Figure 5-1. Relationship Between Drainage Area and Sediment Delivery Ratio

Sediment accumulation in a reservoir is dependent on the sediment delivery to the reservoir and on the trap efficiency. How the accumulated sediment will be distributed within the reservoir depends upon the character of the inflowing sediment, the operation of the reservoir, and other factors.

Trap efficiency is the amount (in percent) of sediment delivered to the site that will remain in the reservoir. It is a function of detention storage time, sediment characteristics, inflow characteristics and other factors. Trap efficiency can be estimated (using Figure 5-2) on the basis of the ratio of the reservoir capacity in acre-feet to the average annual inflow in acre-feet.

Figure 5-2. Trap Efficiency of Reservoirs

2. *Reservoir Sedimentation Survey Method*

Reservoir sedimentation surveys are excellent sources of data for establishing sediment yields to reservoirs. Reservoir deposition and sediment yield are not synonymous. To obtain the sediment yield to a surveyed reservoir, the measured deposition in that reservoir must be divided by its estimated trap efficiency. This takes into account the portion of the sediment inflow that passes through the reservoir and is not deposited. The use of the rate of deposition, established by a sedimentation survey, implies that both the sediment yield rate and the trap efficiency of the reservoir being designed are the same as that of the surveyed reservoir.

Results of available reservoir sedimentation surveys should be reviewed for design purposes. Table 5-3 lists several reservoirs in North Dakota for which sedimentation surveys have been conducted.

If no reservoirs representative of the area have been surveyed, it may be advisable to conduct sedimentation surveys on reservoirs in the area that are at least 10 years old. It is important that the period of sedimentation record be long enough to be representative of average conditions.

It is also important that the history of reservoirs considered for sediment surveys be known. Sediment removal or drying, or changes in spillway elevations affect sediment volume and distribution.

The reservoir drainage areas on which sedimentation surveys have been made for specific sediment design must be similar in topography, soils, and land use to those drainage areas for which information is desired. In addition, if the measured rates are to be applied directly, the size of the drainage areas of the surveyed reservoirs should not be less than one-half nor more than twice that of the structures being designed. For drainage areas outside these limitations, the annual sediment yield may be adjusted for design use on the basis of the drainage areas to the 0.8 power in the following manner:

$$Y_e = Y_m \left(\frac{A_e}{A_m}\right)^{0.8}$$

Where: Y_e = sediment yield to structure being designed (in tons per year)

Y_m = sediment yield to the surveyed reservoir (in tons per year); measured annual deposition ÷ trap efficiency of surveyed reservoir

A_e = drainage area of reservoir being designed

Where: A_m = drainage area of surveyed reservoir

D. Geotechnical Exploration

Geotechnical explorations of potential dam sites must be adequate to determine: (1) the suitability of the foundation and abutments for an earthfill embankment and reservoir; (2) the foundation treatment (preparation) measures required; (3) the excavation slopes of the cutoff trench; (4) the embankment design; and (5) the availability and characteristics of the borrow area materials for the embankment. The explorations should include classification of soils, determination of physical properties, location and extent of soil and rock strata and the variations in ground water levels.

The magnitude of the geotechnical exploration program is governed principally by the complexity of the foundation problems and the design classification of the project. Generally, design class I and II dams may only require two or three augered holes along the centerline of the dam, and two or three augered holes in the proposed borrow area and/or emergency spillway. The centerline auger holes should be 10 or more feet deep, depending on the materials encountered. Usually, no samples are taken and the materials are field classified. If problems are detected, a more extensive program should be undertaken.

Design class III, IV, and V dams require detailed geotechnical explorations. In the preliminary stages of these projects, reconnaissance surveys are undertaken to determine the general suitability of the potential dam sites. The reconnaissance surveys are often completed on several dam locations to determine the most suitable sites. The detailed surveys are made to determine the final dam location and, as quantitatively as possible, determine the geologic conditions that will be encountered during construction.

1. Reconnaissance Surveys

To determine the most suitable site for a dam, reconnaissance surveys are made. These surveys consist of a review of existing geologic information and a visit to the site by an experienced geologist or engineer. The survey normally does not include exploration drilling. The reconnaissance survey is aimed at determining topographically suitable locations and determining the limits of the exploration program. The most common sources of existing information are 7½ minute topographic quadrangle maps, county ground water reports, detailed soils survey reports, aerial photographs and other relevant reports.

The general physiographic features that should be noted include the shapes and types of valleys, the gradients and stages of erosion development, and the terraces (if present along with the valleys). The origin of the terraces is significant, regardless of whether they result from uplift, meandering, structural control, glaciation or landslide.

Observations of ground-water conditions should be recorded. Springs, wells, ephemeral streams, swamps, or other evidences of ground water aid in establishing the water table and the effects of ground water in the area. The reservoir area and road cuts in the vicinity should be examined for stability and strata identification.

2. Detailed Surveys

Reconnaissance commonly brings to light defects disqualifying some of the sites. As the next step, detailed studies are conducted at the more favorable sites. These studies must determine whether there are geological conditions that will affect the stability and

success of the dam and whether these conditions will require special design considerations during foundation preparation and construction.

At this stage of the examination, preliminary cross sections of the valley at potential dam sites should be surveyed and plotted. The drawing of the cross sections may show where more geologic information is needed.

After the surficial explorations, a drilling program can be planned to obtain supplemental geological data. The location of drill holes can also be determined to obtain maximum information. Field exploration is often completed in phases, with the data analyzed between each drilling phase.

A systematic search for suitable construction material for the dam is an important part of the survey. Because of the large volume required for most projects, long haul distances might be prohibitively expensive. Pits and other locations of filter material and riprap should be inventoried, both qualitatively and quantitatively.

3. Soil Classification

Knowledge of soil classification, including typical engineering properties of soil groups, is especially valuable when prospecting for earth materials or investigating foundations for structures. When adequate safety factors are provided, proper soil classification can be used to estimate numerical values of engineering characteristics of soils for use in small dams.

The Unified Soil Classification System is recommended for use in the design and construction of dams. Figure 5-3, the Unified Soil Classification Chart, gives the essentials of the classification system for soils.

In addition to proper classification, it is important to include an adequate description of the soil in reports or logs of explorations. The classification chart contains the information required for describing soils, citing several examples.

4. Sampling

The purposes and uses of samples are numerous. They are required to properly identify and classify soil or rock. They are essential for field density and moisture determinations. Samples are also used in laboratory tests of earth materials, concrete aggregate, filter material, and riprap. To a large degree, samples document the results of explorations for foundations, abutments and construction materials for dams. Obviously, erroneous conclusions will be drawn if the samples are not truly representative of the explorations.

Samples are broadly classified as disturbed or relatively undisturbed. Disturbed samples are those in which no effort is made to maintain the soil structure. Such samples may be secured for general observation and inspection, soil classification, moisture determination, or to obtain compaction characteristics. Relatively undisturbed samples vary from moderately disturbed split-barrel samples to almost completely undisturbed handcut samples. The importance of obtaining representative samples cannot be overemphasized. This requires considerable care because of the variations in natural deposits of earth materials. Representative samples are comparatively easy to secure in trenches, test pits, and cutbanks because the various undisturbed strata can be inspected visually. Bore holes, however, do not permit a visual inspection of the profile. It is also more difficult to secure representative samples by use of bore holes.

Samples may be either individual or composite. An individual sample is a single sample representing one stratum or type of soil. A group of individual samples, representing all the strata from a single test pit, may be combined in the same ratio as the thicknesses of the strata from which the samples were taken to form a composite sample. A sample may also be composited to any desired ratio of the soil types involved. It is usually preferable to obtain individual samples from each stratum of a soil deposit rather than to composite the sample in the field, since the most desirable depth and method of borrow excavation may be determined by trying several composite samples in the laboratory.

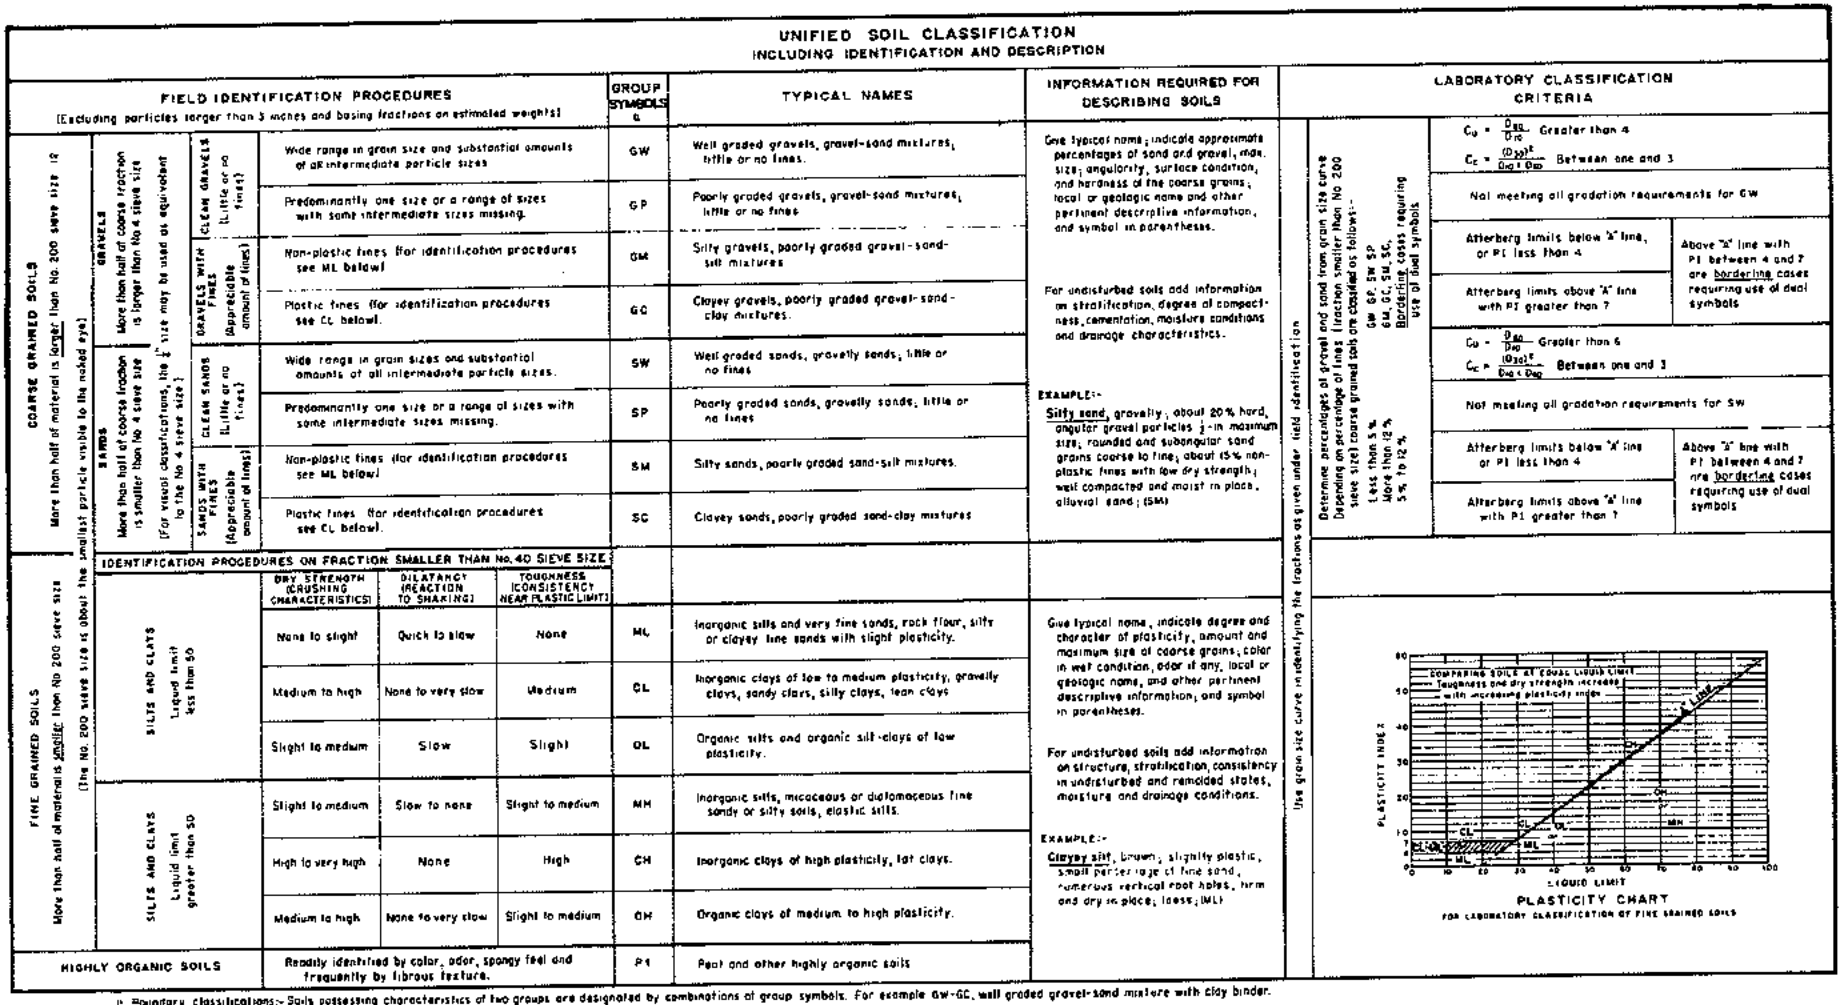
The sizes of samples required depend on the nature of the laboratory tests which may be required. The size of the samples will be determined by the laboratory doing the soil mechanics testing. Table 5-4 may be used as a guide.

