouse.

(4) The fee as required by Water Code Section 6300, as made specific by Section 314 of this subchapter.

NOTE: Authority cited: Section 6078, Water Code. Reference: Sections 6200-6206, Water Code; and Sections 21002.1(d) and 21083, Public Resources Code.

311. Criteria for Determining Completeness.

(a) Applications will be considered complete when the department has received the completed, signed application form, the information and fee required in Water Code Sections 6201 and 6206 and Section 310(d)-(f), and the fee required by Sections 6300-6302 of the Water Code.

(b) The department on its own motion may waive any information required for a complete application, including but not limited to the requirements of Section 303 where it determines that it has sufficient information to commence and complete a review within applicable time limits, and that all requirements for issuance of an approval will be met within such time limits.

(c) The requirements published by the department pursuant to Section 310 shall set forth the procedures that the department will follow to review an application.

(d) Failure to comply with a request for information pursuant to such procedures within a reasonable time and in a reasonably responsive manner shall be cause for the department to disapprove the application.

NOTE: Authority cited: Section 6078, Water Code. Reference: Section 65941, Government Code.

312. Standard Terms

(a) The following are standard terms and conditions included in any approval of a dam safety application:

(1) Construction work shall be started within one year from date of approval.

(2) No foundations or abutments shall be covered by the material of the dam until the Department has been given an opportunity to inspect and approve the same.

(b) General Safety Requirement. In addition to the above terms and conditions, the law requires that a dam shall at all times be designed, constructed, operated and maintained so that it shall not or would not constitute a danger to life or property, and the Department may, at any time, exercise any discretion with which it is vested, or take any action necessary to prevent such danger.

NOTE: Authority cited: Section 6078, Water Code. Reference: Sections 6075, 6260-6267, Water Code.

313. Automatic Approval of Applications.

Applications approved in accordance with Government Code Section 65956 shall contain the terms and conditions set forth in Section 311. Such approvals may be revoked or modified at any time and under any conditions which would apply to any other approval granted under Division 3, Part 1 of the Water Code.

NOTE: Authority cited: Section 6078, Water Code. Reference: Section 65956, Government Code; and Sections 6260-6267, Water Code.

314. Filing Fee.

(a) Amount of Fee. The estimated cost of the dam and reservoir or enlargement as specified in Section 6302 of the Water Code shall include engineering, geologic, surveying, construction supervision, and administrative costs.

NOTE: Authority cited: Section 21082, Public Resources Code; Section 6078, Water Code. Reference Section: 21089 Public Resources Code; Sections 6301-6305, Water Code.

Article 3. Annual Fee.

315. Annual Fee.

(a) Determination of Amount. The department shall determine the amount of the fee in accordance with Section 6307 of the Water Code. Each owner shall be informed of the amount of the fee by April 30 of each year.

(b) Penalty for Delinquent Payment of Annual Fee. An owner who fails to pay any part of any annual fee on or before July 1, as required by Section 6307 of the Water Code, shall be penalized in accordance with Section 6428 of the Water Code.

NOTE: Authority cited: Section 6078, Water Code. Reference: Section 161, Water Code; and Sections 6307 and 6428, Water Code.

316. Inoperative Dams.

A dam will not be considered to be substantially completed or in operation for annual fee purposes, where the department determined that it has been rendered inoperative on other than a temporary basis. In making its determination the department will consider the following circumstances, among others, with respect to the dam:

(a) Alteration of the outlet facilities to assure maximum possible uncontrolled water release through the outlet works.

(b) Absence of water impounding capability under reasonably foreseeable conditions, taking into account the size of the drainage area.

(c) Absence of benefit from the dam and reservoir to the owner or others.

The Department may determine that a dam is no longer inoperative when investigation reveals that conditions which rendered the dam inoperative on other than a temporary basis have changed. In this event the dam will be considered substantially completed or in operation on the date such determination is made, and the annual fee shall be charged on a pro rata basis.

NOTE: Authority cited: Section 6078, Water Code. Reference: Section 6307, Water Code.

Article 4. Small Dams Review Board

320. Small Dams Review Board.

In the Department there shall be a Small Dams Review Board consisting of a chairperson who shall be the Division Chief, Division of Design and Construction; a qualified engineer or geologist appointed by the Division Chief, Division of Safety of Dams; and, for each review, a consulting engineer who would be agreed upon by the Department and the dam owner.

NOTE: Authority cited: Section 6078, Water Code. Reference: Section 6054, Water Code.

321. Scope of Review

(a) The Board shall be convened upon the request of any owner of a small dam or proposed small dam to review any decision or order of the department respecting any technical standard, study requested, engineering requirement or other technical matter required by the department where the owner disputes the basis for such requirement, the need for such requirement, or the facts found by the department.

(b) No review shall be undertaken if, in the opinion of the department, there exists an immediate hazard to life or property. This subsection shall not be construed to bar a Small Dams Review Board proceeding after, in the judgment of the department, an immediate hazard to life and property no longer exists.

NOTE: Authority cited: Section 6078, Water Code. Reference: Section 6054, Water Code.

322. Small Dam Defined.

“Small Dam” means any dam less than 25 feet in height with a reservoir storage less than 2,000 acre-feet.

NOTE: Authority cited: Section 6078, Water Code. Reference: Sections 6054 and 6055, Water Code.

323. Time to Request Board Review; Filing Fee.

(a) The owner must request board review within 60 days of the disputed departmental action. The request must be made to the Division Chief, Division of Safety of Dams, and must state the facts and circum-stances on which such owner bases his grievance.

(b) The owner shall remit, at the time the grievance is filed the amount of $250 to partially defray the cost and expense of the Board.

(c) If the Board meets for more than one day, the department shall bill the owner for its additional costs incurred for subsequent days.

NOTE: Authority cited: Section 6078, Water Code. Reference: Sections 6054 and 6055, Water Code.

324. Time and Conduct of Review.

The Board shall review the owner's grievance promptly after such grievance is filed. The review shall be conducted in an informal manner. The Board shall consider all relevant information and data presented by the owner, his engineer, or any other person.

NOTE: Authority cited: Section 6078, Water Code. Reference: Section 6054, Water Code.

325. Findings of the Board.

Based upon information and data secured during the review, the Board shall refer its findings to the Division Chief, Division of Safety of Dams, regarding the matter which led to the grievance. Decisions made by the Division Chief shall be final.

NOTE: Authority cited: Section 6078, Water Code. Reference: Section 6054, Water Code.

Article 5. Dams Owned by the Department of Water Resources

330. Consulting Board.

Pursuant to Section 6056 of the Water Code, the department shall retain a board of three consultants to report to the Director on the safety of dams owned by the department.

NOTE: Authority cited: Section 6078, Water Code. Reference: Section 6056, Water Code.

331. Scope of Review.

The consulting board shall make independent findings with regard to conditions which may affect the safety of the dam and reservoir as specified in Section 6081 of the Water Code, and the board shall also make independent findings that the dam is safe to impound water, as specified in Section 6355 of the Water Code.

NOTE: Authority cited: Section 6078, Water Code. Reference: Sections 6056, 6081, 6355, Water Code.

332. Actions for Which Board is Retained.

(a) The department shall retain a consulting board:

(1) To review the adequacy of the design of a dam and reservoir the department proposes to construct, or

(2) To review the safety of the completed construction and the terms and conditions to be included

in a certificate of approval for any dam owned by the department as issued, renewed or modified, no later than six months following any such action.

(b) Where a board is retained to review the adequacy of the design of a dam and reservoir, it shall report its findings to the Director prior to the approval of an application to construct or enlarge the dam.

NOTE: Authority cited: Section 6078, Water Code. Reference: Section 6056, Water Code.

333. Periodic Review.

In addition to the times specified in Section 332, the department shall retain a review board at least once every five years to review the operational performance of department owned dams. The Federal Power Commission's five year independent review may be substituted if it is comparable to the review required by this article.

NOTE: Authority cited: Section 6078, Water Code. Reference: Section 6056, Water Code.

CURRENT PRACTICES
OF THE
DEPARTMENT OF WATER RESOURCES
IN
SUPERVISION OF DAMS AND RESERVOIRS

Introduction

The following is provided to help the reader comply with the requirements of the foregoing sections of the Water Code (WC) and the California Code of Regulations (CCR). Current practices of the Department of Water Resources in supervision of dams and reservoirs in State jurisdiction are given. Information required for applications is outlined. (CCR 310)

Division of Safety of Dams

Responsibility for supervision of dams and reservoirs is assigned to the department and delegated to the Division of Safety of Dams (DSOD).

Dams and Reservoirs in State Jurisdiction

Water Code Sections 6000 to 6004.5 and 6025.5 identify dams and reservoirs that are in State jurisdiction. Note that dams and reservoirs owned by the United States are not subject to State jurisdiction except as otherwise provided by federal law.

The Division will review the physical description on request of existing or proposed impoundments and determine if they are or will be in State jurisdiction. Plans for proposed impoundments are usually required before determinations can be made.

Proposed Dams and Reservoirs

The Division of Safety of Dams inspects sites, reviews preliminary plans, and comments on firm proposals for proposed dams and reservoirs. It attempts to inspect representative field exploration, unique laboratory testing, etc., for proposed facilities. However, any comments based on preliminary plans and data are not binding on the Division's later consideration of applications.

In matters relating to the California Environmental Quality Act (CEQA), the Department of Water Resources is the lead or responsible agency for dams and reservoirs. Environmental consideration for dams and reservoirs not directly related to safety is assigned to the Department's four districts. Usually, the Division of Safety of Dams makes preliminary reviews of dam and reservoir proposals, as discussed above, before environmental documentation is prepared. Other water related concerns are handled by the appropriate district.

Procedure for Construction or Enlargement of Dams and Reservoirs

1. If adequate water rights are not already held, file an application for water rights with the State Water Resources Control Board, Division of Water Rights, 901 P Street, Sacramento, California 95814. Evidence of water rights is required before a construction or enlargement application can be approved. (CCR 303)

2. Pre-application meetings are not required by the statutes or regulations. Practice, however, has shown that early involvement

of DSOD in projects is most beneficial for aggressive project schedules. CEQA scoping meetings, early site visits to view exploration, preliminary design discussions, project schedule reviews, and submittal of preliminary 60 percent plans, specifications, and geologic data are recommended to expedite review leading to final approval.

3. File application for construction or enlargement of dam. (CCR 310) Include:

   (a) Application forms (DWR 3) in duplicate to Department of Water Resources, Division of Safety of Dams, P.O. Box 942836, Sacramento, California 94236-0001, (2200 X Street, Suite 200), plus one copy to the Fish and Game Commission in-care of the State Department of Fish and Game, 12th Floor, Resources Building, 1416 Ninth Street, Sacramento, California 95814, if the dam is in a stream. (WC 6500) Sign all copies.

   (b) Plans prepared by registered civil engineer pursuant to California law. (CCR 304) Such plans shall be filed in duplicate in the form of paper prints. Unsigned, nearly complete, prints should be submitted.

   (c) Specifications in duplicate. Nearly complete specifications should be submitted.

   (d) Filing Fee. (WC 6300-6309 and CCR 314). The Current fee structure is listed on the Division Website under "Fees."

   (e) Certain additional information may be desirable, or may be required, depending upon the magnitude of the project. Such added information may include soils data, logs of borings or other exploratory data, geologic reports, hydrologic data, structural and hydraulic design notes, etc.

   (f) Information to enable the department to comply with the California Environmental Quality Act and regulations. This information is as appropriate:

      (1) A copy of the final adopted environmental impact report or initial study--negative declaration prepared by a lead agency, or

      (2) Data and information necessary for the department to act as lead agency to prepare the environmental documentation.

The environmental documentation in either case must be submitted to the State Clearinghouse for processing as required by State law.

4. Within 30 days after receipt of an application, the Division informs the applicant that the application is complete or of the information necessary to make it complete.

5. After review of plans, specifications, etc., and inspection of the site, changes in the plans and specifications, and any supplemental data necessary for approval, will be identified.

6. Submit signed drawings in triplicate and final specifications in duplicate for application approval when review comments are resolved.

7. All civil engineering work is to bear the seal or stamp of the responsible civil engineer and shall be signed across the face with the expiration of the certificate shown on or adjacent to the seal. Civil engineering work includes plans, specifications, reports, and documents which are prepared under the Civil Engineering Practice Act.

8. Notify the Division when construction is to begin and keep DSOD field engineers informed as to the status of construction work at all times. Inspections are made during construction as deemed necessary. No foundations or abutments shall be covered until the DSOD field engineer has inspected and approved them.

9. Upon completion of construction, notify the Division by letter. Final inspections are made as soon as practicable after notice is received.

10. As soon as possible after completion of the dam and final inspection by the division's field engineer, file the following:

    (a) Affidavit of cost of construction. Attach breakdown of costs, including engineering.

    (b) Additional filing fee if final cost exceeds estimated cost by more than 15 percent.

    (c) As-constructed plans, if required, in the form of paper prints.

11. A Certificate of Approval will be issued upon a finding that the dam and reservoir are safe to impound water within the limitations prescribed in the certificate. Impoundment of water must not commence until this certificate is issued.

Procedure for Repair or Alteration of Dams or Reservoirs

The procedure is the same as for construction or enlargement except for the following:

1. Evidence of water rights is not required.

2. Use application form DWR 4.

3. Plans and specifications may not be required for minor repair work.

4. Repair and maintenance qualify for an exemption under the California Environmental Quality Act.

5. Only two sets of signed plans are required for application approval.

6. The Certificate of Approval is only modified when the alteration or repair lowers the approved water surface elevation.

Procedure for Removal of Dams and Reservoirs

The procedure is the same as for construction or enlargement except for the following:

1. Evidence of water rights is not required.

2. Use application form DWR 5.

3. Only two sets of signed plans are required for application approval.

4. The Certificate of Approval, if any, is returned to the Department.

Draft
Simplified Dam Failure Analysis for Inundation Mapping Using HEC-1

By
J. J. DeVries[1]

Introduction

This paper describes a simplified approach to dam failure analysis using HEC-1 to provide input hydrographs for the hydrodynamic model Mike 21. Mike 21 was used in combination with digital elevation models (DEM) to analyze the dambreak flood and produce inundation maps.

The California Office of Emergency Services (CA OES) was directed by the Governor of the State of California to develop dam failure inundation maps for all non-federal dams in the state. The flood mapping was done using a 2-D hydrodynamic model (Mike 21) using existing topographic information available from the USGS. Nearly 500 dam failure inundation maps were produced in a four-month period. The purpose of this study was not to produce detailed dam-failure flood maps, but to reveal those dams for which detailed mapping studies are required. This was a screening study and not a study to provide the final detailed inundation maps for individual dams.

The modeling tools were chosen on the basis of convenience of use and the ability to link the generation of flood maps to the inundation process. CA OES selected two models: a modified version of NWS DAMBRK and the Danish Hydraulic Institute Mike 21 model for the dambreak flood analyses. However, nearly all of the maps were based on the 2-D Mike 21 modeling.

Mike 21 requires an input hydrograph since the program does not simulate a dam failure or provide reservoir routing to compute the outflow hydrograph through the breach as it develops with time. HEC-1 has these features so it was used to simulate the dam failures. HEC-1 also has an option for writing the calculated hydrograph data to user-formatted files. A utility program was used to reformat the HEC-1 output as Mike 21 input.

The database for dam and reservoir characteristics for the State of California is maintained by the Division of Dam Safety of the California Department of Water Resources for dams under their jurisdiction. The information includes the height of the dam, crest elevation and length, reservoir storage capacity, and reservoir area.

To simulate a dam failure HEC-1 requires breach characteristics, including total failure time, and an elevation-capacity curve for the reservoir. These were developed from the published values of crest elevation, crest length, dam height, and reservoir storage capacity.

Background

The California Office of Emergency Services dam failure inundation mapping and emergency procedure program applies to dams meeting specific size requirements making them subject to the jurisdiction of the State of California. Dams owned by agencies of the United States government are not under the jurisdiction of this program. The legislative intent of the original CA OES seismic safety of dams legislation was to establish emergency procedures for the evacuation and control of populated areas below

[1] David Ford Consulting Engineers and State of California

dams which could be used to save lives and reduce injury in the event of a dam failure. Dam owners submit inundation maps to CA OES for review and approval in accordance with guidance issued by CA OES. Inundation maps represent the best estimate of where water would flow if a dam failed completely and suddenly with a full reservoir. Based upon approved inundation maps, or the delineated areas, cities and counties with territory in the mapped areas are required to adopt emergency procedures for the evacuation and control of populated areas below the dams.

HEC-1 dam failure analysis

Breach analysis—Because a large number of dams had to be analyzed, it was not possible to define specific characteristics for each dam am and reservoir. Dams were classified as either an earth or rockfill dam or a concrete dam. The following table shows the parameters for the two types of dams.

Assumptions concerning dam failure:

- "Sunny-day" failure
- Reservoir is full
- Failure is rapid

  Earth dam: 15 minutes for full failure

  Concrete dam: 9 minutes for full failure
- Failure is for full height of dam
- The maximum expected breach width occurs

Table 1. Dam breach parameters:

Parameter	Earth/rockfill Dams	Concrete Dams
Side slope of breach	**1.0**	**0.2**
Time until breach reaches its maximum size (hr)	**0.25**	**0.15**
Bottom width of breach (ft)	**5 * H**	**1 * H**
Discharge through turbines(cfs)	**10, 100, 1000**	**Value kept as small as possible.**
Elevation of water surface in reservoir at failure	**Weir Crest Elevation**	**Weir Crest Elevation**
Inflow at upstream end of reservoir	**Small dams : 10 cfs Medium dams: 100 cfs Large dams : 1000 cfs**	**Inflow to reservoir = discharge through turbines**

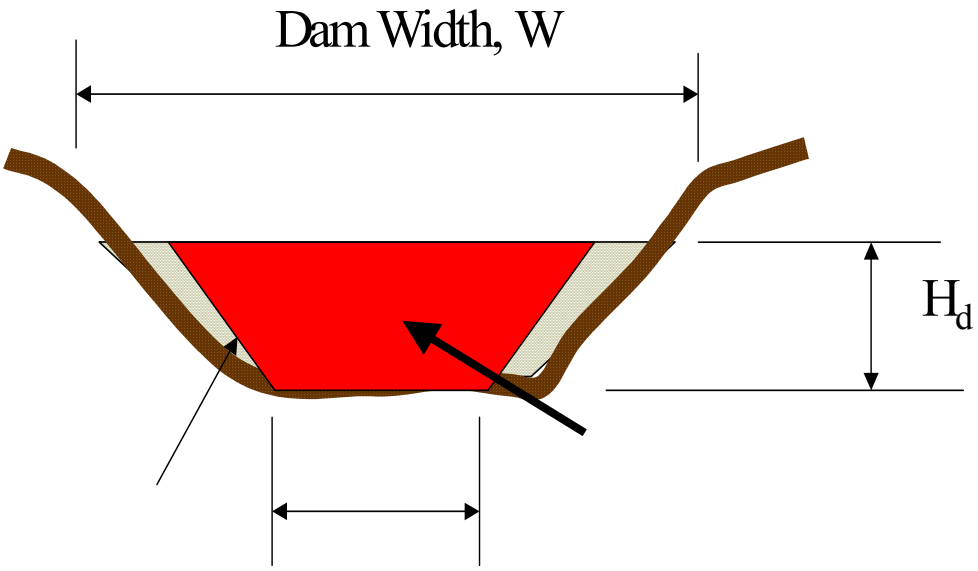

Figure 1. Breach geometry for earthen dams

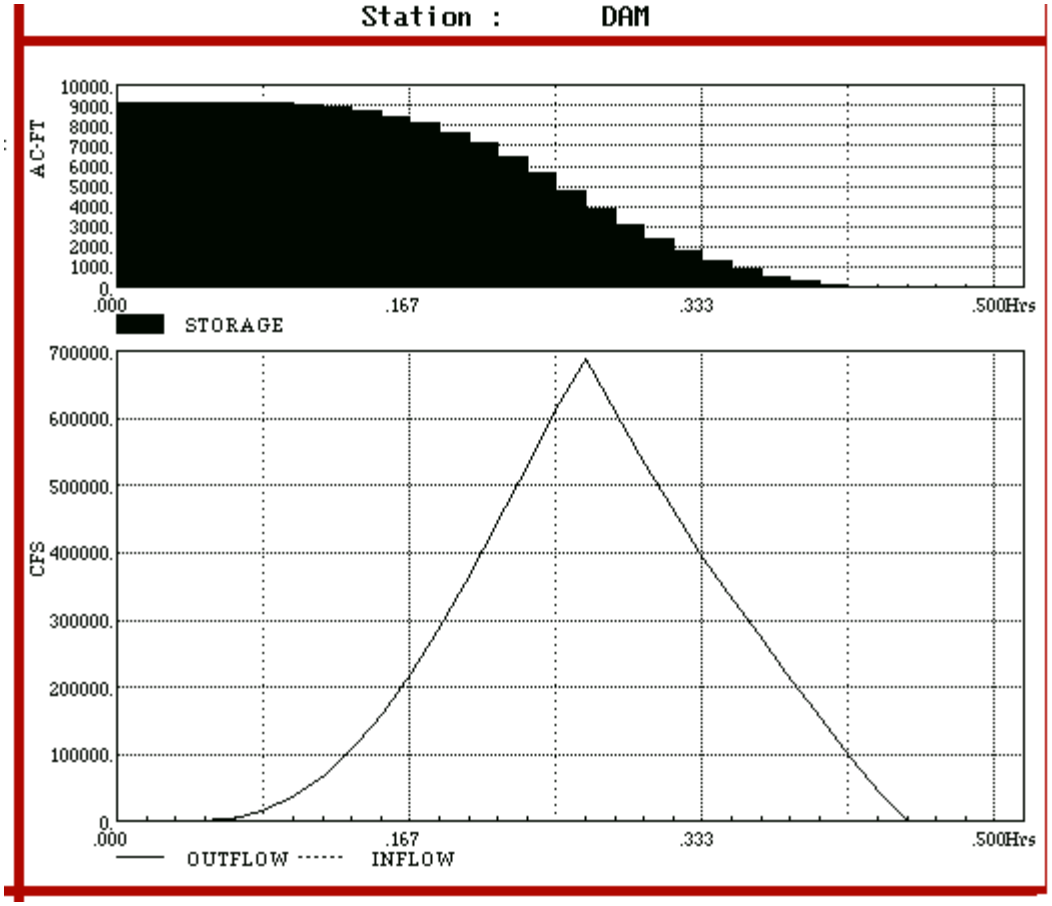

Figure 2: Dam failure hydrograph generated by HEC-1

Hydrodynamic model

MIKE 21 BACKGROUND

The version of Mike 21 used in this study simulates water level variations and flows in response to a variety of forcing functions in water bodies. The water levels and flows are resolved on a rectangular grid covering the area of interest when provided with the bathymetry, bed resistance coefficients, wind field, hydrographic boundary conditions, etc. The system solves the full time-dependent non-linear equations of continuity and conservation of momentum. The solution is obtained using an implicit ADI finite difference scheme of second-order accuracy.

Mike 21 parameters:

The only changes to the modeling parameters used for all individual inundation models were to the Manning's n values used for boundary resistance. Higher values were used in canyon areas than in the floodplains. A single value was used for the entire model. No effort was made to vary Manning's n by land use. Each 30-meter grid cell was represented by a single elevation value and a single roughness coefficient. The dam failure hydrograph generated by HEC-1 had an initial steady flow and a constant base flow added at the end of the hydrograph. Model stability problems occurred without adding these to the hydrograph.

Table 2. Parameters used in Mike 21.

Parameter	Value used
Eddy Viscosity	**5 m^2/s**
Wind Conditions	**No wind**
Dry Depth	**0.04 m**
Flood Depth	**0.10 m**
Manning's n - Canyons	**0.06 to 0.08**
Manning's n - Floodplain	**0.04 to 0.05**

Results

The assumptions used produced conservatively large flows from the simulated dam failure; the Manning's n-values were considered conservatively low; and many of the detailed features of the surface geometry were not represented in the 30-m DEMs. It was concluded that the inundation maps developed using these data typically over-predict expected inundation areas that could occur as a result of a dam failure.

A primary purpose of this study was to identify dams for which flooding due to dam failure could cause major risk to people and property. It is the dam owner's responsibility to submit inundation maps to CA OES for review and approval in accordance with guidance issued by CA OES. Based on the results of this study various dam owners were directed to have dam failure inundation studies made.

Several maps developed in this study were compared with inundation maps prepared by engineering firms for dam owners. None of the previous comparison studies used two-dimensional flood models. In general the tools used for dambreak flood analysis have been the one-dimensional unsteady-flow DAMBRK model or steady flow one-dimensional models (HEC-RAS or HEC-2). For the latter, dambreak flood hydrographs were generated by HEC-1 or the National Weather Service model BREACH.

Maps developed in this study showed good agreement with maps produced in previous studies, especially in steeper areas and areas with well-defined channelizing features. The results differed in flatter floodplain areas, especially where flow could split around small hills and other topographic forms.

More accurate definition of potential inundation areas could be obtained using two-dimensional hydrodynamic models. However, accurate topographic information is required. The widely available 30-m DEMs do not provide very accurate information on topography, and more detailed topographic data should be obtained.

Conclusions

This study was conducted to establish emergency procedures for the evacuation and control of populated areas below dams that could be used to save lives and reduce injury in case of a dam failure. Inundation maps represent the best estimate of where water would flow if a dam failed completely and suddenly with a full reservoir. Based upon approved inundation maps, or the delineated areas, cities and counties with territory in the mapped areas are required to adopt emergency procedures for the evacuation and control of populated areas below the dams.

More detailed investigations of individual dams would produce more accurate definition of potential inundation areas, and these are expected to be done in the future. The results from this study were judged to be appropriate in the light of the purpose of the study, and on the basis of comparisons of inundation maps submitted by dam owners appeared to provide approximately the same level of accuracy as obtained by commonly used inundation mapping methods.

Current Hydrologic Practices, Problems, and Needs
Within California's Dam Safety Program

By
Melissa Collord

Introduction

There are over 1,200 dams within the jurisdiction of the California Department of Water Resources (DWR), Division of Safety of Dams (DSOD). The dams are located throughout the state and have drainage basins that vary in size from portions of an acre to thousands of square miles. DSOD requires that all dams within its jurisdiction be capable of adequately passing a selected design flood. A method was developed by DSOD to estimate flood hydrographs for ungaged or poorly gaged watersheds for use in spillway evaluation.

Methodology

The procedure devised by DSOD in 1981 to determine the hydrologic adequacy of any spillway in California consists of eight parts:

1. Assessment of the potential downstream hazard
2. Determination of appropriate storm return period
3. Development of precipitation
4. Development of synthetic unit hydrograph parameters
5. Development of loss rate parameters
6. Computation of the flood hydrograph
7. Routing of the flood hydrograph through the reservoir
8. Evaluation of the spillway adequacy

The following discussion will focus on parts 4 thru 6, their basic concepts and shortcomings.

Unit Hydrograph

DSOD utilizes Clark's method to develop a synthetic unit hydrograph. Clark's unitgraph parameters are obtained from a generalized study, conducted in 1971, of observed rainfall and runoff events, which related these parameters to drainage basin characteristics by regression analysis. The study is applicable to the State of California except the area south of the Tehachapi Mountain Divide and the area east of the Sierra Nevada Divide. The regression equations relate the drainage basin characteristics of stream length, area, elevation, and ground cover to the time of concentration (t_c) and Clark's storage coefficient (R) for development of a basin-specific unit hydrograph. The study also presents guidelines for estimating loss rate parameters.

Flood Hydrograph

The flood hydrograph is developed using the computer program HEC-1 (Hydrologic Engineering Center, 1981). The program obtains the flood hydrograph by convolution of the effective rainfall increments with Clark's unitgraph. Losses due to surface retention and infiltration are estimated by the exponential loss rate function within HEC-1. The general criteria is that the percent runoff should not be less than 70 when the mean annual precipitation (MAP) at the basin is greater than 25 inches and should not be less than 60 when the MAP is 25 inches or less.

If applicable, allowances for snowmelt, base flow in the basin, runoff from prior storms, import of water, etc., are added to the storm runoff hydrograph to obtain the design flood hydrograph for the watershed.

Problems Faced

The regression equations provide a rational, consistent and simplistic method to developing a basin-specific synthetic unit hydrograph. However, with the advent of faster and more sophisticated computers and programs, such as HEC-HMS, calibration of basin models has become easier and a more widely used approach. The optimization feature in HEC-HMS estimates unit hydrograph and loss rate parameters with observed rainfall and flow data. Unfortunately, there still exists the problem of a lack of basic hydrologic data in most small drainage basins. This makes it impossible to calibrate a basin's unitgraph and loss rate or to check the reasonableness of a synthetic unit hydrograph. Therefore, we highly recommend that more research be conducted into developing unit hydrographs and determining loss rates for small ungaged basins.

Modeling large ungaged drainage basins that range in size from 100 to 1000 square miles present an even more difficult task. In addition to determining the unit hydrograph parameters for each subbasin, channel routing or lag time must now be included in the analysis. The methods that are available in determining routing parameters (DSOD typically uses the Muskingum routing method) are imprecise and our level of confidence in accurately defining the routing conditions is low.

Utilization of HEC-HMS as our primary tool to perform our hydrology and reservoir routing calculations will occur in a very gradual process as more staff members are exposed or are given training to operate the program. Several staff members have already received some training on HEC-HMS, but are unable to use the program since the exponential loss rate function is no longer available and in some cases snowmelt calculation is needed. DSOD can certainly modify loss rate assumptions to be compatible with HEC-HMS, but we do encourage HEC to incorporate snowmelt calculations into HMS as soon as practical.

Rules and Regulations
For
Dam Safety and Dam Construction

Rule 1. Title:

The title of these Rules and Regulations is "The Rules and Regulations for Dam Safety and Dam Construction." They may be referred to herein collectively as the "Dam Safety Rules" or "Rules" and individually as a "Rule".

Rule 2. Authority:

These Rules are promulgated pursuant to the authority granted the State Engineer in sections 37-87-102 and 37-87-105, C.R.S.; and section 37-80-102(1k), C.R.S.; and section 24-4-103, C.R.S.

Rule 3. Scope and Purpose:

3.1 These Rules apply to any dam constructed or used to store water in Colorado. These Rules apply to applications for review and approval of plans for the construction, alteration, modification, repair, enlargement, and removal of dams and reservoirs, quality assurance of construction, acceptance of construction, non-jurisdictional dams, safety inspections, owner responsibilities, emergency action plans, fees, and restriction of recreational facilities within reservoirs. Certain structures defined in Rule 17 are exempt from these Rules.

3.2 The purpose of these Rules is to provide for the public safety through the Colorado Safety of Dams Program by establishing reasonable standards and to create a public record for reviewing the performance of a dam.

Rule 4. Definitions:

4.1 **Statutory Definitions -** The terms are defined in section 37-87-102, C.R.S., 37-87-122 C.R.S. and 35-49-103 C.R.S. and shall have the identical meanings when used in these Rules.

4.2 **Specific Definitions -** Unless expressly stated otherwise, the following terms when used in these Rules shall have the meaning indicated by this Rule. Words in the singular shall include the plural. Words in the masculine gender include the feminine and neuter.

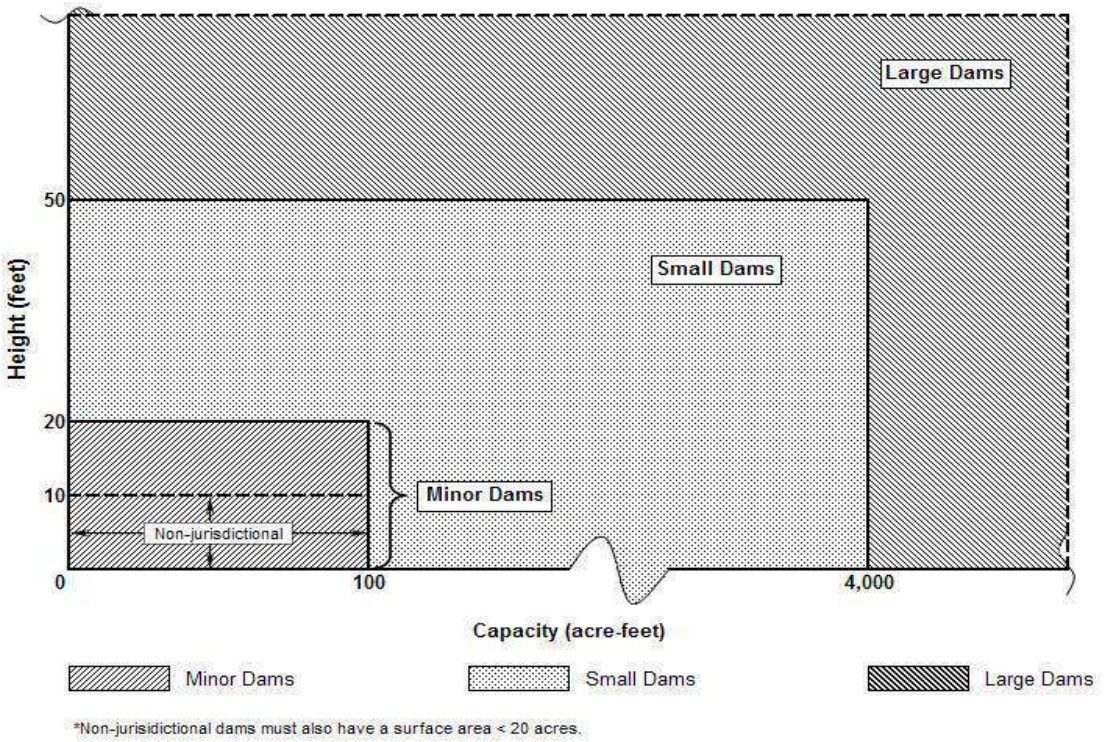
4.2.1 "**Alteration, Modification, or Repair of an Existing Dam and Appurtenant Structures**" means to make different from the originally approved construction plans and specifications or the existing configuration, except for ordinary repairs and general maintenance as defined in Rule 12.

4.2.2 "**Appurtenant Structure**" means components other than the material structure of the dam itself such as the outlet works and controls, spillways and controls, access structures, bridges, and other systems directly related to the safe operation of a dam.

4.2.3 "**Breach Order**" is an order issued by the State Engineer, or the State Engineer's designee, for removal of all or part of a dam to permanently reduce the maximum storage level, minimize the risk of failure and/or the potential of damage downstream due to the failure of the dam.

4.2.4 "**Capacity**" is the volume of water a reservoir is capable of impounding at the high-water line, expressed in acre-feet. Dead storage below the natural surface of the ground or low-level outlet is generally excluded.

4.2.5 "**Dam**" means a man-made barrier, together with appurtenant structures, constructed above the natural surface of the ground for the purpose of impounding water. Flood control and storm runoff detention dams are included.



4.2.5.1 "**Jurisdictional Size Dam**" is a dam creating a reservoir with a capacity of more than 100 acre-feet, or creates a reservoir with a surface area in excess of 20 acres at the high-water line, or exceeds 10 feet in height measured vertically from the elevation of the lowest point of the natural surface of the ground where that point occurs along the longitudinal centerline of the dam up to the crest of the emergency spillway of the dam. For reservoirs created by excavation, or where the invert of the outlet conduit is placed below the surface of the natural ground at its lowest point beneath the dam, the jurisdictional height shall be measured from the invert of the outlet at the longitudinal centerline of the embankment or from the bottom of the excavation at the longitudinal centerline of the dam, which ever is greatest. Jurisdictional height is defined in Rule 4.2.19. The State Engineer shall have final authority over determination of the jurisdictional height of the dam.

4.2.5.2 "**Non-jurisdictional Size Dam**" is a dam creating a reservoir with a capacity of 100 acre-feet or less and a surface area of 20 acres or less and with a height measured as defined in Rules 4.2.5.1 and 4.2.19 of 10 feet or less. Non-jurisdictional size dams are regulated and subject to the authority of the State Engineer consistent with sections 37-87-102 and 37-87-105 C.R.S.

4.2.5.3 "**Minor Dam**" is a jurisdictional size dam that does not exceed 20 feet in jurisdictional height and/or 100 acre-feet in capacity (see Figure 1).

4.2.5.4 "**Small Dam**" is a dam with a jurisdictional height greater than 20 feet but less than or equal to 50 feet and/or a reservoir capacity greater than 100 acre-feet, but less than 4,000 acre-feet (see Figure 1).

4.2.5.5 "**Large Dam**" is a dam greater than 50 feet in jurisdictional height, and/or greater than 4,000 acre-feet in capacity (see Figure 1).

DAM SIZE DETERMINATION

Figure 1

4.2.5.6 "**Diversion Dam**" is a dam constructed for the purpose of diverting water from a natural watercourse into a canal, tunnel, ditch, or pipeline that typically impounds an insignificant volume of water, and for which the impacts of failure are not a significant public safety hazard.

4.2.5.7 "**Flood Control Dam**" is a special purpose dam that is normally dry and has an un-gated outlet structure for the controlled release of water impounded during and subsequent to a flood event. The jurisdictional size and classification of the dam are determined using the height and capacity of the reservoir to the emergency spillway elevation, or using the elevation of the maximum routed water surface elevation if no emergency spillway is provided.

4.2.6 "**Dam Failure Inundation Map**" is a map depicting the area downstream from a dam that would reasonably be expected to be flooded in the event of a failure of the dam.

4.2.7 "**Day**" as used in these Rules means a calendar day. For computation of time periods as used in these Rules, Colorado Rules of Civil Procedure 6(a) shall apply.

4.2.8 "**Emergency Action Plan (EAP)**" is a written document prepared by the dam owner, describing a detailed plan of actions for response to emergency or unusual events, including alerting and warning emergency officials in the event of a potential or imminent dam failure or other emergency related to the safety of the dam and public.

4.2.9 "**Engineer**" means a Professional Engineer registered and licensed in Colorado in accordance with section 12-25-101, C.R.S. The Engineer must be sufficiently qualified and experienced in the design, construction, and safety evaluation of the type of dam under consideration. The Engineer will be the Professional Engineer responsible for the design. In general, the Engineer is responsible for the following:

4.2.9.1 Demonstrating a minimum of five years of experience as a Professional Engineer in the design, construction, and safety evaluation of the type of dam under review.

4.2.9.2 Understanding all applicable regulatory requirements of the project and the required work and analyses needed to complete a safe design of the project.

4.2.9.3 Using current state of the practice methods and means to locate and design dams with safety as the primary goal and complete engineering methodology that represents the professional level of care exercised by qualified engineers.

4.2.9.4 Assembling and supervising a team of qualified engineers, engineering geologists/geological engineers and other professionals required to address all of the disciplines necessary for the design and construction of a dam.

4.2.10 "**Enlargement of an Existing Dam or Appurtenant Structure**" means any alteration, modification, or repair that increases the reservoir volume and/or jurisdictional height of a dam as defined in Rules 4.2.4 and 4.2.19.

4.2.11 "**Extreme Precipitation Event**" means a precipitation event based on Colorado extreme storm data approved by the State Engineer, maximized through modern meteorological techniques.

4.2.12 "**Extreme Storm Precipitation (ESP)**" means the maximum precipitation possible, as developed using the Dam Safety Branch's Extreme Precipitation Analysis Tool (EPAT) or a site-specific hydrometeorologic analysis. The greatest depth of precipitation for a given duration that is physically possible over a drainage basin through the application of modern meteorological techniques, based on Colorado extreme storm data approved by the State Engineer.

4.2.13 "**Freeboard**" means the vertical dimension between the crest (or invert) of the emergency spillway and the crest of the dam.

4.2.13.1 "**Residual Freeboard**" means the vertical dimension between the maximum water surface elevation at the peak of the inflow design flood and the lowest point on the crest of the dam at which the dam would be first overtopped.

4.2.14 "**Hazard Classification of a Dam**" is the placement of a dam into one of four categories based on the hazard potential derived from an evaluation of the probable incremental adverse consequences due to failure or improper operation of the dam.

Conditions for evaluation are absent flooding, and the reservoir is assumed to be full to the high water line. The hazard potential classification does not reflect the current condition of the dam with regard to safety, structural integrity, or flood routing capacity. (See Rule 5.4, Hazard Classification Study, for a more detailed description of determining which hazard category a given dam shall be placed.) The Hazard Classification evaluation method must be approved by the State Engineer.

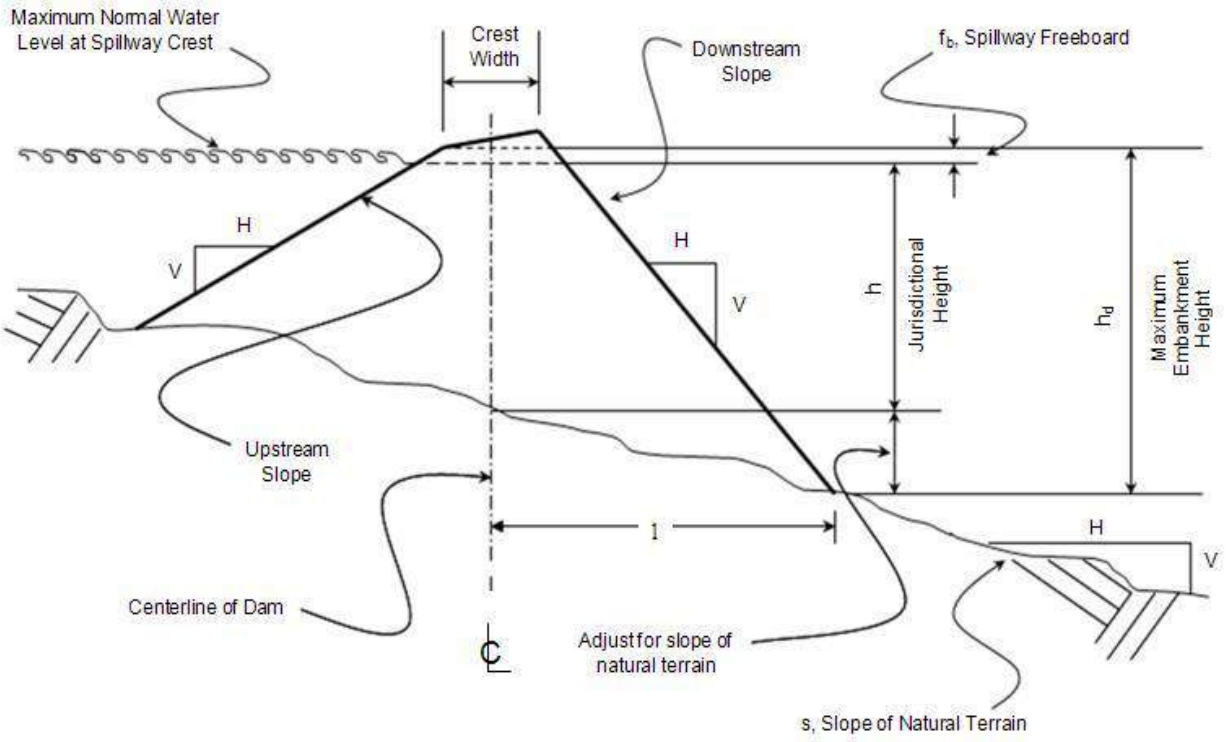
4.2.14.1 "**High Hazard Dam**" is a dam for which loss of human life is expected to result from failure of the dam. Designated recreational sites located downstream within the bounds of possible inundation should also be evaluated for potential loss of human life.

4.2.14.2 "**Significant Hazard Dam**" is a dam for which significant damage is expected to occur, but no loss of human life is expected from failure of the dam. Significant damage is defined as damage to structures where people generally live, work, or recreate, or public or private facilities. Significant damage is determined to be damage sufficient to render structures or facilities uninhabitable or inoperable.

4.2.14.3 "**Low Hazard Dam**" is a dam for which loss of human life is not expected, and significant damage to structures and public facilities as defined for a "Significant Hazard" dam is not expected to result from failure of the dam.

4.2.14.4 "**No Public Hazard (NPH) Dam**" is a dam for which no loss of human life is expected, and which damage only to the dam owner's property will result from failure of the dam.

4.2.15 "**High Water Line**" is the water surface elevation of the reservoir at the crest (or invert) of the emergency spillway, or, if no emergency spillway exists, at the crest of the dam.



4.2.16 "**Impound Water**" means to accumulate water in a reservoir for immediate or future use, including the purpose of flood control and detention.

4.2.17 "**Incremental Damage Analysis**" means a comparative study of two floods of differing magnitude used to identify differential impacts for loss of human life and property damage in the zone above the lesser magnitude flood (incremental zone).

4.2.18 "**Inflow Design Flood**" **(IDF)** means the flood hydrograph used to determine if the emergency spillway's hydraulic capacity meets the safety standards as defined in Rules 5 and 6 (or in absence of a spillway, the reservoir is capable of *storing* the IDF). The required magnitude of the IDF is defined by these Rules.

4.2.19 "**Jurisdictional Height**" means the vertical dimension measured from the elevation of the lowest point of the natural surface of the ground, or from the invert of the outlet pipe if excavated below the natural surface of the ground, whichever is lower, where the low point occurs along the longitudinal centerline of the dam, up to the spillway crest of the emergency spillway. For existing dams, the jurisdictional height shall be measured by using the slope of

the downstream channel and the height of the dam at the downstream toe by extrapolating the measured height to the longitudinal centerline of the dam. The formula for determining the vertical height of existing dams is: $h = h_d - f_b - (s*l)$; where h = jurisdictional height, h_d = height of dam from downstream toe, f_b = freeboard, s = slope of the natural surface of the ground downstream of the dam, and l = measured or computed horizontal distance between the downstream toe and the longitudinal centerline of the dam. The State Engineer shall have final authority over determination of the height of the dam (see Figure 2).

Determination of Dam Vertical Height at the Maximum Cross Section

Figure 2

4.2.20 "**Natural Surface of the Ground**" means the undisturbed ground surface before excavation, or the undisturbed bed of a natural watercourse.

4.2.21 "**Normal Water Line**" means the elevation of the water at the crest of the principal or service spillway.

4.2.22 "**One-hundred-year Flood**" means a potential flood having a magnitude (peak discharge) which is expected to be equaled or exceeded on the average once during any one-hundred-year period (recurrence interval) and has a one percent chance of being equaled or exceeded during any year (0.01 exceedance probability). The terms “one-hundred-year flood" and "one percent chance flood” are synonymous.

4.2.23 "**Outlet**" means a conduit (usually regulated by gates or valves) used for controlled or regulated releases of impounded water from the reservoir.