Disturbed samples should be placed in bags or other suitable containers which will prevent loss of moisture and the fine fraction of the soil. Samples of silty and clayey soils proposed for borrow which are obtained for laboratory Atterberg limits test and Proctor compaction tests should be protected against drying and should be shipped in waterproof bags or other suitable containers to retain the natural moisture.

5. Special Consideration

Certain geologic conditions require special consideration beyond the minimum explorations. They are:

(a) subsidence — the potential for surface subsidence due to past or future solid, liquid (including ground water) or gaseous mineral extraction. In certain relatively dry fine-grained colluvial soils in southwestern North Dakota, sudden subsidence may take place upon saturation and loading. Suspected soils should be examined and brought to the attention of the designer;



(b) emergency spillways — relatively large dams with emergency spillways in soft rock or cemented soil materials that cannot be classified as soil nor as rock as generally defined for engineering purposes, and spillways in rock with defects require special and individual evaluation;

(c) mass movements — landslides and landslide potential at dam and reservoir sites, especially those in shales. Summarize the history of mass movement in the project area. Emergency spillway cuts and full reservoir effects must be given careful consideration;

(d) multi-purpose dams — the ground water and hydraulic characteristics of the entire reservoir area should be evaluated for leakage, and water budgets developed to determine if reservoir sealing is needed; and

(e) other — special studies and evaluations may be necessary where shales, dispersive soils, coal seams, and artesian water occur at a site. The economic and physical impacts of the pre-emption of mineral deposit, sand, gravel, coal, and oil by a reservoir should also be evaluated.

Figure 5-3. Unified Soil Classification Chart

UNIFIED SOIL CLASSIFICATION
INCLUDING IDENTIFICATION AND DESCRIPTION

FIELD IDENTIFICATION PROCEDURES (Excluding particles larger than 3 inches and basing fractions on estimated weights)				GROUP SYMBOLS	TYPICAL NAMES	INFORMATION REQUIRED FOR DESCRIBING SOILS	LABORATORY CLASSIFICATION CRITERIA
COARSE GRAINED SOILS: More than half of material is larger than No. 200 sieve size (The No. 200 sieve size is about the smallest particle visible to the naked eye)	GRAVELS: More than half of coarse fraction is larger than No. 4 sieve size (For visual classifications, the ¼" size may be used as equivalent to the No. 4 sieve size.)	CLEAN GRAVELS (Little or no fines)	Wide range in grain size and substantial amounts of all intermediate particle sizes	GW	Well graded gravels, gravel-sand mixtures, little or no fines.	Give typical name; indicate approximate percentages of sand and gravel, max. size; angularity, surface condition, and hardness of the coarse grains; local or geologic name and other pertinent descriptive information, and symbol in parentheses. For undisturbed soils add information on stratification, degree of compactness, cementation, moisture conditions and drainage characteristics. EXAMPLE:- Silty sand, gravelly; about 20% hard, angular gravel particles ½-in. maximum size; rounded and subangular sand grains coarse to fine; about 15% non-plastic fines with low dry strength; well compacted and moist in place; alluvial sand; (SM)	Determine percentages of gravel and sand from grain size curve. Depending on percentage of fines (fraction smaller than No. 200 sieve size) coarse grained soils are classified as follows:- Less than 5%: GW, GP, SW, SP More than 12%: GM, GC, SM, SC 5% to 12%: Borderline cases requiring use of dual symbols $C_U = \frac{D_{60}}{D_{10}}$ Greater than 4 $C_C = \frac{(D_{30})^2}{D_{10} \times D_{60}}$ Between one and 3 Not meeting all gradation requirements for GW Atterberg limits below "A" line, or PI less than 4 — Above "A" line with PI between 4 and 7 are borderline cases requiring use of dual symbols Atterberg limits above "A" line with PI greater than 7 $C_U = \frac{D_{60}}{D_{10}}$ Greater than 6 $C_C = \frac{(D_{30})^2}{D_{10} \times D_{60}}$ Between one and 3 Not meeting all gradation requirements for SW Atterberg limits below "A" line or PI less than 4 — Above "A" line with PI between 4 and 7 are borderline cases requiring use of dual symbols Atterberg limits above "A" line with PI greater than 7
			Predominantly one size or a range of sizes with some intermediate sizes missing.	GP	Poorly graded gravels, gravel-sand mixtures, little or no fines.		
		GRAVELS WITH FINES (Appreciable amount of fines)	Non-plastic fines (for identification procedures see ML below)	GM	Silty gravels, poorly graded gravel-sand-silt mixtures		
			Plastic fines (for identification procedures see CL below).	GC	Clayey gravels, poorly graded gravel-sand-clay mixtures.		
	SANDS: More than half of coarse fraction is smaller than No. 4 sieve size	CLEAN SANDS (Little or no fines)	Wide range in grain sizes and substantial amounts of all intermediate particle sizes.	SW	Well graded sands, gravelly sands, little or no fines		
			Predominantly one size or a range of sizes with some intermediate sizes missing.	SP	Poorly graded sands, gravelly sands, little or no fines		
		SANDS WITH FINES (Appreciable amount of fines)	Non-plastic fines (for identification procedures see ML below)	SM	Silty sands, poorly graded sand-silt mixtures.		
			Plastic fines (for identification procedures see CL below).	SC	Clayey sands, poorly graded sand-clay mixtures		
FINE GRAINED SOILS: More than half of material is smaller than No. 200 sieve size (The No. 200 sieve size is about the smallest particle visible to the naked eye)	IDENTIFICATION PROCEDURES ON FRACTION SMALLER THAN No. 40 SIEVE SIZE						
		DRY STRENGTH (CRUSHING CHARACTERISTICS)	DILATANCY (REACTION TO SHAKING)	TOUGHNESS (CONSISTENCY NEAR PLASTIC LIMIT)			
	SILTS AND CLAYS: Liquid limit less than 50	None to slight	Quick to slow	None	ML	Inorganic silts and very fine sands, rock flour, silty or clayey fine sands with slight plasticity.	Give typical name, indicate degree and character of plasticity, amount and maximum size of coarse grains; color in wet condition, odor if any, local or geologic name, and other pertinent descriptive information; and symbol in parentheses. For undisturbed soils add information on structure, stratification, consistency in undisturbed and remolded states, moisture and drainage conditions. EXAMPLE:- Clayey silt, brown; slightly plastic, small percentage of fine sand, numerous vertical root holes, firm and dry in place; loess; (ML)
		Medium to high	None to very slow	Medium	CL	Inorganic clays of low to medium plasticity, gravelly clays, sandy clays, silty clays, lean clays	
		Slight to medium	Slow	Slight	OL	Organic silts and organic silt-clays of low plasticity.	
	SILTS AND CLAYS: Liquid limit greater than 50	Slight to medium	Slow to none	Slight to medium	MH	Inorganic silts, micaceous or diatomaceous fine sandy or silty soils, elastic silts.	
		High to very high	None	High	CH	Inorganic clays of high plasticity, fat clays.	
		Medium to high	None to very slow	Slight to medium	OH	Organic clays of medium to high plasticity.	
HIGHLY ORGANIC SOILS		Readily identified by color, odor, spongy feel and frequently by fibrous texture.			PT	Peat and other highly organic soils	

Use grain size curve in identifying the fractions as given under field identification

PLASTICITY CHART
FOR LABORATORY CLASSIFICATION OF FINE GRAINED SOILS

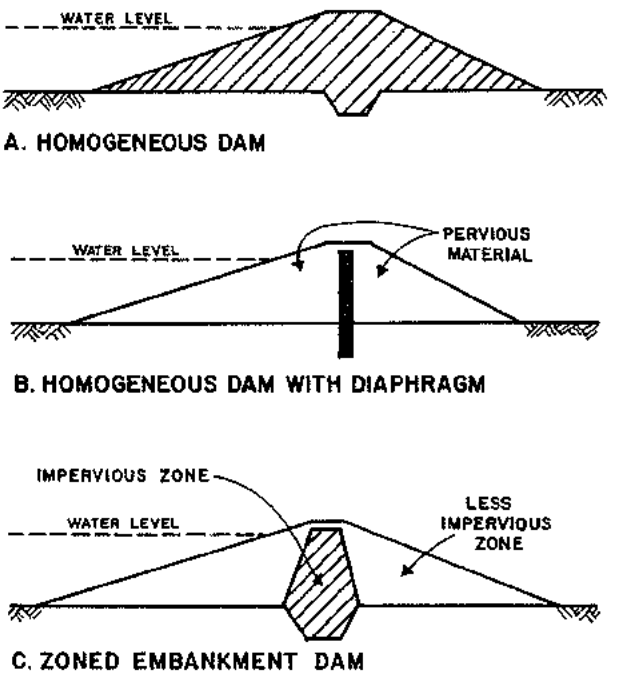
(a) Boundary classifications:- Soils possessing characteristics of two groups are designated by combinations of group symbols. For example GW-GC, well graded gravel-sand mixture with clay binder.
(b) All sieve sizes on this chart are U.S. standard.

ADOPTED BY - CORPS OF ENGINEERS AND BUREAU OF RECLAMATION - JANUARY 1952

Table 5-4. Recommended Sizes of Samples

Purpose of Material	Sample Size	Remarks
Individual and composite samples of disturbed earth materials for classification and proctor compaction tests.	Sufficient material, all passing the 3-inch sieve, to yield 75 pounds passing the No. 4 sieve.	Include information relative to the percentage by volume; 3 inches to 5 inches and plus 5 inches.
Soil-rock permeability tests.	300 pounds passing 3-inch sieve.	Air dried.
Relative density test.	150 pounds passing 3-inch sieve.	Air dried.
Moisture samples, inspection samples of soil, soil samples for sulfate determination.	Sealed pint or quart jars (full).	Individual inspection samples should represent range of moisture and type of materials.
Concrete aggregate.	600 pounds of pit-run sand if screened: 200 pounds of sand, 200 pounds of No. 4 to ¾-inch size, and 100 pounds of each of the other sizes produced, 400 pounds of quarry rock proposed for crushed aggregate.	For commercial sources, include data on plant ownership, and service history of concrete made from aggregates.
Riprap.	200 pounds representative of quality or examine at site.	Method of excavation used, location of sources of supply and size range.
In-place density and water content of fine-grained soils above water table.	8 to 12-inch cubes or cylinders.	Sealed in suitable container.

E. Embankment and Foundation Design



The embankment and foundation design standards are dependent upon the complexity of the individual dam and the design classification of the dam. Generally, design class I and II dams have homogeneous embankments, are constructed without extensive moisture control, and do not have foundation and embankment drains. Design class III dams often require some type of embankment drain, and may require extensive design details. Design class IV and V dams, however, usually require foundation and embankment drains and close control of moisture and density of the fill materials. These dams generally have either a zoned or modified homogeneous embankment. The information in this section was developed to provide general design considerations for all dams along with specific recommendations for design class IV and V dams.

1. Selection of Embankment Type

Rolled earthfill dams are constructed in successive mechanically compacted layers. There are three types: diaphragm, homogeneous, and zoned. Figure 5-4 shows examples of these three types of earth embankment.

With the diaphragm type, the major portion of the embankment consists of a pervious material. A relatively thin diaphragm of impermeable material is provided to form the water barrier. The location of this diaphragm may vary from a blanket on the upstream face to a central vertical barrier. It may be constructed of earth, soil-cement slurry, portland cement concrete, or other material. The blanket or core in an earthfill dam is considered to be a diaphragm if its horizontal thickness at any elevation is less than 10 feet. If the impervious earth zone equals or exceeds this thickness, the design is considered to be of the zoned embankment type. The construction of diaphragm-type earth embankments will be very limited in North Dakota. They should only be

Figure 5-4. Earthfill Embankment Types (drainage systems not shown)

used where the supply of impervious soil is so limited as to preclude the construction of the homogeneous or zoned embankment type of dam.

The homogeneous type of embankment is composed of a single type of material. The material comprising the dam must be sufficiently impervious to provide an adequate water barrier, and the slopes must be relatively flat for stability. The downstream slope of a homogeneous dam may eventually be affected by seepage to a height of roughly one-third the depth of the reservoir pool.

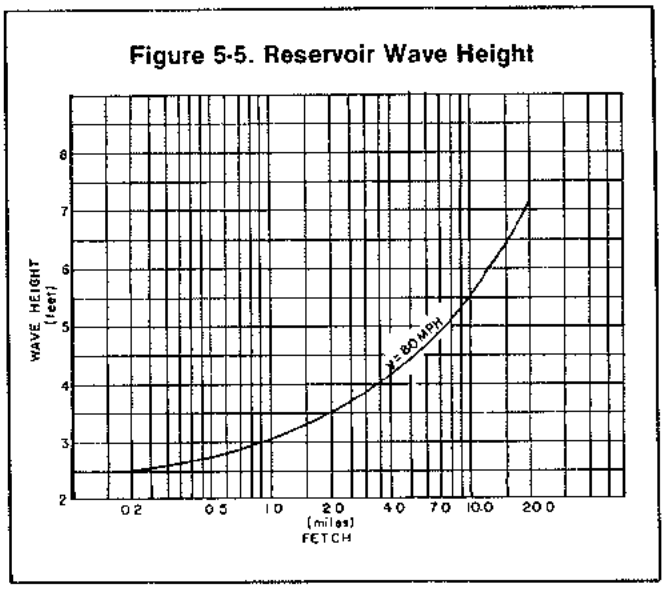
A common type of rolled earthfill dam has a central impervious core, and is flanked by zones of material considerably more pervious. The pervious zones enclose, support, and protect the impervious core; the upstream pervious zone affords stability against rapid drawdown; and the downstream pervious zone acts as a drain to control the line of seepage. For most effective control of seepage, the pervious sections should have, if possible, a progressive increase in permeability from the center to the outer slopes.

The type of rolled-fill dam section selected will primarily be determined by the materials found on the site. Where impervious material is in extremely short supply, a diaphragm type of section may be the only practical alternative. Where the only soil material on the site is impervious, the situation may dictate a homogeneous or modified homogeneous section. Where the materials on the site contain both pervious and impervious materials, the zoned section will probably be preferable because it generally allows steeper embankment slopes.

The designer will have to consider the type of materials which will be excavated from the cutoff trench and the emergency spillway, how these materials can best be used in the embankment design, and what configuration of materials used will result in the most economical section.

2. Foundation Cutoffs

Many of the rolled-earth dam sites contain foundations consisting of alluvial deposits of pervious sand and gravel or shale chips at or near the surface with an impervious stratum of rock, clay, or shale at a greater depth. A positive cutoff is recommended where the impervious stratum joins the foundation with the base of the impervious portion of the embankment. A positive cutoff is desirable, particularly where the water in storage is used for irrigation, municipal or industrial water supply.



Where a positive cutoff is impractical because of the depth to an impervious stratum, a partial cutoff may provide foundation stability and reduce seepage losses to acceptable levels. Regardless of the foundation conditions, the only way to determine the economical feasibility of a positive cutoff or various percentages of partial cutoff is to make a seepage analysis and water balance.

3. Height

The design height of an earth embankment should be sufficient to prevent overtopping during passage of either the freeboard hydrograph (see Table 5-1, page 5), or the velocity hydrograph, plus the freeboard required for wave action, whichever is larger. The design height of the dam should be increased by the amount needed to compensate for settlement. Therefore, the suggested dam height is equal to the greater of the following: (1) the elevation at the normal water level, plus the increase in water level resulting from a freeboard hydrograph event, plus an allowance for settlement; or (2) the elevation at the normal water level, plus the increase in water level resulting from velocity hydrograph event, plus an allowance for wave action, plus an allowance for settlement. The height of reservoir waves are a function of the length of the fetch and the velocity of the wind. Figure 5-5 shows the reservoir wave height based on fetch and an 80 mile per hour wind velocity. The following formula can be used to determine the wave height for other wind velocities:

$H_W = 2.5 + 0.17\sqrt{VF} - \sqrt[4]{F}$, where:
H_W = height of the wave in feet
V = wind velocity in miles per hour
F = length of the fetch in miles

Figure 5-5. Reservoir Wave Height

4. Top Width

The recommended minimum top width of the embankment is shown in Table 5-5.

The width may be greater than those shown above in order to accommodate embankment zoning, provide

Table 5-5. Suggested Minimum Top Width of Embankment

Dam Height (H) (Feet)	Top Width (Feet)
14 or less	8
15 - 19	10
20 - 24	12
25 - 34	14
35 - 95	(H + 35)/5
Over 95	26

roadway access and traffic safety and/or provide structural stability.

When the embankment top is used as a public roadway, the minimum width should be 16 feet for one-way and 26 feet for two-way traffic. Guard rails or other safety measures may be required and should meet the requirements of the state and county highway departments.

5. Berming

There are several reasons for the installation of berms on rolled-fill embankments. Berms may be needed to provide stability to the structure, particularly where the foundation is soft and weak. In this case, the berm or berms may be of considerable width.

Berms may be placed on either the upstream, downstream, or both faces of a dam to provide access to trash racks and instrumentation. Normally, the upstream face of the dam will have protection against destructive wave action and will require no additional protection against water draining off the embankment. However, the downstream face for dams over about 30 feet in height probably will require drainage berms to dispose of the embankment drainage without eroding the downstream face of the embankment. Downstream drainage berms can be thought of as terraces. They are designed to break up the length of the slope and should be analyzed as a terrace. The greater the length of the embankment, the closer the berms should be spaced and, conversely, the shorter the embankment, the further the berms may be spaced apart.

Surface drainage on the abutments and valley floor is easily overlooked in the design of earth dams. This may result in gullying at the contact of the embankment with earth abutments from which vegetation has been removed during the construction operations. This can be controlled by sod chutes, by a pipe outlet or by constructing a gutter along the contact consisting of coarse aggregate or small stones. An analysis should be made to make sure the expected velocities do not move the aggregate used to construct the gutter. Filter cloth should be installed under the rock material.

6. Foundation and Embankment Drainage

The impervious portion of an earthfill dam provides resistance to seepage which creates a reservoir. Soil varies in permeability, but even the tightest clays are porous and cannot prevent all seepage. Therefore, seepage control is a major concern in dam design. The filter and drainage system must have adequate permeability but still control piping through the embankment.

The percolation of reservoir water through the impervious section depends on the fluctuations of the reservoir level, the degree of permeability of the impervious material in the horizontal and vertical directions, the amount of remaining pore-water pressures caused by compressive forces during construction, and the element of time. The upper surface of seepage is called the phreatic surface; in a cross section it is referred to as a phreatic line. Although the soil may be saturated by capillarity above this line, giving rise to a "line of saturation," seepage is limited to the portion below the phreatic line.

Several terms will be used in this section:

Interceptor Drain — a drain that physically intercepts flow paths or fully penetrates water bearing strata.

Pressure Relief Drain — a drain that produces an area of low pressure to which water will flow from adjacent areas of higher pressure.

Filter Material — filter cloth or a layer or combination of layers of pervious materials designed and installed in such a manner as to provide for water movement, yet control movement of solid particles due to flowing water.

Drain Material — sand, gravel or rock that has specific gradation limits designed for required permeability and internal stability.

Base Material — any material (embankment, backfill, foundation, or other filter layer) through which water moves into a drainage system.

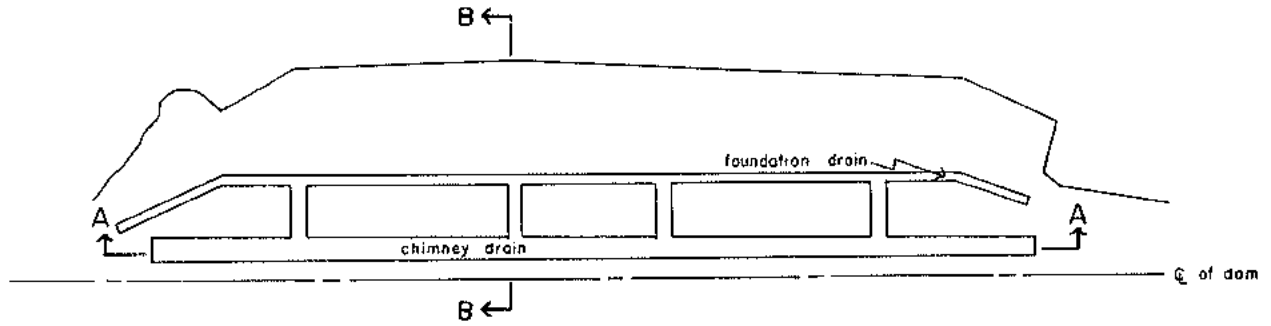
Coefficient of Permeability — the rate of discharge of water under laminar flow conditions through a unit cross-sectional area of a porous medium under a unity hydraulic gradient.

Drains are included in embankments and foundations for two basic reasons:

(a) to prevent piping by controlling migration of soil particles under seepage flow; and

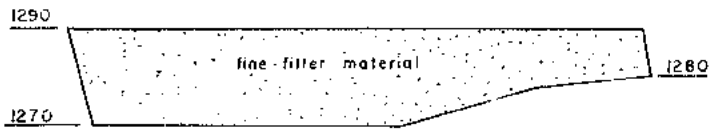
(b) to control pressure build-up by providing adequate capacity to carry the seepage flow.

There are no hard and fast rules for selecting a reasonable margin of safety for drain design. Judgment in this respect must be related to: (1) past experience with similar materials, (2) the detail used in site investigations and testing programs, and (3) the limitations of analyses in representing site conditions.



Where extensive drainage is required, the drainage cost can be a substantial part of the construction cost. For this reason, the designer should be aware of the availability of pervious materials on or near the construction site. Designing the drain to utilize local materials can result in substantial savings, even when processing is required.

Four types of drains and the site conditions are discussed below:



Chimney drains are primarily interceptors that provide positive control of embankment seepage. In this case, water that percolates through the soil is intercepted to ensure that seepage does not occur in materials downstream from the drain.

Chimney drains are applicable where the downstream embankment material cannot be allowed to saturate. The variability of soils in many borrow sources is so great that the engineering properties of the resulting fill cannot be determined with any reasonable degree of accuracy. It may be more economical to place these materials in a "random fill" zone downstream from a positive drain than to waste or disregard them. Materials suspect of undergoing marked and unpredictable changes upon saturation should be placed where they cannot become saturated. Soils containing concentrations of soluble salts and degradable shale derivatives are examples. Middle Branch Park River Detention Dam 10, designed by the Soil Conservation Service, utilizes a chimney drain (Figure 5-6).

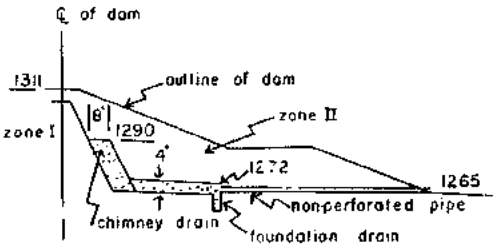


Figure 5-6. Chimney and Foundation Drain System (Middle Branch Park River Watershed Dam, #10-SCS)

PLAN VIEW CHIMNEY DRAIN AND FOUNDATION DRAIN

SECTION A-A. PROFILE OF CHIMNEY DRAIN

SECTION B-B

Chimney drains are also applicable where embankment materials are susceptible to cracking. In this case, water which comes primarily through cracks within the embankment is intercepted to prevent piping and to ensure the overall safety of the dam.

Another type of internal drain is the horizontal blanket drain. The horizontal blanket drain is primarily a pressure relief drain placed in the downstream area of an embankment. Horizontal blanket drains are applicable when: (1) there is no significant difference between the vertical and horizontal permeability of the embankment or the foundation; (2) when bedrock is pervious (drain placed directly on bedrock); or (3) when a good bond cannot be obtained between impervious bedrock and the embankment. Figure 5-7 shows a horizontal blanket drain.

Another type of drain is the foundation drain. The foundation drain is primarily a pressure relief drain. It is most effective when it penetrates all pervious strata. Foundation drains are applicable when the horizontal permeability of the foundation is significantly greater than the vertical permeability. It is often used to relieve pressure from foundation aquifers or to control pipeable foundation materials. Dead Colt Creek Dam near Lisbon, North Dakota utilizes a foundation drain (Figure 5-8).

The final type of drain is pressure relief wells. These wells are generally located near the downstream toe of an embankment for accessibility. Relief wells are particularly adapted for control of pressures from confined and alluvial aquifers that are too deep to drain with foundation drains. Pressure relief wells are often used

in conjunction with the foundation drain as shown in Figure 5-9.

Drain outlets are needed to conduct the accumulated seepage from the embankment or foundation drain to a controlled discharge point. It is recommended that separate outlets be provided for foundation, abutment, embankment and structure drains for ease of monitoring.

There are several special situations which do not conveniently fit any of the four types of drains discussed above. These are:

(a) Embankment Zones — When an embankment zone is to function as a drain, material placed in that zone must meet the permeability and piping requirements for drain material. On-site materials generally contain enough fines to limit permeability. Permeability determinations and flow nets will provide guidance on the effectiveness of these materials for drainage zones.

(b) Springs — It may be necessary to increase the capacity of drains to accommodate flow from springs. In many cases, it is desirable to provide separate drainage outlets for springs.

(c) External Abutment Drains — Drains outside the limits of an embankment should be designed by the procedures used for drains placed under embankments.