4.2.24 "**Owner**" means any person, private or non-profit company, special district, federal, state, or local government agency, or any other entity in direct routine control of a dam and reservoir, and/or directly involved in the physical operation and maintenance of a dam, or proposes to construct a dam. Changes in ownership shall be immediately filed with the State Engineer.

4.2.25 "**Permit**" means a written approval for dam construction, which will be provided by the State Engineer upon approval of the dam plans and specifications. The written approval may be signed by the State Engineer or Deputy State Engineer and identify all contingencies.

4.2.26 "**Plans**" means all necessary drawings, cross-sections, tables, notes, maps and other information necessary to accompany the construction specifications for design review and approval and construction observation and approval.

4.2.27 "**Probable Maximum Precipitation (PMP)**" means the theoretically greatest depth of precipitation for a given duration that is physically possible over a drainage basin at any specific time of year. The PMP values are normally determined from the appropriate Hydrometeorological Report (HMR) (HMR 49 for west of the continental divide, HMR 52 for the eastern plains and HMR 55A for the Front Range). The 100-year, 50-year, and 25-year events are normally determined from the National Weather Service NOAA Atlas #2 "Precipitation-Frequency Atlas of the Western United States" Volume III-Colorado, U.S. Department of Commerce, NOAA, National Weather Service, Silver Springs, Maryland, 1973, (later amendments, editions, or subsequent publications not included).

4.2.28 "**Reservoir**" means a body of water impounded by a dam.

4.2.29 "**Restriction Order**" means an order issued by the State Engineer to limit the maximum water surface elevation of a reservoir as an interim measure to immediately reduce the possibility of failure and risk to the public and property until investigations of a problem can be performed or structural modifications can be made to repair the problem or breach the dam.

4.2.30 "**Routing Capacity**" means the capability of a reservoir and spillway system to attenuate flood inflows, and is calculated as the sum of the spillway discharge(s) and surcharge storage for a specific time increment, expressed in acre-feet.

4.2.31 "**Safe Storage Level**" means the maximum reservoir water surface elevation at which the State Engineer has determined that the dam is safe to impound water based on the safety inspection and/or evaluations.

4.2.32 "**Safety Inspection**" means an evaluation by an engineer to be used by the State Engineer in determining the reservoir's safe storage level. The safety inspection includes, but is not limited to, the review of previous inspections, instrumentation results, reports and

drawings; visual inspections of the dam and appurtenances, seepage control and measurement systems, and any permanent monument or monitoring installations.

4.2.33 "**Spillway**" means an appurtenant structure that conducts overflows from a reservoir.

4.2.33.1 "**Principal or Service Spillway**" means the overflow structure designed to limit or control the operating level of a reservoir, and first to be activated in runoff conditions. The principal or service spillway is designed to pass normal flows, and may not be designed to pass the entire Inflow Design Flood. The principal or service spillway is usually an open channel, pipe, or culvert.

4.2.33.2 "**Emergency Spillway**" means the appurtenant structure designed to pass the Inflow Design Flood in conjunction with the routing capacity of the reservoir and any principal or service spillway(s). Pipe or culvert spillways are not considered acceptable emergency spillways.

4.2.34 "**Spillway Crest**" means the elevation of the floor of a spillway, grade control structure, or ogee crest above which spillway flow begins.

4.2.35 "**Surcharge Storage**" means the volume of water temporarily stored within a reservoir between the high water line and the crest of the dam.

Rule 5. Requirements for Construction or Enlargement of Jurisdictional Size Dams or Reservoirs:

An owner proposing to construct or enlarge a jurisdictional dam or reservoir shall submit an application package, in a form acceptable to the State Engineer, and shall receive approval of the construction plans and specifications and Permit for Dam Construction from the State Engineer prior to commencing construction. The application package shall be prepared by an engineer and shall consist of the following:

1. Application Form
2. Construction Plans
3. Construction Specifications
4. Hazard Classification Report
5. Hydrology Report
6. Geotechnical Report
7. Design Report
8. Instrumentation Plan
9. Cost Estimate
10. Filing Fee

The requirements for each of these items are as follows:

5.1 **Application Form -** A completed application form provided by the State Engineer. This form will be the only information normally available to the public before the project is approved for construction. The application form shall be signed by the dam owner or an authorized representative of the dam owner. The engineer responsible for the preparation of the design and

construction may not act as an authorized representative of the dam owner unless written authorization for the engineer to act as the owner's representative is provided by the dam owner.

5.2 **Construction Plans -** Construction plans/drawings shall meet the following requirements:

5.2.1 The plans shall show the design of the dam and each appurtenant structure in sufficient detail so that the contractor or builder is able to construct the proposed structure from the plans and the specifications.

5.2.2 The front cover sheet of the plans shall have as a minimum, the name of the dam; the county, Water Division and Water District in which the dam is located; and a project location map. A list of the drawings that follow the cover sheet should be provided on the second sheet of the plans and a note should be added to the cover sheet indicating the location of the list of the drawings. The construction drawings and plans shall display the design engineer's seal (crimp type not acceptable) in accordance with current practice defined by The Bylaws and Rules of Procedure of the State Board of Registration for Professional Engineers and Professional Land Surveyors. The original signed mylar coversheet will be returned to the engineer after being approved and signed by the State Engineer. The original signed mylar cover sheet with any appropriate revisions is required to be returned to the State Engineer at the completion of the construction project in accordance with Rule 10. The design engineer's certification statement, the State Engineer's approval signature block, and the design engineer's AS-CONSTRUCTED statement shall be located in the lower right quadrant of the cover sheet in the following format:

Design engineer signature
Printed Name, Colo. P.E. No. xxxxx

Approved on the _____day of _____20___.

_____
State Engineer
By:_____
Deputy State Engineer

And,

These plans represent the AS-CONSTRUCTED conditions of _____ Dam to the best of our knowledge and judgment, based in part on information furnished by others, as of the _____ day of _____, 20__.

_____ _____
(Engineer's printed name) (Signature)

5.2.3 Drawings filed with the State Engineer shall be originals, drawn with permanent ink on high quality mylar or equivalent, or a high quality reproducible archival copy of the original, and shall be prepared in an appropriate scale so details are legible with an overall size of 24 inches high and 36 inches wide or 22 inches high and 34 inches wide.

5.2.4 Drawings shall have a minimum margin of two inches on the left and 1/2-inch on the right, top, and bottom.

5.2.5 All drawings shall have bar scales to allow scaling of reduced drawings.

5.2.6 All drawings shall have a 1/2- by 3-inch space for the State Engineer's file number inside the margin in the lower right-hand corner. A unique project file number will be assigned by the State Engineer prior to final approval of the project documents for construction and shall be placed in bold characters on all of the drawings.

5.2.7 Each sheet shall be numbered sequentially with the first sheet being sheet number one along with the total number of sheets; e.g., 1 of 6.

5.2.8 Minimum lettering size on full size drawings (24 inches high and 36 inches wide or 22 inches high and 34 inches wide) shall be 12 pitch.

5.2.9 Spillway and outlet discharge rating curves and tables, and reservoir area-capacity curves and tables meeting requirements of Rule 5.9.6 shall be placed on the drawings.

5.3 **Construction Specifications -** Construction Specifications shall meet the following requirements:

5.3.1 The front cover of the specifications shall show the title or name of the dam (identical to the title on the plans), the county, the Water Division and the Water District in which the dam is located. The specifications shall display the design engineer's seal (crimp type not acceptable) in accordance with current practice defined in The Bylaws and Rules of Procedure of the State Board of Registration for Professional Engineers and Professional Land Surveyors. The first page behind the front cover shall show the name of the dam (identical to the name on the plans), the county, Water Division and Water District in which the dam is located, the engineer's certification statement, seal and signature, and the State Engineer's approval statement as follows:

Approved on the _____ day of _____, 20__
_____, State Engineer
By: _____, Deputy State Engineer

5.3.2 The specifications shall have an index.

5.3.3 Final specifications shall be bound and submitted on white 8 1/2 by 11-inch paper. Specifications bound in a loose or loose-leaf manner, including 3-ring binders, are not acceptable.

5.3.4 The general conditions shall include statements that the plans and specifications cannot be significantly changed without the prior written approval of the State Engineer in accordance with Rule 9.1.8.

5.3.5 The general conditions shall include the provision that construction shall not be considered complete until the State Engineer has accepted the construction in writing.

5.3.6 The specifications shall provide that the owner's engineer will monitor the quality of construction as specified in Rule 9. The engineer monitoring the construction for the owner is responsible for the quality of construction, compliance with the approved design and specifications, preparation of the necessary documentation for the State Engineer's review and approval of all construction change orders, and preparation of the project completion documents required in Rule 10.

5.3.7 The specifications shall include as a minimum, but are not limited to, the following:

5.3.7.1 The quality of materials used in construction;

5.3.7.2 The acceptable quality of workmanship;

5.3.7.3 The reference to applicable standards, if any;

5.3.7.4 The required tests and estimated frequency of testing; and,

5.3.7.5 The action to be taken if unsatisfactory materials or workmanship are discovered in the construction.

5.4 **Project Design Reports**

5.4.1 **Hazard Classification Report -** The hazard classification report shall identify the size and hazard classification category for the proposed dam, or enlarged existing dam. A report is not required for dams that are declared as High Hazard; however, a dam failure inundation map will be required for the Emergency Action Plan pursuant to Rule 16. The report shall include sufficient information regarding assumptions, calculations and data used to develop the dam failure flood hydrograph and an assessment of the impact of the dam failure upon the downstream floodplain. The dam shall be classified according to the definitions of Rule 4. The hazard classification report must be approved by the State Engineer, and shall be in a form that meets the State Engineer's requirements, including, but not be limited to:

5.4.1.1 Dam failure inundation maps are required for all dams classified as High and Significant Hazard. Inundation maps are required for dams classified as Low Hazard unless the dam is located in a remote area where no development exists downstream of the dam;

5.4.1.2 Cross-sections along the watercourse, drawn to scale, showing water surface elevations at critical locations where structures may be impacted by the flood wave. Cross-sections shall show discharge in cubic feet per second, average velocity in feet per second, and structures located in the flooded section. References to all computer programs, data sources and related documents used in the evaluation shall be included; and

5.4.1.3 Supporting documentation and tabulation of assumed parameters, including Manning's "n" values for the stream channel and the floodplain shall be included.

5.4.2 **Hydrology Report -** A hydrology report is required that presents the inflow design flood (IDF) for determining the required spillway capacity. The IDF may be determined through any of the four methods described in Rule 5.9.1; Extreme Precipitation Analysis Tool (EPAT), site specific hydrometeorologic analysis (SSHMA), Hydrometeorological Report (HMR), and Incremental Damage Analysis (IDA). The precipitation determined through use of the Extreme Precipitation Analysis Tool (EPAT) and site specific hydrometeorologic analysis is the most probable extreme precipitation event for the specific basin determined through modern meteorologic techniques and therefore, the IDF determined from the analysis is probable. No reduction of IDF is allowed for dams classified as High hazard or large size Significant hazard dams. The reduction in the IDF determined through the use of Hydrometeorological Report (HMR), is allowed as provided in Rule 5.9.1.5. Spillways designed in accordance with these Rules will not be required to be enlarged due to subsequent revisions to the IDF as a result of changes to the probable maximum precipitation estimates or EPAT extreme storm database unless, in the opinion of the State Engineer, there is a substantial threat to public safety.

5.4.2.1 The hydrology report is required to be reviewed and approved by the State Engineer and shall be in a form acceptable to the State Engineer and shall include, but not be limited to the following:

5.4.2.1.1 A topographical map delineating the drainage area tributary to the dam, with the drainage area size labeled in square miles; the location of the proposed dam by quarter section, section, township, range, and principle meridian; the bearing and distance from Station 0+00 on the dam to a section corner, or, the location of Station 0+00 on the dam determined by GPS, NAD83 datum, provided as UTM coordinates; the name of the natural watercourse on which the dam is located or indicate the dam is off-stream, and the name of the primary watercourse which the dam is tributary, or the name of the drainage basin in which the dam is located; and the elevation of the dam crest;

5.4.2.1.2 A description of all basin response factors, including the topography, geology, and vegetative cover of the tributary drainage area;

5.4.2.1.3 A summary of all hydrologic parameters for the method used, the inflow design flood hydrograph, volume of the flood, and hazard classification of the dam;

5.4.2.1.4 A spillway discharge rating table (in cubic feet per second) for each foot of elevation above the spillway crest up to the crest of the dam, including the equations used for determining the discharge rate; and

5.4.2.1.5 A table showing the reservoir area (in acres) and storage capacity (in acre-feet) for each foot of elevation from the invert of the outlet to the crest of the dam; and indicating the amount of dead storage (in acre-feet), elevation of the invert of the

outlet, elevation(s) of the spillway crest(s), and elevation of the dam crest. All elevations shall be based on USGS datum, referenced to the invert of the outlet.

5.4.3 **Geotechnical Report -** A geotechnical report is required that evaluates the suitability of the foundation, stability of the dam and the slopes along the reservoir rim, and addresses issues regarding suitability and quantity of material available for construction of the dam as designed. The geotechnical report shall include, but not be limited to, the following:

5.4.3.1 A geological assessment of the dam and reservoir site is required for all dams classified as High or Significant Hazard. The geological assessment shall address at a minimum regional geologic setting; local and site geology; geologic suitability of the dam foundation and reservoir area; slope stability and seepage potential of the reservoir and abutment areas; seismic history and potential; and other potential geological hazards posed by the site and proposed construction. The geological assessment shall include the preparation of a site-specific geological map based upon field observations and mapping by a geologist or geological engineer.

5.4.3.2 Foundation investigations for High and Significant Hazard dams shall include drilling to a depth 1.5 times the height of the dam or at least 10 feet into bedrock, whichever is less; logs of borings and test pits; standard penetration or other field density tests; field and laboratory classification of soils; measurement of the water level in each drill hole; in-situ permeability tests; gradation tests of foundation materials, especially at the locations of proposed drains; determination of liquefaction potential; and whether clay type foundation materials exhibit residual strength properties and dispersivity. Where tunneling or other underground construction is anticipated, subsurface investigation depths, orientations, methods and testing shall be tailored to the geologic setting and details of underground construction anticipated at each site. All investigations for underground facilities shall be performed under the direction of a qualified professional engineering geologist with prior relevant underground experience. The boring logs in the geotechnical report shall include detailed written descriptions of each sample and stratum encountered including observations of the drilling action, drilling and sampling methods and any other observations pertinent to developing a detailed understanding of the subsurface conditions. Graphical "stick" logs alone are not acceptable.

5.4.3.3 The report shall document the suitability of proposed borrow materials or other material sources to be used in construction for High and Significant Hazard dams. The following information and data are required, as a minimum, to be included in the Geotechnical Report:

5.4.3.3.1 Standard index tests and soil classification of all materials;

5.4.3.3.2 Compressibility and/or consolidation tests of soils;

5.4.3.3.3 Permeability of placed materials;

5.4.3.3.4 Shear strength of natural and placed materials (dynamic shear strength tests if applicable);

5.4.3.3.5 Proctor Compaction tests; and

5.4.3.3.6 Identification of potentially dispersive clays.

5.4.3.4 For Low Hazard dams, the report shall include field classification of soils, logs of borings and test pits, standard penetration test results, and the requirements of Rules 5.4.3.3.1, 5.4.3.3.2, and 5.4.3.3.5. The foundation exploration shall include drilling to a depth 1.5 times the height of the dam or 10 feet into bedrock, whichever is less.

5.4.3.5 For NPH dams, the report shall include, as a minimum, field and laboratory classification of natural and placed soils.

5.4.3.6 For all dams, except Minor Low Hazard and all NPH, with a spillway located on a soil foundation, the report shall include the following:

5.4.3.6.1 Laboratory Classification of soils along the alignment of the spillway;

5.4.3.6.2 A profile of soils along the channel extending to a depth of at least five feet below the bottom of the spillway; and

5.4.3.6.3 Density or bearing capacity of foundation soils beneath spillway structures except for riprapped or unlined sections of the channel.

5.4.3.7 For all dams, except minor Low Hazard and all NPH, with spillways located on a rock foundation, the report shall include a geologic description of the rock, description of the bedding and jointing patterns, and an evaluation of the site's suitability to accommodate the spillway.

5.4.4 **Design Report** - A Design Report shall be submitted with the application package. The report shall include information sufficient to evaluate the design of the dam and appurtenances, including references and page numbers, to support any assumptions or criteria used in the design. The report shall also include information on the construction sequence needed to complete the dam along with a summary of any water quality permits that will be required prior to the start of construction. The report shall include calculations and be sufficiently detailed to accurately define the final design of the proposed dam as represented in the construction plans. The following is a typical list of topics to be addressed in the design report:

5.4.4.1 Introduction - Project description and review process.

5.4.4.2 Project Components - Main dam, spillway, and outlet works.

5.4.4.3 Site Requirements - The dam site and reservoir area design requirements.

5.4.4.4 Flood Hydrology and Results of Flood Routings (a summary of Hydrology Report) - This section should include the final results of the routing of the IDF through the reservoir and spillway system for the purpose of determining the size of the spillway or spillways.

5.4.4.5 Spillway and Outlet Works Hydraulics - This should include spillway hydraulics and the development of a spillway discharge rating curve, stilling basin hydraulics, a tailwater rating curve including effects of streambed degradation, hydraulic design assumptions for the design of entire outlet system, and development of an outlet works discharge curve. Design of stilling basins for stepped chute spillways shall include assumptions, calculations, and applicable references for estimating energy dissipation and stilling basin entrance velocities.

5.4.4.6 Foundation Designs - These designs are to include information of local geology (alluvium and topsoil nature and engineering properties), bedrock nature and engineering properties, groundwater impacts, dam foundation requirements, foundation excavation requirements, surface treatment of foundation, seepage control and foundation drainage, piping control measures, downstream erosion, and overtopping control measures. (Refer to the Geotechnical Report requirements for additional requirements, Rule 5.4.3).

5.4.4.7 Seismic Hazard Assessment - This section include seismic sources (seismotectonic setting, historical seismicity, earthquake sources), ground motion hazard (ground motion attenuation, deterministic analysis, probabilistic analysis), and recommended ground motions (time histories).

5.4.4.8 Dam Analysis and Design - This section should include material properties (earth and/or concrete, foundation geology for dam, foundation strength parameters), analysis methodology and model results (load combinations, static analysis, dynamic analysis), conclusions and recommendations. In addition for Roller Compacted Concrete (RCC) dams, this section should also include required in-situ material properties for concrete or RCC, RCC trial mix program, mix proportions, and RCC placement requirements (RCC joint treatment, contraction joint spacing, upstream and downstream facing systems).

5.4.4.9 Structural Design - This section should include structural design criteria and allowable stresses, design of spillway crest, spillway walls and slabs, design of spillway foundation anchors, design of outlet works intake and outlet structures, and outlet conduit.

5.4.4.10 Dam Instrumentation - This section should include a description of the instrumentation per the requirements of Rule 5.5 and including any other monitoring devices and equipment such as automatic data acquisition system.

5.4.4.11 Mechanical and Electrical Design - Design of gates, valves, trash racks and mechanical systems, systems for operating gates and valves, and electrical power requirements and emergency backup power.

5.4.4.12 Quality Assurance and Quality Control Plan - Project management plan, project quality plan, and testing procedures and frequency requirements.

5.4.4.13 River Diversion During Construction - Anticipated construction scheduling and historical river flows, diversions hydrology and selection of diversion flood, proposed diversion system, and potential risks to public safety during construction.

5.4.5 **Project Design Report** - A Project Design Report incorporating all of the aforementioned reports into one design document is permitted. The report should fully document and provide defendable reasoning for the design of the dam and appurtenant structures.

5.5 **Instrumentation Plan -** An instrumentation plan is required and shall meet the following requirements:

5.5.1 All instrumentation shall be properly identified in the field to correspond to the identification of the instrumentation in the long-term monitoring plan required in Rule 10.

5.5.2 Gage rods shall be installed in the close proximity to the outlet on all dams. The zero mark of the gage shall be aligned with the invert elevation of the entrance to the outlet. The gage shall be clearly marked in feet and tenths of feet, and extend to within one foot of the crest of the dam. If the Division Engineer so requires, the gage shall be marked in hundredths of a foot. Markings and numbers on the gage rod shall be of sufficient size to allow for the reading of the gage rod from a distance 50 feet or further if the gage rod is placed on an intake tower within the reservoir.

5.5.3 High and Significant Hazard dams shall have the following minimum instrumentation:

5.5.3.1 Monuments that allow measurement of the horizontal and vertical movements of the dam, installed in accordance with industry standards and in a manner acceptable to the State Engineer. Control or benchmark monuments shall be placed on the abutments in areas not subject to movement;

5.5.3.2 Weirs, flumes, or other measuring devices installed in a manner acceptable to the State Engineer, to allow monitoring of seepage through the embankment or foundation. Positive drainage away from all seepage monitoring devices should be provided to prevent the device from becoming submerged;

5.5.3.3 Station markers at least every 100 feet along the crest of the dam; and

5.5.3.4 Piezometers to allow monitoring of the phreatic surface within the dam, installed in accordance with industry standards and in a manner acceptable to the State Engineer. As a minimum, the construction of the open well piezometers shall be in accordance with the requirements of a monitoring well as presented in the Division of Water Resources' "Rules and Regulations for Water Well Construction, Pump Installation and Monitoring

an Observation Hole/Well Construction," later amendments, editions or subsequent publications are not included.

5.5.3.5 Piezometers or equivalent instruments shall be installed to measure uplift pressures in the dam and foundation for concrete dams, when the reduction of uplift pressures are required to meet the factors of safety and stress requirements of the design of the dam.

5.5.3.6 Where drainage galleries are provided for concrete dams, seepage measuring devices should be provided at the appropriate locations and be accessible for making the necessary readings.

5.5.4 Low Hazard dams shall have weirs, flumes or other measuring devices installed, as approved by the State Engineer, to allow monitoring and measurement of leakage through the embankment or foundation.

5.5.5 NPH dams are not required to have instrumentation other than gage rods in accordance with Rule 5.5.2.

5.6 **Cost Estimate -** A detailed cost estimate of the construction of the dam including the engineering fees. The cost estimate will remain confidential until after the construction contract is executed.

5.7 **Fees -** A filing fee of $3.00 per $1,000.00 (or fraction thereof) of the cost estimate, limited to a maximum of $3,000.00, with a minimum filing fee of $100.00.

5.8 **Design Review Approvals and Limitations**

5.8.1 **Approval of Plans and Specifications -** Acceptable plans and specifications will be certified by the State Engineer or designee and approved for construction.

5.8.2 **Approval Limitation -** If construction, alteration, or repair of a reservoir dam is not commenced within five years of approval of the application, the State Engineer's approval shall be void. The owner must resubmit the application and receive approval before commencing construction, and shall meet the requirements of the current Rules.

5.8.3 **Design Review Limitation -** The design review performed by the State Engineer shall be limited to three years from the date of the review. Re-submittal of the design package shall be required if resolution of the design review comments does not occur within three years.

5.9 **Design Requirements**

5.9.1 **Inflow Design Flood (IDF) Requirements**

5.9.1.1 The IDF shall be determined considering basin size, the elevation of the basin, various soil permeabilities, the various vegetative covers, and other factors related to the routing of the storm event. Historical precipitation data of the National Weather Service may be used for determining the IDF provided applicable stochastic procedures are used as outlined in the National Weather Service NOAA Atlas #2 "Precipitation-Frequency Atlas of the Western United States" Volume III-Colorado, U.S. Department of Commerce, NOAA, National Weather Service, Silver Springs, Maryland, 1973, or other methods approved by the State Engineer.

5.9.1.2 The National Weather Service, NOAA, Atlas #2 "Precipitation-Frequency Atlas of the Western United States" Volume III-Colorado, U.S. Department of Commerce, NOAA, National Weather Service, Silver Springs, Maryland, 1973, may be used for determining the precipitation for l00-year, 50-year and 25-year rainstorm events for the purpose of calculating the magnitude of the resulting flooding.

5.9.1.3 Extreme Precipitation Analysis Tool - The Inflow Design Flood (IDF) requirements for determining the spillway capacity may be developed through the use of the Extreme Precipitation Analysis Tool (EPAT). The process and procedures for use of the EPAT are available from the State Engineer. The IDF requirement determined through the use of the EPAT Extreme Storm Precipitation (ESP) for determining spillway capacity are summarized in Table 5.1:

TABLE 5.1

INFLOW DESIGN FLOOD REQUIREMENTS
USING EPAT

DAM SIZE	HAZARD CLASSIFICATION			
	High	Significant	Low	NPH
Large	ESP	ESP	100 YR	50 YR
Small	ESP	0.5 ESP	100 YR	25 YR
Minor	ESP	100 YR	50 YR	25 YR

5.9.1.3.1 New Large, Small, and Minor High Hazard dams and enlargements shall have spillways capable of passing, as a minimum, the Inflow Design Flood (IDF) generated by the Extreme Storm Precipitation (ESP), unless an Incremental Damage Analysis (IDA) demonstrates a lesser inflow design flood is applicable.

5.9.1.3.2 New Large, Significant Hazard dams and enlargements shall have spillways capable of passing, as a minimum, the Inflow Design Flood (IDF) generated by the Extreme Storm Precipitation (ESP), unless an Incremental Damage Analysis (IDA) demonstrates a lesser inflow design flood is applicable.

5.9.1.3.3 New Small, Significant Hazard dams and enlargements shall have spillways capable of passing, as a minimum, the inflow design flood generated by 50 percent of the Extreme Storm Precipitation (ESP), unless an Incremental Damage Analysis (IDA) demonstrates a lesser inflow design flood is applicable.

5.9.1.3.4 New Minor, Significant Hazard plus new Large and Small, Low Hazard dams and enlargements shall have spillways capable of passing, as a minimum, the inflow design flood generated by a 24-hour, l00-year rainstorm event.

5.9.1.3.5 New Minor, Low Hazard dams and new Large, NPH Dams and enlargements shall have spillways capable of passing the inflow design flood generated by a 24-hour, 50-year rainstorm event.

5.9.1.3.6 New Small and Minor NPH dams and enlargements shall have spillways capable of passing the Inflow Design Flood (IDF) generated by a 24-hour, 25 year rainstorm event.

5.9.1.3.7 The minimum size spillway for all High Hazard, Significant Hazard, and Large and Small, Low Hazard jurisdictional size dams for which an IDA shows a smaller spillway is justifiable under Rule 5.9.7.1 shall be capable of passing the inflow design flood generated by a 24-hour, 100-year rainstorm event. For all other jurisdictional size dams, the minimum size spillway shall be capable of passing the IDF generated by the appropriate rainstorm event presented in the above table.

5.9.1.4 Hydrometeorological Report PMP - The Inflow Design Flood (IDF) requirements for determining the spillway capacity may be developed through the use of the most current Probable Maximum Precipitation (PMP) estimates from the Office of Hydrology, National Weather Service, NOAA Hydrometeorological Report Series. The PMP values are normally determined from the appropriate Hydrometeorological Report (HMR). Currently, HMR 52 and 55A are applicable for drainage basin located to the east of the Continental Divide and HMR 49 for drainage basin west of the Continental Divide. The IDF requirements for determining the spillway capacity using the appropriate HMR are summarized in Table 5.2:

TABLE 5.2

INFLOW DESIGN FLOOD REQUIREMENTS
USING HYDROMETEOROLOGICAL REPORTS (HMR)

DAM SIZE	HAZARD CLASSIFICATION			
	High	Significant	Low	NPH
Large	0.90 PMP	0.68 PMP	100 YR	50 YR
Small	0.90 PMP	0.45 PMP	100 YR	25 YR
Minor	0.45 PMP	100 YR	50 YR	25 YR

5.9.1.4.1 New Large and Small, High Hazard dams and enlargements shall have spillways capable of passing, as a minimum, the Inflow Design Flood (IDF) generated by 90 percent of the Probable Maximum Precipitation, unless an incremental damage analysis demonstrates a lesser inflow design flood is applicable.

5.9.1.4.2 New Minor, High Hazard dams and enlargements shall have spillways capable of passing, as a minimum, the Inflow Design Flood generated by 45 percent of the Probable Maximum Precipitation (PMP), unless an Incremental Damage Analysis (IDA) demonstrates a lesser IDF is applicable.

5.9.1.4.3 New Large, Significant Hazard dams and enlargements shall have spillways capable of passing, as a minimum, the Inflow Design Flood (IDF) generated by 68 percent of the Probable Maximum Precipitation (PMP), unless an Incremental Damage Analysis (IDA) demonstrates a lesser IDF is applicable.

5.9.1.4.4 New Small, Significant Hazard dams and enlargements shall have spillways capable of passing, as a minimum, the Inflow Design Flood (IDF) generated by 45 percent of the Probable Maximum Precipitation (PMP), unless an Incremental Damage Analysis (IDA) demonstrates a lesser IDF is applicable.

5.9.1.4.5 New Minor, Significant Hazard and new Large and Small, Low Hazard dams and enlargements shall have spillways capable of passing, as a minimum, the Inflow Design Flood (IDF) generated by a 24-hour, l00-year rainstorm event.

5.9.1.4.6 New Minor, Low Hazard dams, and new Large, NPH Dams and enlargements shall have spillways capable of passing the Inflow Design Flood generated by a 24-hour, 50-year rainstorm event.

5.9.1.4.7 New Small and Minor, NPH dams and enlargements shall have spillways capable of passing the Inflow Design Flood (IDF) generated by a 24-hour, 25-year rainstorm event.

5.9.1.4.8 The minimum size spillway for all High Hazard, Significant Hazard, and Large and Small, Low Hazard jurisdictional size dams for which an IDA shows a smaller spillway is justifiable under Rule 5.9.7.1 shall be capable of passing the Inflow Design Flood (IDF) generated by a 24-hour, 100-year rainstorm event. For all other jurisdictional size dams, the minimum size spillway shall be capable of passing the IDF generated by the appropriate rainstorm event presented in the above table.

5.9.1.5 Elevation Reduction - The HMR PMP used to determine the IDF may be reduced based on the average elevation of the drainage basin. The HMR PMP value may be adjusted for the determination of the IDF for drainage basins above 5,000 (ft) MSL in accordance with Table 5.3:

TABLE 5.3

HMR PMP INFLOW DESIGN FLOOD REQUIREMENTS
REDUCED FOR ELEVATION

DAM SIZE	STORM TYPE	ELEVATION	HAZARD CLASSIFICATION	
			High	Significant
Large	General Storm East	6,000 - 12,000 ft MSL	0.80 PMP	0.60 PMP
		Above 12,000 ft MSL	0.70 PMP	0.53 PMP
	General Storm West	5,000 - 8,000 ft MSL	0.80 PMP	0.60 PMP
		Above 8,000 ft MSL	0.70 PMP	0.53 PMP
	Local Storm	10,000 - 11,500 ft MSL	0.80 PMP	0.60 PMP
		11,501 - 13,000 ft MSL	0.70 PMP	0.53 PMP
		Above 13,000 ft MSL	0.60 PMP	0.45 PMP
Small	General Storm East	6,000 - 12,000 ft MSL	0.80 PMP	0.40 PMP
		Above 12,000 ft MSL	0.70 PMP	0.35 PMP
	General Storm West	5,000 - 8,000 ft MSL	0.80 PMP	0.40 PMP
		Above 8,000 ft MSL	0.70 PMP	0.35 PMP
	Local Storm	10,000 - 11,500 ft MSL	0.80 PMP	0.40 PMP
		11,501 - 13,000 ft MSL	0.70 PMP	0.35 PMP
		Above 13,000 ft MSL	0.60 PMP	0.30 PMP
Minor	General Storm East	6,000 - 12,000 ft MSL	0.40 PMP	Not Applicable
		Above 12,000 ft MSL	0.35 PMP	Not Applicable
	General Storm West	5,000 - 8,000 ft MSL	0.40 PMP	Not Applicable
		Above 8,000 ft MSL	0.35 PMP	Not Applicable
	Local Storm	10,000 - 11,500 ft MSL	0.40 PMP	Not Applicable
		11,501 - 13,000 ft MSL	0.35 PMP	Not Applicable
		Above 13,000 ft MSL	0.30 PMP	Not Applicable

5.9.1.6 Site Specific Hydrometeorologic Analysis - Site Specific Hydrometeorologic Analysis (SSHMA) may be used to determine the appropriate site specific extreme storm precipitation (SSESP) for the determination of the IDF. Site-specific evaluations are subject to approval by the State Engineer. Any procedures developed and approved by the State Engineer shall be used to determine the applicable Extreme Precipitation Event. Snowmelt conditions shall be considered as base flow when appropriate. The percentage reduction of the PMP as shown in Rule 5.9.1.5 are not applicable or allowed in the determination of site specific extreme storm precipitation or PMP values determined by the procedures and analysis provided for in this Rule for all High Hazard dams and Large Significant Hazard dams. The IDF requirement developed through the use of site specific analyses for determining spillway capacity are summarized in Table 5.4:

TABLE 5.4

INFLOW DESIGN FLOOD REQUIREMENTS
FOR SSHMA

DAM SIZE	HAZARD CLASSIFICATION			
	High	Significant	Low	NPH
Large	SSESP	0.75 SSESP	100 YR	50 YR
Small	SSESP	0.5 SSESP	100 YR	25 YR
Minor	SSESP	100 YR	50 YR	25 YR

5.9.1.7 Incremental Damage Analysis - An Incremental Damage Analysis (IDA) used to justify an Inflow Design Flood (IDF) less than the requirements of Rule 5.9.1.3 through Rule 5.9.1.6, shall be based on a comparison of two floods: first, a base flow flood of the minimum magnitude which exceeds the capacity of all spillways, resulting in overtopping of the dam routed through the downstream floodway assuming no dam is in place; and second, the dam failure flood which occurs due to overtopping, and is routed downstream with the base flow flood. The spillway capacity and IDF will be acceptable where it can be shown that the dam failure flood would cause no additional loss of life nor additional significant property damages downstream within the zone between the two floods.

5.9.1.7.1 No loss of life or significant damage is expected to occur if the increased depth of flow is two feet or less and the product of the flood flow velocity in the incremental zone and the depth of flow at critical locations along the floodway is less than seven.

5.9.1.7.2 Documentation for the IDA shall include but not be limited to: a plot showing both the base flow and dam break flood on topographic maps of the affected areas; cross-sections of the downstream channel showing flood stages, velocities, and discharges for the two floods at the critical locations; incremental damage and loss of life determinations; and a summary of all assumed hydraulic parameters. A table summarizing the results of the IDA at the various downstream cross sections showing that the criteria in Rule 5.9.1.7.1 has been satisfied shall be included in the IDA study report. Documentation shall also include, if deemed necessary by the State Engineer, channel profiles with the various flood stages, aerial photographs of the affected areas, and computer printouts showing flood discharges, stage, and velocities with respect to time.

5.9.1.8 The minimum freeboard requirements for new or enlarged dams shall be based upon the dam height required to prevent overtopping by wave action, or the sum of the inflow design flood maximum water surface level plus one foot of residual freeboard, but not less than five feet unless the State Engineer approves a lesser amount. Except for concrete dams where the design engineer has demonstrated that overtopping of the dam will not be detrimental to the safety of the dam, the inflow design flood can be

accommodated with zero residual freeboard or the overtopping depth at which the dam still meets the stability and stress requirements of Rule 5.9.5.

5.9.1.9 For any dam whose spillway is not designed to pass the inflow design flood as defined previously in Rule 5.9.1, the engineer may as an alternative, provide documentation of the analysis that overtopping of the dam by floods which exceed the spillway capacity up to the design flood will not cause failure of the dam. Otherwise, overtopping protection shall be provided.

5.9.1.10 Spillway Design Exemption - Spillways designed and constructed in accordance with the requirements of the Rules dated September 30, 1988 are exempt from the requirements of these Rules.

5.9.2 **Seismicity Design Requirements**

5.9.2.1 Dams classified as High or Significant hazard shall be analyzed for seismic stability. Seismic analysis for water storage dams shall be based on full reservoir under steady state seepage conditions. Flood control dams with ungated outlets shall be designed for earthquake loads under empty reservoir conditions and need not consider steady-state seepage for seismic analysis. Dams sited on active faults shall obtain a waiver from the State Engineer. To obtain a waiver, the analysis shall show that the location of the dam is unavoidable and the dam must be designed to withstand anticipated fault movement without compromising its integrity. Appropriate data sheets, calculation sheets and computer program output computations from manual or computerized analysis shall be provided. The seismic analysis shall meet the following minimum requirements:

5.9.2.1.1 A seismological investigation for the dam area and reservoir area. This study may be part of the geotechnical report for the structure, or may be a separate report. The study shall determine and justify the appropriate seismic parameters to be used for design. The seismic parameters shall be based on the following design earthquake:

5.9.2.1.1.1 Dams classified as High Hazard and with a height greater than or equal to 30 feet, other than flood control structures, shall be designed for the maximum credible earthquake or for an earthquake with a minimum 5000-year return frequency.

5.9.2.1.1.2 Dams classified as High Hazard and with a height less than 30 feet, other than flood control structures, shall be designed for either: a) the maximum credible earthquake or an earthquake with a minimum 5000-year return frequency, or b) for a peak ground surface acceleration equal to twice the acceleration for the site with a 2% chance of exceedance in 50 years (approximately 2500-year return frequency), as estimated and published by the U.S. Geological Survey.

5.9.2.1.1.3 Dams classified as Significant Hazard or High Hazard dams whose sole purpose is for flood control shall be designed for a 2% chance of exceedance in 50 years (approximately 2500-year return frequency).

5.9.2.2 An analysis of materials in the foundation, reservoir area and proposed embankment shall be completed to determine the potential for liquefaction, earthquake-induced sliding, or other seismic sensitivity, which may be accomplished as part of the geotechnical investigation.

5.9.2.3 Pseudostatic analysis for embankment dams will be acceptable for the following cases:

5.9.2.3.1 The embankment is to be mechanically compacted to at least 95% of the maximum standard Proctor density, ASTM D698, or at least 90% of the maximum modified Proctor density, ASTM D1557 or at least 70% relative density per ASTM D4253 and ASTM D4254, if Proctor testing is not appropriate; no materials prone to liquefaction are present in the foundation and the design peak bedrock acceleration is 0.20g or less; or

5.9.2.3.2 The embankment is to be mechanically compacted to at least 95% of the maximum standard Proctor density, ASTM D698, or at least 90% of the maximum modified Proctor density, ASTM D1557; potentially submerged portions of the embankment except for internal drain elements are constructed of clayey material; the dam is constructed on clayey soil or bedrock foundation and peak bedrock acceleration is 0.35g or less; and

5.9.2.3.3 All static stability safety factor requirements of these Rules are met; minimum freeboard requirements of these Rules are met; and the pseudostatic coefficient selected for analysis must be at least 50% of the design peak bedrock acceleration, but not less than 0.05g and the factor of safety under pseudostatic analysis shall be 1.0 or greater. In determining the factor of safety for pseudostatic analysis, a search for the critical failure surface shall be made.

5.9.2.4 Pseudostatic analysis for concrete dams will be acceptable and shall meet the requirements Rule 5.9.5.

5.9.2.5 For dams not satisfying the requirements for pseudostatic analysis, a deformation analysis is required. The resulting embankment must be capable of withstanding the design earthquake without breaching and with at least 3 feet of freeboard remaining after deformation. The analysis shall also assess the potential for internal erosion as a result of cracking during earthquake-induced deformation.

5.9.2.6 The seismic assessment shall also address the stability of appurtenant structures to the dam during the design earthquake, as appropriate, unless failure of an appurtenance due to earthquake does not represent an immediate threat to the dam, in which case a lesser operating basis earthquake may be used, as approved by the State Engineer.

5.9.3 **Geotechnical Investigation and Foundation Requirements**

5.9.3.1 Geological and geotechnical investigations are required to describe the geology and geotechnical conditions for construction of the dam and reservoir. The report shall include the geological and geotechnical analyses required for the design and construction of the dam. The report shall describe the foundation conditions for the dam and provide justification for foundation strength, deformation, sliding stability and seepage parameters assumed for design. The foundation requirements for design of the dam will vary based upon the foundation conditions, geology, rock jointing and faulting, dam size and use of the reservoir.

5.9.3.2 Geological and geotechnical engineering exploration shall be conducted under the supervision of a Licensed Professional Engineer or an Engineering Geologist experienced in geotechnical or geological engineering for dams.

5.9.3.3 Geological mapping is required for the dam and reservoir area. The geological mapping shall include the dam, dam abutments and the locations of appurtenant structures.

5.9.3.4 Subsurface investigations shall be conducted for all new dams and for all major modifications to existing dams. The subsurface investigation is typically required to evaluate the depth and geologic classification of the bedrock foundation excavatability and characterize the foundation competency under the dam. The subsurface investigation shall include, test holes, test pits, geophysical survey, insitu-testing, water packer test, pressure meter, and block shear tests.

5.9.3.5 The number and depth of test holes and test pits are typically based on the geological conditions, the complexity of the geological conditions and the size of the dam and depth of the reservoir. The number of foundation drill holes shall not be less than three.

5.9.3.6 Direct shear strength testing and compressive strength testing is required to evaluate design values for shear strength and bearing capacity. Strength properties of discontinuities and the weakest foundation materials are required, as these will generally control foundation behavior. Shear strength testing is also required on rock discontinuities including pre-existing shear planes or faults in the dam foundation. Typical test requirements could include stress-strain properties, shear wave velocity, density and tensile strength.

5.9.3.7 The geological and geotechnical basis for the foundation grouting design for the dam should be prepared. This documentation includes the basis for the design of the curtain grouting and consolidation grouting of the dam footprint.

5.9.3.8 Foundation excavation requirements necessary to provide a firm foundation for the dam shall be documented in the Geotechnical Report. The Geotechnical Report shall provide excavation requirements for shaping of the foundation to provide more uniform foundation stresses or to minimize dam cracking.

5.9.3.9 Foundation drainage design shall be provided including justification for reduction in uplift pressures on the dam. The efficiency of the drainage system to reduce uplift pressures under the dam shall be based upon the geology of the dam foundation. The ability to maintain the drainage system to meet the requirements assumed for the design of the dam shall be addressed.

5.9.3.10 Confirmation of foundation design assumptions is required after the foundation for the dam has been exposed. The project geologist and design engineer shall confirm foundation conditions assumed for the design. Changes in foundation conditions from assumptions made in the Geotechnical Report shall be communicated to the State Engineer when they are identified during construction. Changes to the foundation design for the dam shall be submitted to State Engineer's Office in a formal Change Order Request during construction per the requirements of Rule 9.

5.9.4 **Embankment Dam Design Requirements**

5.9.4.1 Stability Analysis - Embankment dams shall be designed to have stable slopes during construction, and under all conditions of reservoir operation, including rapid draw-down of the reservoir.

5.9.4.1.1 Factors of safety shall be evaluated by slope stability analyses methodologies that are acceptable to the State Engineer. The analysis models shall adequately represent, for the critical cross section (or sections) of the dam, the embankment geometry and internal zoning; shear strengths and unit weights of each material; pore water pressures; and external loading or other relevant factors. Shear strength and pore pressure assumptions used in stability analyses should be obtained from tests that appropriately model the loading condition being analyzed. Where appropriate, the analyses shall consider non-circular or wedge-shaped failure surfaces, as well as circular failure surfaces. All parameters and assumptions used in the analysis shall be summarized in a table, and justified in the Geotechnical Report. A scale drawing, utilizing the same scale for vertical and horizontal dimensions, shall be provided for each cross-sectional model used in the analysis, with the critical failure surface(s) identified. Appropriate data sheets and representative computer program output shall be provided in the report.

5.9.4.1.2 Minimum factors of safety for slope stability of embankment dams for various loading conditions other than seismic loading are summarized in Table 5.5.

TABLE 5.5

MINIMUM FACTORS OF SAFETY FOR SLOPE STABILITY
OF EMBANKMENT DAMS

Loading Condition	Minimum Factor of Safety[1]
Steady seepage with phreatic surface fully developed for reservoir at normal pool elevation	1.5
End of Construction	1.3
Rapid draw-down (upstream slope)	1.2

[1]Not applicable for embankment dams on clay shale foundations; residual shear strength may be appropriate and required factors of safety shall be determined on a case-by-case basis by the State Engineer.

5.9.4.1.3 For Low hazard or NPH dams, the State Engineer may waive the requirements for stability analysis if it can be demonstrated that conservative slopes and competent materials are used in the dam design. Dams classified as Low hazard or NPH shall have upstream slopes no steeper than 3:1 (horizontal:vertical), and downstream slopes no steeper than 2:1 (horizontal:vertical).

5.9.4.2 Seepage and Internal Drainage Design - The evaluation of the steady state seepage and internal drainage conditions shall be performed for all High and Significant Hazard Dams. The seepage and internal drainage analyses shall include, but not be limited to, the following:

5.9.4.2.1 Flow nets or numerical analysis computer programs shall be used in the analyses. Data sheets and output files from these analyses shall be provided or made available where requested. The hydraulic conductivity parameters used in these analyses shall be obtained from field permeability tests, laboratory permeability tests, or empirical/correlative permeability determinations, and the sources of the estimated hydraulic conductivities shall be clearly documented.

5.9.4.2.2 The analyses shall quantify the anticipated seepage beneath, around and through the dam. Seepage exiting on the downstream face of the dam shall not be permitted. Internal drains and filters shall be constructed of granular soil materials (sands and gravels), and the filter and drain zones shall be of sufficient thickness to be constructed without significant contamination or loss of continuity that would adversely impact the performance of these features.

5.9.4.2.3 The filter compatibility of the drain and embankment material shall be evaluated utilizing current state of the practice methodologies, such as those published by the Natural Resources Conservation Service, the U.S. Bureau of Reclamation or the U.S. Army Corps of Engineers.

5.9.4.3 For embankment dams, the following design considerations must be addressed and documented in the Design Report.

5.9.4.3.1 Geometric and Design Requirements - Dam geometry shall be supported by the slope stability and seismic analysis, and shall meet the following minimum requirements:

5.9.4.3.1.1 The crest width shall be equal to the jurisdictional height of the dam in feet divided by 5, plus 10 feet. The maximum crest width required shall be 25 feet.

5.9.4.3.1.2 The crest shall have a camber sufficient to maintain the design freeboard, based on the anticipated magnitude of crest settlement. The anticipated magnitude of crest settlement shall be based on engineering analyses. In no case shall the camber be less than 0.5 feet.

5.9.4.3.1.3 Guidelines for minimum dimensions of impervious core zones for zoned embankment dams up to 50 feet high are defined in the "Design of Small Dams," United States Department of the Interior, Bureau of Reclamation, Third Edition, 1987, U.S. Government Printing Office, Washington, D.C., 20402, (later amendments, editions or subsequent publications not included). Zone dimensioning for dams over 50 feet shall be evaluated using industry standard analyses.

5.9.4.3.1.4 Roads located on the dam crest shall have appropriate surfacing to provide a stable base that resists rutting and provides adequate traction for safety in wet conditions.

5.9.4.3.1.5 The crest design shall include details to protect impervious cores from desiccation or frost penetration, as approved by the State Engineer.

5.9.4.3.1.6 The crest shall be provided with adequate cross slopes to the upstream edge to prevent ponding.

5.9.4.3.1.7 Minimum dimensions for internal granular filter and drain zones shall meet requirements of Rule 5.9.4.2.

5.9.4.3.1.8 The embankment shall be protected against external erosion.

5.9.4.3.1.9 The downstream slope of the embankment dams shall be provided with a well maintained vegetative cover to prevent surface erosion from occurring. No landscaping or planting of trees or large vegetation shall be permitted within 25 feet of the footprint of the dam.

5.9.4.3.1.10 The shear strengths of the foundation soils (including suitable factors of safety) shall not be exceeded under any foreseeable loading conditions.

5.9.4.3.1.11 Seepage through the embankment, abutments, and foundation shall be controlled to prevent internal erosion and external sloughing.

5.9.4.3.2 Compaction Requirements - Material compaction requirements shall meet the minimum requirements:

5.9.4.3.2.1 Minimum compacted density for embankment materials shall be 95 percent of maximum dry density for ASTM D698 (Standard Proctor) or 90 percent for ASTM D1557 (Modified Proctor), as found in the 2006 "Annual Book of ASTM Standards", Section 04.08, Soil and Rock; 100 Barr Harbor Drive, West Conshohocken, PA 19428, (later amendments, editions or subsequent publications not included). Impervious zones with clay fines shall be controlled using Standard Proctor criteria to maintain the plastic nature of the material; and

5.9.4.3.2.2 The minimum density for cohesionless materials shall be 65 to 75 percent relative density as determined by ASTM D4253 and D4254 as found in the 2006 "Annual Book of ASTM Standards," Section 04.08, Soil and Rock; 100 Barr Harbor Drive, West Conshohocken, PA 19428, (later amendments, editions or subsequent publications not included).

5.9.4.3.3 Rock Riprap - Rock Riprap shall be well graded, durable and sized to withstand design wave action or channel velocities, and shall be placed on a well-graded pervious sand and gravel bedding or geotextile fabric. Soil cement for erosion protection may be used in lieu of rock riprap, but shall be designed and constructed in accordance with standards acceptable to the State Engineer. Slope protection for wave action is required to be provided on the entire upstream face of the dam, unless lesser coverage is justified based on engineering analysis and reservoir operational criteria and approved by the State Engineer.

5.9.4.3.4 Filters and Drains - The design of all drains, filter blankets, and toe drains shall be performed in accordance with Rule 5.9.4.2 and must be acceptable to the State Engineer.

5.9.4.3.5 Internal Drain Pipes - Pipes to collect and distribute seepage flows from internal filters and drains shall:

5.9.4.3.5.1 Be comprised of material that is non-corrodible and non-collapsible for the estimated overlying earth pressures and anticipated settlement or ground movement associated with dam construction.

5.9.4.3.5.2 Be surrounded with free-draining material that is filter compatible with the surrounding earth material in accordance with current filter criteria of such organizations as the Natural Resources Conservation Service, the U.S. Bureau of Reclamation, and the U.S. Army Corps of Engineers.

5.9.4.3.5.3 Have slots or perforations that are filter compatible with the surrounding free-draining material in accordance with current filter criteria of such organizations as the Natural Resources Conservation Service, the U.S. Bureau of Reclamation, and the U.S. Army Corps of Engineers.

5.9.4.3.5.4 Be installed in such a manner to be accessible for internal camera inspection and repair.

5.9.4.3.5.5 Be designed to flow with a water depth no greater than ¼ of the diameter of the pipe for the estimated seepage flows.

5.9.4.3.5.6 Be no smaller than 6 inches in diameter.

5.9.4.3.5.7 Discharge into locations where discharge flows can be evaluated and monitored, such as galleries, manholes, or daylight (ground surface) areas.

5.9.4.3.5.8 Be inspected after a maximum of 3 to 5 feet of fill placed over pipe, and again after remaining fill has been placed.

5.9.4.3.5.9 Be equipped with rodent screens in locations where the discharge ends of the pipes are accessible to animals.

5.9.4.3.5.10 Be designed with multiple discharge points in order to isolate seepage to various sections of the dam and foundation.

5.9.4.3.6 Geosynthetics - The use of geosynthetics shall be evaluated by the State Engineer on a case-by-case basis for each dam. Geosynthetics materials shall be used in accordance with the manufacturers' recommendations and intended use for each product. Use of geosynthetics shall comply with the following general design considerations:

5.9.4.3.6.1 Geosynthetics will not be accepted where the geosynthetic is the sole element employed to perform a function that is an element of the dam were failure of the geosynthetic, could result in a catastrophic release of the reservoir. Redundant design features are required whenever geosynthetics are used for these functions.

5.9.4.3.6.2 The use of a geotextile as a filter layer may be allowed if the geotextile is placed such that it does not jeopardize the stability or safety of the dam or appurtenant structures due to failure of the geotextile (such as clogging), and the geotextile can be repaired or replaced without jeopardizing the stability or safety of the dam.

5.9.5 **Concrete Dam Design Requirements**

5.9.5.1 For concrete dams, the following design considerations must be addressed and documented in the Design Report

5.9.5.1.1 Access to the dam crest shall be provided from at least one of the abutments of the dam. Access shall be provided to the side of the dam where the control of the outlet works used for the emergency release of the reservoir volume is situated.

5.9.5.1.2 The crest of the dam shall have a width of not less than 15 feet.

5.9.5.1.3 Concrete dam crests, if designed as emergency spillway, shall not be overtopped for floods more frequent than the 100-year storm. Emergency spillway discharge for flows up to the inflow design flood shall not cause excessive downstream erosion of the abutments and foundation.

5.9.5.1.4 If the design of the concrete dam includes drainage features and the reduction in uplift pressures is required to meet factors of safety and stress requirements, a gallery shall be provided in the dam to access, monitor and clean or re-drill the dam and foundation drains.

5.9.5.2 Arch Dam Design - Concrete arch dams are not specifically addressed in these Rules and shall be designed in accordance with principles provided in U.S. Bureau of Reclamation publication "Design of Arch Dams," 1977 or U.S. Army Corps of Engineers publication “Arch Dam Design” EM 1110-2-2201 1994, (later amendments, editions, or subsequent publications not included).

5.9.5.3 Gravity Dam Design - Concrete gravity dams (conventional or roller compacted concrete (RCC)) shall be designed in accordance with the following Rules and with principles provided in U.S. Bureau of Reclamation publication "Design of Gravity Dams," 1976, or U.S. Army Corps of Engineers publications “Gravity Dam Design” EM 1110-2-2200 1995 and “Roller-Compacted Concrete” EM 1110-2-2006 2000 (later amendments, editions or subsequent publication not included).

5.9.5.3.1 The structural stability and stress analyses of a concrete gravity dam for both non-overflow and spillway sections shall be performed using the gravity method of stress and stability analysis, as described in the aforementioned publications. The trial-load twist method of analysis may be used for the stability analysis when keyed or grouted transverse contraction joints are provided. The finite element method may be used to supplement the gravity method and to investigate specific features where areas of maximum stresses may occur within the dam and foundation.

5.9.5.3.2 Loads to be considered as a minimum in the stability and stress analyses are as follows: dead weight of the dam and appurtenant structures, headwater and tailwater pressures, uplift pressures in the dam and foundation, earth and silt pressures, ice pressure, seismic forces, and temperature, if appropriate. Ice pressure shall be equivalent to a force of 10,000 pounds per linear foot applied at one foot below the normal water surface elevation.

5.9.5.3.3 Concrete gravity dams shall be designed for full hydrostatic uplift pressures along appropriate planes within the dam and foundation. The uplift pressure shall vary linearly from full hydrostatic pressure at the upstream face of the dam to the tailwater pressure at the downstream dam face or zero if no tailwater conditions exist. Reduction in the uplift pressures will be allowed when dam and foundation drains are provided. The effectiveness of the drains will be required to be verified and monitored through the installation of piezometers.

5.9.5.3.4 The following loading conditions shall be investigated in the design of a concrete gravity dam, as a minimum. Other loading condition could be required depending on site conditions:

5.9.5.3.4.1 Usual Loading Condition – Reservoir at the normal water surface with minimum tailwater pressure, uplift pressures, and earth, silt and ice pressures, if applicable.

5.9.5.3.4.2 Unusual Loading Condition – Usual loading condition with no ice pressure and with hydrostatic pressures as a result of the flooding condition produced by the appropriate inflow design flood.

5.9.5.3.4.3 Extreme Loading Condition – Usual loading condition with no ice pressure and with seismic forces in the downstream direction.

5.9.5.3.5 The minimum factors of safety and allowable stresses as a result of the loading condition shall be as provided in Table 5.6:

TABLE 5.6

MINIMUM FACTORS OF SAFETY AND ALLOWABLE STRESSES FOR CONCRETE GRAVITY DAMS

Loading Condition	Resultant Location within Base	Min. Sliding Factor of Safety	Concrete Compressive Stress	Concrete Tensile Stress
Usual	Middle 1/3	3.0	$0.3\ f'_c$	0
Unusual	Middle 1/2	2.0	$0.5\ f'_c$	$0.5\ f_t$
Extreme	Within Base	1.0	$0.9\ f'_c$	$1.0\ f_t$

5.9.5.4 Roller Compacted Concrete Design Requirements - Design of new RCC dams shall meet all requirements for concrete dams regarding field investigations, testing, foundation treatment, stability and stresses. RCC dam design shall also meet the following additional requirements:

5.9.5.4.1 An RCC mix design study shall be submitted with the design report, containing proposed aggregate data, source of aggregate, strength test results, and proposed cementitious contents.

5.9.5.4.2 The dam design shall include adequate control of cracking in upstream facing system and RCC mass caused by thermal shrinkage of the concrete. Crack control provisions shall also include control of excessive heat of hydration by use of fly ash and limit in-place temperature of RCC.

5.9.5.4.3 Design dimensions shall be constructable with conventional earthwork equipment, particularly between the upstream face of the dam and the drainage gallery, and the "chimney section" width.

5.9.5.4.4 Adequate cold joint treatment shall be provided in the specifications to prevent formation of unbonded lift joints that are potential paths of seepage.

5.9.5.4.5 RCC dams with a structural height of 100 feet or higher shall be designed with a drainage gallery, when dam and foundation drains are provided.

5.9.5.4.6 Specifications shall include provisions for placing RCC under cold weather, hot weather, and rain.

5.9.5.4.7 RCC spillway chute steps shall be protected with conventional facing concrete, or equivalent protection, unless the State Engineer approves a lesser standard for good cause shown. Design of stilling basins for RCC stepped chute spillways shall include assumptions, calculations, and applicable references for estimating energy dissipation and stilling basin entrance velocities.

5.9.5.4.8 Outlet works gate and spillway towers shall be designed as temporary free-standing tower, if structures are proposed to be completed before any RCC placement.

5.9.5.5 Roller Compacted Concrete Dam Construction Requirements - The construction of RCC dams shall meet the following additional requirements.

5.9.5.5.1 An RCC test section shall be constructed outside the dam footprint at least 21 days before production placement of the RCC. The final design mix and the method of construction shall be approved by the SEO prior to production placement.

5.9.5.5.2 The Owner shall provide full-time qualified field observation during RCC production placement.

5.9.5.5.3 Locations of all cold joints shall be documented.

5.9.5.5.4 Representative RCC cores shall be taken from the completed dam to verify design strengths. RCC cores shall be 6-inch diameter.

5.9.5.5.5 Because a RCC dam can be completed within a short period of time, the dam shall be allowed to gain adequate strength before initial filling of the reservoir.

5.9.5.6 Concrete Slope and Overtopping Protection - The design of RCC and soil-cement dam rehabilitation shall meet the following additional requirements.

5.9.5.6.1 Soil-cement mix design shall meet guidelines of Portland Cement Association or the U.S. Bureau of Reclamation.

5.9.5.6.2 Soil-cement slope protection shall be designed for a minimum 56-day strength of 750 psi for durability considerations.

5.9.5.6.3 Soil-cement shall not be used for emergency spillway or embankment overtopping protection, unless it can be demonstrated that the soil-cement can withstand the anticipated flow rates and velocities.

5.9.5.6.4 RCC emergency spillway or RCC embankment overtopping protection shall not operate for floods more frequent than the 100-year storm.

5.9.5.6.5 Normal thickness of soil-cement or RCC shall be a minimum of 2 feet.

5.9.6 **Spillway and Outlet Works Design Requirements**

5.9.6.1 Spillway Design - All spillways shall be designed and constructed in a manner acceptable to the State Engineer and meet the following criteria.

5.9.6.1.1 The spillway flows must be safely routed back to the natural channel or drainage way that would exist if the dam were not built. Where the spillway channel discharges into an adjacent basin, apart from the drainage on which the dam is located, the owner shall possess title to the property, a right-of-way, or easement for the flood channel downstream to the location where the maximum discharge would no longer cause damage beyond what naturally would occur on the adjacent drainage.

5.9.6.1.2 Log booms or other methods approved by the State Engineer shall be installed in the spillway approach where logs and other debris may block spillway flow or damage the spillway structure.

5.9.6.1.3 Pipe emergency spillways are not acceptable.

5.9.6.1.4 The Design Report shall include discharge tables (in cubic feet per second) for all spillways showing the discharge for each foot of head between the crest of the spillways and dam. The equation(s) used for determining the discharge shall also be included. Crest elevations of all spillways and the dam shall be clearly noted on the table.

5.9.6.1.5 For floodwater detention and flood control dams, the required principal spillway and outlet conduit discharge rate shall be coordinated with the Division Engineer for the Water Division in which the dam is located.

5.9.6.2 Outlet Works Design - All outlet systems shall be designed and installed in a manner acceptable to the State Engineer and shall meet the following criteria:

5.9.6.2.1 The outlets for High Hazard dams shall be capable of releasing the top five feet of the reservoir capacity in five days, and for all other classes of dams as required by the State Engineer. The outlet shall be capable of releasing the entire reservoir in a reasonable period of time. In addition, outlets shall be capable of passing inflow to the reservoir with a minimum of ten feet of head, in order to meet the demands of downstream senior water rights and the owner's release requirements. The minimum size required for outlet conduits and controls is 12 inches. For all other Hazard dams, the outlets should be sized to draw down the reservoir under emergency conditions in a reasonable period of time, as determined by the State Engineer.

5.9.6.2.2 All principal outlets connected to a pipeline shall have a by-pass valve that will meet the capacity criteria as defined in Rule 5.9.6.2.1.

5.9.6.2.3 Outlet conduits for all dams, except for dams with un-gated outlets, shall have a guard gate installed at the upstream end of the conduit

5.9.6.2.4 Intake structures for outlet works shall have trash racks unless exempted by the State Engineer for good cause shown.

5.9.6.2.5 The Design Report shall include an outlet discharge table (in cubic feet per second) showing the discharge for each foot of head between the invert of the intake structure and the crest of the dam. The equation(s) used for determining the discharge shall also be included. Elevations of all outlets and spillways shall be clearly noted on the table.

5.10 **Reservoir and Water Diversion Requirements**

5.10.1 **Reservoir and Site Requirements**

5.10.1.1 The area to be submerged by the new or enlarged reservoir shall be cleared of logs and debris.

5.10.1.2 Borrow areas shall be located at least 200 feet from either toe of the dam. The dimension of this limit may be reduced using engineering analyses indicating that the reduced dimension will not negatively impact dam stability and/or foundation seepage.

5.10.1.3 The dam crest and appurtenant structures shall be accessible by equipment and vehicles for emergency operations and maintenance.

5.10.1.4 The dam owner shall possess title to the property, or a permanent easement, including permanent access, for a minimum distance of fifty feet or the height of the dam, whichever is greater, downstream from the downstream toe of the dam for the purpose of maintenance and the removal of trees and large vegetation along the downstream toe of the dam.

5.10.1.5 Pipelines, utility lines or any other construction that penetrate through dam abutment areas below the dam crest elevation, or that are within a distance of 50 feet or the height of the dam, whichever is greater, from either toe of the dam shall not be allowed without prior written approval by the State Engineer. To be considered for approval, such penetrations must be designed to protect against seepage and piping through trench backfill materials and avoid temporary or permanent impacts to dam stability, and must be documented with as-constructed survey data and installation details submitted to the State Engineer.

5.10.1.6 The design of a new reservoir or enlargement of an existing dam and reservoir shall not result in the inundation of properties (except marina-type structures) during the Inflow Design Flood (IDF) unless the dam owner owns or obtains flood right-of-ways for all areas which may be inundated by the reservoir surcharge. The owner shall submit a written statement certifying they own the properties, or own the right-of-way on all affected properties, or possess a right-of-way easement for the reservoir inundation zone.

5.10.1.7 Flood easements for spillway discharges shall meet the requirements of Rule 5.9.6.1.1.

5.10.2 **River Diversion During Construction Requirements**

5.10.2.1 A water diversion plan to control surface water during construction meeting the requirements of Rule 9 may be developed by the construction contractor based on information and requirements provided by the Engineer, or the Engineer may prepare these plans.

5.10.2.2 In developing the requirements of the plan during the project design, the design storm for the construction period, including the estimated volume or flow rate that must be managed during construction should be clearly specified in the Design Report.

5.10.2.3 The contractor may be allowed flexibility to develop the methods and means to divert the water in coordination with other aspects of the construction.

5.10.2.4 Regardless of who prepares the detailed water diversion plan, the plan must be prepared and submitted to the State Engineer for review in advance of construction of the diversion facilities in accordance with Rule 9. The plan must be prepared under the direction of a qualified Professional Engineer registered in the State of Colorado.

5.10.2.5 The water diversion plan meeting the intent of Rule 9 should include the following items.

5.10.2.5.1 Design drawings and specifications depicting the constriction of cofferdams, spillways, conduits, gates, or other temporary features that may be required to control the water.

5.10.2.5.2 Stability analysis of the cofferdam, under both normal and design flood loading condition.

5.10.2.5.3 Hydraulic calculations showing the capacity of spillways or conduits used for diversion.

5.10.2.5.4 The plan for the removal or abandonment of cofferdams, spillways, conduits, or other temporary features after construction is complete.

Rule 6. Requirements for Alteration, Modification, or Repair of an Existing Dam:

6.1 An owner proposing to alter, modify, or repair an existing dam shall submit an application package in a form acceptable to the State Engineer and receive approval of the construction plans and specifications from the State Engineer prior to construction. The provisions of Rule 6 shall apply to such application only to the extent directly related to work for which approval is being sought.

6.1.1 **Design Requirements -** The requirements of Rule 5 shall apply except as modified by Rules 6.1.2 and 6.1.3. A Hydrology Report, Geotechnical Report, Design Report, and Instrumentation Plan are required as a minimum to support the scope of the work described on the application.

6.1.2 **Application and Approval Requirements for High Hazard, Significant Hazard, and Large, Low Hazard Dams -** Plans for repair of an existing dam, or alteration of existing High Hazard, Significant Hazard, and Large, Low Hazard dams to non-jurisdictional size may be approved by the State Engineer by letter without meeting requirements set forth in Rules 5.2 and 5.3, subject to the following conditions:

6.1.2.1 A completed application form provided by the State Engineer shall accompany appropriate specifications and necessary drawings depicting minimum details for the repair or alteration. Plans and specifications must be prepared by an engineer. The provisions of Rules 5.6, 5.7, and 11 shall apply.

6.1.2.2 The plans and specifications shall contain sufficient detail to enable a contractor to prepare a bid and construct the repair, or alter the dam to non-jurisdictional size. The provisions of Rule 9 shall apply. The engineer shall give the State Engineer not less than 7 days notice of the start of construction.

6.1.2.3 Upon completion of repair or alteration, the engineer shall file as-constructed plans in conformance with Rule 5 and Rule 10.

6.1.2.4 The requirement for submitting as-constructed plans for altering an existing jurisdictional size dam to non-jurisdictional size dam will be determined by the State Engineer.

6.1.3 **Application and Approval Requirements for Small and Minor, Low Hazard and NPH Dams -** Plans for repair of Small and Minor, Low Hazard dams, or NPH dams; and plans for the alteration of all Low Hazard or NPH dams to non-jurisdictional size are exempt from the provisions of Rules 5, 6, 9, and 10, except as specified in Rule 6.1.3.1 through Rule 6.1.3.3.

6.1.3.1 Notice - The dam owner must provide at least thirty days advanced written notice to the State Engineer. The written notice must contain the name of the dam, the location of the dam, the name of the owner, and a clear description of the work to be performed.

6.1.3.2 Determination - If the State Engineer determines that plans and specifications prepared by an engineer are necessary for the repair, the owner will be notified within five working days from the date the owner's notice was received. A cost estimate and filing fee will also be required. The owner cannot begin construction until the plans and specifications are approved by the State Engineer. If plans and specifications are not required, the State Engineer will inform the dam owner of engineering and construction requirements, if any, and will perform construction inspections as determined necessary.

6.1.3.3 Project Completion - The dam owner must keep the State Engineer informed of the project status and provide the State Engineer with as-constructed drawings and specifications within sixty days following completion of the work. The as-constructed drawings must be drawn on good quality mylar with permanent ink (or equivalent), and the drawings shall be reproducible, and suitable for a long lasting permanent record.

6.1.4 **Inflow Design Flood Requirements -** The inflow design flood (IDF) requirements for all existing dams shall be determined in accordance with Rule 5. Structures with spillways designed and approved prior to 1988 and in accordance with the methods published in the U.S. Department of the Interior, Bureau of Reclamation, "Design of Small Dams," Second Edition 1973, (later amendments, editions or subsequent publications not included) shall be considered adequate for the original hazard classification. If the classification has changed, then the provisions of these Rules and specifically Rule 5 apply.

6.1.4.1 The methods of Rule 5 apply, but may be reduced for good cause shown. Spillways designed in accordance with these Rules will not be required to be enlarged due to subsequent revisions in ESP or PMP estimates, unless, in the opinion of the State Engineer, a substantial increased threat to public safety exists.

6.1.4.2 The minimum size spillway for all existing High Hazard dams and Large and Small Significant Hazard dams, for which an incremental damage analysis shows a smaller spillway is justifiable under Rule 5.9.1.7, is the spillway size required to safely accommodate the flood generated by a 24-hour, 100-year rainstorm event.

6.1.5 **Freeboard -** The minimum freeboard requirements for an existing dam shall be the maximum required to either prevent overtopping by wave action or to pass the IDF without overtopping, but not less than three feet.

6.2 **Approval Limitation -** If construction, alteration, or repair of a reservoir dam is not commenced within five years of approval of the application, the State Engineer's approval shall be void. The owner must resubmit the application and receive approval before commencing construction, and shall meet the requirements of the current Rules and Regulations.

6.3 **Design Review Limitation -** The design review performed by the State Engineer shall be limited to three years from the date of the review. Re-submittal of the design package shall be required if resolution of the design review comments does not occur within three years.

Rule 7. Requirements for Removing or Breaching an Existing Dam:

7.1 **Breach Plan and Application -** An owner proposing to permanently remove or breach a dam shall submit an application package in a form acceptable to the State Engineer prior to commencing work. Plans for Removal or Breach of a dam shall meet the following requirements:

7.1.1 **Application -** A completed application shall be submitted on a form provided by the State Engineer.

7.1.2 **High and Significant Hazard Dams -** For High and Significant Hazard dams, a breach plan shall be prepared by an engineer.

7.1.2.1 The dam shall be excavated down to the level of the natural ground, or as necessary in accordance with Rule 7.1.2.3, at the maximum section; and shall be of sufficient width to pass the 24-hour, 100-year flood with a maximum increase in reservoir depth of five feet. However, the maximum breach width shall not exceed the width of the original natural channel before the dam was constructed, regardless of the 100-year flood magnitude unless approved by the State Engineer for improved public safety.

7.1.2.2 The sides of the breach shall be excavated to a slope that is stable, but not steeper than 2:1 (two horizontal to one vertical). Slope stability analysis that provides an adequate factor of safety for steeper slopes may be accepted by the State Engineer, but in no case shall the slopes be steeper than 1:1.

7.1.2.3 The breach shall be designed to prevent silt previously deposited in the reservoir and material excavated for the breach from washing downstream.

7.1.2.4 Water impounded in the reservoir area shall be released in a controlled manner that will not endanger lives or damage downstream properties.

7.1.2.5 The drawing(s) of the plan for the breach of a dam shall include the location, dimensions and lowest elevation of the breach.

7.1.2.6 The removal or breaching of the dam shall be performed under the purview of an engineer.

7.1.2.7 The engineer shall submit written notice of the completion of the removal or breaching of the dam along with as-constructed plans in conformance with Rule 10.

7.1.3 **Low Hazard and NPH Dams -** For Low Hazard and NPH dams the owner shall submit a written notice of intent to breach the dam to the State Engineer. The State Engineer shall determine the size of the breach in accordance with the following:

7.1.3.1 The bottom width of the breach shall be one-half the height of the dam but not less than ten feet;

7.1.3.2 The side slopes of the breach shall not be steeper than one horizontal to one vertical;

7.1.3.3 The breach shall be to original ground at the low point in the foundation of the dam; and

7.1.3.4 The excavated material shall not be placed in the stream channel.

Rule 8. Fees:

The owner shall submit with the application for construction, enlargement, alteration, modification, or repair an amount equal to three dollars for each one thousand dollars or fraction thereof of the estimated cost of construction including engineering costs, but the maximum fee shall not exceed three thousand dollars, nor shall the minimum fee be less than one hundred dollars. When an owner resubmits an application that was previously received and disapproved by the State Engineer, the owner shall submit a new filing fee in accordance with the above. Checks shall be made payable to the Colorado Division of Water Resources.

Rule 9. Construction of Jurisdictional Size Dams:

9.1 **High and Significant Hazard Dams** - For all High and Significant Hazard dams, the owner shall provide an engineer experienced in dam design and construction, who shall be responsible for the following:

9.1.1 **Plan for Construction Observation -** Not less than 30 days prior to construction, the engineer must submit to the State Engineer a general plan for construction observation. The construction observation plan shall include:

9.1.1.1 The date of the start of construction;

9.1.1.2 Names and qualifications of the engineer and staff to be used on the project;

9.1.1.3 A construction observation schedule for the engineer and staff;

9.1.1.4 For dams on rock foundations, a schedule for observations of the foundation by a geologist, or engineering geologist;

9.1.1.5 A schedule for inspection of the gate installation by the gate manufacturer or its representative unless waived by the State Engineer;

9.1.1.6 Identification of the firm that will conduct the construction material tests in the field and in the laboratory; and

9.1.1.7 A schedule of the construction material tests.

9.1.2 **Approval -** Within ten working days of receipt, the State Engineer shall provide written comments and approval, or conditions for approval of the construction observation plan. Construction shall not commence without approval of the observation plan by the State Engineer.

9.1.3 **Pre-Construction Meeting -** Subsequent to submitting the construction observation plan, but no later than two weeks prior to commencement of construction, a meeting shall be held between the engineer, dam owner, State Engineer and the general contractor. The general contractor shall develop and thoroughly explain its construction control plan along with any anticipated construction difficulties. During this meeting, the means used to divert and care for the stream during construction will be identified by the contractor; and if reasonable, the plan will be approved by the State Engineer. The name of the contractors and any principals in charge shall be furnished to the State Engineer at the meeting. Project communication protocol between the owner, engineer and the State Engineer shall be established at the pre-construction meeting.

9.1.4 **Engineer's Observation -** The engineer shall observe the construction of the dam. It is the engineer's responsibility to observe the progress and quality of the construction to determine whether the construction is proceeding in accordance with the approved plans and specifications. The engineer shall endeavor to prevent defects and deficiencies in the construction of the dam and appurtenant structures, and shall disapprove or reject work failing to conform to the approved plans and specifications. To assure independent review and proper quality assurance, in cases where the engineer has a contractual relationship with the general construction contractor to provide engineering services, the owner shall provide an independent, third-party engineer to perform the engineering quality assurance observations.

9.1.5 **Construction Records -** The engineer shall maintain a record of construction that, as a minimum, shall include: daily activity and progress reports; all test results pertaining to construction; photographs sufficient to provide a record of foundation conditions and various stages of the construction through completion; all geologic information obtained; and construction problems and remedies.

9.1.6 **Progress Report -** A construction progress report summarizing the contents of Rule 9.1.5 shall be submitted to the State Engineer every 30 days or more frequently if directed by the State Engineer. A summary report of all the items in Rule 9.1.5 shall be submitted at the end of construction in accordance with Rule 10.

9.1.7 **Notice for Inspection -** The engineer shall give the State Engineer at least five days advance notice of initial materials placement on the dam's foundation, in the cutoff trench, outlet backfill, outlet foundation and any appurtenance requested by the State Engineer in the approval of the plan for construction observation, to allow for observation by the State Engineer.

9.1.8 **Change Order -** When unforeseen site conditions or material availability require that the construction work differ significantly from the approved plans and specifications, a change order, including details, must be provided by the engineer to the State Engineer. No change shall be executed until approved by the State Engineer. Major changes must be submitted in writing with supporting documentation, and approved in writing by the State Engineer. Minor changes may be transmitted verbally by the engineer and approved by the State Engineer verbally.

9.1.9 **Final Inspection -** The engineer shall give the State Engineer at least 10 days advance written notice prior to the projects final construction inspection.

9.1.10 **Completion of Construction -** The engineer shall notify the State Engineer of the completion of the construction in accordance with Rule 10.

9.2 **Low Hazard and NPH Dams -** Low Hazard and NPH dams require the owner to provide an engineer experienced in dam design and construction, who shall be responsible for the following:

9.2.1 **Construction Plan -** Not less than 30 days prior to construction or as soon as possible for dams whose construction season is affected by freezing weather, the engineer shall notify the State Engineer in writing of the date construction will begin, the name of the engineer in charge of the project, and the name of the contractor.

9.2.2 **Engineer Observation -** The engineer shall observe, or provide for the observation by a qualified technician directly responsible to the engineer, the construction work on the dam, the cutoff trench, and outlet works foundation to see that they are in substantial accordance with the approved plans. The engineer shall endeavor to guard against defects and deficiencies in the construction of the dam, and shall disapprove or reject work failing to conform to the approved plans and specifications.

9.2.3 **Inspection, Testing and Reporting -** Tests of construction materials shall be taken and inspections of the construction made to verify that the work is completed in accordance with the approved plans and specifications. Periodic progress reports shall be submitted as requested by the State Engineer. The engineer shall compile a record of all tests conducted, and any problems and remedies, for submittal to the State Engineer at the end of construction.

9.2.4 **Change Orders -** Change orders shall be submitted in accordance with Rule 9.1.8.

9.2.5 **Final Inspection -** The engineer shall give the State Engineer at least 10 days advance written notice prior to the projects final construction inspection.

9.2.6 **Completion of Construction -** The engineer shall notify the State Engineer of the completion of construction in accordance with Rule 10.

Rule 10. Acceptance of Construction of Jurisdictional Size Dams:

10.1 **Acceptance of Construction -** Construction for which application has been made pursuant to Rule 5 or Rule 6 shall not be deemed complete nor shall storage of water be permitted until the State Engineer furnishes to the owner a written statement of acceptance, unless temporary approval of storage is granted by the State Engineer. The acceptance shall specify the vertical height, freeboard, length of the dam, the capacity of the reservoir in acre-feet, and any limitation upon, or requirements for the use of the dam. The State Engineer shall furnish the acceptance or denial within 60 days of receipt of a complete notification of completion.

10.2 **Construction Completion Documents -** The engineer shall provide the following construction documentation within 60 days of the final construction inspection in order for the project to be deemed complete:

10.2.1 A written notification that the project is complete and in general conforms with the approved plans, specifications and change orders;

10.2.2 As-constructed drawings that meet the format requirements of Rule 5;

10.2.3 A final construction report containing the following information, if applicable, in accordance with the requirements of Rule 9; a summary of construction, problems encountered, and solutions implemented to resolve the problems; a summary of construction material tests and geologic observations; photographs of construction from exposure of the foundation to completion of construction;

10.2.4 A record of the location of permanent monuments and instrumentation as well as installation details and initial surveys and readings shall be submitted, if applicable;

10.2.5 A schedule for the first filling of the reservoir specifying fill rates, water level elevations to be held for observation, and a schedule for inspecting and monitoring the dam. No filling schedule is required for minor dams rated Low Hazard and all NPH dams or if waived by the State Engineer for good cause shown. The dam owner, however, shall monitor the dam frequently during the first filling; and

10.2.6 A long-term instrumentation monitoring plan for new dams and enlargements (except for minor Low Hazard and all NPH dams) that shall include: the frequency of monitoring; the data recording format; graphical presentation of data; and, the parties who will perform the work.

10.3 The engineer shall provide periodic review of the data included in the long-term monitoring plan on at least an annual basis for the first five years, whereupon the monitoring shall continue in accordance with Rule 15. The engineer shall submit the data and a written assessment of the dam's performance to the State Engineer annually.

10.4 Upon written request by the owner and for good cause shown, the State Engineer may temporarily approve storage of water prior to full compliance with Rule 10. The written request shall include a schedule for compliance with Rule 10, a certification letter signed and sealed by the engineer in accordance with Rule 10.2.1, a schedule for the first filling of reservoir in accordance Rule 10.2.5, and a monitoring plan for observing the behavior of the dam and appurtenances during the initial filling or refilling of the reservoir. For High and Significant Hazard dams, an Emergency Action Plan prepared in accordance with Rule 16 shall be developed by the owner and approved by the State Engineer prior to placing any water in the reservoir. Only a partial reservoir filling will be granted under this Rule. Final acceptance of the construction for full use of the reservoir will not be granted until the requirements of Rule 10 have been satisfactorily completed.

10.5 The engineer and/or owner shall submit an Emergency Action Plan that conforms to Rule 16 within 60 days after the final construction inspection.

Rule 11. Construction, Modification, Alteration, Repair, and Breach of Non-jurisdictional Size Dams:

11.1 **Notice of Construction -** Any person intending to construct a non-jurisdictional size dam other than a Livestock Water Tank or Erosion Control Dam, must submit notice of the intent to construct the dam on forms provided by the State Engineer not less than 45 calendar days prior to the proposed construction. The State Engineer shall determine the potential hazard for loss of life or significant damage due to failure of the structure and determine if the submittal of plans and specifications and approval of the plans and specifications by the State Engineer is required prior to construction. The forms shall be submitted to the Division Engineer of the Water Division in which the dam is to be located. The Division Engineer shall respond to the owner within 45 days after receipt of the complete notice of intent to construct form. All dam owners shall be required to comply with the applicable dam safety and water administration requirements.

11.2 **Modification or alteration to Non-jurisdictional Size Dam -** Jurisdictional size dams proposed to be modified or altered to non-jurisdictional size shall comply with the following requirements:

11.2.1 For High or Significant Hazard dams, the owner shall submit plans for approval in accordance with Rule 6.1.2.

11.2.2 For Low Hazard or NPH dams, the owner shall submit written notice of the intent to alter the dam to the State Engineer in accordance with Rule 6.1.3.

11.2.3 The engineer shall submit written notice of the completion of the project and file as-constructed plans in conformance with Rule 10.

11.3 **Repair and Breaching of Non-jurisdictional Dams -** Repair and breaching of existing non-jurisdictional size dams shall meet the following requirements:

11.3.1 Owners who intend to repair, modify, breach or entirely remove a non-jurisdictional dam shall submit written notice to the State Engineer prior to construction.

11.3.2 High or Significant Hazard non-jurisdictional size dams shall have the plans for repair or breaching prepared by an engineer and submitted to the State Engineer for approval before construction. The plans shall be of sufficient detail to allow review and provide for the quality control of the work and must meet the requirements of Rule 7.1.2, if the dam is being breached.

11.4 **Spillway Requirements -** Spillway sizing requirements shall meet the criteria for the appropriate hazard classification of the dam for a Minor size dam as specified in the appropriate Table of Inflow Design Flood Requirements in Rule 5.9.1.

11.5 **Construction of Non-Jurisdictional Size Dams under Rule 11 -** The construction of non-jurisdictional size dams under these provisions with freeboard in excess of five feet with the intent to convert the dam to a jurisdictional size structure with only minor modifications to the spillway will not be approved. The modification of a non-jurisdictional size dam to a jurisdictional size dam will not be permitted within 10 years of the construction of the original structure and/or without meeting the requirements of Rule 5.

Rule 12. General Maintenance, Ordinary Repairs, and Emergency Actions:

12.1 **General Maintenance -** General maintenance and ordinary repairs that do not require prior approval of the State Engineer for the purpose of this Rule shall be those activities that do not impair the safety of the dam. These maintenance and repair activities include:

12.1.1 Removal of brush or tall weeds.

12.1.2 Cutting of trees and removal of slash from the embankment or spillway. Removal of small stumps is acceptable provided no excavation of more than 3 feet into the embankment occurs. An engineer must oversee removal of trees and stumps larger than 12" diameter.

12.1.3 Rodent control, removal or extermination. Repair of minor rodent damage is acceptable provided it does not involve excavation of more than 3 feet into the embankment.

12.1.4 Repair of erosion gullies on the embankment or in the spillway. Large gullies that have already weakened the dam must be repaired in accordance with Rule 6.

12.1.5 Surface grading of the embankment crest or spillway to eliminate potholes and provide proper drainage provided that the freeboard is not reduced. Material placed on the dam crest to restore the design freeboard must be compacted to specifications outlined in Rule 5. The State Engineer must be provided notice prior to placement of material on the dam crest of greater than 1 foot in depth for approval. Placement of material in excess of 1 foot in depth to provide freeboard is not considered general maintenance.

12.1.6 Placement of additional riprap and bedding on the upstream slope, or in areas of the spillway that have sustained minor damage. Such placement shall be limited to restoring the original riprap protection where the damage has not yet resulted in weakening of the dam. An engineer must oversee restoration of the embankment.

12.1.7 Painting or caulking metal structures, or lubricating mechanical equipment.

12.1.8 Patching, sealing, or caulking spalled or cracked concrete surfaces to prevent deterioration.

12.1.9 Removing debris, rock, or earth from outlet conduits, outlet channels or spillway channels.

12.1.10 Patching or sealing surface damage to prevent further deterioration within outlet conduits.

12.1.11 Replacement of worn or damaged parts of outlet valves or controls to restore to original condition.

12.1.12 Repair or replacement of fences intended to keep traffic or livestock off the dam or spillway.

12.1.13 Landscaping of new and existing dams and spillway channels is not general maintenance and will not be allowed without the prior approval of the State Engineer. No trees or large vegetation shall be planted within 25 feet of the footprint of the dam.

12.2 **Excavation and Determination of General Maintenance -** General maintenance and ordinary repair which may impair safety such as excavation into or near the dam, construction of new appurtenant structures for the dam, and repair of damage which has already significantly weakened the dam must be done in accordance with Rule 6. When questions arise concerning this Rule, the determination of general maintenance and ordinary repair will be made by the State Engineer.

12.3 **Emergency Action -** Emergency actions not impairing the safety of the dam may be taken before consultation and guidance can be provided by an engineer, and do not require prior approval of the State Engineer. Emergency actions are interim solutions only and may not serve as a permanent solution to the problem being addressed. Additional remedial actions may be required after the emergency passes. Emergency actions may include:

12.3.1 Stockpiling materials such as riprap, earthfill, sand, sandbags and plastic sheeting;

12.3.2 Lowering the reservoir level by making controlled releases through the outlet or a gated spillway, by pumping, or by siphoning. Where large releases are to be made, the Division Engineer shall be notified;

12.3.3 Armoring eroding areas by placing sandbags, riprap, plastic sheeting, or other available material;

12.3.4 Plugging leakage entrances on the upstream slope;

12.3.5 Increasing freeboard by placing sandbags or temporary earthfill on the dam;

12.3.6 Diverting flood waters around the reservoir or closing inflow diversions;

12.3.7 Constructing training berms to control flood waters;

12.3.8 Placing sandbag ring dikes around boils at the downstream toe to provide back pressure; and/or

12.3.9 Removing obstructions from outlet or spillway flow areas.

12.4 **Emergency Excavation -** Lowering the water level by excavating the spillway or embankment is prohibited unless failure is imminent.

12.5 **Emergency Notification -** The State Engineer shall be notified as soon as reasonably possible of any emergency condition that exists and any emergency action taken with or without prior approval of the State Engineer.

12.6 **Emergency Action Plan -** For all High and Significant Hazard dams, the Emergency Action Plan must be implemented in conjunction with any emergency actions taken in accordance with Rule 12.

Rule 13. Determination of Safe Storage Level:

13.1 **Authority to Determine Safe Storage Level -** The State Engineer is assigned the responsibility to determine the safe storage level for every reservoir in the state. The reservoir owner shall not store water in excess of the amount so determined by the State Engineer to be safe.

13.2 **Restriction of Storage -** If the dam safety inspection or information from other reliable sources reveals problems affecting the safe storage level of the reservoir, the State Engineer will issue an order restricting reservoir operations until the problems have been resolved. The dam owner shall comply with the restriction order at all times. The restriction order will be removed or modified by the State Engineer only after receipt and approval of engineering evaluations which indicate that the problems have been adequately remediated and after completion of required repairs.

13.3 **Review of Potential Hazard Classification** - As part of the determination of safe storage level, the State Engineer will periodically review the classification of existing dams by evaluating the consequences of failure applying the definitions of Rule 4. If the State Engineer's review indicates the consequences of failure have increased or decreased due to changes in development within the dam failure inundation area, the State Engineer will assign an appropriate new classification and will require that, the dam meet the requirements of these Rules as they apply to the new classification, within a reasonable period of time.

Rule 14. Safety Inspections Performed by the Owner's Engineer:

14.1 **Owner Safety Inspection -** An owner may provide a safety inspection report to the State Engineer regarding the safe storage level of a reservoir. The State Engineer may utilize the owner's safety inspection report in lieu of a State Engineer safety inspection report if said report is written by a qualified engineer, as defined below. The owner's engineer must notify the State Engineer and submit a written summary of qualifications at least 14 days prior to the scheduled safety inspection.

14.2 **Engineer Qualifications -** An engineer shall be considered qualified to provide information to the State Engineer regarding the safe storage level of a reservoir if the engineer meets the following minimum qualifications:

14.2.1 Registration as a professional engineer in Colorado;

14.2.2 Three years of experience in the field of dam safety; and

14.2.3 Experience in conducting safety inspections of dams.

14.3 **Scope of Inspection -** Dam safety inspections by the owner's engineer shall include, but are not limited to: review of previous inspections, reports and drawings; site inspection of the dam, spillways, outlet facilities, seepage control and measurement system; and evaluation of data from permanent monument or monitoring installations, if any. The inspection shall include an assessment of all parts of the dam which are related to the dam's safety. (See Rule 15.1 for outlet inspection requirements.) The engineer shall prepare an inspection report that describes the findings, and lists actions the dam owner must take to improve the safety of the dam to an acceptable level. The report shall include the engineer's recommendation of the safe storage level.

14.4 **Retaining an Engineer** - If the owner elects to retain an engineer to conduct safety inspections, such inspections shall be conducted in accordance with current policies and Rules of the State Engineer.

Rule 15. Dam Owner's Responsibilities:

15.1 **Outlet Inspection -** It is the dam owner's responsibility to provide for inspection of outlet facilities associated with the dam. The frequency of outlet inspections and the requirements of those inspections are as follows:

15.1.1 High and Significant Hazard dams shall receive a Type A outlet inspection in conjunction with safety inspections, and Type B inspections at least once every ten years unless the condition indicates more frequent inspections are necessary. A Type B inspection of the entire outlet conduit shall only be required on dams without upstream gates if ordered by the State Engineer in conformity with Rule 15.1.4. Type B inspections may be waived where the condition of the outlet conduit would not be considered detrimental to the safety of the dam.

15.1.2 Low Hazard and NPH dams shall receive a Type A outlet inspection in conjunction with routine periodic safety inspections of the dam. A Type B inspection may be required by the State Engineer to determine the safe storage level.

15.1.3 Type A outlet inspections shall consist of observation of exposed surfaces of the inlet and discharge structures, control valves or gates and vaults; a test of the outlet valve(s) for proper operation, observation of the downstream end of the conduit and adjacent embankment for leakage; and observation of the dam (upstream slope, crest, downstream

slope or natural ground) in the vicinity of the outlet alignment for signs of distress which would indicate failure of the outlet system.

15.1.4 Type B outlet inspections shall consist of a complete Type A inspection, a close inspection of the interior of the conduits, outlet wells, and access ways, and operation of the outlet valve(s) or gates through the full operating range. In cases where the conduits are too small for a person to safely enter, the owner shall provide for an inspection using video or other remote sensing equipment capable of detecting flaws or imperfections within the conduit. A written report of inspection findings, including the opinion of the owner's engineer, must be submitted to the State Engineer unless waived by the State Engineer for good cause. A Type B inspection of the normally inundated outlet conduit of a dam without upstream guard gates shall be required only when existing baseline data available to the State Engineer is inadequate to permit an evaluation of the condition of the outlet conduit. Thereafter, such inspections shall only be required if the criteria set forth in ACER Technical Memorandum No. 6, U.S. Department of the Interior, Bureau of Reclamation, 1985, (later amendments, editions or subsequent publications not included) indicates the need for an inspection. In ordering such inspections, the State Engineer shall coordinate with the dam owner and make all reasonable efforts to prevent expense and waste of water consistent with ensuring dam safety.

15.1.5 At any time the water level in a dam without upstream gates on the outlet conduit will be lowered to the invert of the conduit, or the normally inundated conduit will be otherwise dewatered and available for inspection, the dam owner shall inform the State Engineer in writing. The dam owner is responsible to provide for inspection of outlet facilities associated with the dam and may take advantage of the low water level conditions to perform the necessary outlet inspection. The State Engineer may require an inspection of the conduit when conditions warrant and/or based on the period of time since the last outlet inspection.