(d) Abutment Well Drains — These are either horizontal or slanted wells for drainage of deeply fractured rock abutments and other deep, pervious abutment materials. Design procedures are beyond the scope of this handbook. For detailed information on site investigation requirements and design procedures and considerations, consult soil mechanics textbooks or specialized manuals, and soil mechanics notes issued by the Bureau of Reclamation, Corps of Engineers, or Soil Conservation Service.

Two recent, excellent discussions on this subject are part of the Journal of Geotechnical Engineering, Vol. 110, No. 6, June, 1984. These papers, authored by Sherard, Dunnigan, and Talbot, are entitled: "Basic Properties of Sand and Gravel Filters" and "Filters for Silts and Clays."

7. Structural Stability

Potential failure from sliding, sloughing or rotation should be analyzed and documented. Embankment and foundation design and geotechnical exploration should be consistent with the complexity of the site and the potential for failure. Anticipated settlement, seepage, and cracking should also be considered and documented.

A seismic coefficient of 0.05 should be used for the entire state of North Dakota in a slope stability analysis. The seismic coefficient is the fraction of a weight to be used as a horizontal force in a quasi-static analysis.

At the present time, various procedures are available for calculating the factors of safety of embankment sections. Generally, the basic methods include either the circular arc or the sliding wedge method or both. However, in lieu of the circular arc, the logarithmic spiral method and the sliding wedge method may be modified by use of various arcs, lines of radii of curvature, or composite curves.

The slope stability criteria used in this manual is that used by the SCS. Other agencies or textbooks have excellent discussions and criteria for slope stability, although they often use different nomenclature. The nomenclature used by the SCS for the various shear tests and that commonly used by the geotechnical profession are shown in Table 5-6.

Analyses are to be made for the conditions that are most critical during the design life of the structure. Conditions analyzed are based on various water and loading conditions of the embankment and foundation. The following conditions should be considered: (1) end of construction; (2) steady seepage; (3) rapid drawdown; and (4) seismic. For each case, the analysis should be based on the shear strengths shown in Table 5-7. Minimum safety factors for each condition are also shown in the table. The factor of safety calculations should be based on the ratio of the shear strength available to the shear strength mobilized.

Table 5-6. Nomenclature of Shear Strength Tests

Test Condition	Common Literature Description	Reference for Suggested Test Procedure
Unconsolidated, Undrained	UU or Q	ASTM D2850
Consolidated, Undrained	CU or R	[1] [2]
Consolidated, Undrained with Pore Pressures Measured	CU or R	[1] [2]
Consolidated, Drained	CD[3] or S	[1] [2]

[2] U.S. Army Corps of Engineers, "Laboratory Soils Testing," EM 1110-2-1906, Washington, D.C, 1970.

[3] If the CD tests are run slow enough, the shear strength parameters obtained may be used in lieu of CU parameters.

8. Protection of Embankment Surface

It is generally necessary to provide some protection to the upstream face of a dam. Design class I and II dams seldom need more than vegetative protection on the upsteam face. The orientation and length of the permanent pool, the purpose of the reservoir, and the duration of stages in flood control pools all affect the need for and the type of embankment protection.

Protection for design class III, IV and V dams may consist of rock riprap, either dumped or hand-placed, soil cement, scoria or combinations of the above. Scoria is generally not used if rock is available as it breaks down easily through weathering and requires considerable maintenance. Rock riprap should consist of hard durable rock, well graded, placed at a minimum thickness of 18 inches on 6 inches of well-graded gravel or a layer of engineering fabric (filter cloth).

Judgment is required in the design of the vertical height of the riprap. The ultimate in protection would be to riprap the face of the dam from the toe to the crest, which has been done on some large Corps projects in North Dakota. This is expensive and may not be justified on smaller dams. An alternative for protection above the principal spillway would be to riprap the portion of the embankment that would be underwater for a 48-hour period during the principal spillway design event (Table 5-1, page 5), plus an allowance for wave height (Figure 5-5, page 13). Steep embankment slopes and erodible soils may require additional protection.

The protection below the normal pool elevation is dependent upon several factors including the purpose of the reservoir and the base flow of the inflow stream. A water supply reservoir will generally have a wide range of stages during the year due to withdrawals. A recreation dam on a stream with a base flow may only require riprap from three feet below the permanent reservoir elevation. The same type of reservoir on a stream with little base flow may require that the riprap extend six or more feet below the permanent elevation. Recreation reservoirs are subject to wave action from boats and water-skiers and, therefore, it is necessary to provide adequate riprap above and below the normal reservoir water level.

Recommended references on slope protection include the Soil Conservation Service Technical Release No. 56, "A Guide for Design and/or Layout of Vegetative Wave Protection for Earth Dam Embankments," and No. 69, "Riprap for Slope Protection Against Wave Action."

9. Instrumentation

Instrumentation can significantly improve the overall safety of a dam by providing continuous surveillance of the structure. Instrumentation is normally associated with large - high hazard dams, but it is also used in dams with unusual design features. The State Engineer recommends that instrumentation be incorporated into all class V dams and that it be considered for all class IV dams.

Instrumentation refers to the method and equipment used to make physical measurements of dams. Instrumentations is not, however, a substitute for inspection, but is a supplement to visual observations and inspections. Visual examinations are aided by monitoring instruments that measure seepage and leakage through and around the embankment, movements of the embankment and foundation, and water levels and pressures within the embankment and the foundation. Adequate records of such measurement devices, along with the visual observations, should be maintained. To be effective, these records should be continuous and periodically reviewed by a professional engineer versed in the design and vulnerability of embankment structures. These reviewers should be able to distinguish the important indicators from the unimportant. A tendency toward change in behavior of the dam should signal a need for further review and analyses.

Measurements and readings should be taken frequently during construction and after completion of the project. The number of measurements may be reduced if the structure performs satisfactorily. If the structure shows any tendency toward weakness or unsatisfactory performance, the time interval between measurements should be shortened appropriately to provide analytic data that can warn of impending problems. Post-construction monitoring should continue for several cycles of reservoir operation to document cyclic changes.

There are three general types of instruments used to monitor dams. These include seepage monitoring instruments, embankment movement instruments and water pressure instruments (piezometers). Table 5-8 provides additional information on various monitoring instruments.

a) Seepage and Leakage

All dams will leak to varying degrees, but every leak should be monitored and recorded. If there is a flow, the quantity flowing should be measured by creating a drop and installing a pipe, a v-notched weir, a weir, or a flume. A record should be kept of the discharge and the reservoir elevation. Toe and/or foundation drains should

Table 5-7. Slope Stability Criteria for Dams (Dam Design Class III, IV, and V only)

Design Condition	Primary Assumption	Remarks	Shear Strength To Be Used 1/2/	Minimum Factor of Safety (Dam Design Class)
I. End of construction	Significant construction pore pressures expected	1. Embankment containing impervious soils at water contents equal to or greater than the optimum water content and/or 2. Saturated impervious foundation strata too thick to consolidate during construction	UU	1.4 (all classes) (1.3 is acceptable for embankments on strong foundations, i.e., the failure surface is located entirely in the embankment)
	For soil zones where significant construction pore pressure is not expected	pervious embankment zones and/or foundation strata	$\overline{CU}$ or CD	
II. Rapid drawdown	Drawdown from the emergency spillway crest to the crest of the lowest gated or ungated outlet	Failure surface can be confined to the embankment or extend into the foundation if low permeability soils are involved	Use alternative 1 or 2 below 1. Lowest shear strength from composite envelope of CU and $\overline{CU}$, or 2. Most limiting of CU 3/ and $\overline{CU}$	1.2 (all classes)
III. Steady seepage without seismic forces	1. Water surface at the principal spillway 2. Phreatic surface fully developed through the embankment	Failure plane confined to the embankment only	$\overline{CU}$ or CD	1.5 (class IV, V) 1.4 (class III)
	3. Piezometric surface for estimating uplift in saturated soil zones is determined with reservoir at the emergency spillway crest	Failure plane extends into the foundation	Most limiting 3/ of four combinations as follows: Comb. No. 1: Found Soil CU, Emb. Soil CU Comb. No. 2: Found Soil CU, Emb. Soil $\overline{CU}$ Comb. No. 3: Found Soil $\overline{CU}$, Emb. Soil $\overline{CU}$ Comb. No. 4: Found Soil $\overline{CU}$, Emb. Soil CU	1.4 (all classes) 1.4 1.5 1.5
IV. Steady seepage with seismic forces	1. Water surface at the crest of the principal spillway 2. Phreatic surface fully developed through the embankment	Failure plane may be confined to the embankment or may extend into the foundation	Most limiting 3/ of four combinations as follows: Comb. No. 1: Found Soil CU, Emb. Soil CU Comb. No. 2: Found Soil CU, Emb. Soil $\overline{CU}$ Comb. No. 3: Found Soil $\overline{CU}$, Emb. Soil $\overline{CU}$ Comb. No. 4: Found Soil $\overline{CU}$, Emb. Soil CU	1.0 (all classes) 1.0 1.1 1.1

1/ Always use $\overline{CU}$ or CD shear strength for pervious soil zones within the foundation or embankment.

2/ Use infinite slope stability analysis whenever the C or $\overline{C}$ intercept strength is zero for free draining soils that are tested to simulate low confining pressures. This situation exists for failure planes located near the embankment surface.

3/ Most limiting is the combination resulting the lowest factor of safety. Some combinations may be eliminated by inspection and judgement. Additional combinations may be necessary for some stratified foundations.

Table 5-8. Monitoring Instruments

Type	Purpose and Use	Remarks
1. Piezometers		
a) observation wells (hydraulic piezometer)	measures water height in a free stand pipe or vertical tube as a result of water pressure at the openings in the stand pipe.	a, b, c, e, j, and k
b) electronic piezometer	measures pore water pressure by deflecting a calibrated membrane and the deflection is measured electronically to give water pressure. It provides a check on seepage conditions and performance of the drainage system.	a, c, d, g, h, i, and j
c) gas pressure piezometer	measures pore water pressure by balancing it with pressurized gas in a calibrating unit. It also provides a check on seepage conditions and performance of the drainage system.	a, c, d, g, h, i, j, and l
2. Inclinometers	it is a vertical tube placed in the embankment after construction, and used to monitor internal displacements or movements within the embankment or foundation of usually higher dams. These movements will undoubtedly be detected before the effects appear on the surface. The system uses special casting with grooves on the inside at the quarter points.	c, f, and j
3. Triangulation and trilateration	iron pins and concrete monuments usually installed along an upper edge of the embankment and/or along a downstream slope. survey instruments are used to note location and elevations. Sometimes a base line can be set up and also points on the downstream slope of a dam. These distances can be checked then with an EDM.	
4. Tiltmeters	use to measure internal deformation rotational and tilting.	b, c, i, and j
5. Earth pressure cells	measures earth pressures at contact plane between soil and structure.	c, d, and j

REMARKS

a) can be used to determine phreatic line when a set of wells runs perpendicular to centerline.
b) can be installed after dam is completed.
c) the reservoir elevation should also be recorded.
d) usually installed during construction.
e) should be capped when not being read.
f) relatively expensive to install and monitor.
g) can be installed in the original foundation.
h) has a better response to small pressure changes than an observation well.
i) an engineer should be consulted to evaluate the soils and supervise the installation of piezometers.
j) each instrument reading should be plotted, graphed and compared to previous readings.
k) observation wells may be read in the following ways:
   (1) measuring tape with weight — record depth and length wetted from known top of case elevation;
   (2) placing air pipe and gage into well. Pressure indicates depth of water above lower end of pipe;
   (3) a graduated electric cord and current meter;
   (4) sonic sounder and recorder;
   (5) pressure transducer; and
   (6) float and recording drum.
l) gas appears to be more trouble-free than the electronic.

also be monitored and recorded along with the reservoir elevation. Any wet spots should be noted and the location, size and condition recorded.

b) Embankment Movements

Considerable movement of embankment dams can be anticipated during and immediately after construction. Much of the movement may be attributed to foundation settlement under the loading of the embankment. The embankment will also move as the reservoir is filled for the first time and may periodically cycle movements as the reservoir is emptied and filled in succeeding seasons. Movements are determined by periodic measurements of monuments placed in or on the structure and abutments. For existing dams, monumentation to measure movements is usually limited to the crest and downstream slopes. The monuments usually consist of steel rods or surveyor's markers imbedded in concrete placed in excavations on the embankment of the abutments. Differences in elevation and location of the monuments are measured by transit and level surveys of the monuments.

Measurements of the locations of the monuments on the surface of the embankment should be such that changes in both vertical and horizontal locations are measured. The measurements should be reduced to graphical displays of changes in vertical location, changes in horizontal location along the axis of the embankment, and changes in horizontal location transverse to the axis of the embankment (upstream and downstream). The water surface elevation in the reservoir at the time of measurement of the monument is important and should be recorded along with the

monument location data. Whenever possible the monuments should be tied to a bench mark that is outside the influence of the dam and reservoir. Monuments should be located such that they are not damaged by normal traffic or operations.

c) Piezometric Pressures

A primary indicator of the performance of an embankment is the water pressure distribution within the structure and its foundation. Water pressures in the embankments are measured by piezometers. There are basically three types of piezometers in common usage: (1) a hydraulic piezometer in which the water pressure is obtained directly by measuring the elevation of water standing in a pipe or vertical tube; (2) an electronic piezometer in which the water pressure deflects a calibrated membrane and the deflection is measured electronically to give the water pressure; and (3) a gas pressure unit in which the water pressure is measured by balancing it with a pressurized gas in a calibrated unit.

Piezometers should be installed in an embankment structure so that the location of the free water surface or phreatic line can be determined. The line of piezometers would be perpendicular to the longitudinal axis of the embankment. In large structures there may be several lines of piezometers, while in smaller structures and existing dams perhaps one line would be adequate.

F. Principal Spillway Design

1. General

The design standards and criteria for the principal spillway are primarily dependent on the dam design classification and purpose. Design classification I and II dams may not require a principal spillway, only a grassed emergency spillway. The requirement for a principal spillway on a small dam is more dependent on the drainage area and on the presence of base flow. If a class I or II dam does not need a principal spillway, it is advisable to include a small pipe to protect the vegetation in the emergency spillway from long duration flows. This pipe should be large enough to pass the normal summer flows.

It is suggested that the class III, IV, and V dams be designed in accordance with the hydrologic criteria shown in Table 5-1, page 5. In addition to these criteria, the following must be considered in determining the design capacity: (1) the purpose of the dam; (2) the amount of storage provided by the retarding pool; (3) the kind of emergency spillway; (4) the stream channel capacity and stability downstream; (5) the potential damage from prolonged storage in the retarding pool; (6) the potential damage from prolonged high outflow rates; (7) the possibility of substantial runoff from two or more storms before the retarding pool has emptied; (8) the limitations imposed by water rights or other legal requirements; (9) the environmental concerns; (10) the planned or potential alterations of the channel downstream; (11) the planned or potential development of the downstream floodplain; and (12) the necessity to pass base and flood flows during construction.

In addition to the principal and emergency spillways, downstream water rights may require a low level riparian outlet or an alternative method of water release. The required discharge capacity and frequency of use will normally determine the type of riparian release.

Corrugated metal pipes (CMP) are not recommended for design classification IV and V dams. When used in smaller dams, the CMP should be coated for longer life. The use of corrugated metal is more advisable for use in dry dams than dams with permanent storage. Design classification IV and V dams normally require concrete principal spillways — monolithic concrete box, concrete pipe, steel cylinder concrete pipe or a concrete chute.

The quality and type of concrete used in dams is also dependent on the design classification. Generally, 3,000 psi concrete is adequate for classes I, II and III dams. Air entrained 4,000 psi concrete is suggested for design class IV and V dams.

2. Types of Principal Spillways

There are two general types of principal spillways commonly used in North Dakota, a conduit (pipe or box culvert) and a chute spillway. Heart Butte Dam near Elgin, North Dakota, utilizes a conduit type main spillway (See Figure 5-10). Figure 5-11 shows the chute spillway system for Epping Dam in North Dakota.

a. Conduit Principal Spillway

Conduit spillways consist of an inlet structure, a closed discharge pipe or box culvert and an outlet structure or plunge pool. A conduit spillway can be used advantageously on most dams in North Dakota. One advantage of this type of spillway is that near maximum capacity is attained at relatively low heads. This characteristic makes the spillway ideal for use where the maximum spillway outflow is to be limited. However, there is little increase in capacity at higher reservoir levels.

The inlet structure should be designed: to maintain the reservoir pool level near the inlet crest elevation during low flood periods; to establish full pipe flow at as low a head as practical; and to operate without excessive surging, vibration, or vortex action. This requires the inlet to have a larger cross-sectional area than the main conduit.

Inlet structures should be designed to exclude trash too large to pass freely through the spillway and the outlet structure. Trash racks should be designed to provide positive protection against clogging of the spillway under any operating level. The average velocity of flow through a clean trash rack should not exceed 2.5 feet per second under the full range of stage and discharge. Velocity should be computed on the basis of the net area of opening through the rack.

If the inlet structure is used to keep the sediment pool drained, the trash rack or riser should extend above the anticipated sediment elevation. The velocity through the net area of the trash rack should not exceed two feet per second when the water surface is five feet above the top of the trash rack or riser inlet.

For small design class I and II dams and for dry dams, the inlet structure may consist of only a flared section or a hooded-inlet to improve the hydraulic efficiency of the conduit entrance. An inlet weir box is commonly

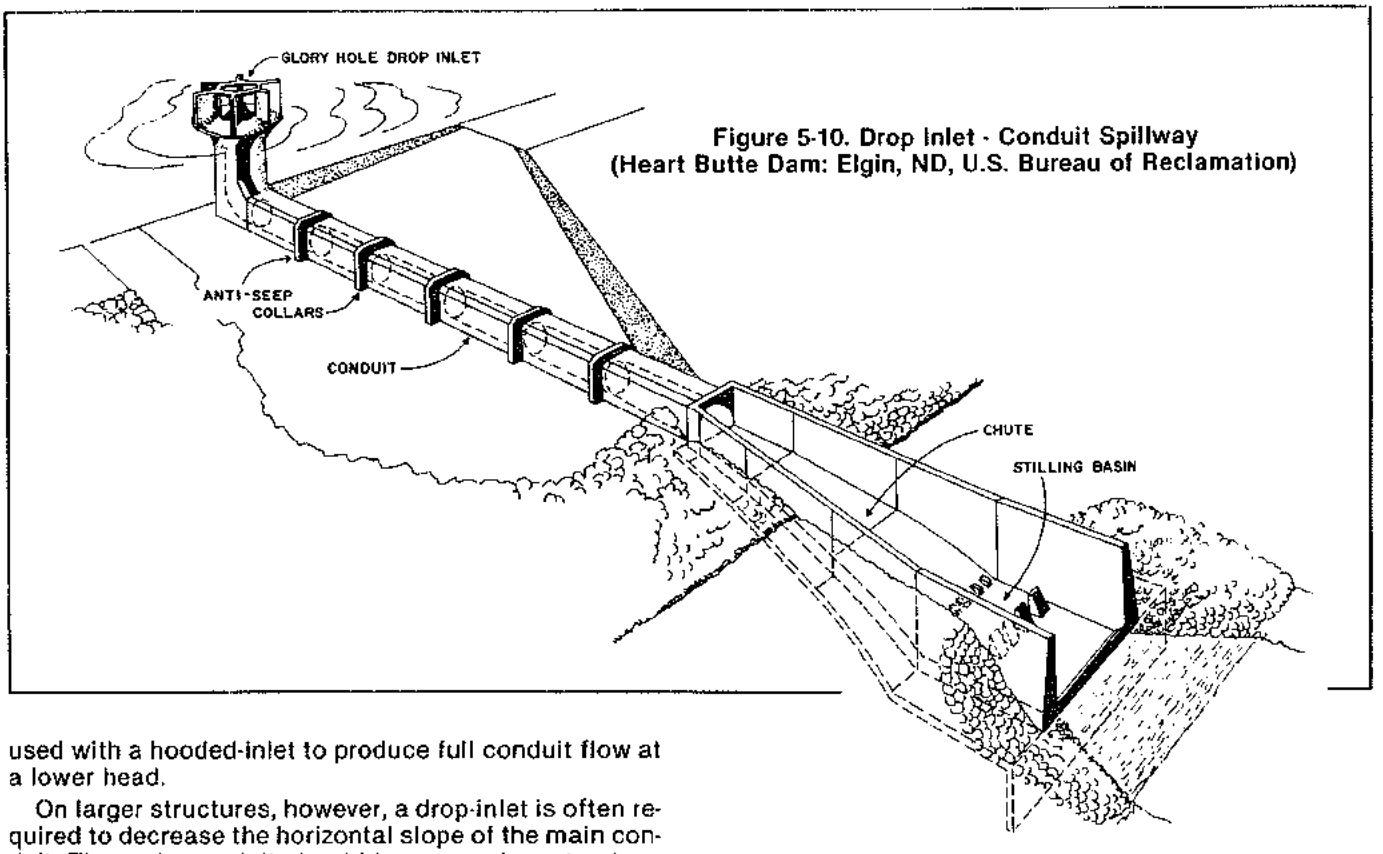

Figure 5-10. Drop Inlet - Conduit Spillway (Heart Butte Dam: Elgin, ND, U.S. Bureau of Reclamation)

used with a hooded-inlet to produce full conduit flow at a lower head.

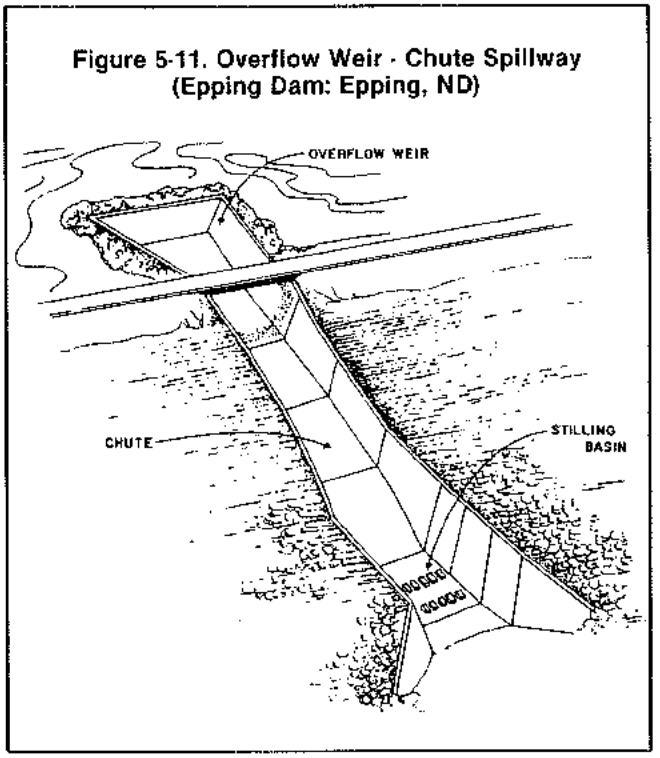
On larger structures, however, a drop-inlet is often required to decrease the horizontal slope of the main conduit. The main conduit should have an adequate slope to ensure free drainage of all sections of the conduit including camber, but the maximum slope should not exceed five percent. The drop-inlet structure should be designed to structurally withstand all water, earth, ice, and earthquake loads to which they may be subjected. Figure 5-12 shows the drop-inlet structure for Dead Colt Creek Dam located near Lisbon, North Dakota.

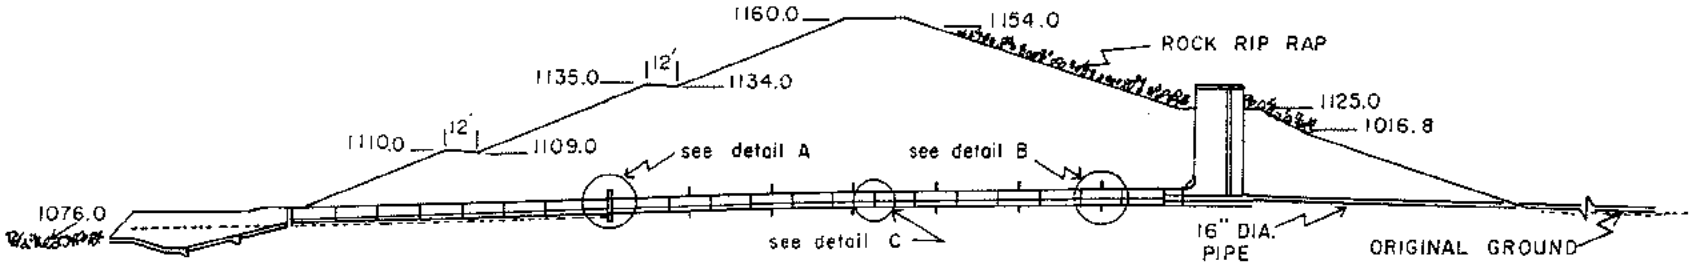
Standard drop-inlet structures have been developed by the Soil Conservation Service. These have an inside width equal to the diameter of the conduit and an inside length equal to three times the diameter of the conduit. All closed conduit spillways designed for pressure flow require adequate anti-vortex devices.

The conduit should be straight in alignment when viewed in plan. Changes from straight alignment should be accomplished by watertight angle changes at joints or by special elbows having a radius equal to or greater than the diameter of the conduit. Thrust blocks are to be provided if special pipe elbows are used. Thrust blocks distribute the thrust caused by change in direction, providing for the maximum possible discharge.

Discharge characteristics of the drop-inlet spillway may vary with the range of the head. The control will shift according to the relative discharge capacities of the weir, the transition, and the conduit. Therefore, hydraulic model testing should be considered if the maximum total head on the spillway is more than 40 feet or if the conduit velocity exceeds 40 feet per second.