15.2 **Owner Observations -** The owner is responsible for ensuring frequent observation of the dam, unless prohibited by weather or difficulty of access to the dam, especially at times when the reservoir is full, during heavy rains or flooding, and following an earthquake. When the reservoir water level is greater than half the full storage capacity, High and Significant Hazard dams shall be observed at least twice a month, and a Low Hazard dam shall be observed at least every three months. The observations shall be conducted in accordance with methods acceptable to the State Engineer. Conditions which threaten the safety of the dam must be reported to the State Engineer in accordance with the Emergency Action Plan for High and Significant Hazard dams as soon as reasonably possible, after discovery of the conditions. If dam failure appears imminent, the county sheriff (or local emergency manager) must be immediately notified. The owner is responsible for the safety of the dam and shall take action to lower the reservoir if it appears that the dam has weakened or is in danger of failing.

15.3 **Monitoring Instrumentation -** The owner of a dam is responsible for installing, maintaining, and monitoring the required instrumentation. All instrumentation plans shall be submitted to the State Engineer for review and approval prior to installation of instrumentation, survey monuments, weirs, flumes or other measuring devices.

15.3.1 The following minimum instrumentation is required on existing dams; however, the State Engineer may require additional instrumentation when he deems it necessary.

15.3.1.1 High Hazard dams shall have survey monuments to monitor horizontal and vertical movement of the dam and appurtenant structures, and weirs, flumes or other structures that are acceptable to the State Engineer to monitor seepage. Installation of piezometers to measure the internal water surface of the embankment or adjacent abutments and foundation of the dam may be required by the State Engineer for determination of the safe storage level in the reservoir.

15.3.1.2 Significant and Low Hazard dams shall have weirs, flumes or other structures that are acceptable to the State Engineer to monitor seepage. Significant Hazard dams may require piezometers be installed as described in Rule 15.3.1.1.

15.3.1.3 All dams shall have gage rods pursuant to Rule 5.

15.3.2 The dam owner shall measure seepage during each routine observation of the dam. Owners of High Hazard dams shall also be responsible for providing first order surveys of horizontal and vertical movement monuments. These surveys are required annually for five years (including the year of installation of the monuments) on new and recently enlarged dams, and then once every five years thereafter. The State Engineer may also approve other methods for monitoring movement monuments on the dam and may require monitoring at any frequency deemed necessary based upon review of inspection data and past measurement results.

15.3.3 The dam owner is responsible for ensuring that all instrumentation data is properly recorded in an acceptable format and sent to the State Engineer annually. The State Engineer may require that instrumentation data for High and Significant Hazard dams be evaluated by the owner's engineer and the analysis sent to the State Engineer annually, unless more frequent reporting is required by the State Engineer.

15.3.4 The dam owner shall promptly notify the State Engineer of any abnormal changes in the dam based on the results of evaluation of instrumentation data, as compared to historical patterns and trends.

15.4 **Responsibility for Maintenance -** The owner is responsible for adequate and timely maintenance of the dam. The owner shall establish an annual maintenance plan to ensure that the maintenance, as identified in Rule 12, is accomplished.

15.5 **Trash Racks -** The owner shall ensure that trash racks are installed on all outlet structures unless waived in writing by the State Engineer.

15.6 **Change In Ownership -** Changes in ownership of a dam shall be immediately filed with the State Engineer.

Rule 16. Emergency Action Plans (EAP):

16.1 **Emergency Action Plans (EAP) -** Owners of High and Significant Hazard dams shall prepare and maintain an Emergency Action Plan. An EAP is a formal document that identifies potential emergency conditions at a dam and specifies preplanned immediate actions to prevent failure of the dam, reduce the potential for loss of life, and minimize property damage downstream. An EAP shall contain, as a minimum, the following key elements:

16.1.1 **Emergency Condition Detection** – The conditions, incident, events, or measures for detection of an existing or potential emergency shall be described.

16.1.2 **Emergency Level Determination** – Guidance shall be provided for classifying the emergency level following incident detection using the system of:

16.1.2.1 Emergency Level 1 – A non-emergency incident, unusual event, or slowly developing situation, which if not mitigated, endangers the structural integrity of the dam or results in uncontrolled releases of water causing flooding downstream;

16.1.2.2 Emergency Level 2 – Potential dam failure situation, rapidly developing, and;

16.1.2.3 Emergency Level 3 – Urgent, dam failure is imminent or in progress.

16.1.3 **Notification and Communication -** Prioritized notification lists and flowcharts applicable to each of the emergency levels shall be provided to enable communication and notification of the emergency level and with applicable Local, State and Federal emergency agencies, engineering and construction support personnel, the State Engineer's office, and other affected parties as appropriate.

16.1.4 **Expected Actions** –Description of actions necessary to prevent a dam failure incident or to help reduce the effects of a dam failure and facilitate response to an emergency, including, but not limited to, identification of equipment, manpower, and material available for implementation of the plan.

16.1.5 **Inundation Mapping -** A dam failure inundation map for High and Significant Hazard dams showing the stream which will be flooded, including urban and rural impacts. Inundation mapping for High and Significant Hazard dams shall contain the following minimum information:

16.1.5.1 - Inundation mapping for High Hazard dams shall show the calculated extents of the dam breach flood wave. Include cross sections at critical locations showing lateral and vertical flood extents, flood wave velocity and flood wave arrival time. Inundation mapping shall be extended downstream to a location where no potential for loss of life and no significant property damage exist.

16.1.5.2 - Inundation mapping for Significant Hazard dams shall show the route of the dam breach flood wave, the estimated time of arrival of the flood wave at critical

sections, and the estimated lateral extent of inundation. The inundation mapping shall be extended downstream to a location where no significant property damage exists. The inundation mapping requirements for Significant Hazard dams may be modified for good cause, with the approval of the State Engineer.

16.1.6 **Termination** – A description of the roles and responsibilities for declaring that the emergency or incident at the dam is terminated, and a discussion of the requirements for follow up evaluation including, but not limited to, documenting the event in a summary report.

16.2 **EAP Guidelines -** The State Engineer's guidelines are available to aid in the preparation and/or revision of EAPs for all High and Significant Hazard dams.

16.3 **EAP Distribution -** The owner shall submit a copy of the EAP to the Colorado Division of Emergency Management (CDEM), all emergency response coordinators involved in the plan, and other affected parties, as necessary. A distribution list that includes the names and contact information for all parties who have been provided with a copy of the EAP shall be included in the EAP. The owner shall incorporate reasonable recommendations from the CDEM, the State Engineer, emergency coordinators, and other parties affected by the plan.

16.4 **EAP Updates –** The owner shall review the EAP annually and update as necessary and appropriate. The updates shall be distributed to all parties shown on the distribution list.

16.5 **EAP Testing -** The owner shall test the EAP as necessary to ensure the effectiveness of the EAP, that the EAP is up to date, and to obtain information for revisions or corrections, as deemed necessary. All Revisions and corrections shall be distributed to all parties on the distribution list.

Rule 17. Exempt Structures:

17.1 **Exempt Structures -** Existing or proposed structures not designed or operated for the purpose of impounding water above the natural surface of the ground other than flood detention are exempt from these Rules. Exempt structures include:

17.1.1 Highways, road-fills, and railroad embankments with an ungated outlet conduit;

17.1.2 Diversion dams if less than jurisdictional size, and all diversion dams of any size if Low Hazard or NPH;

17.1.3 Refuse embankments (e.g., solid waste disposal facilities); and,

17.1.4 Structures which store water only below the lowest point of the natural ground are exempt from these Rules, unless an outlet works is constructed to develop water.

17.2 **Mine Tailing Impoundments -** Mill tailing impoundments which are permitted under the Colorado Mined Land Reclamation Act, sections 34-32-101 through 125, C.R.S. or the Colorado Surface Coal Mining Reclamation Act, sections 34-33-101 through 137, C.R.S. are exempt from these Rules. Any solution process impoundment permitted under the Colorado Mined Land

Reclamation Act, or the Colorado Surface Coal Mining Reclamation Act, are exempt from these Rules and Regulations. Siltation structures which are permitted under the Colorado Surface Coal Mining Reclamation Act, sections 34-33-101 through 137, C.R.S. are exempt from these Rules.

17.3 **Uranium Mill Tailing Dams -** Uranium mill tailing and liquid impoundment dams permitted under the authority of the Colorado Department of Public Health and Environment are exempt from these Rules. Raw and potable water dams, sewage effluent dams, and water treatment sludge dams associated with the uranium mill are not exempt.

17.4 **Livestock Water Tanks -** Livestock Water Tanks as defined in the Livestock Water Tank Act of Colorado, Sections 35-49-101 through 116, C.R.S., are exempt from these Rules.

17.5 **Erosion Control Dams -** Erosion Control Dams as defined in Section 37-87-122, C.R.S., are exempt from these Rules.

Rule 18. Restriction of Recreational Facilities within Reservoirs:

18.1 **Restriction on Construction -** No person, including any state or federal agency, quasi-municipal corporation, or political subdivision, shall construct any permanent recreational structure within a reservoir below the elevation of the bottom of the spillway unless:

18.1.1 The facility is constructed to withstand partial or complete inundation without significant damage; or

18.1.2 The facility is necessary to the operation of the reservoir; and

18.1.3 The facility is capable of being restored with a minimum amount of cleaning or expense. Boat ramps, docks, and marinas are exempt from these Rules.

18.2 **Existing Facilities -** This Rule does not apply to facilities completed prior to July 1, 1984, but shall apply to any subsequent enlargements or modifications to such facilities.

18.3 **Construction Requirements -** Any person planning on constructing, enlarging, or modifying any facility coming under this Rule shall notify the State Engineer in writing 180 days in advance of construction. The notice shall include the following information:

18.3.1 The name and location of the reservoir and/or dam;

18.3.2 Whether the recreational facility is new, or an enlargement or modification to a facility completed prior to July 1, 1984;

18.3.3 A description of the facility, its intended purpose, and its location within the reservoir including depth below the high water line; and

18.3.4 A description of how the facility will be able to withstand the damage from the inundation without a significant amount of cleaning or expense to restore it.

18.4 **Approval Prior to Construction -** No person shall be allowed to construct, enlarge, or modify any facility coming under this Rule until approved by the State Engineer.

Rule 19. Waiver or Delay of Enforcement of Rules by the State Engineer:

The State Engineer may waive or delay the enforcement of any of the responsibilities of dam owners under the foregoing Rules in particular cases if, in the State Engineer's judgment, dam safety will not be reasonably impaired and the circumstances of the individual case so warrants. Such circumstances may include, but are not limited to, the benefits that would be realized by full enforcement, the cost or difficulty of complete compliance, the owner's good faith efforts to comply, the expected remaining life of the structure, and the impacts to beneficial use of water in Colorado.

Rule 20. Appeal of Requirements or Approval:

The applicant or any other person affected or aggrieved by the State Engineer's approval or disapproval of plans and specifications for construction of a reservoir/dam, or the alteration, modification, repair or enlargement of a reservoir or dam which will affect the safety of the structure may request an adjudicatory hearing before the State Engineer pursuant to section 1.1.4(2)(vi) of the Division of Water Resources' Procedural Regulations, 2 CCR 402-5. Such request must be made within thirty (30) days of the date of the State Engineer's determination and must identify the person(s) requesting the hearing and the basis upon which they believe error was committed in the determination. All adjudicatory hearings will be conducted pursuant to the requirements of the Division of Water Resources' Procedural Regulations and the State Administrative Procedures Act, section 24-4-105, C.R.S.

Rule 21. Rules by Reference:

Certified copies of the complete text of the materials incorporated by reference in these Rules shall be maintained by the Office of the Engineer and state publications depository and distribution center and shall be available for public inspection during business hours. The title and address of the Office of the State Engineer is: 1313 Sherman Street, Room 818, Denver, CO 80203.

Rule 22. Severability:

If any portion of these Rules and Regulations for Dam Safety and Dam Construction is found to be invalid, the remaining portion of the Rules shall remain in force.

Rule 23. Revision:

The State Engineer may revise these Rules and Regulations for Dam Safety and Dam Construction in accordance with section 24-4-103, C.R.S. Such revisions may be the result of new data or technology, or the submittal of a petition by an interested person pursuant to section 24-4-103(7), C.R.S. and 2 C.C.R. 402-5 1.1.3.B.2.

Rule 24. Statement of Basis and Purpose Incorporated by Reference:

The Statement of Basis and Purpose for the adoption of these Rules and Regulations for Dam Safety and Dam Construction is incorporated by reference as part of these Rules.

Rule 25. Effective Date:

These Rules shall become effective on January 1, 2007.

FOR REFERENCE

COLORADO REVISED STATUTES
TITLE 37, ARTICLE 87

RESERVOIRS

37-87-101. Storage of water.

(1) (a) The right to store water of a natural stream for later application to beneficial use is recognized as a right of appropriation in order of priority under the Colorado constitution. No water storage facility may be operated in such a manner as to cause material injury to the senior appropriative rights of others. Acquisition of those interests in real property reasonably necessary for the construction, maintenance, or operation of any water storage reservoir, together with inlet, outlet, or spillway structures or other facilities necessary to make such reservoir effective to accomplish the beneficial use or uses of water stored or to be stored therein, may be secured under the laws of eminent domain.

(b) State agencies shall, to the maximum extent practicable, cooperate with persons desiring to acquire real property for water storage structures.

(2) Underground aquifers are not reservoirs within the meaning of this section except to the extent such aquifers are filled by other than natural means with water to which the person filling such aquifer has a conditional or decreed right.

37-87-102. Definitions - natural streams and use thereof by reservoir owners.

(1) As used in this article, unless the context otherwise requires:

(a) "Mean annual flood" means a flood which has a magnitude (peak discharge) which is expected to be equalled or exceeded on the average once every 2.33 years and has a forty-three percent chance of being equalled or exceeded (0.43 exceedence probability) during any year, by application of the criteria defined in subsection (2) of this section.

(b) "Natural stream" means a place on the surface of the earth where water naturally flows regularly or intermittently with a perceptible current between observable banks, although the location of such banks may vary under different conditions.

(c) "One-hundred-year flood" means a flood which has a magnitude (peak discharge) which is expected to be equalled or exceeded on the average once during any one-hundred-year period (recurrence interval) and has a one percent chance of being equalled or exceeded during any year (0.01 exceedence probability). The terms "one-hundred-year flood", "one percent chance flood", and "intermediate regional flood" are synonymous.

(d) "One-hundred-year floodplain" means that area in and adjacent to a natural stream which is subject to flooding as a result of the occurrence of a one-hundred-year flood.

(e) "Ordinary high watermark" of any stream means the visible channel of a natural watercourse within which water flows with sufficient frequency so as to preclude the erection or maintenance of man-made improvements without special provision for protection against flows of water in such channel or the channel defined by the mean annual flood, whichever is greater.

(2) Whenever the records basic to a determination of probable future water flows, either with respect to this section or by other requirements of law, extend for a period of one hundred or more years, the calculation based upon those results shall be deemed conclusive. If such records do not extend for a period of one hundred or more years the determination shall be made by interpolation and correlation to a full one hundred years of records by relating them to known

records of water basins as similar as reasonably possible to the basin under consideration or by other acceptable methods.

(3) (a) In any case in which a determination of probable future surface water flows at any place in the state is required, the calculation shall be based upon past surface water runoff at the place in question supplemented as provided in this section. Such probable flows shall be determined by reference to the records of reliable stream gauging stations. A stream gauging station record shall be deemed reliable if made by the state of Colorado or the United States as part of a regular program of either of those entities, except as to any part of such records which the state engineer shall have designated as being unreliable, on the basis of facts so showing. Whenever a designation of probable future runoff is required at a place other than the location of a reliable stream gauging station, the determination of probable runoff at such other place shall be made by relating the probable future runoff at that place to the recorded runoff at a comparable gauging station or gauging stations by the interpolation of reasonable hydrologic, geologic, and natural vegetative factors supplemented as provided in this section. Unless clearly unrelated, the factors of the comparison shall include, but not be limited to, the following elements or characteristics:

(I) The water basin contributing to the probable future flow at the place where probable future runoff is to be determined, considering:

(A) The size;

(B) The altitude or altitudes;

(C) The various soil permeabilities;

(D) The various vegetative covers;

(II) The known runoff as determined by reliable stream gauging stations using interpolations when necessary from comparable gauging stations and relating interpolations to the characteristics of the basin measured by the comparable gauging stations as related to the basin of runoff being determined;

(III) The slope or slopes of the terrain whose surface runoff contributes to the surface water flows at the place at which a determination of probable future surface water flows is required.

(b) The state engineer shall promulgate rules pursuant to section 24-4-103, C.R.S., which include other factors for consideration in any area or situation in which calculations based on the criteria in paragraph (a) of this subsection (3) will probably be made more accurate by use of other or additional criteria. Whenever conditions are such that records of past precipitation are an appropriate factor, he may designate any portion of official precipitation records of agencies of the United States or of the state of Colorado which are appropriate in evaluating probable future water flows. He may approve use of factors referred to in this paragraph (b) with respect to particular areas or design of specific structures when requested to do so.

(c) No dam safety requirement shall be imposed to meet a potential hazard of a flood whose magnitude is such that the hazard would probably exist whether or not the dam failed.

(3.5) Whenever a determination of probable future surface water flows, or the probability of frequency of their recurrence, at any place in Colorado is required by relation to a longer period of flow than that for which there is a reliable record of flow as defined in subsection (3) of this

section, the determination shall be made by interpolation and correlation of known records to the longer period by relating known records of water basins as similar as reasonably possible to the place of determination or basin under consideration, or by use of geologic determinations, or by use of other methods reasonably calculated to formulate an accurate estimate of probable future flows or the probability of frequency of their recurrence at the place of determination of such flows.

(3.7) Calculations of probable flows or frequency of recurrence based upon application of the principles set forth in subsections (3) and (3.5) of this section shall relieve anyone acting in accordance with such principles of any liability respecting an occurrence different than that predicted. This exemption from liability shall apply to the state and its public officials or employees when acting in performance of their public duties.

(4) The owners of any reservoir may conduct the waters legally stored therein into and along any of the natural streams of the state, but not so as to raise the waters thereof above ordinary high watermark, and may take the same out again at any point desired if no material injury results to the prior or subsequent rights of others to other waters in said natural streams. Due allowance shall be made for evaporation and other losses from natural causes for the protection of all rights to the waters flowing in said streams, such losses to be determined by the state engineer.

37-87-103. Notice of release of stored waters.

The owners of reservoirs who avail themselves of the provisions of this section and section 37-87-102 shall give reasonable prior notice to the irrigation division engineer of the irrigation division in which the reservoir is located or to the chief administrative water official of such irrigation division of the date on which they desire to release stored waters into any natural streams, together with the quantity thereof in cubic feet per second of time, the length of period to be covered by such releases, and the name of the ditch, canal, pipeline, or reservoir to which the water so released from storage is to be delivered, to the end that the water officials in responsible charge of any stream into which such stored water is released shall have ample time in which to make the necessary observations measurements of flow and storage and records thereof and to provide for a proper patrol of the said stream, for the protection of the reservoir owner and also all other appropriators along the stream whose interests might be affected as a result of such reservoir release. Such notice may be given to the division engineer when the reservoir from which the water is to be released and the point where the water is to be taken from the stream or again stored are in the same water district.

37-87-104. Liability of owners for damage.

(1) Any provision of law to the contrary notwithstanding, no entity or person who owns, controls, or operates a water storage reservoir shall be held liable for any personal injury or property damage resulting from water escaping from that reservoir by overflow or as a result of the failure or partial failure of the structure or structures forming that reservoir unless such failure or partial failure has been proximately caused by the negligence of that entity or person. No entity or person shall be required to pay punitive or exemplary damages for such negligence in excess of that provided by law. Any previous rule of law imposing absolute or strict liability on such an entity or person is hereby repealed.

(2) No such entity or person shall be liable for allowing the inflow to such reservoir to pass through it into the natural stream below such reservoir.

(3) (a) No stockholder, officer, or member of a board of directors of an owner of a reservoir shall be liable for any personal injury or property damage resulting from water escaping from such reservoir or as a result of the failure or partial failure of the structure or structures forming such reservoir for which the owner shall have been found liable if a valid liability insurance policy, or adequate substitute as provided in paragraph (b) of this subsection (3), has been purchased by the owner of the reservoir and is in effect at the time such damage occurs. Such insurance policy shall insure against such damages and provide coverage in an amount of not less than fifty thousand dollars for each claim and in an aggregate amount of not less than five hundred thousand dollars for all claims which arise out of any one incident. The policy may provide that it does not apply to any act or omission of a stockholder, officer, or member of a board of directors of an owner if such act or omission is dishonest, fraudulent, malicious, or criminal. The policy may also contain other reasonable provisions with respect to policy periods, territory, claims, conditions, and other matters common to such policies of insurance. The limitation of liability pursuant to this paragraph (a) shall not apply to any criminal, fraudulent, or malicious act or omission by a member of the board of directors of the owner, an officer of the owner, or a stockholder of the owner, nor shall it apply to any ultra virus act of the owner or of a member of the board of directors, an officer, or a stockholder of such owner. The provisions of this paragraph (a) shall not be deemed to impose any liability upon a member of the board of directors, an officer, or a stockholder of the owner of a reservoir beyond that provided in section 7-42-118, C.R.S.

(b) An adequate substitute for such insurance may be in the form of:

(I) A good and sufficient bond, in an amount equal to such recovery limitations duly executed by a qualified corporate surety approved by the commissioner of insurance, conditioned upon the payment by the entity or person who owns, controls, or operates a water storage reservoir of any valid and final judgment for damages imposed within the judgment limitations established in this subsection (3);

(II) A good and sufficient escrow of acceptable securities, as defined in section 24-91-102, C.R.S., or an annual irrevocable letter or annual letters of credit issued by any national or state bank or any bank for cooperatives as chartered under Title III of the "Federal Farm Credit Act of 1971", as amended, and deposited with an escrow agent pursuant to an escrow contract or agreement requiring the escrow agent to pay from the escrow account amounts necessary to discharge a valid and final judgment for damages within the limits established in this subsection (3). Such escrow contract or agreement shall provide that it cannot be revoked or amended until after any claims for damage against such entity or person have been discharged or until applicable statutes of limitations pertaining thereto have expired.

(III) A combination of insurance and any of the substitutes described in this paragraph (b).

37-87-104.5. Notification of ownership of dam - when person in control deemed owner.

The person or persons actually in control of the physical structure of any dam shall be deemed, for determining liability arising from ownership of a dam and with respect to operation thereof, to be the owners thereof unless notice of the name and address of the true owner thereof, together

with reasonable evidence of such ownership, has been filed in the office of the state engineer by January 1, 1985. Any change in ownership shall be immediately filed in the office of the state engineer.

37-87-105. Approval of plans for reservoir - notice of modification.

(1) No dam shall be constructed in this state to impound water above the elevation of the natural surface of the ground for the purpose of creating a reservoir with a capacity of more than one hundred acre-feet of water or with a surface area at the high water line in excess of twenty acres or if the height of the dam will exceed ten feet measured vertically from the elevation of the lowest point of the natural surface of the ground, where that point occurs along the longitudinal centerline of the dam, up to the flow line crest of the spillway of the dam before plans and specifications for that dam have been filed in the office of the state engineer and approved by him in accordance with regulations established by the state engineer governing such structures.

(2) Repealed.

(3) In making his determination for approval, the state engineer shall be guided by dam, spillway, and construction regulations established pursuant to this article. Such regulations may include less stringent requirements than those dictated by consideration of probable maximum precipitation. The state engineer shall issue his written decision regarding the approval of plans and specifications within one hundred eighty days of submittal to him. The state engineer shall have authority to require the material used and the work of construction to be accomplished in accordance with regulations which the state engineer may establish. No work shall be deemed complete until the state engineer furnishes to the owners of such structures a written statement of acceptance, which statement shall specify the dimensions of such dam and capacity of such reservoir. The state engineer shall render his written decision regarding acceptance within sixty days of written notification by the owner that construction has been completed.

(4) No alteration, modification, repair, or enlargement of a reservoir or dam which will affect the safety of the structure shall be made without prior written notice and approval in accordance with this section to the state engineer. General maintenance, ordinary repairs, or emergency actions not impairing safety shall be excluded from the terms of this subsection (4).

37-87-106. Cost of inspections and observation. (Repealed)

37-87-107. Safety inspections - amount of water to be stored.

Dam safety inspections shall be made on all dams within the state by qualified, experienced personnel as often as the state engineer deems necessary or appropriate for the protection of public health and safety so that a determination of the amount of water which is safe to impound in the reservoir can be made by the state engineer. The dam safety inspections shall include, but shall not be limited to, review of previous inspections, reports and drawings, site inspection of the dam, spillways, outlet facilities, seepage control and measurement system, and permanent monument or monitoring installations, if any. Based upon inspection reports and other information affecting the safety of each dam, the state engineer shall determine the amount of water which is safe to impound in the reservoir. It is unlawful for the owners of any reservoir to

store in said reservoir water in excess of the amount so determined by the state engineer to be safe.

37-87-108. Withdrawal of excess water.

If the owners of any such reservoir impound water therein to a depth greater than that determined by the state engineer to be safe, it is the duty of the division engineer of the district wherein such reservoir is located to forthwith proceed to withdraw from said reservoir so much of the water as shall be in excess of the amount so determined by the state engineer to be safe, and the division engineer shall close the inlets to the same to prevent said reservoir from being refilled to an amount beyond what said state engineer has designated as being safe. If the owners of said reservoir, or any other persons, interfere with the division engineer in the discharge of said duty, the said division engineer shall call to his aid such persons as he deems necessary and employ such force as the circumstances demand to enable him to comply with the requirements of this section. Any costs incurred by the state engineer in rectifying a failure of compliance by the owner may be recovered in a suit for civil damages.

37-87-108.5. Emergency actions.

(1) If, in the opinion of the state engineer, conditions of any dam or reservoir are so dangerous to the health and safety of life or property as not to permit time for issuance and enforcement of an order relative to construction, modification, maintenance, or restriction of storage, or the dam is threatened by any large flood, the state engineer may immediately employ remedial measures necessary to protect such life and property.

(2) (a) The state engineer shall maintain complete control of any such dam or reservoir which, pursuant to subsection (1) of this section, has been determined to be dangerous to life or property until such dam or reservoir is deemed safe, or until any emergency conditions which precipitated the state engineer taking control of any such dam or reservoir, pursuant to subsection (1) of this section, have abated. The state engineer is hereby empowered to determine the proper time at which to relinquish control of any such dam or reservoir.

(b) For purposes of this paragraph (b), measures taken by the state engineer pursuant to subsection (1) of this section shall be deemed final action by the state engineer for purposes of judicial review. The owner or operator of any dam upon which the state engineer has employed remedial measures pursuant to subsection (1) of this section may seek judicial review of the propriety of such measures by filing an action in the state district court for the district in which such dam is located.

(3) (a) Any necessary and reasonable costs and expenses incurred by the state engineer in fulfilling the duties mandated by subsections (1) and (2) of this section in connection with a remedial or emergency action shall be recoverable by the state engineer from the owner of any such dangerous or threatened dam.

(b) Any owner failing or refusing, after written notice has been given, to pay the reasonable costs and expenses incurred by the state engineer pursuant to paragraph (a) of this subsection (3) shall be, upon complaint by the state engineer to the attorney general, subject to reasonable attorney fees incurred in the recovery of such costs and expenses.

(4) (a) All moneys collected by the state engineer pursuant to subsection (3) of this section shall be credited to the emergency dam repair cash fund created in section 37-60-122.5, to the extent necessary to replenish the account. Moneys collected in excess of such amount shall be credited to the Colorado water conservation board construction fund.

(b) The general assembly shall make annual appropriations from the emergency dam repair cash fund created in section 37-60-122.5, for the direct and indirect costs incurred by the state engineer in the performance of those duties authorized to be carried out by the state engineer in this section.

37-87-109. Complaint that reservoir is unsafe.

Upon complaint being made to the state engineer by one or more persons residing or having property in such a location that their homes or property would be in danger of destruction or damage in the event of a flood occurring on account of the breaking of the embankment of any reservoir within the state, that said reservoir is in an unsafe condition, or that it is being filled with water to such an extent as to render it unsafe, it is the duty of the state engineer to forthwith examine said reservoir and determine the amount of water it is safe to impound therein. If, upon such examination, the state engineer finds that said reservoir is unsafe, or is being filled with water to such an extent as to render it unsafe, it is his duty to immediately cause said water to be drawn from said reservoir to such an extent as will, in his judgment, render the same safe. If water is then flowing into said reservoir, he shall cause it to be discontinued

37-87-110. Engineer may use force.

The state engineer is authorized to use such force as is necessary to perform the duties required of him in section 37-87-109 and to have and exercise all of the powers conferred upon the division engineer by section 37-87-108. If, after any of such reservoirs have been examined by said state engineer, the owners thereof, or any other person, fills or attempts to fill them, or any of them, to a point in excess of the amount the state engineer has determined to be safe, then it is the duty of the division engineer of the district wherein such reservoir is located to proceed as directed by section 37-87-108. All direct, actual, and necessary expenses incurred in performing any action authorized by this section shall be recoverable by the state engineer from the owner of the affected reservoir and if not reimbursed may be collected by action brought by the state engineer in the district court of the county in which the reservoir, or part thereof, is located.

37-87-111. Expense of examination.

The person calling upon the state engineer to perform the duty required of him by section 37-87-109, if the request is frivolous or made in bad faith, shall pay him any invoiced expenses and mileage at the rate prevailing for state officers and employees under section 24-9-104, C.R.S., for each mile actually and necessarily traveled in going to and from said reservoir, and, should the state engineer find upon examination that such reservoir is in an unsafe condition, the owners thereof shall be liable for all expenses incurred in such examination.

37-87-112. Review of action of state engineer.

Any action of the state engineer under section 37-87-110 shall be subject to review in a de novo proceeding commenced by complaint of the owner in the district court in and for the county where the affected structure is located. When the state engineer has directed that certain measures shall be taken immediately for the protection of the public safety, any such judicial proceeding shall be accelerated on the court's calendar and determined immediately upon the conclusion of such proceeding. The judgment and action of the state engineer shall control until judicial determination of the cause.

37-87-113. Breakage of reservoir - damages. (Repealed)

37-87-114. Penalty - disposition of fines.

(1) Any reservoir owner or operator failing or refusing, after notice in writing has been given, to obey the reasonable directions of the state engineer as to the construction or safe operation of any reservoir shall be subject to a fine of not less than five hundred dollars for each offense, and each day's continuance after time of notice has expired shall be considered a separate offense. Such fines shall be recovered by civil action in the name of the people by the district attorney, upon the complaint of the state engineer, in the district court of the county where the injury complained of occurred. The proceeds of all fines, after payment of costs and charges of the proceedings, shall be paid into the county treasury for the use of the general fund of the county.

(2) Upon the complaint of the state engineer, the attorney general is authorized to commence proceedings against any reservoir owner or operator for refusing, after notice in writing has been given, to obey the directions of the state engineer as to the construction or safe operation of any reservoir to secure compliance with any such reasonable direction necessary for public safety in the district court of the county wherein any portion of such reservoir is located, pursuant to the Colorado rules of civil procedure; except that, if it appears to the court that the public safety is in jeopardy as the result of a failure to obey the directions of the state engineer, the court shall expedite the proceedings so that determinations may be made with respect to the directions of the state engineer commencing not later than twenty days from the service of the complaint on the owner or operator of a reservoir.

37-87-114.4. Annual report.

The state engineer shall submit an annual report to the general assembly by November 1 of each year concerning the activities of the state engineer and the division of water resources relating to sections 37-87-105 to 37-87-114 for the preceding fiscal year. In addition to the copies required to be filed as provided in section 24-1-136 (9), C.R.S., a copy of such report shall be provided to each of the following: The governor and the chairmen of the committees of reference of the senate and the house of representatives dealing with agriculture and natural resources. Such report shall include but not be limited to information on the following: Approvals of plans and specifications for construction of dams and reservoirs and for alterations, modifications, repairs, and enlargements; number of safety inspections made and the results thereof; use of appropriated funds; receipts generated for inspections of dams and reservoirs; rules and regulations adopted or amended; enforcement orders and proceedings; dam failures and reasons therefor; and other available data regarding the effectiveness of the state's dam and reservoir safety program.

37-87-114.5. Applicability of provisions - exemptions.

(1) The provisions of sections 37-87-105 to 37-87-114 shall not apply to:

(a) Structures not designed or operated for the purpose of storing water;

(b) Mill tailings impoundment structures permitted under article 32 or 33 of title 34, C.R.S.;

(c) Uranium mill tailings and liquid impoundment structures permitted under article 11 of title 25, C.R.S.; except that the state engineer shall render such consultation as necessary for the permitting of such structures;

(d) Siltation structures permitted under article 33 of title 34, C.R.S.; or

(e) Structures which store water only below the elevation of the natural surface of the ground.

37-87-115. Damages.

The provisions of this article are undertaken by the state of Colorado in the discretionary exercise of its governmental authority; therefor, neither the state of Colorado nor the state engineer, any member of his staff, or any person appointed by him shall be liable in damages for any act done by him or for his failure to act in pursuance of the provisions of this article. In addition, the state engineer, any member of his staff, and any person appointed by him shall have the same immunity from liability as other public employees pursuant to the provisions of article 10 of title 24, C.R.S.

37-87-116. Tax reduction where reservoirs located. (Repealed)

37-87-117. Landowner to submit plans. (Repealed)

37-87-118. State engineer's authority over construction. (Repealed)

37-87-119. Completion of dam. (Repealed)

37-87-120. Reduction in valuation for assessment. (Repealed)

37-87-121. Application to existing dams. (Repealed)

37-87-122. Erosion control dams.

(1) The provisions of sections 37-87-101 to 37-87-108 shall not apply to erosion control dams of the character defined in this section, unless such dams also come within the specification requirements of said sections.

(2) Erosion control dams for reservoirs may be constructed on watercourses, the channels of which have been determined by the state engineer to be normally dry, having a vertical height not exceeding fifteen feet from the bottom of the channel to the bottom of the spillway, and having a capacity not exceeding ten acre-feet at the emergency spillway level, upon approval of an application for such erosion control dam by the state engineer, which application shall be accompanied by a fee of fifteen dollars. The approval by the state engineer of an erosion control dam shall be chronologically numbered in order of approval and in concert with any livestock water tanks approved pursuant to section 35-49-109, C.R.S. When such reservoirs are to be constructed with such height exceeding fifteen feet and such capacity exceeding ten acre-feet, they shall be constructed in accordance with section 37-87-105.

(3) Such reservoirs may be constructed with a capacity in excess of two acre-feet if, at or below the two acre-feet level, an ungated outlet tube is installed, with twelve inches minimum diameter and large enough to assure adequate capacity to drain within thirty-six hours any impoundment in excess of two acre-feet.

(4) The state engineer shall prepare and keep on file at the office of the state engineer standard specifications for erosion control dams which shall be subject to revision by the state engineer and shall in general be used as a guide by persons proposing to construct such dams.

(5) The fees collected pursuant to subsection (2) of this section shall be deposited by the state engineer with the state treasurer, who shall credit all such fees to the general fund of the state.

37-87-123. Dam and reservoir information. (Repealed)

37-87-124. Restriction of facilities within reservoirs.

(1) The general assembly hereby declares that the prevention of seasonal flooding which causes destruction of property and crops, loss of livestock, and risk or loss of human life is manifestly of greater concern and benefit to this state than the availability of recreational facilities and other

facilities, not functionally related to the operation of the reservoir, constructed below the high water level of a reservoir.

(2) In order to achieve the purposes of subsection (1) of this section, no person, including any state or federal agency, quasi-municipal corporation, or political subdivision, shall construct any permanent recreational structure within a reservoir below the elevation at the crest of the spillway of the reservoir unless such facility is constructed in such a manner as to withstand partial or complete inundation and sustain minimal or no damage thereby or unless such facility is necessary to the operation of the reservoir. Said facility should be capable of being restored to full recreational use with a minimum amount of cleaning or expense. This subsection (2) and subsection (3) of this section shall not apply to facilities completed before July 1, 1984, but shall apply to any enlargement or remodeling of such facilities.

(3) The state engineer shall order the removal of any facilities constructed, enlarged, or remodeled in violation of this section. Such order may be appealed by the affected person or enforced by the state engineer pursuant to article 4 of title 24, C.R.S.

37-87-125. Notice of intent to construct impoundment structure.

Any person proposing to construct a reservoir for the purpose of storing water, other than a reservoir specified in section 37-87-105 (1) or a livestock water tank as described in section 35-49-103, C.R.S., shall submit notice thereof to the state engineer prior to the beginning of any construction. Such notice shall include the location of such proposed reservoir with reference to section, township, and range and the dimensions of the reservoir, the dam, and the spillway. If any reservoir is constructed without the notice required by this section, the state engineer may prohibit the storage of water in such reservoir or direct the withdrawal of water from such reservoir. The provisions of this section shall not apply to structures listed in section 37-87-114.5.

FOR REFERENCE

COLORADO REVISED STATUTES
TITLE 35, ARTICLE 49

LIVESTOCK WATER TANKS

35-49-101. Short title.

This article shall be known and may be cited as the "Livestock Water Tank Act of Colorado".

35-49-102. Legislative declaration.

It is the policy of the state of Colorado to encourage and improve range conditions for livestock within its borders through the construction of watering tanks, to provide a system of priorities of right of use thereof, and to protect adjudicated water rights and the public interest by providing an official record and reasonable public supervision of such watering tanks.

35-49-103. Definitions.

As used in this article, unless the context otherwise requires:

(1) "Livestock water tanks" includes all reservoirs created by dams constructed after April 17, 1941, on watercourses, the channels of which are normally dry as determined by the state engineer, having a capacity not exceeding ten acre feet and a vertical height not exceeding fifteen feet from the bottom of the channel to the bottom of the spillway to be used for stock watering purposes.

35-49-104. Statutes inapplicable.

The provisions of sections 37-87-101 to 37-87-108 and 37-87-114 to 37-87-115, C.R.S., shall not apply to livestock water tanks of the character defined in section 35-49-103.

35-49-105. Not used for irrigation.

No livestock water tanks constructed under the provisions of this article shall be used for irrigation purposes, and nothing contained in this article shall be construed as conferring upon the owner of any such livestock water tank a priority of use superior to any vested water right or to an adjudicated appropriation of water pursuant to state laws. Unless built upon an intermittent or perennial main stream, dams creating such livestock water tanks shall be deemed to have a rebuttable presumption that there is no injury to adjudicated water rights when built pursuant to the specifications set forth in section 35-49-103. If used solely for watering of livestock in areas known to be deficient in windmill water, having a pumping capacity of less than five gallons per minute, dams of greater capacity than those designated in section 35-49-103 may be constructed on any ephemeral stream, but in such event, the state engineer may require the construction of drainage facilities to reduce the water impounded in the reservoir to the capacity prescribed in section 35-49-103, within a thirty-six hour period.

35-49-106. Plans submitted to state engineer.

Anyone proposing to construct a dam for the creation of a livestock water tank, as described in section 35-49-103, shall submit to the state engineer for approval an application on a form provided by the state engineer showing the general location of such proposed dam with reference

to section, township, and range, location and dimensions of spillway, and the number, location, and size of dams already constructed within the watersheds of the dry channel on which such dam is proposed to be built. Nothing contained in this section shall be construed to specify plans and specifications of such technical detail or nature as to require preparation by an engineer or construction of such stock water tanks under the supervision of an engineer; it being the intent and purpose of the provisions of this section that the state engineer shall be apprised by the completed application of pertinent information sufficient to enable the state engineer to ascertain the general location of the water tank, its operation in relation to tanks already constructed, its relative priority rights, its effect on existing appropriations of water, its capacity, its dam dimensions, the necessary and reasonable factors of safety, and its compliance with the provisions of this article.

35-49-107. Construction requirements.

(1) The state engineer shall examine each application submitted and, if the state engineer approves the same, shall return one copy of each such application with the approval of the state engineer thereon to the person submitting the same and file the other copy at the office of the state engineer. If the state engineer disapproves such application, or any part thereof, the same shall be returned to the applicant for correction and revision. In cases where the state engineer deems it necessary, before approval thereof, the state engineer may inspect the proposed water tank site and make such independent investigation as necessary. Whether the state engineer approves such application, or disapproves it and returns the same for correction and revision, the state engineer shall act within fifteen days after the application is submitted. Until the approval by the state engineer of an application has been obtained, the construction of such dam is prohibited.

(2) The provisions of this section and section 35-49-112 specifying approval by the state engineer and providing a fee therefor shall not apply to dams having a vertical height not exceeding five feet from the bottom of the channel to the bottom of the spillway and which impound not more than two acre feet of water.

(3) Anyone proposing to construct a dam for the creation of a livestock water tank, as described in section 35-49-103, shall comply with section 35-49-106. Every owner of a proposed reservoir for stock watering purposes who desires to obtain a priority number for such structure shall comply fully with all pertinent provisions of this article.

35-49-108. State engineer to inspect dam.

When such a dam is completed the state engineer shall be notified of such completion and, thereafter, may inspect said stock water tank. If the state engineer finds that the construction fails to conform with the application approved by the state engineer, it then becomes the duty of the owner of such dam to make such change and corrections therein as the state engineer has determined to be necessary to correct such failure, and when the same have been made, the state engineer shall provide in writing approval of such structure. Approval shall be granted by the state engineer upon reasonable compliance with the approved application and standard specifications. A livestock water tank shall not be disapproved because of failure to observe technical engineering details in construction.

35-49-109. Priority determined, how.

The state engineer's certificate of approval of a livestock water tank on each normally dry stream and its tributaries shall be chronologically numbered in the order of approval and in concert with any erosion control dams approved pursuant to section 37-87-122, C.R.S. Priority of right as between such tanks located on or within the watershed of each such dry stream shall be determined by such numbers seriatim, number one being first in such right.

35-49-110. Standard plans - publication.

The state engineer shall prepare and keep in file at the office of the state engineer standard plans, drawings, and specifications for livestock water tanks, which shall be subject to revision by the state engineer and shall in general be used as a guide by persons proposing to construct such tanks. Publication of these plans shall be subject to the approval and control of the executive director of the department of natural resources.

35-49-111. When conduits not required.

Where, in the judgment of the state engineer, tanks upon any stream and its tributaries do not require conduits for purposes of safety or the protection of prior livestock water tank rights, it is lawful for the state engineer to approve an application not calling for conduits. Nothing in this section shall abrogate the right of any owner of a vested water right or appropriation of water to require such conduits in any case where necessary to protect such senior right.

35-49-112. Fees deposited in general fund.

Each application for a livestock water tank submitted to the state engineer under the provisions of this article shall be accompanied by a fee of fifteen dollars. This fee shall be deposited by the state engineer with the state treasurer who shall credit all such fees to the general fund of the state.

35-49-113. Assignment of priority number. (Repealed)

35-49-114. Approval required for reservoir. (Repealed)

35-49-115. Penalty.

The owner of any dam or reservoir failing to comply with the provisions of this article shall be subject to a penalty of not more than twenty-five dollars nor less than five dollars, to be recovered and disposed of as are fines for violations of section 37-87-114, C.R.S.

35-49-116. Appropriation - transfer of funds.

The general assembly shall annually appropriate from the general fund moneys for the administration of this article.

E.7. Connecticut

This document contains the Connecticut regulations for Dam Safety. This document was prepared by the State of Connecticut Department of Environmental Protection and is provided for the convenience of the reader. This is not the official version of the regulations. The official regulations are published by the State of Connecticut, Judicial Branch, Commission on Official Legal Publications in the Connecticut Law Journal. In the event there is inconsistency between this document and the regulations as published in the Connecticut Law Journal, the Connecticut Law Journal publication will serve as the official version.

DAM SAFETY REGULATIONS

Section 1. Subsection (a) of Section 22a-409-1 of the Regulations of Connecticut State Agencies is amended to read as follows:

Section 22a-409-1. Registration of dams and similar structures.

(a) Definitions. AS USED IN SECTION 22A-409-1 and 22A-409-2:

(1) "Abutment" means natural ground that borders on either end of the dam structure.

(2) "Acre-Foot" means a unit of volume equal to 43,560 cubic feet or 325,853 gallons (one foot depth over one acre).

(3) "Average Daily Traffic" (ADT) means a measure of the number of vehicles using a specific road in an average twenty-four hour period.

(4) "Appurtenance" means any structure or mechanism other than the dam itself which is associated with its operation.

(5) "Breach" means an alteration of a dam either deliberately or accidentally in such a way as to release its impounded waters.

(6) "Commissioner" means the Commissioner of Environmental Protection.

(7) "Dam" means any barrier of any kind whatsoever which is capable of impounding or controlling the flow of water, including but not limited to storm water retention or detention dams, flood control structures, dikes, and incompletely breached dams.

(8) "Dam Height" means the vertical distance from the crest of the dam or similar structure to the downstream toe of such dam or similar structure.

(9) "Embankment" means the fill material, usually earth or rock, placed with sloping slides providing a barrier which impounds water.

(10) "Flood" means a general and temporary condition of partial or complete inundation of normally dry land areas.

(11) "Hazard Potential" means probable damage that would occur if the structure failed, in terms of loss of human life and economic loss or environmental damage.

(12) "Owner" means any individual, firm, partnership, association, syndicate, company, trust, corporation, municipality, agency or political or administrative subdivision of the state, or any other legal entity of any kind holding legal title to the dam.

(13) "Structure" means the dam, its appurtenances, abutments and foundation.

(14) "Toe" means the base portion of the impounding structure which intersects with natural ground at the upstream and downstream sides.

Section 2. The Regulations of Connecticut State Agencies are amended by adding Section 22a-409-2. Dam Safety Inspection Regulations.

Section 22a-409-2. Dam Safety Inspection Regulations.

(a) Jurisdiction. All dams which must be registered pursuant to Section 22a-409 of the Connecticut General Statutes shall be under the jurisdiction of the Commissioner. Dams of the State, or any political subdivision thereof, and all dams within the State except those of the United States or its instrumentalities are included within the jurisdiction conferred by this section.

(b) Periodic inspections. The following dams shall be regularly inspected by the Department of Environmental Protection at a frequency as described in Section 22a-409-2(e)(2) of these regulations:

(1) Dams which pose a significant (B) or high (C) hazard to life or property as defined in Section 22a-409(d);

(2) Dams which are:

(A) greater than twenty-five (25) feet in height with an impoundment capacity greater than fifteen (15) acre-feet; or

(B) greater than six (6) feet in height but less than or equal to twenty-five (25) feet in height with an impoundment capacity greater than fifty (50) acre-feet; or

(3) All other dams with an impoundment capacity of three (3) acre-feet or more.

(c) Periodic Inspection Procedures.

(1) Each periodic inspection shall consist of, but not be limited to, the following:

(A) Visual inspection of the dam, its appurtenances, abutments, downstream toe and all other areas which could affect the safety of the dam. In addition, inspection and operation of mechanical systems, and inspection of the abutments downstream, the components of the dam which are under water during normal operation, or the interior of outlet conduits shall be made by the owner, if required by the Commissioner to more completely assess the condition of the dam;

(B) Review and analysis of available data on the design, construction, operation, maintenance and performance of the structure;

(C) Observation of the nature and extent of downstream development which would be subject to inundation in the event of a dam breach for purposes of assessing the potential hazard which the dam poses;

(D) Evaluation of the general condition of the structure, including when possible, assessment of its hydrologic and its hydraulic capabilities and structural stability.

(E) Evaluation of the operation, maintenance and inspection procedures employed by the owner.

(F) Evaluation of any other conditions which constitute or could constitute a hazard to the integrity of the structure.

(2) The inspection shall be performed by qualified personnel of the D.E.P. Dam Safety Program with technical training in the inspection of dams and under the supervision of a civil engineer.

(3) A standard dam inspection checklist based upon accepted standards of visual dam inspection and guidelines which direct the proper use of the checklist shall be prepared by the Commissioner and will be utilized by the inspection team. The Commissioner will issue a written report based on the findings of the periodic inspection which shall include, but not be limited to, the following:

(A) An assessment of the condition of the structure based on the visual observations, available data on the design, construction, operation, maintenance and performance of the structure, the hydrologic and hydraulic capacities and the structural stability of the structure;

(B) Recommendations for any emergency measures or actions, if required to assure the immediate safety of the structure;

(C) Recommendations for remedial measures and actions related to design, construction, operation, maintenance and inspection of the structure, if required; and

(D) Recommendations for additional detailed studies, investigations and analyses, if required; and

(E) Recommendations for routine maintenance and inspection by the owner, if required.

(4) The Commissioner shall furnish a copy of the written report to the owner.

(A) The owner shall within thirty (30) days of receipt of the written report, inform the Commissioner in writing of his or her schedule of implementation of any required recommendations.

(B) A copy of the report will be kept on file with the records of the Commissioner pertaining to dam safety.

(d) Classification of Dams:

(1) The Commissioner shall assign each dam to one of five classes according to its hazard potential. Such classification shall be determined by the Commissioner during the initial periodic inspection.

(A) A Class AA dam is a negligible hazard potential dam which, if it were to fail, would result in the following:

(i) no measurable damage to roadways;

(ii) no measurable damage to land and structures;

(iii) negligible economic loss.

(B) A Class A dam is a low hazard potential dam which, if it were to fail, would result in any of the following:

(i) damage to agricultural land;

(ii) damage to unimproved roadways (less than 100 ADT);

(iii) minimal economic loss.

(C) A Class BB dam is a moderate hazard potential dam which, if it were to fail, would result in any of the following:

(i) damage to normally unoccupied storage structures;

(ii) damage to low volume roadways (less than 500 ADT);

(iii) moderate economic loss.

(D) A Class B dam is a significant hazard potential dam which, if it were to fail, would result in any of the following:

(i) possible loss of life;

(ii) minor damage to habitable structures, residences, hospitals, convalescent homes, schools, etc.;

(iii) damage to or interruption of the use of service of utilities;

(iv) damage to primary roadways (less than 1500 ADT) and railroads;

(v) significant economic loss.

(E) A Class C dam is a high hazard potential dam which, if it were to fail, would result in any of the following:

(i) probable loss of life;

(ii) major damage to habitable structures, residences, hospitals, convalescent homes, schools, etc.;

(iii) damage to main highways (greater than 1500 ADT);

(iv) great economic loss.

(2) The classification of a Class A, BB, B, and C dam shall be reviewed during each periodic inspection.

(3) All dams will be subject to reclassification at any time the Commissioner determines that the hazard potential has changed.

(4) Potential future development of the area downstream from the dam that would be affected by its failure shall be considered in determining the classification.

(5) Where a dam is so located that its failure would likely cause a downstream dam to fail, the hazard classification of this dam shall be at least as great as that of the downstream dam.

(6) Potential damage to habitable structures will be considered minor when habitable structures are not within the direct path of the probable flood wave produced upon failure of a dam and when such structures will experience:

(A) No more than 1.5 feet of rise of flood water above the lowest ground elevation adjacent to the outside foundation walls; or

(B) No more than 1.5 feet of rise of flood water above the lowest habitable floor elevation of the structure; the lower of the elevations governing.

(7) The extent of potential damage resulting from a dam breach may, notwithstanding the above, justify designating damage as either major or minor. Such a designation may be made after a detailed analysis has established the relative impact of the probable dam breach and has considered the following factors:

(A) The conditions prior to and after a dam breach;

(B) The extent to which, access has been affected, both before and after a dam breach;

(C) The extent of damage.

(e) Inspection Schedule.

(1) The Commissioner or his representative may enter upon private property at any time to investigate or inspect any dam.

(2) The Commissioner shall periodically inspect all dams in accordance with the following schedule. These time periods are the minimum time between inspections, more frequent inspections may be performed at the discretion of the Commissioner.

HAZARD CLASS	INSPECTION FREQUENCY
Class A (low)	10 years
Class BB (moderate)	7 years
Class B (significant)	5 years
Class C (high)	2 years

(3) Inspections scheduled according to the time period set forth above, may be modified, at the discretion of the Commissioner, in special cases where it is desirable to observe a dam under particular conditions (i.e. wet season, dry season, foliage…).

(4) The Commissioner may require scheduled inspections on a more frequent basis if particular conditions exist which require more frequent monitoring.

(5) The Commissioner may require Class B and C dams to be inspected after the occurrence of a major flood event. The date of these post-flood inspections will be the starting date from which the date of the next regularly scheduled periodic inspection will be computed.

(6) The Commissioner shall exempt from periodic inspections, any dam which, after an initial inspection, impounds less than three (3) acre-feet of water, or any Class AA dam, unless the Commissioner determines that such dam poses a unique hazard.

(f) Inspection by the Owner.

(1) A dam owner may elect to employ the services of a professional engineer registered in the State of Connecticut, experienced in the design, construction and inspection of dams to inspect the owner's dam according to the following schedule:

HAZARD CLASS	INSPECTION FREQUENCY
Class A (low)	10 years
Class BB (moderate)	7 years
Class B (significant)	5 years
Class C (high)	2 years

(2) The owner shall furnish a copy of each completed inspection report in a format determined by the Commissioner within thirty (30) days of the date of the inspection to the DEP Dam Safety Program.

(3) The inspection report shall be sealed by a professional engineer registered in the State of Connecticut and shall include:

(A) Those items listed in Section 22a-409-2(c), and

(B) Correspondence from the owner stating his or her intent to implement such recommendations, if required.

(4) If the dam owner elects to comply with subdivisions (1) through (3), inclusive, the Commissioner shall periodically inspect the dam according to the following schedule:

HAZARD CLASS	INSPECTION FREQUENCY
Class A (low)	20 years
Class BB (moderate)	14 years
Class B (significant)	10 years
Class C (high)	6 years

The year the Commissioner inspects the dam, the owner shall be exempt from conducting his or her own inspection.

(g) New Dam Construction.

(1) All dams, and dams which have a high or significant hazard classification undergoing substantial repairs according to the permit authorization of the Commissioner, must be inspected by the professional engineer employed by the dam owner for construction services according to the following schedule:

(A) Upon first filling of the impoundment, after completion of new construction or substantial repairs, inspection should be performed to assure proper functioning of dam components.

(B) Upon attainment of full impoundment, inspections of the dam should be performed frequently for the first two (2) months.

(C) These dams shall be inspected at least annually for the first three (3) years of operation.

(D) After the third year of operation, these dams will be inspected according to the inspection schedule set forth in Section 22a-409-2-(e).

(E) The Commissioner may exempt from the requirements of this subsection repairs to high and significant hazard dams which he determines do not affect the immediate safety of the dam.

(2) The inspection report must be submitted by the owner's engineer to the Commissiner on a form prescribed by him, within thirty (30) days after:

(A) The last inspection performed during the first two (2) months after full impoundment was attained; and

(B) Each annual inspection as set forth in Section 22a-409-2(g)10(C).

(h) Fees for Inspection by the State.

(1) Each owner shall pay an inspection fee to cover the cost to the State of making both scheduled inspections and post-flood inspections. Such fee bill shall accompany the written report and shall be paid within thirty (30) days after receipt by the owner.

(2) The owner shall submit the inspection fee by check or money order payable to DEP Dam Safety Program.

(3) Pursuant to Sec. 22a-409 of the CT General Statutes, as amended by P.A. 6806, fees for Class A, BB, B and C dams are $525.00.

(4) The Commissioner shall waive the inspection fee for any dam which is owned by the State of Connecticut.

(i) Notification.

(1) The Commissioner shall notify a dam owner of the upcoming date for a regularly scheduled inspection at least ninety (90) days before the inspection.

(2) If, the Commissioner does not receive notification of the owner's intent to perform the inspection with his or her own engineer thirty (30) days prior to the date of the scheduled inspection, the Commissioner shall inspect the dam and charge the owner the appropriate fee.

(3) If after notification by the owner of his or her intent to perform the inspection, the Commissioner does not receive a copy of the inspection report within thirty (30) days of the scheduled inspection date, the Commissioner shall inspect the dam and charge the owner the appropriate fee.

(j) Responsibility of the Owner.

(1) Inspections by the State do not relieve an owner of the dam of the legal duties, obligations or liabilities incidental to the ownership or operation of the dam.

(2) The owner or his or her representative shall inspect the dam on a frequent basis to assure that no unsafe conditions are developing including but not limited to, weather related damage, animal activity or vandalism. Class B and Class C dams shall be inspected by the owner of his or her representative at least quarterly and a written record shall be maintained and be made available to the Commissioner upon request.

(3) The owner or his representative shall inspect the dam during and after the occurrence of major flood events to assure that the structure is withstanding the flood waters safely.

(4) The owner shall fully and promptly advise the Commissioner of any sudden or unpredicted floods, unusual circumstances or major changes in the condition of the dam.

(5) The owner shall report to the Commissioner any major damage which the dam suffered, such as, overtopping by flood waters, erosion of the spillway discharge channel and any major problems which are observed to have developed such as, new seepage or a significant increase in seepage quantities, settling, cracking or movement of the embankment or any component of the dam.

(6) To facilitate visual inspection during the intervals between regularly scheduled inspections, the dam owner shall be required to maintain the structure and adjacent area free of brush and tree growth.

(A) Brush and tree growth shall be cleared from embankments and within twenty-five (25) feet of the downstream toe and the abutment embankment contact;

(B) Grass or other suitable vegetative cover must be established and maintained on abutments and embankments.

(7) The owner shall maintain a written record of all inspections and maintenance work performed. This record shall include observations made regarding areas of concern on the structure and descriptions of the major and minor repairs performed and materials utilized.

Statement of Purpose: To establish a schedule for the frequency of inspection of dams and similar structures and the inspection fees for regularly scheduled inspection sufficient to cover the reasonable cost to the State of making these inspections. For further information, contact the Bureau of Water Management's Inland Water Resources Division, Dam Safety Section at (860) 424-3706.

Effective: 4/30/87

E.8. Delaware

DEPARTMENT OF NATURAL RESOURCES AND ENVIRONMENTAL CONTROL

DIVISION OF SOIL AND WATER CONSERVATION

Statutory Authority: 7 Delaware Code, Chapter 42 (7 **Del.C.**, Ch. 42)

FINAL

Secretary's Order No. 2009-S-0044

5103 (DELAWARE DAM SAFETY REGULATIONS
Date of Issuance: November 16, 2009
Effective Date: December 11, 2009

Under the authority vested in the Secretary of the Department of Natural Resources and Environmental Control ("Department" or "DNREC") the following findings, reasons and conclusions are entered as an Order of the Secretary in the above-referenced rulemaking proceeding.

Background and Procedural History

This Order considers proposed regulation entitled "Delaware Dam Safety Regulations." The Department's Division of Soil and Water Conservation commenced the regulatory development process with Start Action Notice 2006-16, which was approved on ….DSWC's Dam Safety Program held 4 meetings with the regulatory advisory committee, as required by the Dam Safety Act (Act), and a public workshop on December 11, 2008.

The Department published the proposed regulations in the April 1, 2009 *Delaware Register of Regulation* and held a public hearing on April 27, 2009. The Department's presiding hearing officer, Robert P. Haynes, prepared a Hearing Officer's Report dated November 9, 2009 (Report). The Report recommends certain findings and the adoption of as a final regulation as "Delaware Dam Safety Regulations," attached to the Report as Appendix A (Regulation).

Findings and Discussion

I find that the Regulation is well-supported by the record developed by DSWC and adopt the Report to the extent it is consistent with this Order. DSWC's experts developed the record and the Regulation was drafted with the cooperation and coordination by members of the regulatory advisory committee. In addition, DSWC held a public workshop. As a result of the extensive informal regulatory development process, the proposed regulation only received two public comments. DSWC and the Report recommend that one comment's editorial and clarifying changes be reflected as non-substantive changes and the other comment was on a specific problem with one pond that did not require any change to the proposed regulation.

I find that the Department's experts in DSWC fully developed the record to support adoption of the final regulations. As final regulations, the Department will have improved authority to regulate dams, particularly the existing 53 dams that are subject to the Department's regulation. The regulation also will regulate to any new dams that fall within the size and classification that are subject to the regulation. The regulations will require annual inspections of high hazard dams and inspections of the significant hazard dams every two years. All dams will be subject to review and supervision by a licensed Delaware professional engineer. The dams that are regulated are public owned dams that have a certain height or size of impoundment or hazard classification to warrant regulation under the Act, or any privately owned dam that may seek to be regulated by agreement.

The regulation adopted by this Order provides more details and clarification to the owners of dams regulated by the Act. The regulation's procedures set forth how to apply to the Department for permission to design, construct, operate, maintain, inspect and abandon a regulated dam. The regulation that this Order adopts will provide a comprehensive and sound basis to regulate those dams in Delaware that are subject to regulation under the Act. In conclusion, the following findings and conclusions are entered:

1.) The Department has jurisdiction under its statutory authority to issue an Order adopting this final

regulation;

2.) The Department provided adequate public notice of the proposed regulation and provided the public with an adequate opportunity to comment on the proposed regulations, including at a public hearing;

3.) The Department held a public hearing on the proposed regulations in order to consider public comments before making any final decision, and has considered all relevant and timely public comments it received;

4) The Department's Hearing Officer's Report, including its recommended record and the Recommended Regulation, as set forth in Appendix A, are adopted to provide additional reasons and findings for this Order;

5.) The Recommended Regulation does not reflect any substantive changes from the Proposed Regulation published in the April 1, 2009, *Delaware Register of Regulations*;

6.) The Recommended Regulation should be adopted as a final regulation because it is consistent with the Act and its purposes to reduce the risk of loss of life and property damage from a failure of a dam subject to the Act's regulation, will enable the Department to administer its duties under the Act, and is well supported by documents in the record; and that

7.) The Department shall submit this Order approving the final regulation to the *Delaware Register of Regulations* for publication in its next available issue, and provide such other notice as the law and regulation require and the Department determines is appropriate.

Collin P. O'Mara
Secretary

5103 Delaware Dam Safety Regulations

Scope and Applicability

Legislation

The Delaware State Legislature passed House Bill No. 514 on June 30, 2004 to amend Section 1 Title 7 of the Delaware Code by enacting in Part IV a new "Chapter 42, Dam Safety." These Regulations have been promulgated pursuant to Title 7 of the Delaware Code, Chapters 42 and 60. The text of House Bill No. 514 is attached as Appendix A. The Act provides for the regulation of publicly owned dams that meet the definition of a dam as defined by the Act and these Regulations and have a hazard classification of High or Significant Hazard Potential.

Purpose of Regulations

It is the purpose of these Regulations to provide for the proper design, construction, operation, maintenance, and inspection of dams in the interest of public health, safety, and welfare, in order to reduce the risk of failure of dams and to prevent death or injuries to persons; damage to downstream property, infrastructure, and lifeline facilities; and loss of reservoir storage.

1.0 Regulating Agency

1.1 The Delaware Dam Safety Program shall be administered by the Delaware Department of Natural Resources and Environmental Control (Department). The program shall be administered and directed by an engineer, licensed in the State of Delaware, or by an individual otherwise clearly qualified by training and experienced in the design, construction, reconstruction, enlargement, repair, alteration, breach, removal, maintenance, operation, and abandonment of dams and reservoirs.

1.2 The Department shall have the authority to review and approve the design, construction, reconstruction, enlargement, alteration, repair, maintenance, operation, breach, abandonment, and removal of dams and reservoirs for the protection of life, property, public infrastructure, and lifeline facilities.

1.3 In making any investigation or inspection necessary to enforce these Regulations, the Department or its representatives may enter upon such private property of the dam owner as may be necessary.

1.4 When the Department determines that a dam and reservoir constitute a risk to life or property, the agency shall order the owner to take such action as necessary to remove the resultant risk to life and property.

1.5 No action shall be brought against the State of Delaware, or any agent of the Department, or any employee of the State of Delaware or the Department for damages sustained through the partial or total failure of any dam, its misoperation, or its maintenance by reason of any supervision or other action taken pursuant to or under these Regulations. Nothing in these Regulations shall relieve an owner or operator of a dam from the legal duties, obligations, and liabilities arising from such ownership and operation.

2.0 Definition of Terms

The following words, terms, and phrases, when used in these Regulations, shall have the meanings ascribed to them except where the context clearly indicates a different meaning:

"**Abandonment**" means to render a dam non-impounding by dewatering and filling the reservoir created by that dam with solid materials and by diverting the natural drainageway around the site.

"**Adverse consequences**" means negative impacts that may occur upstream, downstream, or at other locations remote from the dam. The primary concerns are loss of human life, economic loss (including property damage), disruption of lifeline facilities, and environmental impact.

"**Alterations**", "**modifications**" or "**repairs**" means only alterations, modifications, or repairs to existing dam and appurtenant structures that may directly affect the operation, performance, or safety of the dam, spillway, outlet works, ancillary structures, or reservoir, as determined by the Department. This definition does not include maintenance or minor repairs.

"**Application approval**" means authorization in writing issued by the Department to an owner who has applied to the agency for permission to construct, reconstruct, enlarge, repair, alter, remove, maintain, operate, or abandon a dam and which specifies the conditions or limitations under which work is to be performed by the owner or under which approval is granted.

"**Appurtenant works**" include, but are not limited to, structures such as spillways, either in or separate from the dam; the reservoir and its rim; low-level outlet works; and water conduits such as tunnels, pipelines, or penstocks either through the dam or its abutments.

"**As-Built Drawings**" or" **Record Drawings**" mean the approved post-construction plans;

(1) With verification of all significant as-constructed values, dimensions, and elevations; and

(2) Bearing the seal of the supervising engineer responsible for certifying that to the best of his/her knowledge, the construction was completed in accordance with the approved plans and specifications or with changes approved by the Department.

"**Auxiliary Spillway**" means the second used spillway during flood flows which is not the emergency spillway.

"**Breach**" means partial removal of a dam, creating a channel through the dam to the original stream bottom elevation.

"**Dam**" shall mean any artificial barrier, including appurtenant works, with the ability to impound or divert water, wastewater, or liquid-borne materials. No obstruction in a canal used to raise or lower water shall be considered a dam. A fill or structure for highway or railroad use, or for any other purpose that may impound water, may be subject to review by the Department and shall be considered a dam if the criteria in these Regulations are found applicable and if it is classified as a high hazard potential or significant hazard potential dam.

"**Danger reach**" means that area downstream of a dam that will be flooded by the sudden release of waters resulting from failure of the dam.

"**Days**" when used in establishing deadlines, means calendar days including Sundays and holidays.

"**Department**" means the Delaware Department of Natural Resources and Environmental Control.

"**Design freeboard**" means the minimum freeboard which would exist during passage of the design flood.

"**Dominant discharge**" means the flow rate capacity, in cubic feet per second, of the stream channel considering steady, uniform flow.

"**Emergency Action Plan**" (EAP) means a plan prepared by the dam owner and approved by the Department that identifies emergency conditions at a dam and specifies preplanned actions to minimize loss of life and property damage in the event of a potential dam failure.

"**Emergency condition**" means a sudden unforeseen occurrence or condition requiring exigency or a circumstance that the Department determines constitutes a present or imminent danger to the public health or safety or to the environment. This includes, but is not necessarily limited to: breaches and all conditions leading to or causing a breach, overtopping, or any other condition in a dam and its appurtenant structures that may be construed as unsafe or threatening to life or property.

"**Emergency Spillway**" means the spillway capable of passing the spillway design storm with the principal and/or auxiliary spillway blocked.

"**Enlargement**" means any change in or addition to an existing dam or reservoir, which raises or may raise the water storage elevation of the water impounded by the dam.

"**Floodplain**" means that area along or adjacent to a stream or a body of water of that is capable of storing or conveying flood waters. As used herein, "floodplain" may or may not be the same area depicted as a special flood hazard zone on the Flood Insurance Rate Maps prepared by the Federal Emergency Management Agency.

"**Formal inspection**" means the inspection by a Delaware licensed professional engineer to reevaluate the safety and integrity of the dam and appurtenant structures to determine if the structure meets current design criteria, including a field inspection and a review of the records on project design, construction and performance.

"**Freeboard**" means the vertical distance to the top of a dam above the maximum design water surface elevation.

"**Independent Review Board**" means one or more independent professional engineers who are qualified in the design, construction and rehabilitation of dams to perform a review of the project design and construction.

“**Informal Inspection**” means the visual inspection of the dam by the dam owner or operator to detect apparent signs of deterioration or other deficiencies of the dam structure or function.

"**Hazard potential**" means the possible adverse incremental consequences that result from the release of water or stored contents due to failure of the dam or appurtenances. The hazard potential classification of a dam does not reflect in any way on the current condition of the dam and its appurtenant structures (e.g., safety, structural integrity, flood-routing capacity).

"**Height of dam**" means the vertical distance from the lowest point on the downstream toe of the dam to the lowest point on the top of the dam, independent of low points caused by partial failure or collapse.

"**High Hazard Potential Dam**" shall mean any dam whose failure or misoperation will cause probable loss of human life.

"**Incremental**" means the difference in impacts, under the same conditions (e.g., flood, earthquake, or other event), that would occur due to failure of the dam or those that would have occurred without failure of the dam and appurtenances.

"**Inflow design flood**" means the size of flood coming into the reservoir that is used as a basis for designing the dam.

"**Low-hazard potential dam**" means any dam whose failure or misoperation is unlikely to cause loss of human life but may cause minor economic and/or environmental losses.

“**Maintenance**” means routine activities associated with keeping the dam and ancillary structures in safe operating condition, including, but not limited to such activities as mowing and vegetation removal, cleaning drains, painting metal parts, lubricating and exercising mechanical parts, cleaning debris from channels and trash racks, etc.

"**Maximum capacity**" means the storage volume of a reservoir, in acre-feet, at the lowest point on the top of dam independent of low points caused by partial failure or collapse.

"**Maximum storage elevation**" means the elevation of the lowest point of the top of dam independent of low points caused by partial failure or collapse.

“**Minor repairs**” means activities that restore sections of the dam, spillway, outlet works, and ancillary structures which exhibit minor deterioration to their intended state and that do not require the alteration (permanent or temporary) of any facilities that would effect performance, operation or safety of the dam as determined by the Department.

"**Normal depth**" means the maximum vertical distance from the streambed invert at the upstream toe of the dam to the normal water surface.

“**One-hundred year storm**” means the storm which is estimated to have a one percent chance, or one chance in 100, of being equaled or exceeded in one year.

“**Outlet**” means an opening through which water can be freely discharged from a reservoir for a particular purpose.

"**Overflow spillway**" means any operating, emergency, or other spillway that discharges with a free water surface over or around the dam as opposed to an orifice, gate, or conduit that discharges through or beneath the dam or nearby ground.

"**Owner**" shall include any one or more of the following who owns, controls, operates, maintains, manages, or proposes to construct, reconstruct, enlarge, repair, alter, remove, or abandon a dam or reservoir: the state and its departments, institutions, agencies, and political subdivisions; every municipal or quasi-municipal corporation; every public utility; every district; every person; the duly authorized agents, lessees, or trustees of any of the foregoing; and receivers or trustees appointed by any court for any of the foregoing.

"**Permit to Impound**" means authorization in writing issued by the Department to an owner who has complied with the conditions specified in the Provisional Certificate to Impound issued by the Department, or has completed construction, reconstruction, enlargement, repair, or alteration of a dam, and which specifies the conditions or limitations under which the dam and reservoir are to be maintained and operated.

"**Person**" means any person, firm, association, organization, partnership, business trust, corporation, or company.

"**Preliminary Hazard Classification**" means the initial hazard potential classification determined by the Department based on approximate methods, and is not based on detailed analyses as described in paragraph 5.3 of these Regulations.

"**Principal spillway**" means the primary or first used spillway during normal inflow and flood flows.

"**Probable**" means likely to occur; reasonably expected; realistic.

"**Probable Maximum Flood**" (PMF) means the most severe flood considered possible in a specific region based on the Probable Maximum Precipitation (PMP), as determined by the National Weather Service.

"**Probable Maximum Precipitation**" (PMP) means the theoretically greatest depth of precipitation for a given duration that is physically possible, over a given size storm area, at a particular geographic location, at a certain time of year.

"**Provisional Certificate to Impound**" means temporary authorization in writing issued by the Department to the owner of a dam that existed prior to June 30, 2004, and that the Department has determined meets the criteria for regulation as contained in paragraph 3.1 of these Regulations, and which specifies the conditions that must be met by the dam owner to obtain a Permit to Impound.

"**Reconstruction**" means removal and replacement of an existing dam.

"**Regular Inspection**" means the visual inspection of a dam by a Delaware licensed professional engineer to detect any signs of deterioration in material, developing weaknesses or unsafe hydraulic or structural behavior.

"**Removal**" means complete elimination of the dam embankment or structure to restore the approximate original topographic contours of the valley.

"**Reservoir**" means any basin that contains or will contain impounded water, wastewater, or liquid-borne materials because it has been impounded by a dam.

"**Secretary**" means the Secretary of the Delaware Department of Natural Resources and Environmental Control.

"**Significant Hazard Potential Dam**" shall mean any dam whose failure or misoperation will cause possible loss of life, economic loss, environmental damage, disruption of lifeline facilities, or can impact other concerns.

"**Standard project flood**" means the most severe flood considered reasonably characteristic of the specific region. This is calculated for a specific dam site using one or more of the recognized methods acceptable to the Department.

"**State or state**" means the State of Delaware.

"**Spillway**" means a structure other than low flow outlets, over or through which flood flows are discharged.

"**Spillway Design Storm**" means the storm upon which the hydraulic capacity of the spillway structure is designed.

"**Supervising Engineer**" shall mean the design engineer who is responsible for conducting dam construction quality assurance inspections in order to certify the construction has been completed in accordance with the approved plans and specifications.

"**Sunny day failure**" means the failure of a dam with the water level at the normal pool elevation and no rainfall.

"**Toe of dam**" means the junction of the downstream face of a dam with the ground surface or the invert of the outlet pipe whichever is the lowest point.

3.0 Permit-By-Rule

3.1 Applicability

3.1.1 These Regulations shall apply to any dam that is owned by the State or any county in the State, or any municipality, or any quasi-governmental agency of the State that is 25 feet or more in height from the natural bed of the stream or watercourse measured at the downstream toe of the barrier or from the lowest elevation of the outside limit of the barrier, or if it is not across a stream channel or watercourse, measured at maximum water storage elevation; or any dam having an impounding capacity, at maximum storage elevation, of 50 acre-feet or more; or any dam that is deemed by the Secretary to be a significant- or high-hazard potential structure due to its location or other physical characteristics.

3.1.2 It is unlawful to construct, reconstruct, enlarge, repair, alter, remove, maintain, operate, or abandon any dam or reservoir that comes under these Regulations except upon application approval of the Department.

3.2 Exclusions

3.2.1 These Regulations shall not apply to any dam that is not in excess of 6 feet in height regardless of storage capacity, or any dam having a storage capacity at maximum water storage elevation not greater than 15 acre-feet regardless of height, or any low-hazard potential dam constructed prior to June 30, 2004, unless deemed by the Secretary to be a significant or high-hazard potential structure due to its location or other physical characteristics.

3.2.2 These Regulations shall not apply to any private owner of a dam unless such owner executes a document with the Department requesting such coverage.

3.2.3 The requirements in these Regulations shall not apply to routine maintenance and operation not affecting the safety of the structure.

3.2.4 These Regulations do not apply to dams that are owned and operated by the Federal Government.

4.0 General Requirements and Prohibitions

4.1 Construction of New Dams

4.1.1 No owner shall begin the construction of any dam to which these Regulations apply without written approval from the Department. Owners intending to construct any dam to which these Regulations apply shall file with the Department a preliminary application that shall include a dam break analysis; the dam height; the maximum impounding capacity; the purpose, location, and determination of hazard class; and other information required by the Department. If, on the basis of this information, it is the opinion of the Department that the proposed dam is exempt from the provisions of these Regulations, the Department shall notify the owner that no approval from the Department pursuant to these Regulations will be required. If, on the basis of the submitted information it is the opinion of the Department that the proposed dam is not exempt, the Department shall notify the owner that construction shall not commence until a full application has been filed by the owner and such application approved in accordance with Sections 6.0 and 7.0 of these Regulations.

4.1.2 The Department shall require Emergency Action Plans (EAPs) and operation and maintenance (O&M) plans for high- or significant-hazard potential dams, and may also require of owners so notified the filing of any additional information it deems necessary, including, but not limited to, stream flow and rainfall data, maps, reports, plans, and specifications.

4.1.3 Every owner applying for approval of a dam subject to the provisions of these Regulations shall also file with the Department a Certificate from a qualified professional engineer licensed in the State of Delaware. The Certificate should state that the engineer is qualified and responsible for the design of the dam; that the design is safe and adequate; and that the engineer shall be responsible for construction quality assurance to certify that the construction has been completed in accordance with the approved plans.

4.1.4 The Department shall send a copy of each completed application to the Delaware Emergency Management Agency and other State, Federal, and local agencies it considers appropriate for review and comment.

4.1.5 Upon receipt of a full application in proper form, the Secretary shall give notice in an advertisement in a newspaper of general circulation in the county in which the activity is proposed and in a daily newspaper of general circulation throughout the State, providing:

4.1.5.1 An announcement of the fact that the application has been received;

4.1.5.2 A brief description of the nature of the application;

4.1.5.3 Notification of location(s) where a copy of the application may be inspected; and

4.1.5.4 Procedures to request a public hearing.

4.1.6 The Secretary shall hold a public hearing on an application if he receives a request from any party whose interests are substantially affected by the proposed application, as determined by the Secretary, if such request is received within 21 calendar days of the public notice. A notice shall

also be sent by mail to any person who has requested such notification from the Department and provides a name and address.

4.2 Repair, Alteration, or Removal of Existing Dams

4.2.1 Before commencing the repair, alteration, or removal of any dam to which these Regulations apply, application shall be made by the owner for written approval by the Department, except as otherwise provided by these Regulations. The installation of utility lines in a dam shall be considered an alteration to the dam and will require permitting under these regulations. The application shall state the name and address of the owner; shall adequately detail the changes it proposes to effect, as well as impacts or modifications to O&M plans and EAPs; and shall be accompanied by maps, plans, and specifications setting forth such details and dimensions as the Department requires.

4.2.2 The Department may waive the requirements of this Section for the repair or alteration of a dam if the proposed action is determined to be minor as defined by the Department by regulation. The application shall contain such other information concerning the dam and reservoir required by the Department; shall include information concerning the safety of any change that it may require; and shall state the proposed time of commencement and completion of the work.

4.2.3 When the Department determines an application has been completed, it may refer the application for agency review and report, as provided by paragraph 4.1.4 of these Regulations in the case of original construction. The application for repair, alteration, or removal of the dam shall be subject to the public notice requirements.

4.2.4 Upon receipt of a full application in proper form, the Secretary shall give notice in an advertisement in a newspaper of general circulation in the county in which the activity is proposed and in a daily newspaper of general circulation throughout the state, providing:

4.2.4.1 An announcement of the fact that the application has been received;

4.2.4.2 A brief description of the nature of the application;

4.2.4.3 Notification of location(s) where a copy of the application may be inspected; and

4.2.4.4 Procedures to request a public hearing.

4.2.5 The Secretary shall hold a public hearing on an application if he receives a request from any party whose interests are substantially affected by the proposed application, as determined by the Secretary, if such request is received within 21 calendar days of the public notice. A notice shall also be sent by mail to any person who has requested such notification from the Department and provides a name and address.

4.2.6 When repairs are necessary to safeguard life and property, they may be started immediately. The Department shall be notified as soon as practical but no longer than 24 hours after such repairs have commenced. The owner shall be required to submit as-built plans and certification from a professional engineer, licensed in Delaware, demonstrating that the repairs comply with these Regulations.

4.3 Supervision by Qualified Engineers; Reports and Modifications During Work

4.3.1 Any project for which the Department's approval is required under these Regulations shall be designed and the construction supervised by a licensed professional engineer in the State of Delaware with related experience in dam design and construction.

4.3.2 During the construction, enlargement, repair, alteration, or removal of any dam to which these Regulations apply, the Department may require such progress reports from the supervising engineer responsible for design and construction quality assurance as it deems necessary.

4.3.3 If, based on inspection reports, construction inspections, or other information, the Department finds that the work is not in compliance with the provisions of the approval and the approved plans and specifications; it shall give written notice to the person who received the approval and to the person in charge of construction of the dam. The notice shall state the particulars of the lack of compliance, and shall order immediate compliance with the terms of approval and the approved plans and specifications. The Department may order that no further construction work be undertaken until such compliance has been effected and approved by the Department. A failure to comply with the approval and the approved plans and specifications shall render the approval revocable unless compliance is made after notice, as provided in these Regulations.

4.4 Notice of Completion; Certification of Final Approval

4.4.1 Within 7 days of completion of construction, reconstruction, enlargement, repair, alteration, or removal of any dam to which these Regulations apply, notice of completion shall be given to the Department. Within 60 days thereafter, supplementary drawings or descriptive matter showing or describing the dam as actually constructed (as-built drawings) in compliance with the approval and the approved plans and specifications shall be filed with the Department in such detail as the Department may require.

4.4.2 Upon completion of the project, the supervising engineers, having inspected the work during construction and upon finding that the work has been done as required and that the dam is safe, shall file with the Department a Certificate and as-built plans demonstrating that the work has been completed in accordance with the approved design plans, specifications, and other requirements. After review of the supervising engineer's Certificate and as-built plans, unless the Department has reason to believe that the dam is unsafe or is not in compliance with any applicable rule or law, the Department shall grant final approval of the work in accordance with the Certificate, subject to such terms as it deems necessary for the protection of life and property.

4.4.3 Pending issuance of the Department's final approval, the dam shall not be filled except on written consent of the Department, subject to conditions it may impose.

4.5 Operation and Maintenance (O&M) of New or Existing Dams

4.5.1 The Department shall require that dam owners and operators develop, use, and update as necessary an operations and maintenance (O&M) Plan that provides guidance and instruction to personnel for the proper O&M of any reservoir or dam to which these Regulations apply in order to safeguard life and property.

4.5.2 The O&M Plan shall be subject to the approval of the Department and may be reviewed, modified, or amended by the Department as deemed necessary to safeguard life and property.

4.5.3 The Secretary may adopt, amend, modify, or repeal standards for the maintenance and operation of dams as may be necessary for the purposes of this Section. The Department may vary the standards applicable to the various dams giving due consideration to the type and location of the structure, the hazards to which it may be exposed, and the peril of life and property in the event of a failure or misoperation of the dam.

4.6 Monitoring and Inspection of New or Existing Dams

4.6.1 The Department shall require regular monitoring and inspection of any dam to which these Regulations apply, to safeguard life and property.

4.6.2 The Secretary may adopt, amend, modify, or repeal standards for the monitoring and inspection of dams as may be necessary for the purposes of this Section. The Department may vary the standards applicable to the various dams giving due consideration to the type and location of the structure, the hazards to which it may be exposed, and the peril of life and property in the event that a dam fails to perform its function.

4.7 Emergency Action Plans (EAPs) for New or Existing Dams

4.7.1 The owner of any new or existing dam that is regulated under these Regulations and is classified as a Class I High Hazard Potential, or Class II Significant Hazard Potential, in accordance with Section 5.0 of these Regulations, shall prepare an Emergency Action Plan (EAP) in accordance with the requirements of these Regulations.

4.7.2 The Department shall inform the Delaware Emergency Management Agency of any dam presenting a risk of peril of life and property in the event that the dam fails.

4.8 Permit to Impound

4.8.1 The owners of all existing dams regulated under these Regulations must apply for and obtain from the Department a Permit to Impound in accordance with the requirements of these Regulations.

4.8.2 Within 60 days of the satisfactory receipt of the Supervising Engineer's Certificate, as-built plans, the O&M Plan, and the EAP, from the owners of new dams or existing dams that have been modified, the Department will issue a Permit to Impound prior to the impoundment of water behind the dam.

5.0 Hazard Classification of Dams

5.1 General Requirements

5.1.1 Dams shall be classified in accordance with the federal classification system into three classes that are rated according to the potential damage that could be caused if the dams fail. Those three classes shall be designated as follows:

5.1.1.1 Class I High Hazard Potential

5.1.1.2 Class II Significant Hazard Potential

5.1.1.3 Class III Low Hazard Potential

5.1.2 Per state legislation and these Regulations, Class III Low-Hazard dams are exempt from the requirements of these Regulations.

5.1.3 The Department will use the guidelines in this section to classify dams according to hazard. Probable future development of the area downstream from the dam, which might be affected by its failure, will be considered in determining the hazard classification.

5.1.4 The Department may, at its discretion, change the hazard class of any proposed or existing dam.

5.2 Description of Hazard Class

5.2.1 Class I – High Hazard Potential: This classification includes any dam whose failure or misoperation will cause probable loss of human life. The existence of normally occupied homes in the area that are susceptible to significant damage in the event of a dam failure will be assumed to mean "probable loss of life." Recreational facilities below a dam, such as a campground or recreation area, may be sufficient reason to classify a dam as having a high-hazard potential.

5.2.2 Class II – Significant Hazard Potential: This classification includes any dam whose failure or misoperation will cause possible loss of human life, economic loss, environmental damage, and disruption of lifeline facilities, or can impact other concerns. This classification applies to predominantly rural agricultural areas, where dam failure may damage isolated homes, major highways, or railroads or cause interruption of service of relatively important public utilities.

5.2.3 Class III – Low Hazard Potential: This classification includes any dam whose failure or misoperation is unlikely to cause loss of human life but may cause minor economic and/or environmental losses. This classification applies to rural or agricultural areas where failure may damage farm buildings other than residences, agricultural lands, or non-major roads. Class III dams are exempted from the requirements of these Regulations.

5.3 Determination of the Hazard Class

5.3.1 The hazard classification shall be determined by establishing a danger reach downstream of the dam by conducting a dam breach analysis and routing the dam breach flood wave through the downstream valley. At the discretion of the Department, this analysis may require routing several spillway design floods through the danger reach, with and without the effects of failure of the dam, including at a minimum the following events:

5.3.1.1 100-year frequency flood

5.3.1.2 50 percent probable maximum flood (PMF)

5.3.1.3 Probable maximum flood (PMF)

5.3.1.4 A sunny day failure for dams with permanent pools

5.3.2 The applicant shall use computational methods for analyzing dam failure flooding that are generally acceptable in the engineering community and are verifiable, reliable, and acceptable to the Department.

5.3.3 The Department shall determine and assign the hazard classification according to the criteria above based on:

5.3.3.1 An evaluation of hydrologic calculations assuming ultimate development of the watershed using existing comprehensive plans and zoning; and

5.3.3.2 Review of potential damage within the danger reach.

5.3.4 Failure damage potential shall consider future development and use of the area flooded throughout the danger reach and the damage that would be expected from a complete breaching of the dam. If, in the opinion of the Department, future development is probable in the area flooded throughout the danger reach, the dam shall be categorized as Class I.

5.3.5 The classification of the proposed dam shall be assigned by the Department after the applicant has provided information on the potential damage within the danger reach, as defined herein. After

the classification has been assigned, the inflow design flood and spillway design may be established.

6.0 Application Procedures

6.1 Application Procedures for Existing Dams

6.1.1 Upon promulgation of these Regulations, the Department shall notify in writing the owner of each regulated dam that existed prior to June 30, 2004, that the Department has determined that they own, or have operational control over, a regulated dam and are subject to the provisions of these Regulations. The Department shall provide to each owner a copy of all information that the Department has gathered about the dam, including photographs, measurements, maps, plans, etc. The notification shall include the dam's Preliminary Hazard Classification as determined by the Department.

6.1.2 Within 90 days of receipt of the Department's notification that they own a regulated dam, each dam owner shall submit a letter to the Department acknowledging ownership or operational control of the dam and shall provide to the Department a copy of any existing information in the owner's possession concerning the dam (plans, surveys, engineering reports, etc.).

6.1.3 In the event that a dam owner wishes to dispute the Department's determination that they own or have operational control over a particular dam, that owner must submit a letter to the Department within 90 days of receipt of the Department's notification of ownership. The owner's letter to the Department shall provide documentation supporting the owner's claim of non-ownership or non-control. In cases of disputed ownership, the Department will review the documentation provided by the dam owner, and may conduct additional investigation as deemed necessary by the Department to resolve the dispute.

6.1.4 Upon receipt by the Department of the owner's acknowledgment of dam ownership, the Department will perform a condition assessment of each dam.

6.1.4.1 If the condition of the dam is determined to be satisfactory, the Department will issue to the owner a Provisional Certificate to Impound.

6.1.4.2 If the condition of the dam is determined to be unsatisfactory, the Department will notify the owner in writing of the deficiencies with the required actions by the owner with deadlines for remedying the unsafe or deficient conditions.

6.1.4.2.1 Within 30 calendar days of receiving notice of an unsatisfactory dam, the owner shall respond to the Department with their intended actions to remedy the deficiencies within the required timeframe.

6.1.4.2.2 Within 30 days of receiving the owner's intended actions, the Department shall make a determination as to whether or not a Permit to Construct, Alter, or Repair a Dam is required and issue a written directive to the owner as to the appropriate course of action.

6.1.4.2.3 If a Permit to Construct a New Dam or a Permit to Alter, Repair or Remove an Existing Dam is required, the owner shall follow the application procedures in Section 6.2 of these Regulations. If such permits are not required, the Department will issue to the owner a Provisional Certificate to Impound within 30 days of remedying the unsatisfactory conditions, as determined by the Department.

6.1.5 Upon issuance of the Provisional Certificate to Impound by the Department, the dam owner will be required to submit to the Department, the following minimum supporting documentation for each dam. The Provisional Certificate to Impound shall include a specific list of the items to be submitted for each dam, and a time frame for the submittal of each item.

6.1.5.1 Application fee in accordance with paragraph 7.2 of these Regulations

6.1.5.2 Basic information about the dam, including:

6.1.5.2.1 Dam location, including the County, nearest town, and stream on which the dam is located

6.1.5.2.2 A map showing the location of the dam

6.1.5.2.3 Dam type

6.1.5.2.4 Dam crest elevation and height, as measured from the downstream toe to the lowest point along the crest

6.1.5.2.5 Steepness of dam slopes

6.1.5.2.6 Seepage controls (if known)

6.1.5.2.7 Slope protection

6.1.5.2.8 Normal pool elevation

6.1.5.2.9 Spillway type and crest elevation

6.1.5.2.10 Spillway capacity in terms of flow

6.1.5.2.11 Storm event return frequency that the spillway is capable of passing without overtopping the dam

6.1.5.2.12 A dam break analysis and downstream danger reach map indicating structures, roads, railroads, critical infrastructure, and other man-made features that are within the danger reach

6.1.5.3 A report, prepared under the supervision of a Delaware-licensed professional engineer experienced with dams, that consists of a site inspection report, documentation of the above information, and an overall evaluation of the condition and safety of the dam and appurtenant facilities

6.1.5.4 An Operations and Maintenance (O&M) Plan

6.1.5.5 An Emergency Action Plan (EAP)

6.1.5.6 Any additional information that exists about the dam, which may include:

6.1.5.6.1 Plans, specifications, and/or engineering analyses and engineering reports

6.1.5.6.2 Inspection reports

6.1.5.6.3 Documentation of repairs and/or modifications to the dam

6.1.5.6.4 Photographs

6.1.5.6.5 Correspondence

6.1.5.6.6 Any other information that exists

6.1.6 The Department will evaluate the information provided by the applicant, make an assessment about its adequacy, and determine whether additional information is necessary to issue a Permit to Impound. The Department shall notify the applicant within 30 calendar days of receipt of the application package if any additional information is required and the nature of that additional information.

6.1.7 Within 90 calendar days of receiving all required information the Department shall issue a Permit to Impound to the dam owner.

6.2 General Application Procedures for Construction of a New Dam or the Repair, Alteration, or Removal of an Existing Dam

6.2.1 The procedures for applying for a Permit to Construct a New Dam or for a Permit to Alter, Repair, or Remove an Existing Dam, and for submitting the supporting engineering documents include the pre-application stage and the application stage, as described below.

6.2.2 The applicant for either type of dam permit referenced in 6.2.1 must use a Delaware-licensed professional engineer (Supervising Engineer) to prepare the plans and specifications and to supervise the inspection of construction, as required in Section 4.0 of these Regulations.

6.2.3 The Department may require any owner or operator of an existing dam to obtain a Permit to Alter, Repair, or Remove an Existing Dam in order to repair or alter the dam, spillway, outlet works, or other and appurtenances where:

6.2.3.1 Repair, alteration, or removal is necessary to for the protection of human health or safety; or

6.2.3.2 Alteration, repair, or removal is required to comply with the provisions of these Regulations, unless compliance is impracticable, and noncompliance poses no unacceptable threat to human health or safety, as determined by the Department.

6.2.4 Except as otherwise provided in these Regulations, any action or determination by the Department under these Regulations shall be subject to appeal to the Environmental Appeals Board in accordance with the provisions of 7 **Del.C.** § 6008.