Conduits under earth embankments must support the external loads with an adequate factor of safety. They must withstand the internal hydraulic pressure without leakage under full external load and settlement and





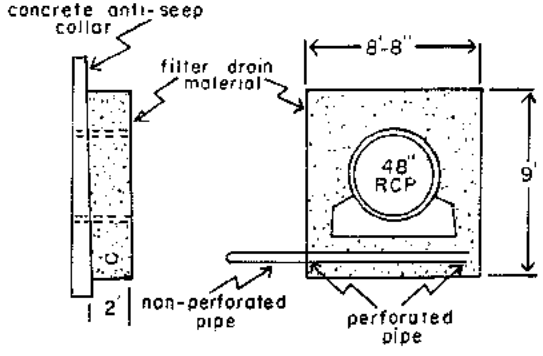


Figure 5-11. Overflow Weir - Chute Spillway (Epping Dam: Epping, ND)

convey water at the design velocity without damage to the interior surface of the conduit. Rigid principal spillway conduits should be designed as positive projecting conduits.

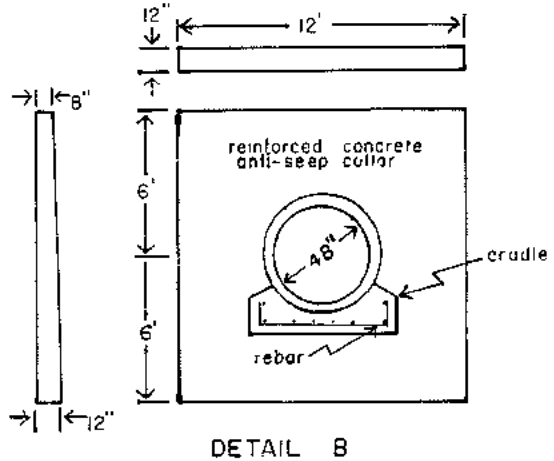

Figure 5-12. Conduit Spillway with Anti-Seep Collar and Concrete Cradle (Dead Colt Creek Dam: Lisbon, ND)

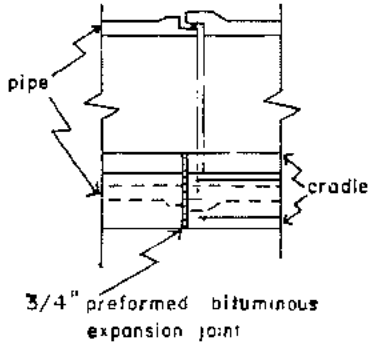

EMBANKMENT ELEVATION VIEW

(not to scale)

DETAIL B
ANTI-SEEP COLLAR
AND CONCRETE CRADLE
(not to scale)

DETAIL C
PIPE AND CRADLE JOINT
(side view)
(not to scale)

The material used for the conduit should be determined by the size of the dam, the economic life of the dam, and the relative ease of replacement. Class IV and V dams should utilize precast reinforced concrete pipe or cast-in-place rectangular reinforced concrete box culverts.

Concrete cradles are recommended under all concrete pipes. It is important to articulate the cradle at all joints. Figure 5-12 shows the concrete cradle design for the Dead Colt Creek Dam near Lisbon, North Dakota.

If corrugated metal pipes are used in larger dams, the joints should be electrically bridged on the outside of the pipe with insulated copper wire, No. 6 AWG or larger, securely attached to the uncoated pipe metal at both sides of the joint. The wire should have a tough waterproof insulation designed for direct burial, with a rating of at least 600 volts. Bare wire and exposed pipe metal at the point of connection should be thoroughly coated with a coating equivalent to the original pipe coating, to prevent the entry of moisture.

Geophysical exploration utilizing electrical resistivity and pH (soil acidity) of the subgrade and backfill materials to be adjacent to the conduit should be made. Resistivity measurements should be made on saturated samples. Cathodic protection should be provided for corrugated steel pipe in soil whose resistivity in a saturated condition is less than 4000 ohms cm or whose pH is lower than five.

Conduits should be designed and constructed to remain watertight under maximum anticipated hydrostatic head and maximum probable joint opening, including the effects of joint rotation and the required margin of safety. The required joint extensibility in concrete pipes is equal to the unit horizontal strain in the earth adjacent to the conduit, multiplied by the length (in inches) of the section of conduits between joints, plus the extension (in inches) due to calculated joint rotation, plus a margin of safety. A margin of safety of not less than 0.5 inch should be used.

The required joint extensibility, plus the maximum permissible joint gap, equals the required joint length. The required joint extensibility depends on the maximum potential foundation consolidation under the spillway barrel. For class IV and V dams, the consolidation should be estimated from adequate foundation borings and samples, soil mechanics laboratory tests, and engineering analysis. For class II dams, where undisturbed foundation samples are not taken for other purposes, approximate procedures based on soil classification and experience may be used for estimating foundation consolidation.

Only joints incorporating a round rubber gasket set in a positive groove should be used on precast concrete pipe conduits. Concrete pipe should have steel joint rings providing rubber to steel contact in the joint.

Articulation of the conduit (freedom for required rotation) should be provided at each joint in the conduit, at the junction of the conduit with the riser and at any outlet structure.

Piping and seepage control around the conduit is an important consideration. For many years, anti-seep collars were required on conduits passing through earth embankment dams. Although no longer used in all dams, anti-seep collars are still an acceptable method for seepage control. When used, the anti-seep collars should be designed such to extend the seepage path by 15 percent through the saturated zone. The major disadvantage of anti-seep collars is that it is difficult to compact earth directly against the concrete structure. A large amount of compaction by hand labor is needed. An alternative to anti-seep collars is a filter drain around a section of the conduit. However, conduit filter drains still require manual compaction around the conduit.

The Dead Colt Creek Dam utilizes both anti-seep collars and a conduit filter drain. Figure 5-12 also shows the embankment and principal spillway of the project including details of the anti-seep collars and the conduit filter drain.

Foundation drains and embankment chimney drains that meet the minimum size and location limits are sufficient without a separate filter drain. The use of anti-seep collars is recommended if a drainage system is not utilized in the structure.

When spillway flows drop from the reservoir pool level to the downstream outlet channel level, the static head is converted to kinetic energy. This energy manifests itself in the form of high velocities which, if not impeded, results in erosion. Means of returning the flow to the river without serious scour or erosion to the toe of the dam or damage to adjacent structures must be provided.

The choice of the type of outlet structure should be based on a careful consideration of all site and flow conditions that may affect operation and energy dissipation. The following guidelines should be considered in selecting the type of outlet structure:

- Cantilever outlet and plunge pools may be installed where their use does not create a piping hazard in the foundation, and where they are compatible with other conditions. Plunge pools are to be designed to dissipate the energy and to be stable. Unless the pool is to be in bedrock or very erosion resistant materials, riprap will be necessary to ensure stability.

  Cantilever outlets should be supported on bents or piers and are to extend a minimum of eight feet beyond the bents or piers. The bents are to be located downstream from the intersection of the downstream slope of the earth embankment, with the grade line of the channel below the dam. They should extend below the lowest elevation anticipated in the plunge pool. The invert of the cantilever outlet should be at least one foot above the tailwater elevation at maximum discharge.
- Saint Anthony Falls (SAF) basins may be used where they are economical and where there is adequate control of tailwater. Care must be taken to ensure that the outlet channel is properly designed and is constructed in accordance with the design. Riprap may be required to ensure that the design tailwater is maintained.
- Impact basins may be used when positive measures are taken to prevent large debris from entering the conduit.

b. Chute Spillway

Chute spillways ordinarily consist of an entrance

channel, a control structure and an outlet channel. The U.S. Bureau of Reclamation's "Design of Small Dams" is an excellent reference.

Favorable factors influencing the selection of chute spillways are: the simplicity of their design and construction, their adaptability to almost any foundation condition, the overall economy obtained by using the spillway excavation in the embankment, and the high discharge-head ratio possible. The disadvantages to chute spillways stem primarily from settlement and uplift problems which may require structure drainage. Chute spillways provide only very limited flood control advantages.

G. Emergency (Secondary) Spillway Design

1. Location

Emergency spillways, whenever possible, should be located away from the dam in an undisturbed area. Topographic saddles generally make good sites. The layout and profile of vegetated or earth spillways should provide a maximum bulk of material to ensure safety against breaching of the spillway during the passage of the freeboard hydrograph.

2. Design Considerations

Excavated spillways consist of three elements: the inlet channel (sometimes referred to as the forebay), the control section, and the exit channel.

The relationship between the water surface elevation in the reservoir and the discharge through the emergency spillway should be evaluated by computing the head losses in the inlet channel upstream of the control section. If a control section is not used, the spillway should be evaluated by computing the water surface profile through the full length of the spillway. Bernoulli's equation and Manning's formula should be used to evaluate friction losses, compute water surface profiles and determine velocities. Subcritical flow exists in the inlet channel. The flow conditions change to critical in the control section.

It is recommended that the inlet channel be level for a minimum distance of 30 feet upstream from the control section. This level part of the inlet channel should be the same width as the exit channel, and its centerline should be straight and coincide with the centerline of the exit channel. A curved centerline is permissible in the inlet channel upstream from the level section, but it must be tangent to the centerline of the level section.

The centerline of the exit channel must be straight and perpendicular to the control section for a distance equal to at least one-half of the maximum base width of the dam. Curvature may be introduced below this point, provided that the flowing water will not impede on the dam should the channel fail at the curve.

The exit channel should be as long as is reasonably practical. It should be of sufficient slope to ensure supercritical flow for all discharges greater than 25 percent of the freeboard hydrograph flows. It is also recommended that the ground-water level be determined in the emergency spillway area. If the ground-water table is at or near the surface, or if the emergency spillway outlet channel intercepts the water table, a drainage system may be necessary.

The maximum velocity limitations for vegetated channels apply to the exit channel (See Table 5-2, page 6). They should not be exceeded in the reach, where an exit channel failure might cause the flow to impinge on the toe of the dam. The velocity limitations are based on the maximum discharge in routing the velocity hydrograph, and on the assumption that uniform flow conditions exist in the exit channel.

H. Design Documentation

All dams that require a construction permit application will also require a minimum amount of documentation. The documentation will be commensurate with the dam classification. The State Engineer may request additional information on a case-by-case basis.

The minimum requirements for class I and II dams include:

- site location map;
- drawings showing dam height, top width, side slopes, and the size, location and elevation of the spillways;
- hydrology runoff computations including drainage area, watershed time of concentration, and other information;
- description of soils analysis; and
- specifications or reference to standard specifications.

It is suggested that a Design Documentation Folder be completed for all class III, IV and V dams designed by those engineering organizations and firms involved in dam design in North Dakota. The level of documentation required by the State Engineer in the review of the permits will vary with the dam design class and other factors. The following is an example outline of a Design Documentation Folder.

DESIGN DOCUMENTATION FOLDER

INDEX

General

- Preliminary Investigation Report
- Structure classification (including a narrative to justify classification)
- Copies of permits

Hydrology

- Watershed map (USGS quad map)
- Runoff infiltration parameter computations
- Time of concentration computations
- Routing parameter computations
- Hydrologic model results
- Historical flood data, if available
- Runoff yield studies, if needed

Hydraulics

- Water surface profiles for tailwater calculations and outlet channel stability check
- Breach routings (class IV and V only)
- Any special routings made for structure evaluation or structure discharges less than the design discharge (For example: check drop spillway design and tailwater at 25, 50 and 75 percent of peak design discharge.)
- Reservoir operation plan, if needed

Geology

- General geology of the area
- Soils explorations
  - — centerline of dam
  - — conduit location
  - — emergency spillway cut
  - — borrow area(s)
- Sediment capacity calculations

Soil Mechanics

- Soil mechanics report
- Slope stability analysis
  - — Design assumptions (full drawdown upstream, steady seepage downstream or drained downstream slope)
  - — Shear strength (from shear testing, correlated from previous dams, based upon geologic descriptions)
- Seepage analysis, as needed
- Foundation settlement (percent consolidation used for each layer)
- Foundation treatment (trench depths, stripping depth, removal of pockets, bedrock treatment)
- Analysis of borrow material (expected compacted values and strengths)
- Construction
  - — compaction and moisture requirements
  - — specific equipment or construction techniques
  - — critical inspection points
- Instrumentation of embankment, as needed

Structural Design

- Uplift calculations
- Overturning calculations, if needed
- Structural design calculations (reinforced concrete, steel or wood design)
- Loading checks on standard details
- Pipe joint elongation calculations
- Camber calculations
- Structure instrumentation plans, as needed

Site Protection and Restoration

- Landscape considerations of visual resource and visual resource quality, as needed
- Biological considerations (water quality, wildlife habitat, fish development), as needed
- Vegetation and seeding requirements
- Temporary and permanent erosion control measures

Quantity Calculations

Include quantity calculations for all individual elements including appropriate sketches and cross sections

Project Plans and Specifications

- Bid proposal
- Complete set of construction drawings and specifications
- Engineer's cost estimate
- Construction schedule

CHAPTER VI:

Modification of Existing Structures

There are several events that might require dam modification. Additional storage may be required for a variety of reasons: modification may be desirable for aesthetic reasons when the area adjacent to the dam has or will become developed; unsafe conditions may have developed in some part of the dam; or compelling new standards are imposed by a regulatory agency. This chapter outlines suggested procedures in investigating modifications to existing structures.

The suggested criteria in Chapter V also applies to the modification of existing dams. It may not be practical, however, to strictly follow the new dam standards with existing structures. Therefore, the State Engineer will consider several factors in the review of existing dams including: the design class and hazard category, the overall safety of the dam prior to and with the modification, and the added cost of the new dam criteria.

A. Land Rights

When the modification of a structure is being considered, the land rights and easements must be thoroughly reviewed for adequacy. Utilities may make new or additional easements necessary, particularly if the area is or has been developed. Additional easements may be required for access roads and for new borrow or disposal areas.

B. Hydrology

The hydrology suggestions outlined in Section B, Chapter V should be followed, if possible, when modifying existing dams. In addition, there are other considerations that are specific to existing dams.

The drainage areas of many existing structures were determined from maps of less detail than the USGS 7½ minute quadrangle maps. Therefore, original drainage area should be reviewed for accuracy. Over the years, diversions may have been constructed, resulting in a larger or smaller drainage area. People enjoy living near water areas and often will construct their homes near reservoirs. This development adds more impervious area such as driveways, parking areas and roofs. This may not only increase the runoff, but may cause a change in peak rates.

Before beginning any hydrologic or hydraulic analysis, a review should be made of any available design records for the dam and spillway. Information such as discharge rating curves or tables, storage capacity, and pertinent dimensions of spillways and outlets should be obtained. Any changes in tailwater condition since the original design should be determined. The procedures used in the design of the spillway(s) should be compared with currently accepted techniques and criteria. If it is evident that the original design basis gave results substantially in accord with current practices, further investigation may be limited to verify that the existing project meets the adopted design objectives. If the results are considerably different from what would be acceptable today, then a revised flood study is required. Storm events that have caused secondary spillway flow during the life of the dam should be analyzed.

If the dam that is proposed for modification stores permanent water for some beneficial use, the reliability of the runoff yield should be reviewed, particularly if additional beneficial storage is to be added.

C. Sediment Storage

A sediment survey of the existing reservoir should be conducted to determine the amount of sediment that has accumulated to date. Future land use should be carefully considered. If the land in the watershed may be developed for residential or other urban uses, strict developmental requirements are needed, or increased storage is needed for sediment allocation. It may be necessary to install sediment basins to reduce sediment delivery to the reservoir.

D. Geological Explorations

The existing embankment and abutments shall be thoroughly examined for cracking, slumping or sloughing and piping. Dye tests or other techniques to locate the source of excessive seeps may be necessary. The downstream area shall be examined for seeps or boils. Borings should be made in the embankment to classify and determine the in-place density of material and the location of the phreatic line. If the dam is to be raised, the original foundation investigation and reports should be thoroughly reviewed for adequacy. If an original foundation report is not available, borings should be made through the embankment and into the foundation to determine its suitability for the increased loadings.

Explorations in the borrow area(s) should be made to determine that there are sufficient quantities available and that the strength and density of the material is adequate. In-place moisture content of the borrow material should be determined.

E. Embankment Design

For embankment dams, the major non-hydraulic causes of failure involve foundation structural instability or foundation seepage stability. Closely associated defects are excessive settlement, slope erosion, malfunctioning drains, problems at the abutments or at the foundation/embankment interface, tree growth, and rodent activity.

Each different defect may require different remedial measures. An excellent list of defects and their possible causes are contained in the publication "Safety of Existing Dams — Evaluation and Improvement," National Academy Press, Washington, D.C., 1983, page 220.

If an existing dam is to be modified, the embankment design must be thoroughly reviewed. In all probability, additional height cannot be added without a modification of the slopes. The same is true regarding increasing the top width.

Stability assessments should utilize in situ properties of the structure, its foundation and pertinent geologic information. "As Built" records should be reviewed along with other geologic information.

Geologic information that should be considered includes groundwater and seepage conditions, lithology, stratigraphy, and geologic details. Foundations may present problems where they contain adversely oriented joints, slickensides or fissured material, faults, seams of soft materials, or weak layers. Such defects along with excess pore water pressures may contribute to instability. Special tests may be necessary to determine physical properties of particular materials. The results of stability analyses afford a means of evaluating the structure's existing resistance to failure and also the effects of any proposed modifications. When possible, results of stability analyses should be reviewed for compatibility with performance experience.

The loading conditions for which the modified or repaired dam should be investigated, along with the minimum factors of safety, are:

1. Rapid drawdown from spillway crest elevation — 1.2.
2. Partial pool with assumed horizontal steady seepage saturation — 1.5.
3. Steady seepage from spillway crest or top of gates with the horizontal permeability to vertical permeability ratio assumed as a minimum of nine — 1.5.
4. Earthquake (cases 2 and 3 with seismic loading) — 1.0.

Modifications to the original seepage design should consider conditions observed in the field inspections and piezometer instrumentation. A seepage analysis should consider the horizontal and vertical permeability ratios resulting from both natural deposition and compaction placement of materials.

The embankment should be carefully examined for activity by burrowing animals. Where the embankment slopes are being modified, the riprap should be removed as well as all of the vegetation. The old slope should be scarified and watered prior to placement of new fill material. Upon completion of the modification the new slope would be seeded and riprapped as appropriate.

F. Principal Spillway Design

The original principal spillway plans should be thoroughly reviewed and field checked to see that the spillway was built as designed. The interior of the principal spillway should be visually inspected by physically entering the conduit or by use of video equipment.

The location and depth of any pools of water should be located on the plans. Pools indicate the absence of camber. The present condition and expected life of the conduit should be noted. Where possible, joint gaps should be measured. If the dam is modified, new joint separation estimates should be calculated.

Inlet modifications shall be carefully planned and designed. When the riser is to be raised, the footings should be checked to see that they are adequate for the additional load. Special attention should be given to the joints between the inlet and the conduit and drawdown facilities.

Barrel repairs or modifications should be commensurate with the importance of the dam. Where damage is sufficiently severe, as when a metal conduit is severely corroded, it may be necessary to remove it and replace it. If the joints have become excessively elongated, it may be necessary to fill the gaps or, in severe cases, to line the entire barrel with a suitable casing.

The outlet conditions should be thoroughly inspected. The scour hole or plunge pool should be measured to determine the amount of lateral extension. If the plunge pool had originally been riprapped, the amount and condition of the riprap should be assessed.

Where the outlet consists of a mechanical energy dissipator, certain elements need careful review. Joint openings should be examined for the integrity of the water stop material. All drains should be examined for defects. The outlet channel should be measured to assure that it will provide the proper tailwater elevation. If modification of the dam would either increase or decrease the principal spillway peak flows, the outlet channel should be reevaluated.

The drawdown facilities should be checked to determine whether the gate seals and operates in a smooth manner. When drawdown facilities are to be added, care should be taken so the hydraulics are compatible with the existing system.

G. Emergency Spillway Design

If the dam is modified, it may be necessary to completely renovate the emergency spillway system. The vegetative cover should be retained, if possible, particularly in the exit section. If evidence of gullying is observed, transverse barriers of erosion resistant material should be installed. If meandering has taken place on the emergency spillway floor, small (4" to 9" high) lateral dikes should be installed. The original freeboard and emergency spillway hydrographs should be reviewed and updated prior to routing through the structure.

H. Design Documentation

Design documentation for modifying existing structures should be as thorough as for new dam design. The design documentation contained in Chapter V, Section H, is suggested.

CHAPTER VII:

Construction Drawings and Specifications

This chapter sets forth the suggested formats for construction drawings and specifications. Design classification I and II dams require less detailed drawings and specifications. For small dams, the SCS uses a hydraulic data sheet for construction drawings (Form ND-ENG-16), and a small booklet for specifications. Form ND-ENG-16 is included in Appendix B. Design class III, IV, and V dams require detailed drawings and specifications. The following two sections are suggested outlines of information to be included on the construction drawings and in the specifications.

A. Construction Drawings

1. Cover sheet

a. title of the project
b. site location map
c. list of cooperators and/or sponsors
d. generally physical informational data such as drainage area, height, etc.
e. index of drawings
f. signature block

2. Watershed Boundary Map

a. structures located and identified, including existing structures
b. farm boundaries
c. landowners' names
d. watershed boundary
e. north arrow and scale
f. section, township and range numbers
g. existing roads and highway numbers

3. Site Maps

a. plan view of site including embankment, emergency spillway, and reservoir area
b. topography of structure site including all topographic features
c. land ownership
d. base lines
e. centerline of embankment and emergency spillway
f. property lines and fence lines
g. construction limits
h. utility lines and pipelines
i. roads, highways and railroads (with names)
j. bench marks
k. borrow areas and waste areas
l. clearing and grubbing areas
m. waterways, diversions, and channel improvements
n. wells
o. fence removal and/or construction
p. scale and north arrow

4. Plan View Sheets

a. plan view of structure site including embankment, principal spillway and emergency spillway
b. topography of structure site including all topographic features
c. stationing along centerline of dam and emergency spillway
d. cross sections
e. soil borings
f. embankment drainage
g. sodding areas
h. topsoil spreading areas
i. scale and north arrow

5. Profile Sheets

a. embankment
b. principal spillway
c. emergency spillway
d. channel improvement, waterways, and diversions
e. outlet channel
f. structural drainage system

6. Cross-Section Sheets

a. embankment and trenches
b. emergency spillway
c. borrow area
d. outlet channel
e. soil borings
f. structural drainage system

7. Structural Detail Sheets

a. structure layout
b. principal spillway
c. barrel and appurtenances
d. inlet-riser, trash rack, safety guard
e. drainage system
f. fence layout and details

8. Standard Detail Sheets

9. Topography for Erosion Control During Construction

a. temporary and permanent diversions
b. bypass channels and sediment traps
c. sediment basins and grade control structures

10. Details for Erosion Control During Construction

a. profile for diversion and bypass channels
b. typical cross sections of diversions, channels, structures and dikes
c. sections along centerline of principal spillway for all sediment and erosion control structures
d. vertical inlet details if needed

B. Specifications

Standard specifications of the U.S. Soil Conservation Service and the North Dakota State Water Commission may be utilized in the preparation of specifications. The specifications will be in the form of a booklet with a cover that identifies the structure, its location, the owner, the name of the preparer and the date.

The first inside sheet is an index list of construction and material specifications. The specifications booklet may incorporate special provisions and other contract details. The specifications may incorporate, by reference, "Standard Specifications for Water Resource Facilities," (North Dakota State Water Commission), as well as ASTM, ASSHTO or other appropriate specifications. It is also recommended that an "Items of Work and Construction Details Section," be included that shows details not covered in the reference specifications, such as methods of measuring quantities. The specifications should be numbered in a manner that can be readily followed by the contractor and inspection personnel during construction operations.

CHAPTER VIII:

Construction Inspections, Records and Completion Documents

The purpose of this chapter is to provide general information on construction inspection, record keeping and completion documents. In many regards, these requirements may be the most important part of dam construction. The best design and specifications mean little if they are not adhered to during construction and documented after construction.

A. Inspections

1. Construction Work Inspections

Construction inspections ensure that the work complies with the project design and specifications. The level of inspection is dependent upon the design classification of the dam and on the type of work being performed. A construction inspected plan will be required for all class IV and V dams. Design classification III, IV and V dams may require continuous inspections, whereas class I and II dams may require only periodic inspections. The level of inspections can also vary with different construction phases. Continuous inspections are suggested for any work in which the quality cannot be accurately determined after the fact and for any work that cannot be readily replaced if rejected. The engineer-designer should designate those items that are to receive full-time inspection. Work items of this type include (but are not limited to): foundation evacuation in which depth must be determined during the course of work, foundation excavation underwater, pile driving, placing compacted earth fill, structural backfill, placing drain fill and filters, placing riprap, placing and bedding pipe, mixing and placing concrete and pneumatically applied mortar, mixing and placing asphaltic concrete, installing relief wells, and performing acceptance tests of machinery and equipment.

Periodic inspection may suffice for certain other types of work, depending on circumstances prevailing at a site. Works of this type may include (but are not limited to): dewatering the work site, clearing, clearing and grubbing, stripping, structure removal, open channel excavation, borrow pit excavation, form construction, placement of steel reinforcement, metal fabrication, timber fabrication, installing water control gates, painting, installing fences, sodding, mulching, and general cleanup. It must be recognized that continuous inspection of such items may be required because of local complications, such as complex site conditions, erratic soil deposits, remote site location, nature of the construction schedule, or contractor's attitude or ability.

The number of samples to be taken and tested varies with the material, the amounts being placed during a designated period, the results of previous tests and the experience and qualifications of the contractor and his work force. In general, concrete and earthwork are the two primary categories that require samples and/or tests.

Concrete requires at least three test cylinders, one slump test and one air entrainment test for each pour. As a guideline, samples should be taken (at random) from at least one third of the redi mix or batch mix delivered to the site. If past test results show borderline strengths and/or air content, etc., each batch should be sampled until the engineer and inspector are satisfied that the quality is satisfactory and uniform.