6.2.5 Appeals of decisions by the Environmental Appeals Board shall be conducted pursuant to 7 **Del.C.** § 6009.

6.3 Pre-Application Stage for the Construction of New Dams or for the Repair, Alteration, or Removal of Existing Dams

6.3.1 The applicant must submit a written Preliminary Report that must include the following:

6.3.1.1 A general description of the dam and all appurtenances thereto, and the proposed dam classification, pursuant to the requirements of these Regulations. The description shall include the following:

6.3.1.1.1 A statement of the purpose for which the dam and appurtenances are to be used; and

6.3.1.1.2 A description of the potential effects of project construction and operation upon the environment.

6.3.1.2 Maps of the area within one-half mile of the dam and impoundment boundary, showing the following:

6.3.1.2.1 The location of the proposed dam and all appurtenances

6.3.1.2.2 The location of all structures

6.3.1.2.3 The county and nearest town

6.3.1.2.4 The boundary of the reservoir

6.3.1.2.5 The location of all streets and roads

6.3.1.2.6 The location of all major utilities, including pipe lines and transmission, telegraph, and telephone lines; all minor utilities shall be identified in the immediate vicinity of the dam impoundment area

6.3.1.2.7 The topography and scale

6.3.1.2.8 All other structures or facilities affected by the proposed dam, including the area downstream from the dam (state, county, and U.S. Geological Survey maps and aerial photographs may be used for this purpose)

6.3.1.2.9 Photographs of the site

6.3.1.3 A written report of the surficial conditions (geology, topography, land-use, existing structures and facilities, etc.), based upon a field reconnaissance by the applicant's engineer

6.3.1.4 Typical cross-sections of the dam and any dike(s) and levee(s), showing proposed elevations, pool levels, and top and bottom widths

6.3.1.5 Preliminary design data, tentative conclusions, and references. The design data shall address hydrologic features such as drainage area and rainfall data, the basis for proposed dam location, the basis for the type of structure and spillway proposed, the soils and geologic engineering criteria, and the basis for design and construction

6.3.1.6 The hydrologic design procedure and the storm durations that are used in the design

6.3.1.7 All documentation and information related to determining hazard classification

6.3.1.8 Other information required by the Department

6.3.2 At this time, the applicant shall also submit an application for a Subaqueous Lands Permit and any other State and Federal permits required.

6.3.3 The Department will review the pre-application, and within 30 days of its receipt, the Department will notify the applicant of what design criteria will apply. The Department may identify key issues for the applicant to address or may request additional information from the applicant.

6.3.4 Applicants for a permit to conduct minor repairs to an existing dam are not required to submit a preliminary report unless the Department determines it to be necessary.

6.4 Application Stage for the Construction of New Dams or for the Repair, Alteration, or Removal of Existing Dams

6.4.1 The application shall be on forms specified and supplied by the Department and must be accompanied by two copies of the final design report and five sets of all plans, drawings, designs, and specifications. Upon the written request of the applicant, the Department may waive certain requirements for documentation in the application stage set forth below for a permit to repair, alter, or remove an existing dam.

6.4.2 The application shall include a Final Design Report, which must contain the following:

6.4.2.1 A report of the field and laboratory investigation(s) of the foundation soils and/or bedrock**[, beneath the dam; and the soil, concrete and rock that will comprise the project structures;]** and a location map to identify borings and the materials that will comprise the dam and any dikes or levees. Stability, settlement, and seepage analyses are required, unless the applicant can demonstrate to the satisfaction of the Department that these analyses are not necessary.

6.4.2.2 The bases, references, calculations, and conclusions relative to hydrologic studies and design of spillway.

6.4.2.3 Structural and hydraulic design studies and calculations. Structural, hydraulic and hydrologic design procedures should be used, as established by one of the following: the U.S. Army Corps of Engineers, the **[~~U.S.~~]** Bureau of Reclamation, the **[~~U.S.~~]** Natural Resource **[~~and~~]** Conservation Service, the Federal Energy Regulatory Commission, and other procedures **[~~universally~~ broadly]** accepted as **[representing]** sound engineering practice

6.4.3 The application must include all drawings necessary to fully describe the proposal. Drawings must be prepared in accordance with the following:

6.4.3.1 All drawings must be prepared under the supervision of a Delaware-licensed professional engineer.

6.4.3.2 Drawings must clearly show the datum to which elevations shown are referred. The North American Vertical Datum of 1988 (NAVD 88) should be used wherever possible. If the N.G.V.D. datum is not used, an appropriate conversion equation must be indicated on the drawings. The Delaware State Plane Coordinate System, North American Datum of 1983 (NAD 83) shall be used as the horizontal datum reference.

6.4.3.3 The applicant must submit drawings showing the following information:

6.4.3.3.1 Existing conditions of the site including topography, property lines, easements, vegetation, existing structures and roads, etc.

6.4.3.3.2 A general plan of the dam, drawn to an appropriate scale, which must show proposed topography, the accurate position of all essential details, such as the spillway and its point of discharge into the stream; pipes through the dam, inlets, outlets, screen chambers, gate or valve houses, head-races, the canal mill or power plant, tailraces and downstream bridges that might cause backwater on the dam

6.4.3.3.3 A longitudinal section of the dam and cross-section of the valley at the site of the dam, showing the elevation of the crest of the dam; the elevation of the normal and design storm flow line of the lake or reservoir; the original surface of the ground; **[a general characterization of]** the nature and depth of the underlying strata; the probable depth of the excavation for the foundation of the dam and for the cutoff; foundation treatment; elevation of the restored surface of the ground; the location and elevation of all pipes or conduits passing through the dam; the core wall, if any; and the spillway structure

6.4.3.3.4 Typical cross sections, including a maximum section of the dam and of a spillway section that shall meet the following requirements;

6.4.3.3.4.1 Cross sections must show the original surface of the ground, **[a general characterization of]** subsurface conditions as disclosed by test pits or borings, the probable depth of excavations for the foundation and for cutoff or other seepage barriers, the elevations of the top of the dam, the crest of the spillway, and the normal flow line or water surface in the reservoir.

6.4.3.3.4.2 For earth dams, the following information shall be shown: the depth of stripping; the position, material, and dimensions of the cutoff or other seepage barriers; the width of the crest; the slopes and the nature and dimensions of the slope protection; the position and dimensions of the outlet pipes or conduits, and the seepage controls to control seepage along such structures; the disposition of different classes of embankment material if of varying composition; internal drains and filters; clay blankets; and other seepage barriers.

6.4.3.3.4.3 For concrete or other composite dams, the cross sections shall show all **[key structure]** dimensions and shall indicate the position and kinds of material to be included in the structure

6.4.3.3.5 If not clearly indicated on one or more of the drawings listed above, the following details shall be shown on additional detail sheets:

6.4.3.3.5.1 Detail of spillway or overflow, showing the length and depth of opening, together with the width and shape of the crest, grade, and shape of the approach and discharge channels, if any; methods of protecting the toe of the dam or end of the discharge channel from erosion; the dimensions of all walls, floors, and paving

6.4.3.3.5.2 Details of the intake and outlet works, showing the location and dimensions of all valves or sluice gates, intakes, screen chambers, racks, outlet towers, and gate houses and appurtenances

6.4.3.3.5.3 For **[~~reinforced~~]** concrete dams **[and reinforced concrete structures]**, detailed drawings must also be submitted, showing the size, spacing, and arrangement of all reinforcing steel **[~~and expansion~~]** joints**[, joint in-filling and other protective treatments.]**

6.4.3.3.5.4 Special drawings shall be submitted showing any special construction features not otherwise shown, such as pilings, fishways, aprons, materials used in the core wall, movable dams, tainter gates and mechanical devices, drains, and instrumentation

6.4.3.3.6 Sediment and erosion control practices

6.4.4 The application must include specifications, containing the following:

6.4.4.1 General provisions, specifying the rights, duties, and responsibilities of the owner, applicant, applicant's engineer, and the builder

6.4.4.2 The estimated project schedule and sequence of work

6.4.4.3 Technical provisions, describing carefully and in detail the approved work methods and procedures, standards for equipment and testing, materials to be used, and the results to be obtained

6.4.5 The applicant shall complete all investigations, including the following, prior to submission of the final design report that shall meet the following requirements:

6.4.5.1 The scope and the degree of precision of investigations required for a specific project shall be based on the complexities of the site, the importance of the proposed structure, and the hazard created by the proposed structure

6.4.5.2 The foundation investigation shall consist of borings, test pits, geophysical investigations, or other subsurface explorations and must be performed so as to **[~~accurately~~ reasonably]** define the soil and rock stratigraphy and the ground water conditions to the satisfaction of the Department

6.4.5.3 Laboratory testing of undisturbed and remolded soil**[, ~~specimens~~ concrete]** and**[/or]** rock samples may be required by the Department

6.4.5.4 The applicant must determine the nature and extent of materials that are proposed for use in the structure (e.g., **[earth and rock]** borrow material, concrete **[~~aggregate~~ constituents (cement, fly ash, coarse and fine aggregates, admixtures)]**, riprap stone, filter materials) and their structural properties when incorporated into the proposed structure

6.4.5.5 Stability analysis and calculations for the proposed structure to ensure safety against failure due to overturning, sliding, or overstressing must be submitted and approved by the Department

6.4.5.6 Topographic surveys must be performed with sufficient accuracy to locate the proposed construction and to define the volume of the storage in the reservoir and the flowage limits. The upstream and downstream areas must be investigated in order to delineate the area of potential damage in case of failure or flooding. Locations of baselines, centerlines, and other horizontal and vertical control points must be shown on the topographic map of the site

6.4.5.7 The drainage area must be accurately **[~~determined~~ delineated]**. Both present and projected future land use **[(based on available information))]** must be considered in determining the runoff characteristics of the drainage area. The most severe of these two conditions must be used in the design. The hydrologic assumptions and design calculations used in spillway designs shall be specified and shall include:

6.4.5.7.1 Drainage area size

6.4.5.7.2 Rainfall and runoff data

6.4.5.7.3 Reservoir inflow hydrographs

6.4.5.7.4 Reservoir area-capacity-elevation data

6.4.5.7.5 Spillway elevation-discharge data

6.4.5.7.6 Reservoir flood routings, except as otherwise provided in this subchapter

6.4.6 All applicants must submit an O&M Plan in accordance with these Regulations, and applicants for Class I and II dams shall prepare and submit an EAP that shall include at a minimum a dam breach analysis, inundation maps, and emergency notification and evacuation plans.

6.4.7 A permit for a dam does not imply approval of other permits. It is the responsibility of the applicant to obtain all other necessary local, State, and Federal permits.

6.4.8 The application to remove or breach a dam shall include the following:

6.4.8.1 Design report, and plans and computations to effect the breach, including size of breach, shape of breach, and disposal of spoil material

6.4.8.2 Plans and computations for stabilization of the lake bed, including the channel upstream of the breach, and for the control of sediment within the lake and downstream of the breach during and after the breach has been effected

6.4.8.3 Computations for design of the method and timing for dewatering the lake, unless waived by the Department

6.4.8.4 Computations detailing the effects of the breach on the downstream channel and demonstrating that the project will not adversely affect flooding conditions downstream during the 10-, 50-, and 100-year storms.

6.4.8.5 Specifications containing the technical provision that describe in detail the proposed work methods and equipment and, in addition, a work schedule for the entire project

6.4.8.6 A plan of the existing dam and lake along with surrounding property lines

6.4.8.7 A description of the potential effects of the dam removal or breach upon the environment

6.4.8.8 A description of the potential effects of the dam removal or breach upon life and property downstream of the dam

6.5 Actions by the Department Upon Applications

6.5.1 Public notice of application shall consist of an advertisement in a newspaper of general circulation in the county in which the activity is proposed and in a daily newspaper of general circulation throughout the state to include the fact that the application has been received, a brief description of the nature of the application, and the location(s) where a copy of the application may be inspected.

6.5.2 Following the receipt of requested comments, the Department shall approve, disapprove, or approve subject to conditions necessary to ensure safety, all applications pursuant to these Regulations.

6.5.3 A defective application shall not be rejected but notice of the defects shall be sent to the owner. If the owner fails to file a corrected application within 30 days of the date of the notice, the original application shall be canceled unless further time is allowed.

6.5.4 If the Department disapproves an application, one copy shall be returned with a statement of its objections. If an application is approved, the approval shall be attached thereto along with a Permit to Construct a New Dam or a Permit to Alter, Repair, or Remove an Existing Dam, as applicable, and a copy returned to the applicant. Approval shall be granted under terms, conditions, and limitations that the Department deems necessary to safeguard life and property.

6.5.5 Construction shall be commenced within 2 years after the date of approval of the application and completed within 5 years of commencement of construction, or the approval is void. The Department upon written application and demonstrated good cause may extend the time for commencing construction or for completing the construction. Notice by registered or certified mail shall be given the Department at least 10 days before construction is commenced.

7.0 Fees

7.1 General Provisions. The fees provided for in this subsection shall be required of all owners of dams that are regulated by these Regulations.

7.2 Application Fees for Existing Dams. Owners of existing dams shall submit a $500 application fee upon issuance of a Provisional Certificate to Impound by the Department.

7.3 Fees for the Construction of New Dams or for the Repair, Alteration, or Removal of Existing Dams

7.3.1 An applicant for the construction of a new dam or for the repair, alteration, or removal of an existing dam shall submit to the Department a fee of $500 at the time the Application is submitted.

7.3.2 The Department will not act on an application until the fee is submitted.

8.0 Requirements for Engineering and Design

8.1 Geotechnical Investigation

8.1.1 A geotechnical investigation shall be conducted to characterize the soil**[, concrete]** and rock conditions at the dam and spillway site and borrow areas (if appropriate) sufficient for design purposes. The investigations may consist of **[~~either~~]** intrusive **[and/]**or non-intrusive techniques that are deemed acceptable to the Department.

8.1.2 The means and methods for conducting the investigation of existing dams shall be selected so as not to jeopardize the integrity of the dam or ancillary facilities.

8.2 Spillway Requirements

8.2.1 The minimum Spillway Design Flood (SDF) used to calculate required spillway capacity shall be determined as follows:

8.2.1.1 Hazard Class I - The SDF shall be the PMF

8.2.1.2 Hazard Class II - the SDF shall be 50% of the PMF

8.2.1.3 Hazard Class III - the SDF shall be the 24-hour, 100-year frequency, Type II storm. Any later technology adopted by the U.S. Department of Agriculture, Natural Resources Conservation Service, may be substituted for the use of the Type II storm with the approval of the Department.

8.2.2 For existing dams, it is recognized that the relationships between valley slope and width, **[**~~T~~t**]**otal reservoir storage, drainage area, and other hydrologic factors have a critical bearing on determining the safe SDF. When appropriate, and upon the approval of the Department, an incremental flooding assessment may be used for the rational selection of a reduced spillway design for specific site conditions based on quantitative and relative impact analysis. The spillway should be sized so that the increased downstream damage resulting from overtopping failure of the dam would not be significant as compared with the damage caused by the flood in the absence of a dam overtopping failure. The minimum design storm for the dam shall be the 100-year storm.

8.2.3 All Class II and III dams shall, where practicable, incorporate in the proposed design the ability to make modifications necessary to increase the spillway capacity of the facility or other alternative measures if the downstream hazard potential increases.

8.2.4 All dams shall have an adequate storage for the SDF or have a spillway system that will safely pass the SDF without endangering the safety of the dam.

8.2.5 Each spillway shall include a satisfactory means of dissipating the energy of flow at its outlet without endangering the safety of the dam.

8.2.6 The capacity of the spillway system shall be equal to the peak inflow of the design flood unless the applicant demonstrates by flood routing procedures that the spillway system has the capacity to safely pass the resulting water flow.

8.2.7 Pipe conduits may be used for the primary (principal) spillway. When so used, the following requirements shall be met:

8.2.7.1 Pipe conduits shall be of such design as to safely support without leakage the total external loads in addition to the total internal hydraulic pressure. The type of construction material used shall be consistent with the anticipated life of the structure. Corrugated metal pipe shall not be used in the construction of new dams

8.2.7.1.1 For Class I and II dams, the minimum allowable inside dimension of the pipe conduit is 30 inches to allow for inspection.

8.2.7.1.2 For Class III dams, the minimum allowable inside diameter of the pipe conduit is 18 inches.

8.2.7.2 All pipe conduits shall convey water at the maximum design velocity without damage to the interior surface.

8.2.7.3 The pipe conduit must be designed so that negative pressures will not occur at any point along the primary (principal) spillway system.

8.2.7.4 Filter diaphragms or other seepage control methods approved by the Department must be installed to control seepage along the conduit.

8.2.7.5 Adequate allowances shall be incorporated in the design to compensate for differential settlement and possible elongation of the pipe conduit.

8.2.7.6 An anti-vortex device must be included in the design, unless the applicant can demonstrate that one is not necessary.

8.2.7.7 A **[self-cleaning]** trash rack, approved by the Department, shall be installed at the intake to prevent clogging of the pipe conduit.

8.2.7.8 An emergency spillway shall be provided.

8.2.7.9 Corrosion protection shall be provided for all steel pipes as necessary.

[8.2.7.10 Concrete cradles or encasements shall be provided for conduits through earth dams.]

8.2.7.**[~~10~~11]** All structural concrete and steel structures shall be designed to resist the anticipated design loads using current design methodologies acceptable to the Department.

8.2.8 Should a vegetated or unlined auxiliary spillway, approved by the Department, be installed, it must be able to pass the SDF without jeopardizing the safety of the structure and with a computed average frequency of use less than:

8.2.8.1 Once in 100 years for Class I dams,

8.2.8.2 Once in 50 years for Class II dams, or

8.2.8.3 Once in 25 years for Class III.

8.3 Outlet Works and Drawdown Requirements

8.3.1 Except for excavated impoundments, dams shall include a device to allow draining of the reservoir within a reasonable amount of time. The following factors shall be considered in determining the reasonable time period for drainage:

8.3.1.1 The risk and nature of a potential dam failure

8.3.1.2 The time likely to be available to avert a failure after notice of conditions threatening the safety or stability of the dam

8.3.1.3 The influence of rapid drawdown on the stability of the dam, its appurtenant works, and the natural upstream slopes of the reservoir

8.3.2 Unless the applicant demonstrates to the satisfaction of the Department that there is a need to locate a valve downstream from the dam and that the areas downstream of the dam will remain protected, all valves or sluice gates in pipe conduit drains must be installed upstream of the dam.

8.3.3 All pipe conduits used as drawdown drains for all dam classifications shall meet the requirements of Section 8.2.7, except that the minimum allowable inside dimension may be less than 30 inches.

8.4 Dam Requirements

8.4.1 The dam design shall designate what materials are suitable for the foundation of the dam, estimate the amount of foundation settlement, and describe the necessary foundation treatment for the structure.

8.4.2 The dam design shall designate what materials are to be used to construct the dam structure and provide the necessary design criteria for those materials. For embankment dams this includes, but is not limited to gradation, plasticity, strength, permeability, compaction and moisture criteria, lift thickness, and other properties that may be required by the Department. The source of the materials for embankment dams shall be designated. For concrete dams, the information provided shall include, but not be limited to the type of concrete, type of cement, aggregates, mix design, unconfined compressive strength, slump, and placement and curing procedures.

8.4.3 The applicant must demonstrate that the dam structure is stable under its various loading conditions, which must include at a minimum: during and after construction case, steady state case, maximum pool case, rapid drawdown case, and appropriate earthquake loading case. The engineering analysis and design shall follow current accepted engineering practices such as those of the U.S Army Corps of Engineers, the Natural Resources Conservation Service, the U.S. Bureau of Reclamation, the Federal Energy Regulatory Agency or other recognized standards and methodologies acceptable to the Department.

8.4.4 A seepage analysis shall be conducted to estimate the quantity of seepage that is anticipated to flow through, beneath, and/or around the dam. Unless it can be demonstrated that they are unnecessary, the design should include seepage reduction and/or control features to limit and/or collect and control seepage. Example techniques to reduce seepage include cut-off trenches, low-permeability cores, slurry trenches, or other proven methodologies acceptable to the Department. Example techniques for controlling and collecting seepage generally include drains, filters, and relief wells or other methodologies acceptable to the Department.

8.4.5 The design shall allow for certain freeboard as a minimum, not to be reduced under any circumstances during the operation of the dam and reservoir. The design freeboard is for that reservoir stage that will exist when the pool has reached maximum level during the spillway design flood with the outlet works and overflow spillway operating as planned. The freeboard is to be calculated to prevent overtopping and protect the dam against the destructive forces of waves, frost, settlement, and surface erosion.

8.4.6 The design shall provide for upstream slope protection against the action of waves and ice.

8.5 Other Requirements

8.5.1 Design references used shall be cited in the information submitted to the Department.

8.5.2 The Department may include, either at the time of granting a Permit to Construct a New Dam, or a Permit to Alter or Repair an Existing Dam or at a later date, a requirement that the owner provide and install devices necessary for the future inspection and surveillance of the dam. The number, type, and location of the devices shall be determined as a result of the Department's evaluation of the site and nature of the dam, the complexity of local natural conditions, and the degree of risk resulting from any future deterioration or failure. The requirement may include provisions for the measurement of the settlement of the crest or slopes of dams, the movement of walls in the valley or reservoir, the increases in pore water pressure in earth or increases in flow from drainage systems, and the installation of other devices required to detect serious changes in the structure or the affected area to allow the repair of deficiencies before more serious risk develops.

8.5.3 The applicant shall demonstrate to the Department that the riparian rights of downstream property owners will be protected during construction, during the period when the reservoir is being filled and during the life of the dam and reservoir.

8.5.4 The Department may require the design and installation of any additional or modified measures by any applicant for a dam permit where appropriate to ensure the protection of human health or safety.

8.5.5 In the case of multiple dams, when they are spaced so that the failure of an upstream dam or structure could endanger the safety of one downstream, the possibility of a multiple failure shall be considered in reviewing the design. **[~~Additional safety shall be provided in either structure by increasing the retarding storage or increasing the emergency spillway capacity, or both.~~]**

8.5.6 Utilities crossing within dam embankments are prohibited unless demonstrated to the satisfaction of the Department that such utilities will not jeopardize the safety of the dam.

9.0 Requirements for Construction

9.1 General Requirements

9.1.1 Construction shall be conducted under the **[~~oversight~~ observation]** of the Supervising Engineer as defined in these Regulations. The Supervising Engineer shall submit progress reports to the Department at least once each month during the construction period.

9.1.2 All applicants shall submit a written description of the work to be performed and schedule of the proposed construction, including:

9.1.2.1 The name and qualifications of the construction firm to perform the work, including the qualifications of their project manager and site superintendent

9.1.2.2 The estimated time to complete the construction activities

9.1.2.3 Where applicable, a description of the means by which stream flow will be diverted around or through the dam site, or otherwise kept from interfering with the work

9.1.2.4 The name of the Supervising Engineer and a description of the construction quality control and testing program including the number, names, and qualifications of on-site representatives working under the direction of the supervising engineer

9.1.2.5 Steps to be taken to minimize erosion and sediment production during construction

9.1.3 The Supervising Engineer shall submit the Construction Quality Control Plan as described below. The plan must be approved by the Department, prior to construction.

9.1.4 **[~~The diversion facility, as outlined above, must remain open and n~~N]**o water may be permanently stored in the reservoir until the applicant demonstrates to the Department that storage of water will neither interfere with construction activities nor create a hazard to life, health, or property.

9.1.5 The applicant shall promptly advise the Department of all proposed changes in the approved design, plans, or specifications. There may be no change in the approved design, plans, or specifications without prior approval of the Department. All approved changes must be recorded on the complete set of as-built plans, as required below. The Department may require the submission of revised designs at any time. Written prior approval from the Department is required for major modifications, which shall include significant changes in scale, use, design, impact, etc., of the project as initially approved. The Department may require written prior approval of any proposed modification.

9.1.6 Within 7 days of completion of construction, the Owner or Supervising Engineer shall notify the Department that construction has been completed.

9.1.7 Within 60 days of completion of construction, the Supervising Engineer shall submit the written Supervising Engineer's Certificate with accompanying project documentation as required in Section 9.3.3.

9.1.8 The Department may, in its discretion, require the owner to obtain the services of an independent review board to oversee the design and construction of any proposed or existing dam.

9.2 Construction Quality Control Plan Requirements. The Construction Quality Control Plan shall be prepared by the supervising engineer and submitted to the Department. The plan shall include the following:

9.2.1 A description of the work that is to be inspected

9.2.2 A description of the tasks to be used to adequately inspect the work to **[~~confirm~~ verify]** that it **[~~is being~~ has been]** conducted **[~~according to~~ in general accordance with]** the approved design, and the frequency or duration of site visits and inspections (such as full-time**[, ~~or half-time~~ during pre-defined critical activities, etc.]**)

9.2.3 A description of the field and laboratory testing, including the types and frequency of tests, the requirements for acceptable tests, and the procedures for **[~~dealing with~~ addressing]** test**[~~s~~ results]** that are out of compliance

9.2.4 The name(s) and qualifications of the site quality control representative(s) who will work under the direction of the Supervising Engineer

9.3 Documentation and Reporting Requirements

9.3.1 The Supervising Engineer shall submit periodic construction progress reports to the Department. Progress report forms and the frequency of reporting will be provided by the Department before construction.

9.3.2 A history of the construction shall be maintained at the construction site by the Supervising Engineer and shall include:

9.3.2.1 Date, location, and results of all materials tests made

9.3.2.2 Narrative of problems encountered during construction and changes in design. Necessity for these changes shall be reported to the **[~~Administration~~ Department]** for approval before proceeding with construction

9.3.2.3 “As built" plans

9.3.3 As required in Section 9.1.7, before filling the reservoir, the Supervising Engineer shall submit to the Department, the above information along with the Supervising Engineer’s Certificate stating that to the best of his/her knowledge, the completed structure has been constructed in **[general]** accordance with plans and specifications and changes approved by the Department. The Supervising Engineer’s Certificate shall state that the structure has been made ready for filling and that the pool area has been cleared of debris. The report shall describe the limitations on the amount of water restrained from flowing downstream and describe the methods to be followed for the surveillance of the project during the period when the structure is receiving its initial loading.

9.4 Department Inspections

9.4.1 The Department may inspect the dam during construction to ensure that it is being built in compliance with the designs, plans, and specifications submitted to the Department. Departmental inspections in no way relieve either the permittee or the Supervising Engineer from the responsibility of providing adequate inspection of the work.

9.4.2 If, at any time during the progress of the work, the Department finds that the work is not being performed in accordance with the approved designs, plans, and specifications and any approved changes, the Department will serve a written notice to that effect on the permittee or his

representative. Such notice will state the particulars with which the work has not complied. Additionally, the Department may order the immediate compliance with such designs, plans, specifications, and changes and order the suspension of all other work until compliance has been effected. If the owner or his representative fails to comply with this order, the permit under which construction is authorized may be revoked or suspended by the Department.

9.4.3 Within 60 days of receipt of the Supervising Engineer's Certificate and as-built plans (as required in Section 9.3.3), the Department will visit the site and issue its final approval with a Permit to Impound if it finds that the construction has been completed in **[general]** accordance with the approved designs, plans, specifications, and approved changes.

10.0Requirements for Operation, Maintenance and Inspections

10.1 General Requirements

10.1.1 The owners and operators of all dams regulated under these Regulations shall operate and maintain the dams according to the requirements of these Regulations.

10.1.2 Specific requirements include the following:

10.1.2.1 Develop and follow an O&M Plan, which provides guidance and instruction to project personnel for the proper operation, maintenance, surveillance, and inspection of the dam and reservoir.

10.1.2.2 Conduct routine surveillance and formal and informal inspections in accordance with the requirements of these Regulations and the O&M Plan.

10.1.2.3 Trees and other woody vegetation shall be prevented from growing on the dam unless waived by the Department.

10.1.2.4 Conduct in a timely manner and document any routine maintenance and any repair work performed at the dam and reservoir citing the date and work performed.

10.1.2.5 Prepare an EAP that complements the O&M Plan and provides detailed guidance on surveillance, including what constitutes an emergency situation and the actions to be followed in the event of an emergency.

10.1.2.6 Review and update **[if necessry]** the O&M Plan on a yearly basis and provide the updated plan to the Department by July 1 of each year.

10.2 Operation and Maintenance (O&M) Plan

10.2.1 The O&M Plan shall describe the steps to be followed by the owner to provide for the continued operation and maintenance of the dam and reservoir during the expected life of the structure. It shall consist of four parts as described in the following sections.

10.2.2 Part One of the O&M Plan shall include an introduction, project description, project authorizations, project history, and list of project **[~~contracts~~ contacts]**.

10.2.3 Part Two of the O&M Plan shall describe the steps to be followed by the owner to provide for the safe operation of the dam and reservoir and the continued minimum releases, withdrawals, etc.

10.2.4 Part Three of the O&M Plan shall describe what work is to be done at periodic intervals (or when necessary) to keep the structure in **[~~good~~ proper operating]** condition. This work could include

mowing or cutting bushy growth on embankments, preventing erosion or gullying of embankment surfaces, clearing toe drains, preventing trash and debris accumulation, protecting against **[or treating]** rust and spalling, and **[lubricating and]** exercising valves or other mechanical equipment. The description of this program shall be submitted to the Department for approval and inclusion among the required conditions of the construction period.

10.2.5 Part Four of the O&M Plan shall describe the requirements for surveillance and inspection of the dam and reservoir and shall reference the EAP in the event that severe deficiencies or signs of a potential emergency condition are encountered.

10.3 Surveillance and Inspections

10.3.1 The owner is responsible for the safety of the dam and for the necessary surveillance and inspections. The surveillance shall be performed by the owner, or a representative of the owner, and shall **[~~provide a close watch~~ focus]** on **[~~the~~]** conditions **[~~affecting~~ important to]** the dam's safety. The owner shall conduct Informal Inspections on at least a quarterly basis and promptly notify the Department of significant changes in condition. The Department has the right to require more frequent Informal Inspections by the owner, if deemed necessary.

10.3.2 The owners or operators of all Class I dams shall have a Regular Inspection performed annually **[~~under the supervision of~~ by]** a Delaware-licensed professional engineer. These inspections must be attended by a professional engineer assigned from the Department. Depending on the degree of hazard and/or condition of the dam, the Department may require the owner of a Class I dam to provide more frequent surveillance, which could be in the form of visual inspections and/or monitoring of instrumentation. The Department may also require the owner to have a Formal Inspection conducted by a Delaware-licensed professional engineer, if deemed necessary to confirm the safety of a given dam.

10.3.3 Owners or operators of Class II dams shall have a Regular Inspection performed at least once every 2 years under the supervision of a Delaware-licensed professional engineer. The Department may also require the owner to have a Formal Inspection conducted by a Delaware-licensed professional engineer, if deemed necessary to confirm the safety of a given dam.

10.3.4 All dam inspections shall be performed from March through December and in compliance with the following requirements:

10.3.4.1 A written guide provided by the Department for the preparation of a Report on Condition of the dam shall be used for all inspections.

10.3.4.2 Regular dam inspections shall be performed **[~~under the supervision of~~ by]** a Delaware-licensed professional engineer **[with experience in dam design and construction]**. The required report shall be submitted to the Department by the engineer within **[~~30~~ 90]** days of completion of the inspection. The report shall indicate the results of the inspection, documenting the condition of the dam and appurtenant facilities, and problems or deficiencies noted as well as the engineer’s conclusions and recommendations.

10.3.4.3 The Department may also require more frequent inspections during the first filling and initial stages of operation of a new dam.

10.3.4.4 Informal or routine inspections may be performed by the dam owner or operator and the Report on Condition shall be part of the owner's or operator's permanent file and, unless requested by the Department, reports shall not be submitted to the Department.

10.3.4.5 Formal Inspections shall be followed up with a report by the Delaware-licensed professional engineer with his/her opinion as to the conformance of the dam to currently accepted design standards and its overall safety with recommendations, as appropriate. The required report shall be submitted to the Department by the engineer within **[~~30~~ 90]** days of completion of the inspection.

10.3.4.6 The Department may extend the time for submission of the required material for up to 30 days, if the owner or operator justifies the need for such extension.

10.3.4.7 Failure by the permittee to inspect within the required time periods or failure to submit the Report on Condition may result in an order to drain the impoundment and/or any other remedy allowed by law.

10.3.4.8 For good cause, the Department may require the owner or operator of any dam to perform an inspection of any type at any time.

10.3.4.9 The owner or operator of all Class I and II dams shall prepare and use an EAP, as described in these Regulations.

10.4 Emergency Action Plan (EAP) and Procedures

10.4.1 The EAP for Class I and II dams shall describe the steps to be followed in the event of a potential emergency condition. This includes requirements for surveillance; definitions of a potential emergency situation; a warning plan for notifying persons whose lives, property, or health may be endangered by failure, improper operation, or other circumstances affecting the safety of the dam; and an action plan for steps to be followed at the dam to mitigate the potential emergency. The warning plan shall identify the most practical and expeditious means for notifying potentially affected persons in close proximity to the dam or property owners.

10.4.2 The EAP shall include:

10.4.2.1 Identification of designated dam inspectors, and designated alternates, to observe the dam during storms anticipated to exceed the 10-year-frequency storm event.

10.4.2.2 A requirement that the dam inspectors measure and record the pool level and observe the dam during storm events and passage of flood peaks.

10.4.2.3 Requirements for observations, including at a minimum the pool level, rate of pool level rise, debris accumulation in the spillway, excessive seepage, and signs of embankment distress.

10.4.2.4 Identification of predetermined pool elevations or signs of distress in the dam to trigger notification and evacuation phases of the plan.

10.4.2.5 Actions to be taken by the dam inspector under specific conditions, including notification of the local emergency management agency.

10.4.2.6 A description of primary and backup capabilities for communications with the local emergency management agency.

10.4.2.7 A notification flow chart showing the agencies and personnel, with telephone numbers, to be contacted to provide a warning or to initiate an evacuation, and the order in which they will be notified.

10.4.2.8 A description of the role of each agency involved in the evacuation.

10.4.2.9 Inundation maps developed from the appropriate dam break modeling discussed in Section 5.0 of these Regulations and danger reach identifying areas and structures to be evacuated, evacuation routes, and roads to be closed.

10.4.2.10 A list of the addresses of structures to be evacuated.

10.4.2.11 Identification of the appropriate local authority to issue evacuation notices and to determine when evacuees may return.

10.4.2.12 Intervention procedures to be taken by the dam owner to alleviate the hazardous condition.

10.4.2.13 Lists of local contractors and material suppliers to be used in the event of an emergency.

10.4.3 A dam owner shall submit the EAP for review and approval by the Department, the state and local emergency management agency, and other local agencies that have a role in the plan.

10.4.4 A dam owner shall review the EAP annually to verify pertinent data, including personnel, telephone numbers, and identification of structures that may have been built within the danger reach. By July 1 of each year, the owner shall submit to the Department modifications and updated information necessary to maintain the EAP, including an annual exercise of the action plan. If no changes have occurred during that year to warrant an updated EAP, the owner shall issue a written statement to the Department to that effect.

10.5 Repairs and Routine Maintenance

10.5.1 Repairs or alterations to existing dams shall be undertaken in accordance with Sections 4.0 and 6.0 of these Regulations.

10.5.2 The owner is not required to contact the Department prior to performing routine maintenance activities, as defined in these Regulations.

11.0 Enforcement Procedures

11.1 Administrative and Legal Actions

11.1.1 The Department may take any administrative or legal action necessary for the enforcement of these Regulations.

11.1.2 An action or proceeding under this subsection may be initiated whenever any owner or any person acting as an agent of any owner:

11.1.2.1 Fails to comply with the requirements imposed by these Regulations or by any application approval, Permit to Construct, Permit to Impound, order, rule, regulation, or requirement of the Department under the authority of these Regulations, or

11.1.2.2 Commits or allows the commission of violations of these Regulations or any application approval, Permit to Construct, Permit to Impound, order, rule, regulation, or requirement of the Department under these Regulations.

11.1.3 Violators of these Regulations shall be fined as follows:

11.1.3.1 Any person who violates any rule, regulation, order, or condition imposed in an approved document or other provision of these Regulations shall be fined not less than $200 or more than $2,000 for each offense. Each day that the violation continues shall constitute a separate offense. The Justice of the Peace Courts shall have jurisdiction of offenses brought under this subsection.

11.1.3.2 Any person who, after written notice to comply, intentionally or knowingly violates any rule, regulation, order, or condition imposed in an approved document or other provision of these Regulations shall be fined not less than $500 or more than $10,000 for each offense. Each day the violation continues shall constitute a separate offense. The Superior Court shall have jurisdiction over offenses brought under this subsection.

11.2 Investigations by the Department

11.2.1 The Department shall make investigations and assemble such data as it deems necessary for a proper review and study of the design and construction of any dams, reservoirs, and appurtenances to which these Regulations applies, and for such purposes the Department or its agents may enter upon private property.

11.2.2 The Department may employ or make such agreements with geologists, engineers, or other expert consultants and such assistants as it deems necessary to carry out the provisions of these Regulations.

11.3 Rights of Investigation, Entry, Access, Inspection, and Protective Action

11.3.1 The Department shall have the right to direct the conduct of such investigations as it may reasonably deem necessary to carry out its duties prescribed in these Regulations, and the Department shall have the right to conduct such investigations. For the purpose of inspections, the employees of the Department and agents of the Department have the right to enter at reasonable times on any property, public or private, for the purpose of investigating the condition, construction, or operation of any dam or associated equipment facility or property, and to require written statements or the filing of reports under oath, with respect to pertinent questions relating to the construction or operation of any dam.

11.3.2 No person shall refuse entry or access to any authorized representative of the Department who requests entry for purposes of inspection and who presents appropriate credentials; nor shall any person obstruct, hamper, or interfere with any representative while in the process of carrying out official duties.

11.3.3 Notwithstanding any other provisions of these Regulations, the Department, upon receipt of information that any dam may present an imminent and substantial hazard to the public health, safety, or welfare, may take such actions as it determines to be necessary to protect the public health, safety, or welfare. The Department may direct the owner or custodian of the dam to take such actions as are necessary to prevent, eliminate, or reduce the hazard. In the event the owner or custodian fails to take such actions, the Department shall have the right to take all appropriate or necessary action including, but not limited to, breaching or draining. The Department may initiate legal proceedings to recover the emergency costs from the dam owner.

11.4 Other Requirements. When the safety and technical considerations pertaining to an application approval, to a Permit to Impound, to a dam, to a reservoir, or to plans and specifications require it, or when requested in writing to do so by the owner, the Department may appoint an Independent Review Board of consultants to report to the Department on the safety features involved. The cost and expense of a consulting board, if appointed on the request of an owner, shall be paid by the owner.

12.0 Owner Financial Responsibility

The Department requires that the applicant post a construction bond, irrevocable letter of credit, or other security acceptable to the Department to ensure that funds are available to complete the construction of the proposed project and for continued maintenance of the project throughout the life of the structure.

12 DE Reg. 1288 (04/01/09) (Prop.)

E.9. Georgia

391-3-8-.09 Standards for the Design and Evaluation of Dams. Amended.(

(1)The design and/or evaluation of new and existing dams shall conform to accepted practices of the engineering profession and dam safety industry. Design manuals, evaluation guidelines, and procedures used by the following agencies can be considered as acceptable design or evaluation references, except as those references differ from Georgia Law and these regulations:
(a)U.S. Army Corps of Engineers;
(b)Natural Resources Conservation Service;
(c)U.S. Department of Interior, Bureau of Reclamation;
(d)Federal Energy Regulatory Commission;
(2)Other design and evaluation methods may be used to demonstrate compliance with the objectives of these rules, but are subject to the approval of the Director.
(3)Design and Evaluation of Dams under Paragraph (1) and (2) above shall, as a minimum, consider the following basic principles:
(a)All dams must be stable under all conditions of construction and/or operation of the impoundment. Details of stability evaluation shall be submitted to the Director for approval. Analyses using the methods, guidelines and procedures of the agencies listed in Paragraph (1) yielding the following Minimum Safety Factors can be considered as acceptable stability:
Earthen Embankments
1. End of Construction1.3
2. Steady State Seepage1.5
3. Steady State Seepage with Seismic Loading1.1
4. Rapid Drawdown (Upstream)1.3
5. Submerged Toe with Rapid Drawdown1.3
Concrete Structures (cohesion included)
1. Normal Reservoir 3.0
2. Normal Reservoir with Seismic Loading1.0
3. Design Flood2.0
(b)Details of the engineering evaluation of material properties in the dam or appurtenant structures shall be submitted to the Director for review and approval. Conservative selections for soil strength values shall be used for analyses or evaluations. Details of any foundation investigation and laboratory testing supporting assumed design or evaluation parameters shall be included for review.
(c)All dams and appurtenant structures shall be capable of withstanding seismic accelerations defined in the most current "Map for Peak Acceleration with a 2% exceedance in 50 years" for the contiguous United States published by the United States Geological Survey (a.k.a. NEHRP maps). The minimum seismic acceleration shall be 0.05g . The seismic accelerations may be reduced or seismic evaluation eliminated if the applicant's engineer can successfully demonstrate to the Director by engineering analyses or judgment that smaller seismic accelerations are appropriate or no seismic evaluation is needed.
(d)All dams shall have a means of draining the reservoir to a safe level as demonstrated by the applicant's engineer. The submittal by the applicant's engineer shall include the computation of the maximum time required to drain the reservoir. Exceptions to this rule

may be given by the Director based on an engineering evaluation demonstrating the lack of this capability would not endanger the public.
(e)All earthen embankments shall be protected from surface erosion by appropriate vegetation, or some other type of protective surface such as riprap or paving, and shall be maintained in a safe condition. Examples of appropriate vegetation include, but are not limited to, Bermuda, Tall Fescue, Centipede grasses and Lespedeza sericea. Inappropriate vegetation on existing dams such as trees shall be removed only after consultation with the Division or other qualified persons on the proper procedures for removal. Hedges and small shrubs may be allowed on existing dams if they do not obscure inspection or interfere with the operation and maintenance of the dam.
(f)Design Storm. Each dam shall be capable of safely passing the fraction of the flood developed from the PMP hydrograph depending on the subclassification of the dam. The design storm for each subclassification of a dam is as follows:
1. Small Dam25 percent PMP
2. Medium Dam33.3 percent PMP
3. Large Dam50 percent PMP
4. Very Large Dam100 percent PMP
Based on visual inspection and detailed hydrologic and hydraulic evaluation, including documentation of completed design and construction procedures, up to 10 percent lower requirement (22.5, 30, 45, 90) may be accepted on existing PL566 (including RC&D structures) and PL 534 Project Dams at the discretion of the Director, provided the project is in an acceptable state of maintenance. The design storm may be reduced on existing dams if the applicant's engineer can successfully demonstrate to the Director, by engineering analysis, that the dam is sufficient to protect against probable loss of human life downstream at a lesser design storm. Earth emergency spillways shall not function until the 50 year storm.
(g)Seepage Control. All dams shall be able to prevent the development of instability due to excessive seepage forces, uplift forces, or loss of materials in the embankment, abutments, spillway areas, or foundation. For new dams, seepage analysis for design, and inspection during construction shall be in sufficient detail to prevent the occurrence of critical seepage gradients.
(i)For new dams, the design shall include a seepage control method which meets the minimum acceptable safety standards, as determined by the Division. All internal drainage systems with pipe collection systems shall have cleanouts.
(ii)In existing dams, seepage shall be investigated by an engineer and appropriate control measures shall be taken as necessary.
(h)Monitoring Devices.
(i)Monitoring devices, including but not limited to piezometers, settlement plates, tell-tale stakes, seepage outlets and weirs, and permanent bench marks may be required by the Director for use in the inspection and monitoring of the safety of a dam during operation.
(ii)For new dams or existing dams where appropriate, a reservoir filling monitoring and surveillance plan to be implemented during reservoir filling or re-filling shall be submitted to the Director for approval prior to start of filling or re-filling.

(i).Design Life. The design life for proposed dams and reservoirs shall be adequate for the dams and reservoirs to perform effectively as planned, as determined by the following criteria:
(i)The time required to fill the reservoir with sediment from the contributing watershed; and
(ii)The durability of appurtenances and materials used to construct the dams.
(j)Freeboard. Appropriate freeboard for wave action shall be considered by an engineer through engineering analysis. The required freeboard shall be provided above the maximum reservoir surface elevation that would result from the inflow from the design storm for the structure. The resulting maximum reservoir surface elevation plus freeboard shall determine the elevation of the top of the dam. In lieu of determining the appropriate amount of freeboard by engineering analysis, a minimum of three (3) feet of freeboard shall be provided on earth dams.
(k)Existing concrete and/or masonry dams and appurtenant structures shall be structurally sound and shall have joints free of trees and other vegetation and shall show no signs of significant structural deterioration such as excessive cracks, spalling, efflorescence and exposed reinforcing steel.
(4). Other design standards may be imposed as deemed appropriate by the Director after review of design of new structures or through a visual inspection of an existing structure conducted pursuant to Rule 391-3-8-.08 (2)(b) of these regulations, or based on a review of the detailed engineering study prepared by an engineer.
Authority O.C.G.A. Secs. 12-5-370. **Administrative History.** Original Rule entitled "Permits for the Construction and Operation of New Dams" was filed as Emergency Rule 391-3-8-0.5-.09 on August 28, 1978, effective July 28, 1978, the date of adoption, to remain in effect for a period of 120 days or until the effective date of a permanent Rule covering the same subject matter superseding said Emergency Rule, as specified by the Agency. **Amended:** Permanent Rule of the same title adopted superseding Emergency Rule 391-3-8-0.5-.09. Filed August 31, 1978; effective September 20, 1978. **Amended:** Rule renumbered as Rule 391-3-8-.10 and Rule 391-3-8-.08 entitled "Design Standards for Existing Dams" amended and renumbered as Rule 391-3-8-.09. Filed October 29, 1985; effective November 18, 1985. **Amended:** F. Aug. 31, 1990; eff. Sept. 20, 1990. **Amended:** F. Oct. 5, 1998; eff. Oct. 25, 1998.

FEMA Workshop on Hydrologic Research Needs for Dam Safety Analysis

Hydrologic Practices in the State of Georgia and other states east of the Mississippi River

By
Francis E. Fiegle II, P. E.[1]

State of Georgia

The Georgia Safe Dams Act regulates high hazard dams that are either 25 feet tall or store more than 100 acre-feet of water at maximum pool. These regulated dams are evaluated to determine if they have adequate spillway capacity and wave action freeboard at maximum design pool to pass the design storm as defined by the Georgia Safe Dams Act (Act) and Rules for Dam Safety (Rules). The spillway capacity is prescribed in the Act based on the height of the dam and/or its maximum storage capacity.

1) Small dams - Those dams with a storage capacity not exceeding 500 acre-feet and a height not exceeding 25 feet - 25 percent PMP spillway design capacity.

2) Medium dams - Those dams with a storage capacity exceeding 500 acre-feet but not exceeding 1000 acre-feet or a height exceeding 25 feet but not exceeding 35 feet - 33 percent PMP spillway design capacity.

3) Large dams - Those dams with a storage capacity exceeding 1000 acre-feet but not exceeding 50,000 acre-feet or a height exceeding 35 feet but not exceeding 100 feet - 50 percent PMP spillway design capacity.

4) Very large dams - Those dams with a storage capacity exceeding 50,000 acre-feet or a height exceeding 100 feet - 100 percent PMP spillway design capacity.

Typically, the Georgia Safe Dams Program develops Visual Inspection Reports which are a streamed lined version of the old USACOE Phase I reports that were done in the late 1970's and early 1980's for state dam safety programs across the United States. In that report, our Program evaluates the spillway capacity of existing dams with respect to compliance with the Act and Rules. Except in rare instances, the hydrology evaluation uses the NRCS/SCS Curve Number, Lag Time methodology. Of note, because the spillway capacity requirements are set forth in the Act, and the design storm is restricted to the 6-hour PMP, the Program requires the use of Antecedent Moisture Condition III for the evaluation of spillway capacity. This dramatically affects the Curve Numbers used. We use HMR 51/52 to develop the design storm. The spillway rating curves are done using standard hydraulic practice accounting for weir, orifice, and full pipe flow for principal spillway pipes/open channel flow in earth emergency spillways, etc. This

[1] Program Manager - Georgia Safe Dams Program

information is imputed into the HECI model with a Type II distribution to evaluate the hydraulic adequacy of the dam.

On very large drainage basins, a unit hydrograph is developed based on existing stream data on the particular stream or one in the area with similar watershed characteristics.

For more detailed information, please see the attached section on Hydrology and Hydraulics, pages 28 to 33 of the Georgia Safe Dams Program's Engineering Guidelines. The Guidelines were developed in conjunction with consulting engineers who are involved with the design of dams in Georgia.

Other states east of the Mississippi River

Because there is a need for the state dam safety regulators to provide significant input on practices, research needs and development needs in the field of hydrology and hydraulics modeling, I polled 26 states east of the Mississippi River including: Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, Connecticut, New York, Pennsylvania, Ohio, Michigan, Indiana, Illinois, Wisconsin, Kentucky, West Virginia, Tennessee, Virginia, North Carolina, South Carolina, Florida, Maryland, New Jersey, Mississippi, Louisiana, Arkansas, and Puerto Rico. Delaware and Alabama were not polled because they had no dam safety laws or programs. I received 19 state responses.

The following questions were asked in the survey and where appropriate, the number of responses are tallied. In some cases, a state regulatory agency may use/accept more than one methodology.

1. **What Hydrologic Model(s) are used/accepted by your state? Do you accept more than one methodology?**

    a. NRCS/SCS Curve Number/Lag Equations - 16
    b. HECI - 17
    c. HECHMS - 10
    d. USGS/State Regression Equations - 9
    e. Unit Hydrographs - 6
    f. Synder Unit Hydrograph - 5
    g. SITES - 6
    h. TR20- 5
    i. TR55 - 3
    j. HydroCAD 5.11 - 3
    k. Others - 1

2. **What are the difficulties/problems you encounter with these models**?

a. HEC1
    - DOS based program - glitches sometimes when loaded on a Windows Operating System.
    - PM card record is outdated for PMF determination in conjunction with the use of HMR51/52.
    - Time distribution of rainfall losses.
    - Unit hydrograph for eastern shore needs to be modified.
b. Lack of site specific data (mentioned 5 times.)
c. HECHMS
    - Does not have the ability to run multiple storm events
    - Bizarre results sometimes.
d. Engineers who do not know how to use the model appropriately. Identified as an issue by six states.
e. Hydro CAD 5.11/SCS unit hydrograph is limited a 24 hour duration storm, surcharge flows are not allowed.

Of note, two states reported no difficulties.

3. **Are extended flow periods (days) vs. single events an issue? Is it dependant on the size of the drainage basin or the location of the dam?**

Yes - One
No - Ten
Maybe - (extremely large drainage basin) - Seven

4. **Please rank the following issues in priority:**

a. low cost/rapid assessment of inflow flood (47 points)
b. extensive detailed investigative assessment of the inflow flood (54 points)
c. risk assessment vs. PMF (34 points)
d. determinate inflow design flood (55 points)
e. all equally important (20 points)

*To evaluate the responses, I assigned a point value of 5 to 1 for the priority ranking with 5 being the highest priority and 1 being the lowest priority.

5. **Any suggestions for short and long terms hydrologic needs and development?**

Short term hydrologic needs

A. HECHMS needs the following:

- level pool routing/results & summaries

- overtopping subroutine
- breaching subroutine
- multiplan feature
- printout of inputs
- other routing subroutines (Muskingum-Cunge)
- link HECRAS to HECHMS
- add Arcview
- develop multiple stage outlet modeling

B. Comparison of USGS Regression inflow curves vs. other methodology. Publish results for different parts of the country.

C. Cooperation between NWS and HEC and other Federal agencies.

Long-term hydrology needs

A. Update NRCS/SCS Curve Number methodology.
B. What is the appropriate time period of the design storm event? PMP is variable across the country and changes within a region.
C. Define what ancedent moisture condition is appropriate for what type of design storm.
D. Couple NEXRAD or IFLOWS for river basins for real time hydrologic forecasting (Virginia).
E. Further development of the Green-Ampt loss rate function nationwide.
F. Additional continuous stream gaging streams.

Conclusions and Recommendations:

The majority of the dams in the United States are regulated by the states. Hydrologic research should focus on creating models for design storms that will produce reasonably accurate results that do not involve extensive data gathering and interactive modeling. The results should be reproducible from universally accepted data sources.

I believe the short terms needs include the following:

- Complete HECHMS model development. Make it compatible with other software and link it to HECRAS, ARCVIEW, and NWS DAMBREAK.
- Improve cooperation between Federal Agencies to develop hydrologic data and software models that states can use.
- Do detailed comparison of various hydrologic methodologies that produce inflow floods including sensitivity evaluations. Make the comparison meaningful by region/sub region. Publish results.

Long term hydrologic needs include further development of certain hydrologic models/modeling methods.

- Update NRCS/SCS Curve Numbers and lag time routines.
- Better regionalization of PMP rainfall events.
- Define and update Antecedent Moisture Conditions.
- Further development of the Green-Ampt loss rate function nationwide. If this was as usable as the NRCS/SCS Curve Number/soils mapping methodology, modeling long terms storm event would be doable with reasonable results.

While I believe that accuracy in hydrologic modeling is important, so is a certain measure of conservatism to account for the undefined and unknown variables that exist in every drainage basin when dealing with public safety.

E.10. Hawaii

NOTICE TO PUBLIC

Addendum No. 1 to Proposed Hawaii Administrative Rules, Title 13, Subtitle 7, Chapter 190.1 as Required by the "Hawaii Dam and Reservoir Safety Act of 2007", Chapter 179D HRS - Dams and Reservoirs

The Department of Land and Natural Resources has posted the following Addendum No 1 to the Proposed Hawaii Administrative Rules, Title 13, Subtitle 7, Chapter 190.1 due to typographical errors in the dam size classification table of Section §13-190.1-4.1 "Additional design requirements". These corrections were made to this table under the impoundment size column, which is consistent with the similar table in the existing Dam Safety Inspection Guidelines.

Should there be any questions on this Addendum or any portion of the rules, please contact anyone of our dam safety staff:

Edwin Matsuda	Ph. (808) 587-0268
Denise Manuel	Ph. (808) 587-0246
Jimmy Leung	Ph. (808) 587-0238
John Dawley	Ph. (808) 587-0272

Internet posting: September 13, 2010

§13-190.1-4.1 Additional design requirements.

(a) Significant and high hazard dams shall also have a stability analysis of the structure demonstrating the stability of the embankment slopes for various loading conditions and minimum factors of safety generated by a methodology accepted by the department.

(b) Regulated dam spillways shall safely pass the appropriate inflow design flood:

Hazard Classification	**Size Classification**	**Inflow design flood**
Low	Small	100 year
	Intermediate	100 year
	Large	½ PMF
Significant	Small	½ PMF
	Intermediate	½ PMF
	Large	PMF
High	All Sizes	PMF

Category	**Impoundment**	
	Storage (Acre-feet)	**Height (feet)**
Small	<1000 and ≥50	<40 and ≥25
Intermediate	≥1,000 and <50,000	≥40 and <100
Large	≥50,000	≥100

Note: PMF or Probable Maximum Flood, is defined as the flood that may be expected from the most severe combination of critical meteorologic and hydrologic conditions that are reasonably possible in the region. The PMF is derived from the 24 hour probable maximum precipitation (PMP), which information is available from the National Weather Service, NOAA, Publication HMR-39, "Hydrometeorological Report No. 39 - Probable Maximum Precipitation in the Hawaiian Islands", or current standard. ½ PMF = PMF divided by two. 100 year is defined as the flood associated with the 1 percent probability storm event that is derived from

the 24 hour 100 year precipitation rate, which is identified in the US Weather Bureau Technical Paper No. 43 Rainfall-Frequency Atlas of the Hawaiian Islands and as updated by NOAA Atlas 14, Volume 4 Precipitation-Frequency Atlas of the United States, Hawaiian Islands, or current standard.

(c) Freeboard shall be the greater of the following:

(1) Two feet above the water level during the peak spillway flow associated with the inflow design flood;

(2) Sum of the wave run-up and reservoir setup resulting from a 100 mph wind speed during the peak spillway flow associated with the inflow design flood. (Eff.) (Auth: HRS §179D-6) (Imp: HRS §179D-8)

IDAPA 37
TITLE 03
CHAPTER 06

37.03.06 - SAFETY OF DAMS RULES

000. LEGAL AUTHORITY (RULE 0).
These rules are adopted pursuant to Chapter 17, Section 42-1714, Idaho Code, and implement the provisions of Sections 42-1709 through 42-1721, Idaho Code. (7-1-93)

001. TITLE AND SCOPE (RULE 1).

01. Title. (7-1-93)

02. Scope. (7-1-93)

a. The requirements that follow are intended as a guide to establish acceptable standards for construction and to provide guidelines for safety evaluation of new or existing dams. The rules apply to all new dams, to existing dams to be enlarged, altered or repaired, and maintenance of certain existing dams, as specifically provided in the rules. The Director will evaluate any deviation from the standards hereinafter stated as they pertain to the safety of any given dam. The standards are not intended to restrict the application of other sound engineering design principles. Engineers are encouraged to submit new ideas which will advance the state of the art and provide for the public safety. (7-1-93)

b. Under no circumstances shall these rules be construed to deprive or limit the Director of the Department of Water Resources of any exercise of powers, duties and jurisdiction conferred by law, nor to limit or restrict the amount or character of data, or information which may be required by the Director from any owner of a dam for the proper administration of the law. State sovereignty as expressed in Policy 1A of the adopted State Water Plan for independent review and approval of dam construction, operation and maintenance will not be waived due to any overlapping jurisdiction from federal agencies. (7-1-93)

002. WRITTEN INTERPRETATION (RULE 2).

003. ADMINISTRATIVE APPEALS (RULE 3).
Any owner who is aggrieved by a determination or order of the Director may request a hearing pursuant to the provisions of Section 42-1701A(3), Idaho Code, and the Department's adopted Rules of Procedure. (7-1-93)

004. -- 009. (RESERVED).

010. DEFINITIONS (RULE 10).
Unless the context otherwise requires, the following definitions govern these rules. (7-1-93)

01. Active Storage. The water volume in the reservoir stored for irrigation, water supply, power generation, flood control, or other purposes but does not include flood surcharge. Active storage is the total reservoir capacity in acre-feet, less the inactive and dead storage. (7-1-93)

02. Alterations, Repairs or Either of Them. Only such alterations or repairs as may directly affect the safety of the dam or reservoir, as determined by the Director. Alterations, repairs does not include routine maintenance items. (See Rule Subsections 055.02.a. and 055.02.b.) (7-1-93)

03. Appurtenant Structures. Ancillary features (e.g. outlets, tunnels, gates, valves, spillways, auxiliary barriers) used for operation of a dam, which are owned by the dam owner or the owner has responsible control. (7-1-93)

04. Board. The Idaho Water Resource Board. (7-1-93)

05. Certificate of Approval. A certificate issued by the Director for all dams listing restrictions imposed by the Director, and without which no new dams shall be allowed by the owner to impound water. A

certificate of approval is also required for existing dams before impoundment of water is authorized. (7-1-93)

06. Dam. Any artificial barrier together with appurtenant works, which is or will be ten (10) feet or more in height or has or will have an impounding capacity at maximum storage elevation of fifty (50) acre-feet or more. Height of a dam is defined as the vertical distance from the natural bed of the stream or watercourse at the downstream toe of the barrier, as determined by the Director, or from the lowest elevation of the outside limit of the barrier, if it is not across a stream channel or watercourse, to the maximum water storage elevation. (7-1-93)

07. Small Dams. Artificial barriers twenty (20) feet or less in height that are capable of storing less than one hundred (100) acre-feet of water. (7-1-93)

08. Intermediate Dams. Artificial barriers more than twenty (20) feet, but less than forty (40) feet in height, or are capable of storing one hundred (100) acre-feet or more, but less than four thousand (4,000) acre-feet of water. (7-1-93)

09. Large Dams. Artificial barriers forty (40) feet or more in height or are capable of storing four thousand (4,000) acre-feet or more of water. (7-1-93)

10. Department Jurisdiction. The following are not subject to department jurisdiction: (7-1-93)

a. Artificial barriers constructed in low risk areas as determined by the Director, which are six (6) feet or less in height, regardless of storage capacity. (7-1-93)

b. Artificial barriers constructed in low risk areas as determined by the Director, which impound ten (10) acre-feet or less at maximum water storage elevation, regardless of height. (7-1-93)

c. Artificial barriers in a canal used to raise or lower water therein or divert water therefrom. (7-1-93)

d. Fills or structures determined by the Director to be designed primarily for highway or railroad traffic. (7-1-93)

e. Fills, retaining dikes or structures, which are under jurisdiction of the Department of Environmental Quality, designed primarily for retention and treatment of municipal, livestock, or domestic wastes, or sediment and wastes from produce washing or food processing plants. (7-1-93)

f. Levees, that store water regardless of storage capacity. Levee means a retaining structure alongside a natural lake which has a length that is two hundred (200) times or more greater than its greatest height measured from the lowest elevation of the toe to the maximum crest elevation of the retaining structure. (7-1-93)

11. Days Used in Establishing Deadlines. Calendar days including Sundays and holidays. (7-1-93)

12. Dead Storage. The water volume in the bottom of the reservoir stored below the lowest outlet and generally is not withdrawn from storage. (7-1-93)

13. Department. The Idaho Department of Water Resources. (7-1-93)

14. Design Evaluation. The engineering analysis required to evaluate the performance of a dam relative to earthquakes, floods or other site specific conditions that are anticipated to affect the safety of a dam or operation of appurtenant facilities. (7-1-93)

15. Director. The Director of the Idaho Department of Water Resources. (7-1-93)

16. Engineer. A registered professional engineer, licensed as such by the state of Idaho. (7-1-93)

17. Enlargement. Any change in or addition to an existing dam or reservoir, which raises or may raise the water storage elevation of the water impounded by the dam. (7-1-93)

18. **Factor of Safety**. A ratio of available shear strength to shear stress, required for stability. (7-1-93)

19. **Flood Surcharge**. A variable volume of water temporarily detained in the upper part of a reservoir, in the space (or part thereof) that is filled by excess runoff or flood water, above the maximum storage elevation. Flood surcharge cannot be retained either because of physical or administrative factors but is passed through the reservoir and discharged by the spillway(s) until the reservoir level has been drawn down to the maximum storage elevation. (7-1-93)

20. **Inflow Design Flood (IDF)**. The flood specified for designing the dam and appurtenant facilities. (7-1-93)

21. **Maximum Credible Earthquake**. The largest earthquake that reasonably appears capable of occurring under the conditions of the presently known geological environment. (7-1-93)

22. **Operation Plan**. A specific plan that will assure the project is safely managed for its intended purpose and which provides reservoir operating rule curves or specific limits and procedures for controlling inflow, storage, and/or release of water, diverted into, passed through or impounded by a dam. (7-1-93)

23. **Owner**. Includes any of the following who own, control, operate, maintain, manage, hold the right to store and use water from the reservoir or propose to construct a dam or reservoir. (7-1-93)

a. The state of Idaho and any of its departments, agencies, institutions and political subdivisions; (7-1-93)

b. The United States of America and any of its departments, bureaus, agencies and institutions; provided that the United States of America shall not be required to pay any of the fees required by Section 42-1713, Idaho Code, and shall submit plans, drawings and specifications as required by Section 42-1712, Idaho Code, for information purposes only; (7-1-93)

c. Every municipal or quasi-municipal corporation. (7-1-93)

d. Every public utility; (7-1-93)

e. Every person, firm, association, organization, partnership, business trust, corporation or company; (7-1-93)

f. The duly authorized agents, lessees, or trustees of any of the foregoing; (7-1-93)

g. Receivers or trustees appointed by any court for any of the foregoing. (7-1-93)

24. **Reservoir**. Any basin which contains or will contain the water impounded by a dam. (7-1-93)

25. **Storage Capacity**. The total storage in acre-feet at the maximum storage elevation. (7-1-93)

26. **Water Storage Elevation**. The maximum elevation of the water surface which can be obtained by the dam or reservoir. It is further defined as the storage level attained when the reservoir is filled to capacity (i.e. to the spillway crest) or an authorized storage level attained by installing flashboards to increase the reservoir capacity, or a specified upper storage limit, which is attained by operation of moveable gates that raises the reservoir to a controlled operating level. The maximum storage elevation is an equivalent term of water storage elevation. (7-1-93)

27. **Release Capability**. The ability of a dam to pass excess water through the spillway(s) and outlet works and otherwise discharge. (7-1-93)

011. -- 024. (RESERVED).

025. DAM SIZE CLASSIFICATION AND RISK CATEGORY (RULE 25).

01. Size Classification. The following table defines the height and storage capacity limits used by the Department to classify dams:

Size Classification	Height (ft)		Storage Capacity
Small	20 ft. or less	and	Less than 100 acre-ft.
Intermediate	More than 20 ft. but less than 40 ft.	or	100 Acre-ft or more, but less than 4000 acre ft
Large	40 ft. or more	or	4000 acre-ft., or more

(7-1-93)

02. Risk Category. The following table describes categories of risk used by the Department to classify losses and damages anticipated in down-stream areas, that could be attributable to failure of a dam during typical flow conditions.

Risk Category	Dwellings	Economic Losses
Low	No permanent structures for human habitation.	Minor damage to land, crops, agricultural, commercial or industrial facilities, transportation, utilities or other public facilities or values.
Significant	No concentrated urban development, 1 or more permanent structures for human habitation which are potentially inundated with flood water at a depth of 2 ft. or less or at a velocity of 2 ft. per second or less.	Significant damage to land, crops, agricultural, commercial or industrial facilities, loss of use and/or damage to transportation, utilities or other public facilities or values.
High	Urban development, or any permanent structure for human habitation which are potentially inundated with flood water at a depth of more than 2 ft. or at a velocity of more than 2 ft. per second.	Major damage to land, crops, agricultural, commercial or industrial facilities, loss of use and/or damage to transportation, utilities or other public facilities or values.

(7-1-93)

03. Determination of Size and Risk Category. The Director shall determine the size and risk category of a new or existing dam. (7-1-93)

026. -- 029. (RESERVED).

030. AUTHORITY OF REPRESENTATIVE (RULE 30).
When plans, drawings and specifications are filed by another person on behalf of an owner, written evidence of authority to represent the owner shall be filed with the plans, drawings and specifications. (7-1-93)

031. -- 034. (RESERVED).

035. FORMS (RULE 35).
Forms required by these rules are available from the Department to interested parties upon request. Construction of a small dam requires the filing of Form 1710 and construction of an intermediate or large dam requires the filing of Form 1712. (7-1-93)

036. -- 039. (RESERVED).

040. CONSTRUCTION PLANS, DRAWINGS AND SPECIFICATIONS (RULE 40).
The following provisions shall apply in submitting plans, drawings and specifications. (7-1-93)

01. Submission of Duplicate Plans, Drawings and Specifications. Any owner who shall desire to construct, enlarge, alter or repair any intermediate or large dam, shall submit duplicate plans, drawings and specifications prepared by an engineer for the proposed work to the Director with required fees. The Director may, however, require the submittal of plans, drawings and specifications prior to the construction of any dam. (7-1-93)

02. Applying for and Obtaining Written Approval. Construction of a new dam or enlargement, alteration or repairs on existing dams shall not be commenced until the owner has applied for and obtained written approval of the plans, drawings and specifications. Alteration or repairs do not include routine maintenance for which prior approval is not required. (See Rule Subsections 055.02.a and 055.02.b) (7-1-93)

03. Plans Shall Be Prepared on a Good Quality Vellum or Mylar. Transparent copies reproducible by standard duplicating processes, if accurate, legible and permanent, will be accepted. Plans may initially be submitted in the form of nonreproducible paper prints. After reviewing the plans, the Director will notify the owner of any required changes. (7-1-93)

04. Preparation and Submission of Plans. Plans and drawings shall be of a sufficient scale with an adequate number of views showing proper dimensions, so that the plans and drawings may be readily interpreted and so that the structure and appurtenances can be built in conformance with the plans and drawings. (7-1-93)

05. Information Included with Plans. Plans for new dams shall include the following information and plans for enlargement, alteration or repair of an existing dam shall include as much of the following information as required by the Director to adequately describe the enlargement, alteration or repair and the affect on the existing dam or its appurtenant facilities: (7-1-93)

a. A topographic map of the dam site showing the location of the proposed dam by section, township and range, and location of spillway, outlet works, and all borings, test pits, borrow pits; (7-1-93)

b. A profile along the dam axis showing the locations, elevations, and depths of borings or test pits, including logs of bore holes and/or test pits; (7-1-93)

c. A maximum cross-section of the dam showing elevation and width of crest, slopes of upstream and downstream faces, thickness of riprap, zoning of earth embankment, location of cutoff and bonding trenches, elevations, size and type of outlet conduit, valves, operating mechanism and dimensions of all other essential structural elements such as cutoff walls, filters, embankment zones, etc.; (7-1-93)

d. Detailed drawings showing plans, cross and longitudinal sections of the outlet conduits, valves and controls for operating the same, and trash racks; (7-1-93)

e. A curve or table showing the capacity of the reservoir in acre-feet vs gauge height (referenced to a common project datum) of the reservoir storage level, and the computations used in making such determinations. (7-1-93)

f. A curve or table showing the outlet discharge capacity in cubic feet per second vs gauge height of reservoir storage level, and the equation used in making such determination; (7-1-93)

g. A curve showing the spillway discharge capacity in cubic feet per second vs gauge height of the reservoir or flood surcharge level above the spillway crest and the equation used in making such determinations; (7-1-93)

h. Detailed drawings of spillway structure(s), cross-sections of the channel heading to and from the spillway and a spillway profile; (7-1-93)

i. Plans for flow measuring devices capable of providing an accurate determination of the flow of the stream above and below the reservoir, and a permanent reservoir or staff gauge near the outlet of the reservoir plainly

marked in feet and tenths of a foot referenced to a common project datum; (7-1-93)

j. Plans or drawings of instruments, recommended by the owner's engineer to monitor performance of intermediate or large dams to assure safe operation, or as may be required by the Director to monitor any dam regardless of size, that is situated upstream of a high risk area. (7-1-93)

06. Specifications. Specifications shall include provisions acceptable to the Director for adequate observation, inspection and control of the work by a registered professional engineer, during the period of construction. (7-1-93)

07. Changes to Specifications. The specifications shall not be materially changed without prior written consent of the Director. Significant design changes, while construction is underway, shall be submitted for the Director's review and approval. (7-1-93)

08. Inspections. The owner shall provide for and allow inspections by the Department to assure the dam and appurtenant structures are constructed in conformance with the approved plans and specifications, or as may be revised by the engineer and approved by the Director if there are unforeseen conditions discovered during site excavation or construction of the dam which potentially jeopardize the future integrity and safety of the dam. Certain stages of construction shall not proceed without inspection and approval by the Director, including the following: (7-1-93)

a. After clearing and excavation of the foundation area and cutoff trench and prior to placing any fill material. (7-1-93)

b. After installation of the outlet conduit and collars and before placing any backfill material around the conduit; (7-1-93)

c. After construction is completed and before any water is stored in the reservoir. (7-1-93)

d. At such other times as determined necessary by the Director. The Director will, upon seven (7) days notice, inspect and if satisfactory, approve the completed stage of construction. The Director may conduct inspections upon shorter notice upon good reason being shown or upon a schedule jointly agreed upon by the Director and the owner. (7-1-93)

09. Inspection, Examination and Testing of Materials. All materials and workmanship shall be subject to inspection, examination and testing by the Director at any and all times. (7-1-93)

10. Rejection of Defective Material. The Director shall have the right to require the owner or engineer to reject defective material and workmanship or require its removal or correction respectively. Rejected workmanship shall be corrected and rejected material shall be replaced with proper material. (7-1-93)

11. Suspension of Work. The Director may order the engineer to suspend any work that may be subject to damage by inclement weather conditions. (7-1-93)

12. Responsibility of Engineer. These provisions shall not relieve the engineer of his responsibility to assure that construction is accomplished in accordance with the approved plans and specifications or to suspend work on his own motion. (7-1-93)

13. Detailing Provisions of Specifications. The specifications shall state in sufficient detail, all provisions necessary to insure that construction is accomplished in an acceptable manner and provide needed control of construction to insure that a safe structure is constructed. (7-1-93)

14. Design Report. Owners proposing to construct, enlarge, alter or repair an intermediate or large dam shall submit an engineering or design evaluation report with the plans and specifications. The engineering report shall include as much of the following information as necessary to present the technical basis for the design and to describe the analyses used to evaluate performance of the structure and appurtenances. (7-1-93)

a. All technical reference(s); equations and assumptions used in the design; (7-1-93)

b. Hydrologic data used in determining runoff from the drainage areas; reservoir flood routing(s); and hydraulic evaluations of the outlet(s) and the spillway(s). (7-1-93)

c. Engineering properties of the foundation area and of each type of material to be used in the embankment. (7-1-93)

d. A stability analysis, including an evaluation of overturning, sliding, slope and foundation stability and a seepage analysis; (7-1-93)

i. Seismic design loads shall be evaluated and applied at all large dams to be located in significant or high risk areas, in Seismic Zone 3, which for purposes of these rules is the area in Idaho east of Range 22 East, Boise Meridian. The evaluation required of large dams, that are classified significant or high risk, shall use the maximum ground motion/ acceleration generated by the maximum credible earthquake, which could affect the dam site. (7-1-93)

ii. Seismic analysis may be required as determined by the Director for large dams located above high risk areas in Seismic Zone 2, which for purposes of these rules is the area in Idaho west of Range 22 East, Boise Meridian. (7-1-93)

15. Additional Information/Waiver. The Director may require the filing of such additional information which in his opinion is necessary or waive any requirement herein cited if in his opinion it is unnecessary. (7-1-93)

16. Alternate Plans. The Director may accept plans and specifications or portions thereof prepared for other agencies which are determined to meet the requirements of Rule 40. (7-1-93)

041. -- 044. (RESERVED).

045. OPERATION PLAN (RULE 45).
An operation plan is required as described in the following rules and shall provide procedures for emergency operations and include guidelines and procedures for inspection, operation and maintenance of the dam and appurtenances, including any instruments required to monitor performance of the dam during normal operating cycles, critical filling or flood periods, or as may be required to monitor new or existing dams subject to earthquake effects. (7-1-93)

01. New, Reconstructed or Enlarged Dams. Prior to the initial filling of the reservoir or refilling the reservoir for a reconstructed or enlarged dam in the following categories, the owner shall file with the Director an operation plan for review and approval: (7-1-93)

a. Small, high risk. (7-1-93)

b. Intermediate, significant risk. (7-1-93)

c. Intermediate, high risk. (7-1-93)

d. Large, any risk category. (7-1-93)

02. Existing Dams. Unless exempted by the Director, owners of the following categories of dams shall file an operation plan with the Director on or before July 1, 1992 for review and approval: (7-1-93)

a. Intermediate, high risk. (7-1-93)

b. Large, significant risk. (7-1-93)

c. Large, high risk. (7-1-93)

03. Alternate Plans. The Director may accept existing studies or plans in lieu of an operation plan if the Director determines the information provided fulfills the requirements of Rule 45. (7-1-93)

046. -- 049. (RESERVED).

050. NEW INTERMEDIATE OR LARGE DAMS (RULE 50).
The following minimum criteria shall be used to evaluate the design of intermediate or large earthfill dams in Idaho. These standards are intended to serve as guidelines for a broad range of circumstances, and engineers should not consider them as a restriction to the use of other sound engineering design principles. Exclusion from this established criteria will be considered by the Director on a case-by-case basis in approving plans and specifications and evaluating dams. Dams constructed of other materials shall comply with these criteria as found appropriate by the Director and with other engineering criteria approved by the Director. (7-1-93)

01. Embankment Stability. Slope stability analyses shall determine the appropriate upstream and downstream slopes. Unless slope stability analysis determines otherwise, the embankment slopes shall be:

Upstream slope	3:1 or flatter
Downstream slope	2:1 or flatter

(7-1-93)

a. For large high and significant hazard dams and intermediate high hazard dams the embankment shall be designed, constructed and maintained to assure stability under static loads and prevent instability due to seepage or uplift forces, or drawdown conditions. Transmission of seepage through the embankment, abutments and foundation shall be controlled to prevent internal removal of material and instability where seepage erodes or emerges. (7-1-93)

b. The design analysis shall consider the need for installing filters, filter fabric and/or toe drains to stabilize the fill and protect against piping of the embankment fill material. (7-1-93)

c. The minimum factor of safety for a dam under steady state condition shall be 1.5. During rapid drawdown of the reservoir, the minimum factor of safety for the embankment shall be 1.2. For dams constructed in Seismic Zone 3, the minimum factor of safety under seismic load shall be 1.0. (7-1-93)

d. The stability of an embankment subjected to earthquake ground motions can be analyzed by dynamic response or pseudo-static analyses. Pseudo-static analyses are acceptable for embankment dams constructed of soils that will not build-up excess pore pressures due to shaking, nor sustain more than fifteen percent (15%) strength loss during earthquake events, otherwise the stability of an embankment dam shall be analyzed by a dynamic response method. A pseudo-static analysis simplifies the structural analysis (i.e. the resultant force of the seismic occurrence is represented by a static horizontal force applied to the critical section to derive the factor of safety against sliding along an assumed shear surface). The value of the horizontal force used in the pseudo-static analysis, is the product of the seismic coefficient and the weight of the assumed sliding mass. (7-1-93)

e. Slope deformation analyses are required for dams located in Seismic Zone 3, that are constructed of cohesionless soils and/or on foundations which are subject to liquefaction, when the peak acceleration at the site is anticipated to exceed 0.15g. (7-1-93)

f. The design analyses for new dams located in high risk areas (in Seismic Zone 2 or 3) shall include geologic and seismic reports, location of faults and history of seismicity. (7-1-93)

g. Where in the opinion of the Director, embankment design or conditions warrant, instrumentation of the embankment and/or foundation will be required. (7-1-93)

h. The design analyses for new large dams located in high risk areas (in Seismic Zone 3) shall include an evaluation of potential landslides in the vicinity of the dam or immediate area of the reservoir, which could cause

damage to the dam or appurtenant structures, obstruct the spillway or suddenly displace water in the reservoir causing the dam to overtop. If potential landslides pose such a threat, they shall be stabilized against sliding, with a minimum factor of safety of 1.5. (7-1-93)

02. Top Width. The crest width shall be sufficient to provide a safe percolation gradient through the embankment at the level of the maximum storage elevation. The minimum crest width (top of embankment) shall be determined by:

W = H / 5 + 10 W = Width, in feet
H = Structural Height, in feet

The minimum top width for any dam is twelve (12) feet. (7-1-93)

03. Cutoff Trenches or Walls. Cutoff trenches shall be excavated through relatively pervious foundation material to an impervious stratum or zone. The trench shall be backfilled with suitable material, compacted to the specified density. The cutoff trench shall extend up the abutments to the maximum storage elevation. (7-1-93)

a. Cutoff trenches shall be wide enough to allow the free movement of excavation and compaction equipment. Side slopes shall be no steeper than one to one (1:1) for depths up to twelve (12) feet, and no steeper than one and one half to one (1 1/2:1) for greater depths to provide for proper compaction. Flatter slopes may be required for safety and stability. (7-1-93)

b. Concrete cutoff walls may be used to bond fills to smooth rock surfaces in a similar manner as cutoff trenches and shall be entrenched in the rock to a depth approximately one-half the thickness of the cutoff wall. Concrete cutoff walls shall be doweled into the rock a minimum of eight (8) inches with a maximum spacing of eighteen (18) inches for three-fourths (3/4) inch steel dowels. Concrete walls shall have a minimum projection of three (3) feet perpendicular to the rock surface and shall have a minimum thickness of twelve (12) inches. (7-1-93)

04. Impervious Core Material. The approved earth materials (silt soils are seldom acceptable) shall be zoned as shown in the plans and placed in the embankment in continuous, approximately level layers, having a thickness of not more than six (6) inches before compaction. Compaction shall be based on ASTM D-698. A minimum compaction of ninety-five percent (95%) is required. (7-1-93)

a. An acceptable working range of moisture content for the core material shall be established and maintained. (7-1-93)

b. The material shall be compacted by means of a loaded sheepsfoot or pneumatic roller to the required density. (7-1-93)

c. No rock shall be left in the core material which has a maximum dimension of more than four (4) inches. The core material shall be free of organic and extraneous material. (7-1-93)

d. The core material shall be carried up simultaneously the full width and length of the dam, and the top of the core material shall be kept substantially level at all times, or slope slightly toward the reservoir. (7-1-93)

e. No frozen or cloddy material shall be used, and no material shall be placed upon frozen, muddy or unscarified surfaces. (7-1-93)

f. All materials used in the dam shall meet the stability and seepage requirements as shown by a design analysis of the structure and shall be properly installed to meet these requirements. (7-1-93)

05. Drains. Toe or chimney drains or free draining downstream material shall be installed where necessary to maintain the phreatic line within the downstream toe. (7-1-93)

a. Filter design for chimney drains, filter blankets and toe drains in clay and silt soils shall be selected using the following design criteria, unless deviations are substantiated by laboratory tests. All tests are subject to

review and approval by the Director.

D15 filter/D15 base > 5 but < 20

D15 filter/D85 base < 5

D50 filter/D50 base < 25

D85 filter > 2 times diameter of pipe perforations, or 1.2 times width of pipe slots. (7-1-93)

b. Filter material requirements are determined by comparing the particle size distribution of the filter to the particle size distribution of the materials to be protected;

e.g. D50 filter
D50 material to be protected

Where D is the particle size passing a mechanical (sieve) analysis expressed as a percentage by weight. (7-1-93)

c. The base material should be analyzed considering the portion of the material passing the No. 4 sieve, for designing filters for base materials that contain gravel size particles. To assure internal stability and prevent segregation of the filter material, the coefficient of uniformity (D60/D10) shall not be greater than 20. (7-1-93)

d. The minimum thickness of filter blankets and chimney drains shall be twelve (12) inches, with the maximum size particle passing the one (1) inch sieve. The maximum particle size may be increased with increasing thickness of the filter, by the rate of one (1) inch per foot of filter. However, the maximum particle shall not exceed three (3) inches. Zoned filters and chimney drains must not be less than twelve (12) inches thick per each zone. The width of granular filters shall not be less than the width of the installation equipment unless the plans and specifications include construction procedures adequate to insure the integrity of a narrower width. (7-1-93)

e. Perforated drain pipes must have a minimum of six (6) inches of drain material around the pipe. The maximum particle size shall not exceed one-half (1/2) inch unless the layer thickness is increased at the rate of one (1) inch per foot of filter. Underdrains and collection pipes must be constructed of noncorrosive material. (7-1-93)

06. Freeboard. The elevation of the top of the embankment shall be constructed and maintained above the flood surcharge level to prevent the dam from overtopping during passage of the inflow design flood and to provide freeboard for wind generated waves. Camber shall be included in the design and incorporated in the construction of the top of the embankment, unless waived by the Director. Camber may be estimated by multiplying the structural height of the dam by five percent (5%). (7-1-93)

a. The height of wind generated waves (H) moving across a surcharged reservoir can be estimated by the following equation:

H = 1.95 (F1/2) where F = fetch, the distance in miles across the reservoir, measured perpendicular to the major axis of the dam. (7-1-93)

b. For large, high risk dams the minimum freeboard shall be two (2) feet plus wave height during passage of the one percent (1%) flood or equal to the surcharge elevation of the reservoir during passage of the inflow design flood whichever is greater. (7-1-93)

c. Estimation of the height of the wind generated wave using the empirical equation in Rule 050.06.a. shall not preclude a more conservative design including consideration of fill materials, embankment zoning, slope surface protection, drainage or other safety factors. (7-1-93)

07. Riprap. All dams which are subject to erosion shall be protected from wave action. The design engineer, with approval of the Director, shall determine whether or not rock riprap or other protection is necessary. (7-1-93)

a. Where rock riprap is used, it shall be placed on a granular bedding material, and extend up the slope, from three (3) feet below the normal minimum operating level to the top of the dam. (7-1-93)

b. Where riprap is required by Rule Subsection 055.07, pipes, cables, brush, tree growth, dead growth, logs, or floating debris are not acceptable substitutes for rock riprap and granular bedding material. (7-1-93)

08. Outlet Conduits. All reservoirs shall be provided with an outlet conduit of sufficient capacity to prevent interference with natural streamflow through the reservoir to the injury of downstream appropriators unless waived by the Director. In addition to any natural flow releases, the outlet conduit should be of sufficient capacity to pass at the same time, the maximum water requirement of the owner. A larger outlet conduit may be required to provide adequate release capability as determined by the Director. (7-1-93)

a. Outlet conduits shall be laid on a firm, stable foundation and normally not be placed on fills which can consolidate, allow differential settlement, and cause separation or misalignment of the pipe. Unless otherwise required, the outlet shall have a minimum inside diameter of twelve (12) inches. The conduits shall be of reinforced concrete or of metal pipe encased in concrete, poured with a continuous seal between the concrete and the trench except as otherwise approved by the Director. Void spaces and uncompacted areas shall not be covered over when the outlet trench is backfilled. Outlets shall be properly aligned on an established grade and may be supported on a concrete cradle, or otherwise supported and kept aligned when the outlet is covered. (7-1-93)

b. Asphalt dipped or other metal pipe is not acceptable unless it is encased in concrete. Exceptions may be made only where conditions warrant, but in no case shall the reasonable life expectancy of the pipe be less than the design life of the dam. (7-1-93)

c. All outlet conduits shall have a seepage path through the impervious zone at least equivalent in length to the maximum head above the downstream end of the system. Only one-third (1/3) the horizontal distance through the impervious zone will be utilized when calculating the length of the seepage path. Collars may be used to satisfy this requirement but all collars shall extend a minimum of two (2) feet outside the conduit for dams up to thirty (30) feet in height and a minimum of three (3) feet for dams above that height. Collars shall be spaced at intervals of at least seven (7) times their height and no collar may be closer to the outer surface of the impervious zone than the distance it extends out from the conduit. (7-1-93)

d. The use of multiple conduits is allowed only upon the written approval of the Director. (7-1-93)

09. Gates. All conduits shall be gated on the upstream end, unless otherwise approved by the Director, with either a vertical or an inclined gate. All conduits shall be vented directly behind the gate unless otherwise determined by the Director. Reservoirs storing water during the winter and subject to severe ice conditions shall have inclined gate controls enclosed in a protective sleeve which is buried. All gate stem pedestals shall be made of concrete. All trash racks shall slope toward the reservoir. At least one (1) of the sides of the inlet structure shall be open to allow water to flow into the outlet conduit and shall be covered with a trash rack. Trash racks should be designed with bars primarily in one (1) direction so they can be cleaned. If fish screens are used, they shall be placed over the trash rack and shall be removable for cleaning, or of the self-cleaning type. (7-1-93)

10. Outlet Controls. Outlet controls shall be installed at a stable location, on the crest or on an elevated platform, or within an enclosure when required, which is readily accessible, but secured to prevent unauthorized operation. (7-1-93)

11. Release Capability. Based on the size of the dam and on the risk category assigned by the Director, the release capability of a dam shall equal or exceed the inflow design flood in the following table:

Downstream Risk Category	Size Classification	Inflow Design Flood
Low	Small	Q50
	Intermediate	Q100

Downstream Risk Category	Size Classification	Inflow Design Flood
	Large	Q500
Significant	Small	Q100
	Intermediate	Q500
	Large	0.5 PMF
High	Small	Q100
	Intermediate	0.5 PMF
	Large	PMF

NOTE: The inflow design flood(s) indicated in the table include specific frequency floods (2%/50yr, 1%/100 yr.) expressed in terms of exceedance with a probability the flood will be equaled or exceeded in any given year (a fifty (50) year flood has a two percent (2%) chance of occurring in any given year and a one hundred (100) year flood has a one percent (1%) chance of occurring in any given year); or PMF - probable maximum flood, which may be expected from the most severe combination of meteorologic and hydrologic conditions that are reasonably possible in the region. The PMF is derived from the probable maximum precipitation (PMP) which is the greatest theoretical depth of precipitation for a given duration that is physically possible over a particular drainage area at a certain time of year. (7-1-93)

a. All spillways shall be stabilized for the discharge of flow by the use of concrete, masonry, riprap or sod, if not constructed in resistant rock. (7-1-93)

b. Where site conditions allow, the spillway shall be constructed independent of embankment dams. The spillway(s) shall guide the discharge of water away from the dam embankment so as not to erode or endanger the structure. (7-1-93)

c. The minimum base width of an open-channel spillway shall be ten (10) feet. Conduits or siphon pipes other than glory hole spillways are not acceptable substitutes for an open-channel spillway. (7-1-93)

d. The effectiveness of spillways shall be undiminished by bridges, fences, pipelines or other structures. (7-1-93)

e. Unless expressly authorized in writing by the Director, or approved as an integral part of an operation plan, stop logs or flashboards shall not be installed in spillways. (7-1-93)

12. Reservoir Site. The dam site shall be cleared of all trees, brush, large rocks, and debris unless otherwise waived by the Director. The reservoir site shall be cleared of all woody material, growth or debris that is large enough to lodge in the spillway, or outlet works, except as otherwise approved by the Director. (7-1-93)

13. Inspection and Completion Reports. As construction proceeds, it is the responsibility of the engineer to submit test reports (e.g. soil material analyses, density tests, concrete strength tests) along with periodic inspection and progress reports to the Director. (7-1-93)

a. Upon completion of construction the owner or his engineer shall provide the Director a short, written narrative account of all items of work. Record drawings and revised specifications shall be submitted to the Director if the completed project has been substantially changed from the plans and construction specifications originally approved. (7-1-93)

b. The engineer representing the owner shall certify that construction, reconstruction, enlargement, replacement or repair of the dam and appurtenances was completed in accordance with the record drawings and specifications, or as revised. (7-1-93)

051. -- 054. (RESERVED).

055. EXISTING INTERMEDIATE OR LARGE DAMS (RULE 55).
All dams regulated by the department shall be operated and maintained to retain the embankment dimensions and the hydraulic capacity of the outlet works and spillway(s) as designed and constructed, or as otherwise required by these rules. (7-1-93)

01. Analyses Required. The analyses required by Rule 40 are not applicable to existing dams except as required in Rule Subsections 055.01.a. and 055.01.e. unless for good cause, the Director specifically requires the analyses. Dams constructed of other than earth material shall comply with these criteria, as determined by the Director, or with other engineering criteria approved by the Director. (7-1-93)

a. For large, significant or high risk dams, the release capability required by Rule Subsection 050.11 shall be evaluated and applied to the structure. Dams of other size and risk are required to provide the release capability of Rule Subsection 050.11 but are not required to conduct the analyses. (7-1-93)

b. Every dam, unless exempted by the Director shall have a spillway with a capacity to pass a flood of one percent (1%) (two percent (2%) for small low hazard dams) occurring with the reservoir full to the spillway crest at the beginning of the flood while maintaining the freeboard required by Rule Subsection 050.06. (7-1-93)

c. The Director may waive the spillway requirement for dams proposing off stream storage or upon a showing acceptable to the Director. (7-1-93)

d. The release capability can include the capacity of spillway(s) and outlet(s), diversion facilities, or other appurtenant structures, and any approved operating procedures which utilize upstream storage, diversion and flood routing storage to pass flood events. The remainder of the required release capacity, if any, may be met by the following: (7-1-93)

i. Reconstruction, enlargement or addition of spillway(s), outlet(s), diversion facilities or other appurtenant structures. (7-1-93)

ii. A showing acceptable to the Director that failure of the dam during a flood of the specified magnitude described in Rule Subsection 050.11 would not substantially increase downstream damages over and above the losses and damages that would result from any natural flood up to that magnitude. (7-1-93)

iii. A showing acceptable to the Director that the release capability of the dam together with other emergency release modes such as a controlled failure or overtopping of the dam would not result in a larger rate of discharge than the rate of inflow to the reservoir. (7-1-93)

iv. A showing acceptable to the Director that limiting physical factors unique to the dam site exist that prevent construction of a spillway or other release capability mechanisms during a flood of the specified magnitude described in Rule Subsection 050.11 provided the owner implements storage operational procedures and/or provides for emergency warning to protect life and property. (7-1-93)

e. For large, high risk dams, the seismic design loads shall be evaluated and applied to dams located east of Range 22E, B.M. The evaluation shall use the maximum ground motion/acceleration generated by the maximum credible earthquake. (7-1-93)

f. The Director may accept existing studies relative to requirements of Rule Subsections 055.01.a. and 055.01.e., if the Director determines the information provided fulfills the requirements of Rule Subsections 055.01.a. and 055.01.e. (7-1-93)

g. The Director may allow until July 1, 1992 for completion of the analyses required in Rule Subsections 055.01.a. and 055.01.g. and may allow the owner of an existing dam a compliance period of up to ten years for completing the studies, to complete structural modifications or implement other improvements necessary to provide the release capability determined to be required (Rule Subsection 055.01.a.) or complete structural modifications necessary to assure the dam and appurtenant facilities will safely function under earthquake loads

(Rule Subsection 055.01.g.). (7-1-93)

h. Within thirty (30) days after completing the analyses required in Rule Subsection 055.01.a. or 055.01.g., the owner of an existing dam that is deficient in either case (Rule Subsection 055.01.a. or 055.01.g.) shall file with the Director a schedule outlining the dates work or construction items will be completed. (7-1-93)

02. Other Requirements. (7-1-93)

a. Routine maintenance items include the following: (7-1-93)

i. Eradication of rodents and filling animal burrows. (7-1-93)

ii. Removal of vegetation and debris from the dam. (7-1-93)

iii. Restoring original dimensions of the dam by the addition of fill material. (7-1-93)

iv. Addition of bedding or riprap material which will not increase the height or storage capacity. (7-1-93)

v. Repair or replacement of gates, gate stems, seals, valves, lift mechanisms or vent pipes with similar equipment. (7-1-93)

vi. Repair or replacement of wingwalls, headwalls or aprons including spalling concrete. (7-1-93)

b. The following are not routine maintenance items: (7-1-93)

i. Reconstruction of embankment slopes. (7-1-93)

ii. Replacement, reconstruction or extension of outlets. (7-1-93)

iii. Foundation stabilization. (7-1-93)

iv. Filter or drain construction or replacement. (7-1-93)

v. Spillway size alteration or modification. (7-1-93)

vi. Installation of instrumentation or piezometers. (7-1-93)

vii. Release capability modification. (7-1-93)

c. Items not specifically described in Rule Subsections 055.02.a. and 055.02.b. will be determined by the Director to be included in one rule or the other upon receipt of a written request from the owner or his representative seeking such a determination. (7-1-93)

d. Where riprap is required to prevent erosion and to maintain a stable embankment, pipes, cables, brush, tree growth, logs, or floating debris are not acceptable substitutes for rock riprap and granular bedding material. Dams or portions thereof which are stable without riprap, are not required to have riprap. (7-1-93)

e. Upon completion of reconstruction of a dam or feature of a dam included in Rule Subsection 055.02.b., the owner or his engineer shall provide the Director a short written narrative account of all items of work. Record drawings and revised specifications shall be submitted to the Director if the completed project has been substantially changed from the plans and construction specifications originally approved. (7-1-93)

f. Upon request, the owner of every dam shall provide his name and address to the Director and shall advise the Director of future changes in ownership. If the owner does not reside in Idaho, the owner shall provide the name and address of the person residing in Idaho who is responsible for the operation, maintenance and repair of the dam. (7-1-93)

056. -- 061. (RESERVED).

060. SMALL DAM DESIGN CRITERIA (RULE 60).
The following provisions apply to small dams. (7-1-93)

01. Design and Construction of Small Dams. Design and construction of small dams located in high risk areas as determined by the Director require submittal of fees, plans and specifications prepared by an engineer and shall follow the same general criteria established under Rules 40, 45, 50, and 55. Other small dams not determined to be in a high risk area shall follow the same general criteria established under Rules 50 and 55 or larger dams, except that submittal of plans, specifications and test results is not required. (7-1-93)

02. Notification Prior to Construction. The owner shall notify the Director in writing ten (10) calendar days prior to commencing construction. (7-1-93)

03. Approval Required. The owner shall not proceed with the following stages of construction without approval from the Director. (7-1-93)

a. After clearing and excavation of the foundation area and cutoff trench, and prior to placing any fill material; (7-1-93)

b. After installation of the outlet conduit, and before placing any backfill material around the conduit; (7-1-93)

c. After construction is completed, and before any water is stored in the reservoir; (7-1-93)

d. At such other times as determined necessary by the Director. The Director, will, upon seven (7) day notice, inspect and, if satisfactory, approve the completed stage of construction. (7-1-93)

04. Notification upon Completion of Construction. The owner shall in writing notify the Director upon completion of construction. (7-1-93)

061. -- 064. (RESERVED).

065. DAMS STORING TAILINGS AND WATER (RULE 65).

01. Construction of Dams Storing Fifty Acre-Feet or More. Construction of dams intended to store or likely to store fifty (50) acre-feet or more of water in excess of the water contained in the tailings material shall meet the requirements specified in Rules 40, 45, 50 and 55 of these rules. The Director may waive any or all of these requirements if, in the opinion of the Director, sound engineering design provided by the owner indicates such requirements are not applicable. (7-1-93)

02. Abandonment Plan. An abandonment plan which provides a stable, maintenance-free condition at any time tailings are not being actively placed for an extended period of time, as determined by the Director, shall be submitted to the Director by the owner of a dam storing tailings and water. This rule may be waived by the Director if determined not to be applicable. (7-1-93)

066. -- 999. (RESERVED).

TITLE 17: CONSERVATION
CHAPTER I: DEPARTMENT OF NATURAL RESOURCES
SUBCHAPTER h: WATER RESOURCES
PART 3702 CONSTRUCTION AND MAINTENANCE OF DAMS
SECTION 3702.30 APPLICABILITY

Section 3702.30 Applicability

a) Classification

1) Dams will be categorized in one of three classes, according to the degree of threat to life and property in the event of a dam failure. The three classes of dams are:

A) Class I – Dams located where failure has a high probability for causing loss of life or substantial economic loss in excess of that which would naturally occur downstream of the dam if the dam had not failed. A dam has a high probability for causing loss of life or substantial economic loss if it is located where its failure may cause additional damage to such structures as a home, a hospital, a nursing home, a highly travelled roadway, a shopping center, or similar type facilities where people are normally present downstream of the dam. This is similar to U.S. Army Corps of Engineers HIGH HAZARD POTENTIAL category as defined in the Corps Guidelines, and the U.S. Soil Conservation Service Class (c) dams as defined in Soil Conservation Service Technical Release No. 60.

B) Class II – Dams located where failure has a moderate probability for causing loss of life or may cause substantial economic loss in excess of that which would naturally occur downstream of the dam if the dam had not failed. A dam has a moderate probability for causing loss of life or substantial economic loss if it is located where its failure may cause additional damage to such structures as to a water treatment facility, a sewage treatment facility, a power substation, a city park, a U.S. Route or Illinois Route highway, a railroad or similar type facilities where people are downstream of the dam for only a portion of the day or on a more sporadic basis. This is similar to U.S. Army Corps of Engineers SIGNIFICANT HAZARD POTENTIAL category and the U.S. Soil Conservation Service Class (b) dams.

C) Class III – Dams located where failure has low probability for causing loss of life, where there are no permanent structures for human habitation, or minimal economic loss in excess of that which would

naturally occur downstream of the dam if the dam had not failed. A dam has a low probability for causing loss of life or minimal economic loss if it is located where its failure may cause additional damage to agricultural fields, timber areas, township roads or similar type areas where people seldom are present and where there are few structures. This corresponds to U.S. Army Corps of Engineers LOW HAZARD POTENTIAL category and U.S. Soil Conservation Service Class (a) dams.

2) Dams will be categorized in one of three size classifications. Such size classifications shall be based on dam height and impounding capacity. If either the height or impounding capacity meets the minimum requirement for the larger size, the dam will be classified in the larger size category.

CLASSIFICATION	IMPOUNDING CAPACITY ACRE-FEET	DAM HEIGHT FEET
Small	Less than 1,000	Less than 40
Intermediate	Greater than 1,000 to Less than 50,000	Greater than 40 to Less than 100
Large	Greater than 50,000	Greater than 100

b) New Dams

1) Class I and II Dams

The owner of a proposed Class I or II dam shall obtain a OWR permit prior to the start of construction. The owner must do all construction and maintenance of the dam in accordance with this Part governing such Class I or II dam.

2) Class III Dams

A) The owner of a proposed Class III dam shall obtain a OWR permit prior to the start of construction if the dam meets any of the following criteria:

i) the drainage area of the proposed dam is 6400 acres or more in a Rural Area or 640 acres or more in an Urban Area, or

ii) the dam is 25 feet or more in height provided that the impounding capacity is greater than 15 acre-feet, or

iii) the dam has an impounding capacity of 50 acre-feet or more provided that the dam height is greater than 6 feet.

B) If a permit is required for the Class III dam under any of these criteria, then the owner must do all construction and maintenance of the dam in accordance with this Part governing Class III dams.

c) Existing Dams

The owner of a dam that was permitted and built in compliance with a OWR permit before September 2, 1980, and that is currently in good repair shall not be required, except in compliance with Sections 3702.150 or 3702.190, to make changes in the design, structure, or construction of such dam. The owner of a dam that was permitted and built before September 2, 1980, but is not in accordance with the OWR permit or is not in good repair, shall be required to meet all current standards for existing dams. The owner of a dam built after September 2, 1980, shall be required to meet all standards for proposed dams existing at the time of its construction. Operation, maintenance, inspection and financial responsibility standards must be complied with at all dams.

1) Class I and II Dams

A) OWR has developed an inventory of dams in Illinois. OWR and federal agencies have conducted and are conducting inspections of existing dams having a potential for loss of life or property damage in case of a dam failure. As inspection reports are completed, OWR will furnish in writing to the owner of the dam a detailed and specific list of defects discovered in the course of the inspection of the dam, including the specific nature of any inadequacies of the capacity of the spillway system and any indications of seepage, erosion or other evidence of structural deficiency in the dam or spillway; together with a statement of the applicable standards found in 17 Ill. Adm. Code 3702 which if complied with by the owner of the dam will put the dam into compliance with this Part.

B) If an inspection by OWR or in which OWR concurs finds that a dam is in an unsafe condition, OWR will notify the appropriate officials of the affected city or county, the State's Attorney of the county in which the dam is located, and the Illinois Emergency Management Agency (IEMA); and will assist IEMA) in any emergency actions deemed necessary by that agency.

C) OWR will notify the dam owner whose dam has been inspected if the owner must obtain a permit or amendment to an existing permit for the dam.

D) If an existing Class I or II dam has been inspected and found to have serious deficiencies requiring major modifications, then within 90 days after receipt of notice from OWR that a permit or amendment to an existing permit is required under this Part, the owner of a Class I or II dam must provide written assurance to OWR of the following: the owner's intention to rectify the deficiencies noted, the date which the owner will submit a completed permit application, the time frame for initiating and completing the appropriate remedial measures, and the methods and designs to be used for the remedial measures.

E) If an existing Class I or II dam has been inspected and found to have no serious deficiencies requiring major modifications, OWR will notify the owner of the dam that he must submit within 90 days a permit application including the following if such has not been previously

provided to OWR:

i) an Operating Plan (Section 3702.40(b)(4));

ii) a Maintenance Plan (Section 3702.40(b)(5));

iii) a Financial Responsibility Statement (Section 3702.40(b)(6)); and

iv) a Right of Access Statement (Section 3702.40(b)(7)(A)).

F) An owner initiating major modifications to an existing Class I or Class II dam must obtain a new permit or amendment to an existing permit prior to the initiation of the modifications.

2) Class III Dams

A) Using the inventory of dams or other similar information, OWR, over a period of time, upon receipt of a complaint or upon its own investigation, may contact owners of those existing Class III dams which

i) have a drainage area of 6400 acres or more in a Rural Area or 640 acres or more in an Urban Area, or

ii) are 25 feet or more in height, provided that the impounding capacity is greater than 15 acre-feet, or

iii) have an impounding capacity of 50 acre-feet or more provided that the dam height is greater than 6 feet.

B) OWR will inform the owners of such dams that they must submit to OWR a maintenance program and a statement indicating actions to be taken to remedy the noted deficiencies.

C) If an inspection by OWR or in which OWR concurs finds that a dam is in an unsafe condition, OWR will notify the appropriate officials of the affected city or county, the State's Attorney of the county in which the dam is located, and IEMA.

D) Owners of existing Class III dams in locations where there is potential for downstream urban development, which could cause a change in dam classification in the foreseeable future, when so notified by OWR, shall be required to report annually the existing land uses downstream of the dam. Extent of downstream land use to be reported is dependent upon factors such as slope and width of flood plain and density and intensity of downstream development. Extent downstream will not exceed 2 miles unless otherwise indicated by OWR. The owner may provide information indicating that an extent downstream which is shorter than 2 miles is appropriate. The width of flood plain shall be the width of the area inundated by the 100-year flood.

E) Owners of Class III dams desiring to make major modifications to their dams shall obtain a OWR permit or an amendment to an existing OWR permit for the work prior to the initiation of the modifications.

d) Designation by OWR of Dam Classification

Before assigning or changing the dam classification for a new or existing dam, OWR shall give notice and opportunity for hearing pursuant to Section 3702.170 to the applicant or existing dam owner and other interested persons of such action.

1) Initial Assignment of Dam Classification

A) New Dams

The classification of new dams will be based upon information available to OWR. Such information includes, but is not limited to, U.S.G.S. quadrangle maps of the downstream area, the preliminary report and support data from the owner's engineer, known elevations of structures downstream of the proposed dam, information from the public, and previous study data. Such information is available from in-house data and data supplied by the owner's engineer, the public, federal or state agencies. The owner of the proposed dam shall submit information to establish the degree of threat to life and property damage in the event of a dam failure.

B) Existing Dams

i) The classification of existing dams which have been inspected by the U.S. Army Corps of Engineers, other federal agencies, or OWR will be based upon the agency's inspection report.

ii) The classification of existing dams which have not been inspected by federal agency or OWR but which have had major modifications proposed by the dam owner will be processed as new dams in accordance with Section 3702.30(d)(1)(A).

2) Change in Dam Classification

Upon receipt and verification of information indicating that significant change in the degree of threat to life or property from a dam failure has occurred since the dam's original classification, the classification of that dam shall be changed to reflect the new hazard potential. Upon reclassification, the dam owner shall be subject to the applicable dam safety requirements for the current classification (Section 3702.30(c)).

e) Removal of Dams

`The owner of a Class I, II or III dam as defined in this Part, who wishes to remove his dam, shall obtain, prior to the initiation of the dam removal, a OWR permit to remove the dam in accordance with Section 3702.50 governing the removal of dams.

Joint Committee on Administrative Rules
ADMINISTRATIVE CODE

TITLE 17: CONSERVATION
CHAPTER I: DEPARTMENT OF NATURAL RESOURCES
SUBCHAPTER h: WATER RESOURCES
PART 3702 CONSTRUCTION AND MAINTENANCE OF DAMS
SECTION 3702.40 REQUIREMENTS FOR APPROVAL OF PERMITS FOR CONSTRUCTION OF NEW DAMS AND MAJOR MODIFICATIONS OF EXISTING DAMS

Section 3702.40 Requirements for Approval of Permits for Construction of New Dams and Major Modifications of Existing Dams

a) The following are OWR requirements which must be met in order to obtain a permit for construction of a new dam or major modification of an existing dam. Applicants are encouraged to submit to OWR a preliminary report for approval of concept prior to completion of the permit application form. The preliminary and all subsequent plans and reports shall be prepared under the direction of an engineer or other qualified personnel. The engineer or qualified personnel may be assisted by other professional personnel applying the disciplines of hydrologic engineering, hydraulic engineering, soil mechanics, structural engineering, or engineering geology.

b) OWR staff will be available for consultation prior to initiation of design studies, and at any time during the development of the permit application if questions should arise.

1) Structural and Geotechnical Design Requirements

The basis for OWR review and approval of the structural and geotechnical design requirements of Class I, II and III dams is the Corps Guidelines subject to modification as indicated in this Part. The criteria for structural and geotechnical design contained in the Corps Guidelines are minimum criteria. Variations from the criteria may be required or allowed by OWR for special physical conditions at the proposed site as necessary or appropriate to meet the interest of the overall structural and geotechnical requirements of this Part. Technical publications, other than the Corps Guidelines, may be used by OWR to assure the use of current and applicable data for the structural and geotechnical review of the dam design.

2) Hydrologic and Hydraulic Design Requirements

The basis for OWR review and approval of the hydrologic and hydraulic design requirements for Class I, II and III dams is the Corps Guidelines, subject to modifications as indicted herein. Technical publications other than the Corps Guidelines may be used to assure the use of current and

applicable data for the hydrologic and hydraulic review of dam design.

A) Proposed Dams

The following minimum spillway design floods shall be used for proposed structures:

i) Principal Spillway Design Flood

CLASSIFICATION	SIZE	PRINCIPAL SPILLWAY DESIGN FLOOD
Class I	All	100-yr.
Class II	All	50-yr.
Class III	All	25-yr.

ii) Total Spillway Design Flood

CLASSIFICATION	SIZE	PRINCIPAL SPILLWAY DESIGN FLOOD
Class I	Small	0.5 PMF
	Intermediate	1.0 PMF
	Large	1.0 PMF
Class II	Small	100-yr.
	Intermediate	0.5 PMF
	Large	1.0 PMF
Class III	Small	100-yr.*
	Intermediate	100-yr.
	Large	0.5 PMF

*For proposed Class III dams where the dam height multiplied by the impounding capacity is less than or equal to 300, no specific total spillway capacity is required.

iii) For all proposed Class II or III dams, a determination of alternatives for increasing the total spillway capacity to accommodate the PMF shall also be submitted to OWR. The initial dam design shall provide for the capability of increasing the spillway capacity. Future downstream land use, land use controls, and growth projections will be considered in the review of the spillway capacity design.

B) Existing Dams

The minimum spillway design flood for modifications to existing dams built after September 2, 1980 shall be the same as the criteria for proposed dams. The minimum spillway design flood for modifications to existing dams that were constructed and in service on or before September 2, 1980, are as follows:

i) Principal Spillway Design Flood

CLASSIFICATION	SIZE	TOTAL SPILLWAY DESIGN FLOOD
Class I	All	100-yr.
Class II	All	50-yr.
Class III	All	No specific requirement.

ii) Total Spillway Design Flood

CLASSIFICATION	SIZE	TOTAL SPILLWAY DESIGN FLOOD
Class I	Small	0.3 PMF
	Intermediate	0.6 PMF
	Large	0.6 PMF
Class II	Small	100-yr.
	Intermediate	0.3 PMF
	Large	0.6 PMF
Class III	Small	100-yr.*
	Intermediate	100-yr.
	Large	0.3 PMF

*For modifications to existing Class III dams where the height multiplied by impounding capacity is less than or equal to 300, no specific total spillway capacity is required.

iii) The Department may approve total spillway design capacities for existing dams other than the spillway design floods listed above. A total spillway design capacity less than the 100-yr. flood will only be allowed for small size, Class III structures with dam height multiplied by impounding capacity less than or equal to 300. Any submittal for variation from the above-listed spillway design flood must include a detailed hydraulic risk assessment that shows that additional spillway capacity will not provide a decrease in potential loss of life or property damage or a detailed economic risk assessment that shows that the chosen spillway design alternative provides the minimum rehabilitation costs plus damage losses; a detailed early warning and emergency evacuation plan coordinated with the local ESDA; and a list (with mailing addresses) of all persons living within the dam breach wave inundation area.

iv) All hearings regarding variation from the above-listed spillway design criteria shall be in accordance with Section 3702.170 of this Part.

C) For Class I and II dams, a dam breach wave analysis for downstream impacts from failure during the total spillway design flood and impoundment initially at normal pool shall be required for:

i) a nearly instantaneous total failure and

ii) should the applicant so desire, a failure to the degree and timing believed reasonable by the applicant.

D) Dewatering Capabilities

i) All new Class I and II dams, all new Class III dams unless exempted by OWR for functional reasons, and existing Class I and II dams requiring major modifications shall have a capability for dewatering the reservoir within a reasonable period of time. In determining a reasonable time period, OWR shall consider the damage potential posed by possible failure, risk and nature of potential failure, purpose of the dam and reservoir, capability and stability of available drainage courses to convey the waters released in the event of an emergency dewatering, and influence of rapid drawdown on stability of the dam. Although each permit must be considered based on its individual circumstances, in general, a reasonable time to dewater 50% of the normal pool storage volume is 7 days for Class I dams, 14 days for Class II dams and 30 days for Class III dams.

ii) No dewatering capability shall be required for any existing Class III dam or for any existing Class I or II dam which OWR determines to require no major modifications thereto under this Part.

E) Specific requirements for minimum freeboard allowances are not appropriate because of the many factors involved in such determinations. The applicant must assess the factors affecting the individual project and develop the appropriate minimum freeboard allowance. Many projects are reasonably safe without freeboard allowance because they are designed for overtopping, or because other factors minimize possible overtopping. Conversely, freeboard allowances of several feet may be necessary to provide a safe condition for some dams. Factors that should be considered include the duration of high water levels in the reservoir during the design flood; the effective wind fetch and reservoir depth available to support wave generation; the probability of high wind speed occurring from a critical direction; the potential wave runup on the dam based on roughness and slope; and the ability of the dam to resist erosion from overtopping waves.

F) The applicant must provide stilling basins or other appropriate structures or devices capable of dissipating the energy created at the outlet of the principal spillway and at dewatering outlets for all

flows.

3) Erosion Protection Requirements

A) As a minimum the applicant shall adequately protect by structural or nonstructural means the upstream face of earth embankment dams from an elevation below normal pool of two feet or 0.50 times the anticipated wave height (if greater than 2.0 feet) up to the minimum freeboard elevation. In addition, if normal pool water surface varies, the upstream face shall be protected within the range of variation.

B) The applicant shall vegetate or otherwise protect from erosion the downstream face and top of earth embankment dams. The applicant should design earth embankment dams to provide a dam section which can be easily maintained.

C) The applicant shall provide riprap or other appropriate protection as necessary at dam abutments, dam slope toes (the line of the dam embankment slopes where it intersects the natural ground at the upstream or downstream edge), spillways, stilling basins, and at other locations which, if left unprotected, could lead to damage to, or failure of the dam.

D) If the spillway design of the dam requires that an earth emergency spillway pass any portion of the 100-year flood, the applicant shall protect the earth emergency spillway against erosion consistent with the dam classification and physical characteristics of the dam site. The applicant must construct all earth emergency spillways on in situ material or on well compacted cohesive materials that will be stable during design flows.

E) The applicant shall submit plans for control of erosion and water pollution during the anticipated construction or major modifications, including plans for adequate measures to limit the erosion of the soil from exposed slopes after completion of construction. Such plans shall indicate that adequate control measures will be taken during construction to protect the quality of stream flow below the project site, and during the estimated time for filling.

4) Operating Requirements

An applicant for a Class I or II dam shall submit an operational plan specifying the method and schedule for the operation of the dam and the routine operating procedures to keep the dam in good working order, including an emergency warning plan. The emergency warning plan must outline the procedures to be followed during major storm events or other emergency situations. Under this plan, a person designated by the dam owner would monitor dam conditions, and would warn appropriate state and local officials if major problems require immediate repairs and would indicate how the owner plans to accomplish the needed repairs, and indicate if evacuation of persons in areas downstream of the dam may be necessary.

5) Maintenance Requirements

As a condition of each permit, dam owners shall submit a maintenance plan detailing the procedures and schedules to be followed to maintain the dam and its appurtenances in a reasonable state of repair. The maintenance plan shall include but not be limited to the following:

A) Class I and II Dams

The dam owner shall retain an engineer or other qualified personnel to make an initial inspection and report and subsequent inspections and reports as required by this Part. The owner of a Class I dam shall submit the report annually on forms furnished by OWR. The owner of a Class II dam shall submit the report every three years on forms furnished by OWR. In the intervals between the engineer or other qualified personnel reports on Class II dams, the owner shall file with OWR an annual statement on forms furnished by OWR stating that he is maintaining the dam in accordance with the maintenance plan prepared by his engineer or other qualified personnel and indicating any change in land use which may have occurred in the 100-year flood plain within the previously accepted limits downstream of the dam. The reports shall outline modifications made to the dam, any deficiencies found, detail the remedial measures necessary, and the method and time the owner will use to correct the deficiencies found. The dam owner may be required to provide additional inspections and reports by an engineer or other qualified personnel, following unusual storms or seismic events; provided such inspection procedures are required as a part of the maintenance plan approved by OWR in issuing a permit. A sketch showing land use in the flood plain downstream of the dam shall be included in the reports. The extent of downstream land use to be reported is dependent upon factors such as slope and width of the 100-year flood plain and the density and intensity of downstream development. The extent downstream will not exceed 2 miles unless otherwise indicated by OWR. The owner may provide information for review by OWR indicating that an extent downstream which is shorter than 2 miles may be appropriate.

B) Class III Dams

The owner of a new Class III dam or owner of an existing Class III dam qualifying under the provisions of Section 3702.30 (relating to the major modification of existing Class III dams), shall retain an engineer or other qualified personnel to make an initial inspection and report and subsequent inspections and reports on a 5-year interval, in accordance with this Part. The dam owner shall submit to OWR on forms furnished by OWR the engineer's initial report and subsequent fifth year reports. The reports shall include a description of flood plain land use downstream of the dam. In the intervals between the engineer's reports, the owner shall file with OWR an annual statement on forms furnished by OWR stating that he is maintaining the dam in accordance with the maintenance plan prepared by his engineer or other qualified personnel and indicating

any change in land use downstream of the dam. The extent of downstream land use to be reported is dependent upon factors such as slope and width of the 100-year flood plain and the density and intensity of downstream development. The extent downstream will not exceed 2 miles unless otherwise indicated by OWR.

6) Financial Responsibility of Owner

A) For Class I and II dams, the owner shall document that he has the financial capability to adequately maintain or breach his dam in a safe condition. This may be established by showing that the applicant has the resources and the authority to obtain funds in the amount required to safely breach the dam within 10 days of receipt of notice of the need to breach or repair. For public bodies, this may be done by showing taxing power or other revenue generating ability and passage of an appropriate ordinance or resolution indicating the authority to take such action if necessary. If the owner cannot adequately demonstrate this financial capability, OWR may require the applicant to post a performance bond. The amount of the bond will be that estimated by OWR as reasonably necessary to safely breach the dam in an environmentally sound manner if the condition of the dam becomes a threat to life or property. The owners shall notify OWR when each performance bond has been renewed or extended in time.

B) Except in emergencies, should the cost of repair to place the dam in a safe condition be less than the cost of breaching, the performance bond may be used to pay for repair, rather than breach of the dam.

7) Other Requirements

A) The owner shall grant the State the right of access to inspect the dam site and immediate vicinity before, during and after construction and for the life of the dam and appurtenances. Except under emergency conditions, such as when the dam is in imminent danger of failure or is in the process of failing, the State shall notify the owner at least 10 days in advance of any inspection.

B) For Class I and II dams, the owner shall notify OWR prior to initiating foundation preparations, including cut-off trench excavation.

C) For Class I and II dams, OWR will require the owner to have continuous inspection during construction. The construction shall be under the direction of an engineer, or other qualified personnel. For Class III dams, OWR may require the owner to have continuous inspection during construction if foundation conditions have not been completely determined or if the dam has been designed with minimal factors of safety.

D) For Class I and II dams – prior to commencing filling operations, or refilling operations after a drawdown, the applicant shall request

OWR inspection of the dam, and must receive authority from OWR before commencing filling. When drawdowns are performed on a frequent basis as a part of the approved operation plan, the authority is not necessary.

E) If OWR has not acted to grant or deny the authorization to fill within 30 days after receipt of request, the owner may proceed with filling or refilling operations.

F) For all new dams, or for major modifications to existing dams, the dam owner shall

i) own or have permanent flood easements for all land that will be inundated in the reservoir up to the proposed 100-year frequency flood pool elevation, or

ii) submit hydraulic computations showing that, for floods up to the 100-year frequency flood, the pool elevation will not be increased above existing conditions.

I. INTRODUCTION

The "Rules for Construction and Maintenance of Dams" require that only engineers which are registered as a structural and/or professional engineer in The State of Illinois, under the Professional Engineering Practice Act [225 ILCS 325] and the Structural Engineers Act [225 ILCS 340], and with expertise in the investigation, design, construction, and operation of dams prepare the engineering data to be submitted with an application for a permit. These guidelines have been written with the intent of providing a basic understanding of the type of information that will need to be provided with an application for a permit to construct a new dam and to modify, remove or abandon an existing dam. They have also been prepared for the engineer to understand the methods of review that will be used by the staff of the Office of Water Resources in reviewing an application for a permit. Some of the information presented herein would also be applicable to the preparation of data for an application for permit to operate and maintain an existing dam.

Section IX of these guidelines has been developed to address and provide guidance concerning the issue of the removal of dams including the abandonment of slurry disposal impoundment dams. Abandonment may differ from removal of a dam in that abandonment may leave the embankment intact. However, both removal and abandonment usually result in the dam ultimately being eliminated from the Office of Water Resources regulatory purview.

It is not the intent of these guidelines to be dictatorial as to the methods to be used to achieve the required data. Rather, the user is provided information concerning generally accepted methods of testing, analysis, and computation.

Questions regarding the preparation of the documentation noted in these guidelines may be directed to the Office of Water Resources offices in Springfield (Tel. No. 217/782-3863), Bartlett (Tel. No. 847/608-3100 ext. 2025).

II. PRELIMINARY DESIGN REPORT

It is strongly recommended that applicants submit a preliminary design report to OWR for approval of the design concept prior to initiation of detailed design studies. This report should include:

A. Ownership and Engineer Information

1. The owner of the dam (names, addresses, telephone numbers)

2. The owner's engineer (names, addresses, telephone numbers, a description of expertise in the investigation, design, construction, and operation of dams, and a listing of previously acquired permits for dams from the Office of Water Resources or its predecessors)

B. Purpose, Location and Configuration - General information regarding the dam and appurtenances. This information should include a statement of the purpose for which the dam is to be used, a legal description of the location of the dam, calculations to verify the drainage area controlled by the dam, the height of the dam and the maximum impounding capacity of the dam.

C. Downstream Hazards and Breach Analysis - In order for OWR to provisionally determine the dam classification, as described in the "Rules for Construction and Maintenance of Dams", information describing the downstream area for a distance of at least two miles is required. This information should include the number of and access to homes and buildings, roads, utilities and other property that would be endangered should failure of the dam occur. Contoured aerial photographs or recent U.S. Geological Survey topographic maps may be used for this purpose. Submittal of additional data, including a dam breach analysis, may be necessary at some sites. If a dam breach analysis is submitted, it should include failures during a range of events from normal pool through the Probable Maximum Flood. The owner should also be cognizant of the possibility for development of the downstream area which could change the dam classification and require modifications to the dam. The original design should provide for these modifications to be more easily accomplished.

D. Topography - Maps showing the location of the proposed structure that include the location of county and State roads, access to the site, the outline of the reservoir at normal pool elevation, the drainage area limits, and the general topography of the dam site and reservoir area. Contoured aerial photographs or recent U.S. Geological Survey topographic maps may be used for this purpose.

E. Plans and Drawings - Preliminary drawings that include cross-sections, plans and profiles of the dam, proposed pool levels, and types of spillways.

F. Basic Design Criteria - Preliminary design criteria including a description of the size, ground cover conditions, and extent of development of the watershed; the proposed geotechnical and exploration testing program, geology and geotechnical engineering assumptions for the foundation and embankment materials; the proposed hydrologic and hydraulic analyses methods; and the type of materials to be used in the dam and the spillway system(s).

III. FINAL DESIGN REPORT

In order for the Office of Water Resources to assess the safety aspects of a dam from an engineering standpoint, the final design report submitted with the Permit Application must contain the information and calculations to verify the adequacy of the design for the given size and downstream hazard potential of the dam. The safety evaluation will be based upon the capability of the project to meet the minimum performance standards established in the "Rules for Construction and Maintenance of Dams". The remaining sections of these guidelines have been written as an aid in the preparation of the data required to support the application for permit.

Computer programs which are used in the preparation of data for submittal should either be federal public domain programs or have sufficient documentation submitted with a copy of the program to allow for the review of the program. Spreadsheet applications which include equations should also be submitted to allow for the review of their equations. The data generated by all computer programs and spreadsheet applications may not be accepted as correctly representing the information required to be submitted.

IV. HYDROLOGIC AND HYDRAULIC INVESTIGATIONS

Various methods of analyzing the hydrologic and hydraulic characteristics of a watershed, reservoir, and dam are available. Some of the procedures which are generally acceptable for determination of the hydrologic and hydraulic characteristics are presented in the paragraphs that follow. In general, procedures developed by the following agencies are acceptable: U.S. Army Corps of Engineers; U.S. Department of the Interior, Bureau of Reclamation; U.S. Department of Agriculture, Natural Resources Conservation Service; and U.S. Department of Commerce, National Weather Service. The Office of Water Resources will use the Corps of Engineers and the National Weather Service computer programs as its primary review aids. The programs typically used by OWR for review include: HEC-1, HEC-HMS, HEC-2, HEC-RAS, and FLDWAV.

A. Maximum Water Surface Based on Spillway Design Flood Peak Inflow:

When the total project uncontrolled spillway discharge capability at maximum pool exceeds the peak inflow of the spillway design flood, a reservoir routing is not required. Flood volume is not controlling in this situation and surcharge storage is either absent or insignificant in relation to the spillway and outlet capacity.

When the 100-year, 50-year, or 25 year floods are applicable under the provisions of the "Rules for Construction and Maintenance of Dams", and streamflow data at or near the dam site are available, the spillway design flood peak inflow can be determined by a flood frequency analysis. The recommended method is outlined in "Guidelines for Determining Flood Flow Frequency" by the U.S. Water Resources Council, Hydrology Committee, Bulletin 17B, Revised March, 1982.

When streamflow data are not available, the recommended method is described in the latest version of documents from the U.S. Geological Survey for estimating the magnitude and frequency of floods on rural streams in Illinois. Adjustments to the computed rural discharges must be made to account for urbanization in the watershed. The U.S. Geological Survey has also published documents to assist in the determination of this adjustment. The methods described in TR55, "Urban Hydrology for Small Watersheds") may also be used if the appropriate rainfall values (see Section B1 below) are used.

B. Maximum Water Surface Based on Spillway Design Flood Inflow Hydrograph:

When either the Probable Maximum Flood (PMF) peak or a fraction thereof is required, the "unit hydrograph-infiltration loss rate technique" is considered the most expeditious method of computing the spillway design flood (SDF) peak inflow for most projects. Both the peak and the volume are required in this analysis. Where the surcharge storage is significant, or where there is insufficient discharge capability at maximum pool to pass the peak inflow of the SDF, considering all possible operational constraints, a flood hydrograph is required. Determination of the probable maximum precipitation (PMP) or the 100, 50, or 25 year precipitations, whichever is applicable, and unit hydrographs will be required, followed by the determination of the spillway design flood hydrograph.

1. Rainfall and Distribution

The PMP value used for dam safety purposes should be of at least a 24-hour duration and should be obtained from the National Weather Service Hydrometeorological Report No. 51, "Probable Maximum Precipitation Estimates, United States East of the 105th Meridian", June, 1978. The method of applying the PMP for HMR51 is described in a companion report, Hydrometeorological Report No. 52, "Application of Probable Maximum Precipitation Estimates - United States East of the 105th Meridian," August, 1982. Generalized rainfall reduction factors, such as the Hop Brook Factor, should not be used for the PMP estimates regardless of the source from which the estimates were obtained.

Rainfall values for frequency events, i.e. 100-year, 50-year and 25-year should be obtained from the Illinois State Water Survey (ISWS) Circular 172, "Frequency Distribution and Hydroclimatic Characteristics for Heavy Rainstorms in Illinois." The suggested method to distribute this rainfall is described in the ISWS publication, Circular 173, "Time Distributions of Heavy Rainstorms in Illinois".

2. Rainfall Excess

Rainfall excess is that portion of the rainfall which is not lost to infiltration, interception, and depression storage. Loss rates should be estimated for computing the rainfall excess. Consideration should be given to the seasonal variation of rainfall amounts, the associated ground cover, and the current land use. Also when applicable, snowmelt runoff rates and appropriate releases from upstream projects should be estimated.

The Natural Resources Conservation Service's weighted watershed curve number (CN) procedure is one of the most widely used methods for determining rainfall excess. If the applicant prefers, a rainfall-runoff relation for the studied basin, or one with similar characteristics, can be developed to determine the rainfall excess.

3. Unit Hydrograph

The unit hydrograph, i.e., the graph of discharge against time, is used to forecast the streamflow at a given point from one inch of direct runoff from a storm of specified duration. The duration selected should not exceed about 1/4 of the time of concentration. The time of concentration is the travel time of water from the hydraulically most distant point of the watershed to the point of interest. There are three basic approaches to the derivation of the unit hydrograph:

(A) Analysis of recorded runoff at a streamflow gaging station at or near the damsite on the same stream.

(B) Transposition of a unit hydrograph from another basin of comparable size and watershed runoff characteristics.

(C) Synthetic unit hydrographs based upon equations relating hydrograph parameters such as peak flow, time to peak, time base, etc. to the physical characteristics of the basin such as area, length, slope, etc.

Several of the more popular accepted methods of synthetic unit hydrograph derivation include:

(1) Clark's method used by the Corps of Engineers in the HEC-l and HEC-HMS computer programs.

(2) Natural Resources Conservation Service's curvilinear or triangular unit hydrograph.

(3) Snyder's method for Illinois developed by the Illinois State Water Survey.

4. Design Storm Inflow Hydrograph

Design storm refers to the intensity-duration combination of the precipitation which produces the most severe flood runoff and/or reservoir stage for the specified precipitation frequency. The time duration for a designated storm will vary depending on the hydrologic and physiographic characteristics of a specified watershed and the affect on the reservoir will depend on the storage-outflow relationship of the proposed reservoir. The design precipitation event is

divided into increments of time equal to the duration of the unit hydrograph using the appropriate distribution methods. The rainfall excess is determined by subtracting the appropriate loss rates from the rainfall depths to determine the runoff values. The ordinates of the unit hydrograph at the same time increment are then multiplied by the rainfall excess, lagged accordingly, then summed to determine the direct runoff inflow hydrograph.

If a storm hydrograph for a ratio of the PMF is required, the total PMF inflow hydrograph to the reservoir must be determined. The appropriate ratio should then be applied to the ordinates of the PMF inflow hydrograph. Ratios should not be taken of the PMP. If there are other dams or flow restrictive structures, upstream of the dam being analyzed, the total PMF hydrograph to the dam and its reservoir should be determined. Ratios can then be applied to the PMF to determine the response of the dam and reservoir to this design storm inflow hydrograph. Upstream dams and restrictive structures should be included in the analysis only if they are assured of remaining in their current configuration, such as a government owned and controlled flood control or water supply dam.

The use of a partial storm hydrograph (such as is noted in TR55, "Urban Hydrology for Small Watersheds") is not appropriate for use when the design storm inflow hydrograph is needed. These methods may be used to determine the peak inflow (see Section A above) if the appropriate rainfall values (see Section B1) are used.

5. Reservoir Area-Storage-Elevation Data

Reservoir surface area and storage capacity versus water surface elevation (tables or curves) are required. These data are usually determined by planimetry from topographic contour maps with scales equal to USGS 7.5 minute quadrangles or better.

6. Spillway Discharge-Elevation Data

Rating curves or tables are required for all discharge facilities contributing to the maximum design flood outflow hydrograph. If flow capacity is developed synthetically based upon semi-empirical equations for weir, orifice, or pipe flow, assumed coefficients and how they were selected should be stated and

referenced. When sufficient criteria and guidance are not available to determine the spillway flow capacity synthetically, a physical hydraulic model study should be performed with all model tests and performance results documented.

7. Downstream Tailwater Discharge-Elevation Data

A tailwater rating curve showing the downstream flow capacity versus elevation is required. Elevations of bankfull (at top of bank) channel capacity, principal and total spillway design floods, and 100-year flood immediately below the dam site should be noted. The method and support calculations used to determine the downstream water surface elevations (i.e., standard step backwater analysis, normal depth solution of Manning's equation, etc.) including all channel and overbank roughness, length, slope or cross section data and tailwaters due to a receiving waterway should be listed.

8. Design Storm Outflow Hydrograph

The outflow hydrograph from a dam spillway system may be estimated by either hydrologic or hydraulic routing methods. One of the simplest and most popular methods of reservoir routing is called the "Modified Puls" storage routing method. This method is described in most hydrology text books. It is also a feature of computer programs such as the Natural Resources Conservation Service's TR-48 or the Corps of Engineer's HEC-l and HEC-HMS. A hydraulic routing procedure is also acceptable and is a better method to be used for situations where a hydrograph is rapidly varying. The NWS computer program FLDWAV, the Corps of Engineers' computer programs UNET and HEC-RAS, and the USGS computer program FEQ have this capability.

C. Potential Upstream Flood Hazard Areas

Areas adjacent to the normal storage retention level that would be potentially subject to flooding should be examined to determine if a hazard to life or property could occur during sudden or frequent increases in the reservoir water surface elevation. Ownership or flood easement agreements are required from upstream property owners up to the 100-year flood elevation for new dams or for modifications to dams which include an increase in the reservoir water surface elevations.

D. Emergency and Normal Drawdown Capability

An assessment of the capability to reduce the reservoir storage within a reasonably rapid time interval to avert impending failure, or to facilitate repairs in the event of structural, embankment, or foundation problems should be made. The capability for dewatering the reservoir within a reasonable time period should be addressed with allowances for reservoir siltation and at least the typical base flow for the waterway. Gravity systems which have the capability of dewatering the entire reservoir should be provided. Other systems, such as siphons or pumps which dewater only a portion of the reservoir, will only be authorized for unique situations such as at existing dams without a current dewatering system. Factors that will be considered by OWR in determining the required drawdown time include: the purpose of the dam and reservoir; the risk and nature of a potential failure; the damage potential posed by possible failure; and the potential damage to downstream properties. Computations and assumptions used for calculating the total reservoir drawdown time and for an emergency drawdown of 50% of the normal pool storage volume, should be submitted. Recommended times for 50% drawdown are 7 days for Class I Dams, 14 days for Class II Dams, and 30 days for Class III Dams.

The capability and stability of available drainage courses to convey the waters released during a dewatering and the influence of a drawdown on the stability of the dam should be assessed. Except for emergency situations, the maximum drawdown rate should not typically exceed approximately 1.0 ft. per day.

E. Freeboard Design

Factors that should be considered in determining the minimum freeboard include the duration of high water levels in the reservoir during the design flood; the wind fetch and reservoir depth available to support wave generation; the probability of high wind speed occurring from a critical direction; the potential wave runup on the dam based on roughness and slope; and the ability of the dam to resist erosion from overtopping waves.

References for the method of analysis and the pertinent data utilized for determining the minimum freeboard should be submitted in order to verify that the dam is safe against overtopping during occurrence of the total spillway design flood and wave action using the maximum wave determination.

F. Upstream Face Protection

It is necessary to protect the upstream face of an earth embankment dam from wave erosion. The orientation, length, and purpose of the reservoir, the duration of higher reservoir stages, and the embankment material all affect the need for and the type of embankment protection. Upstream slope protection usually consists of rock riprap which should consist of a well graded, hard, durable rock. For small reservoirs with minimal change in pool elevation during flood events, a flat slope on the upstream face with a designed vegetative protection method can provide the necessary embankment protection.

The protection must also extend below the normal pool elevation a minimum of 2 ft. or 0.50 times the anticipated wave height (if greater than 2 ft.). In determining the elevation of the protection below the normal pool elevation beyond the minimum requirements, consideration should be given to the potential variation of the pool due to the purpose of the reservoir, operational factors, and the base flow of the inflow stream. The protection also serves the purpose of discouraging muskrats and other burrowing animals from burrowing a den into the embankment. The riprap and filter layer should extend at least 3 ft. below the pool elevation to offer a better deterrent to the animals.

G. Design of the Energy Dissipator Structures

Energy dissipators should be capable of sufficiently reducing the energy to insure against damage to the spillway or outlet system. Types of energy dissipators are numerous. Several of the more common type include the following: hydraulic jump stilling basin; impact-type dissipator; deflector bucket; submerged deflector bucket; plunge pool; and baffled chute. All design computations should include an assessment of the impact of a range of flows up to and including the total spillway design flood. The design should also address variations in the flows and tailwaters in the downstream channel due to flows from the principal and emergency spillways and in the receiving waterway.

A proper design should include the evaluation of the topographic features of the site, the relationship of storage capacity to flood volume, the geologic or foundation conditions, the type and height of the dam, and any other unique conditions pertaining to a particular site. In unusual situations when sufficient criteria and guidance are not available for analytical design, a

physical hydraulic model study should be performed with the model tests and performance results reported.

H. Dam Breach Wave Analysis

Analyses should be made to determine the most adverse failure conditions and the resulting peak outflows and water surface elevations downstream of the dam following failure of the dam. To provide sufficient information for classification of a dam, the breach analyses should also assume nearly instantaneous total (full height) failures covering a range of events from normal pool up to and including the probable maximum flood (PMF). For Class I and II dams, computations for the dam breach wave analysis are required for a nearly instantaneous total (full height) failure of the dam during normal pool and total spillway design flood conditions. Analyses completed for flood conditions should use the maximum reservoir elevation to initiate the modeled failure of the dam. However, if the maximum reservoir elevation overtops the dam, then the lower elevation of the maximum elevation or 1 ft. above the top of the dam should be used to initiate the modeled failure of the dam. Inundation maps on 7.5 minute quadrangles or better mapping should be provided for each failure condition studied.

The term "nearly instantaneous," for the purposes of this document, is the shortest time interval for which the computer model being used will provide mathematically stable results. This time is usually about 5 minutes and typically does not exceed 15 minutes and is consistent with failure times for earth embankment dams. The failure times for concrete dams are typically quicker than those for embankment dams.

Based upon dam failures which have occurred in the past, the average breach width for an embankment dam is usually in the range of 2 to 5 multiplied by the height of the dam. The side slopes of the breach of an embankment dam are typically greater than the angle of repose of the dam materials but may vary between vertical to 1 horizontal:1 vertical.

A dam breach analysis requires several steps: developing the reservoir inflow hydrograph; routing that hydrograph through the reservoir; selecting failure conditions for the structure (i.e., mode, shape, size, and time); calculating the outflow hydrograph from the failed structure; and modeling the movement of the flood wave downstream, including downstream tributary inflows, to determine travel

times, inundated areas, and maximum water surface elevations.

To determine the classification of a dam, the acquisition of additional information relative to the potentially impacted structures downstream of the dam may be necessary. Information such as the types of structures (residences, other building uses, infrastructure) within the breach inundation area, the low entry and first floor elevations of buildings, and the availability of alternate access routes to buildings if the primary access is damaged is typical. In general, the routing of the dam breach hydrograph should continue downstream to the point where the breach versus non-breach water surface profile elevation difference does not exceed 1 foot or the breach wave is contained within the channel.