Earthwork tests are dependent upon the design classification of the dam. The specifications for a class I or II dam may call for machine compaction and visual inspection by a competent inspector. A class III dam may require density and moisture control. At least two moisture density tests should be run per day, averaging one test per 400 to 500 yards.

A large class IV or V dam may have six or more hauling units, with placement of several thousand yards per day. A systematic program of field compaction control should be established and executed, involving determinations of compaction densities and water contents. Sufficient density and moisture tests must be taken to verify the adequate compaction and uniform moisture distribution for each lift during placement and compaction operations. Special emphasis may be required for critical zones within a zoned embankment.

Careful inspection of backfill around imbedded items such as pipe is required on all classes of dams.

Information on inspection, sampling, testing and recording forms are available from numerous sources, including the SWC and the SCS.

2. Material Inspection

Materials used in the construction of earth dams generally fall into one of three categories:

(a) manufactured material such as pipe, reinforcing steel, etc.;

(b) concrete including aggregate, cement, water and admixtures; and

(c) natural materials such as earthfill, sand, gravel, rock riprap, sod and grass seed.

Most manufactured products, including concrete admixtures and cement materials, may be accepted based on certifications furnished by the manufacturer. The manufacturer is to furnish, on request, certifications and test results on the material(s) in question.

Inspection at the factory may be required for special items or major items of mechanical or electrical equip-

ment. Inspection at or near the site of work is required for all materials and work for which compliance with specification requirements can be partially or completely verified by on-site examination and testing. This inspection may take the form of:

(a) examinations, measurements, and tests performed by an inspector at the site of work;

(b) laboratory testing of samples of materials obtained or prepared at the site of work, or at local points of supply; and

(c) periodic inspection of local concrete mixing plants, including operation of these plants.

Some materials must be inspected at the work site. They are:

(a) earthfill materials, rock for fill or riprap, aggregates for concrete or asphaltic concrete, and drain fill materials;

(b) upgraded wood products (such as round timber, wood piles, and posts);

(c) materials manufactured at or near the site of work (such as concrete, pneumatically applied mortar, asphaltic concrete, and concrete piles); and

(d) any other materials such as vegetative materials that may not be accepted on the basis of certification.

3. State Engineer Monitoring

The State Engineer (or designee) will make frequent inspections to determine progress and conformance to construction drawings and specifications. When requested by the consulting engineer or local sponsoring agency, the State Engineer will consider, on a project-by-project basis, uniform scheduling of construction reviews.

Failure of the contractor to conform to the drawings and/or specifications for any cause on any structure may cause rejection and removal of that portion of the work failing to meet requirements. When the SWC is involved in cost-sharing on a project, an agreement between the local sponsors and the SWC shall be executed prior to contract award, setting forth the responsibilities of each — financially and physically — in monitoring the construction of the dam.

B. Records

1. Job Diary

A job diary is to be maintained for each dam to provide a history of the work. Entries are to be made daily or, when continuous inspection is not required, whenever the engineer or inspector are on the job.

Bound job diaries will be required on all dams where a formal contract is entered into between the contractor and the local sponsors and/or the SWC. The SCS uses a bound job diary which may prove of value as a guide. (See Appendix C for example format.)

The job diary is the pertinent history of the project, beginning with the showing of the site to prospective bidders, and concluding with the completion of the job. The diary should be on hand at all times and entries should be completed as the events occur. The following items should be recorded in the job diary on a daily basis: weather, work hours, work force, equipment on site and used, work completed, tests, time delays, cause of delays, rejected work, problems, instructions given to the contractor, job-related visitors, and other significant items.

Photographs are an extremely important part of construction inspections and documentation. It is necessary to have photographic documentation of significant construction conditions, deficiencies, and safety or health violations. Photographs may be included as supplemental information on the job diary.

2. Change Orders

During the progress of the work, the engineer or technician in charge of construction must be sensitive to developments that seem to be significantly different from those assumed in the design. When these developments occur, construction inspection personnel are not to alter the design or allow the contractor to continue construction, until the individual with design approval authority has evaluated the condition and made any adjustments necessary in the plans and specifications.

The contractor should not be allowed to proceed with any of the changed work until a written change order has been approved by the appropriate person(s). (See SWC Form No. 194, Appendix C.) When the SWC is cost-sharing, the project agreement shall designate those persons with authority to execute change orders.

C. Completion Documents

1. As-Built Plans

As-built plans that represent the structure as it was actually constructed may be necessary: to evaluate the structure's design and operation, to provide evidence in legal matters, and to facilitate efficient maintenance or modification. As-built plans and completion reports are suggested for all design class III, IV and V dams. The importance of as-built plans cannot be overstressed. Often the only information available on certain components is what is shown on the as-built plans. The minimum requirement of as-built plans is a documentation of all changes that are not clearly visible after construction.

A complete set of full-size construction plans should be kept at the work site for recording changes. All changes during construction must be recorded on the drawings to indicate as-built conditions. If a structure is altered at any time after its completion, the as-built plans are to be retrieved and revised to indicate the alterations and then are to be processed in the same way as original as-built plans.

Structural or dimensional changes are to be illustrated in detail in order to provide a complete, readable, and true record. Upon completion of the project, the elevations of several of the structural components should be shown including the inlet and outlet structures and the foundation drain outlets. The elevation and gap measurements of the joints in the principal spillway conduit should be shown at the time of installation.

Geologic conditions revealed during construction that differ significantly from those in the geologic

report are to be recorded on the as-built plans. Examples of differences are elevation of rock surfaces, type of rock or soil, joint orientation and openings, or ground-water elevation.

As-built geology should also include:

(a) as-built profile of the core trench;

(b) as-built profile of the pipe trench; and

(c) changes in materials different from those indicated by the logs on the geologic profile shown on the plans for construction. This would include, but is not limited to, borrow, core trench, pipe trench, drains, etc.

It is also recommended that the as-built include a detailed description of the vertical and horizontal control points. These points should be plotted on the appropriate sheets.

The as-built plans should be certified by the design engineer. Copies of the as-built plans shall be furnished to the State Engineer and the primary local sponsoring organization having the responsibility for operation and maintenance.

2. Completion Report

A completion report should be prepared for all class III, IV and V design dams. The report should be in narrative form, giving a chronological history (including pictures or slides) of the construction of the dam, starting with the date of award and the name of successful contractor. It should include a short description of problems encountered, solutions to the problems and any other pertinent information.

CHAPTER IX:

Operations, Inspections and Maintenance

The designer shall prepare an Operation and Maintenance (O&M) plan for all design class III, IV and V dams. The O&M plan shall be tailored to the specific dam. It will generally not be necessary to provide a detailed O&M plan for design class I and II dams. The following should be considered in the preparation of an O&M plan.

OPERATIONS AND MAINTENANCE PLAN

I. OPERATIONS

The owner will be responsible for operating the dam in compliance with applicable federal, state and local laws.

II. INSPECTIONS

There are two types of dam inspections. Routine inspections are directed at observing changes from the as-built condition. Post storm or emergency inspections are directed at surveying storm damages and/or possible deficiencies.

All inspections are the responsibility of the owner(s) and must be made by properly trained people. In general, it is recommended that a design class III dam be inspected every two years, and class IV and V dams once a year. In addition, all dams should be inspected if the emergency spillway is used, or if possible deficiencies are noted. The designer should develop an inspection checklist for the dam (see Appendix D). It is suggested the State Engineer be contacted for possible assistance prior to the inspection of a class III, IV or V dam. All monitoring instruments should be read and the results recorded.

III. MAINTENANCE

The Operation and Maintenance Plan should include specific maintenance measures for the dam. The maintenance measures should be consistent with the dam's original design and the as-built conditions. The maintenance plans should address:

1. vegetation,
2. embankment and structural items,
3. materials,
4. photograph documentation, and
5. monitoring instruments.

CHAPTER X:

Emergency Action Plans

It is intended that the guidelines for the design, construction, operation and maintenance, and inspection of dams will minimize the risk of future dam failures Nevertheless, it must be recognized that despite the adequacy of dam design guidelines and their implementation, the possibility of dam failure still exists. Although the probability of failure is small, pre-planning is required to identify conditions which could lead to failure and to minimize the extent and effects of a failure. This section describes recommended procedures for reacting to an emergency or unsafe condition created by the threat of a dam failure. The action categories and other recommendations listed are only general guidelines. The owner and design engineer should develop an Emergency Action Plan and make a determination of the Categories of Action. The owner should periodically update the action plan.

This section is based on three primary suggestions: The first is that an Emergency Action Plan be developed for all classes of dams. The level of detail included in each plan should be commensurate with the hazard category of the dam. The second suggestion is that two Categories of Action be developed that trigger action by the dam owner. Conditions listed as "Category of Action I" are considered extremely severe occurrences that present an immediate danger to the dam and to downstream areas. Therefore, any Category I condition should immediately activate the Emergency Action Plan. The conditions listed as "Category of Action II" present a potential, but not necessarily immediate, danger to the structure. The Category II conditions could, however, develop into a more serious problem. Therefore, a qualified engineer should be immediately notified and a prompt inspection should be made of any structure with Category II conditions. Examples of Categories of Action are listed in Appendix E.

The third recommendation is that the dam owners and dam design engineers coordinate with the appropriate local emergency management organization. This coordination will ensure that the Emergency Action Plan properly interfaces with local emergency operations warning plans and with local government response and support activities. The State Division of Emergency Management can provide general guidance in the preparation of the plan.

An Emergency Action Plan is a clear, concise plan of action to be followed in the event of a failure or an impending dam failure. Any condition listed as Category of Action I should automatically activate the Emergency Action Plan. The dam owner is responsible for drafting the plan, providing copies to the participants and activating the plan.

A. Emergency Action Plan (Class I and II Dams)

An Emergency Action Plan for design class I and II dams may be only a notification list of individuals and agencies to be contacted upon dam failure. The plan should contain the names, addresses and phone numbers of a few key contacts. At a minimum, the list should include the local water resource board, the Office of State Engineer, the engineering firm or agency that designed the structure (if applicable), the State Division of Emergency Management, the local emergency management coordinator, and downstream landowners that may be affected.

B. Emergency Action Plan (Class III and IV Dams)

The Emergency Action Plan for class III and IV dams includes a downstream inundation map, a detailed notification list and a list of contractors and others that could provide assistance during a failure or a possible failure condition. The notification list should include downstream residents (listed in order beginning with those affected first), the dam design engineer or agency, the local water resource board, the Office of State Engineer, State Division of Emergency Management, the local emergency management coordinator, and various other emergency services. A sample directory is included in Appendix E.

The list of downstream residents with phone numbers should be shown on a downstream inundation map. The map should be equivalent to the USGS 7½ minute quadrangle maps. The map should extend a minimum distance of 10 miles downstream or until the stream enters a significantly larger stream or river that would quickly attenuate the flood levels. The map should show the locations of residents indexed to the notification directory, along with roads, bridges and anything else that may suffer significant damage because of a dam break.

C. Emergency Action Plan (Class V Dams)

The Emergency Action Plan for a design class V dam needs to be adequately detailed, well-organized and well-prepared. The notification directory needs to be completed in detail. The inundation map needs to be based on the results of a dam break routing procedure. The routing procedure must extend downstream to a

point where the floodwaters are within the channel banks or the threat of resident inundation no longer exists. The inundation map for class V dams should be adequately detailed, identifying dwellings and significant features that are likely to be affected. The maps should also show the estimated travel time and depth at selected locations.

Downstream warning systems should be considered for all design class V dams, with the precise procedure detailed in the Emergency Action Plan. Existing local government emergency operation plans for warning should be consulted for proper interface and inclusion of downstream warning procedures. The plan should be reviewed with downstream individuals and entities.

The Emergency Action Plan Directory must be reviewed and updated, if necessary, on a yearly basis by the dam owner. The North Dakota Division of Emergency Management should be furnished an annual status report of the Emergency Action Plan Directory, including modifications.

CHAPTER XI:

Glossary

ABUTMENT — The part of the valley side against which the dam is constructed. Right and left abutments are those on respective sides of an observer when viewed looking downstream.

ANNUAL RUNOFF — The total discharge of a stream for a year, usually expressed in inches, depth or acre-feet.

ANTECEDENT MOISTURE CONDITION (AMC) — The degree of wetness of the soil in a watershed at the beginning of a storm. (See Section 4, National Engineering Handbook, SCS.)

ANTI-SEEP COLLAR — A projecting collar, usually of concrete, built around the outside of a pipe, tunnel, or conduit, under an embankment dam, to lengthen the seepage path along the outer surface of the conduit.

AXIS OF DAM — The plane or curved surface, arbitrarily chosen by a designer, appearing as a line, in plan or in cross section, to which the horizontal dimensions of the dam can be referred.

BACKWATER — The resulting high water surface in a given stream due to a downstream restriction or a high stage in an intersecting stream.

BAFFLE BLOCK — A block of concrete or concrete and steel constructed in a channel or a stilling basin to dissipate the energy of water flowing at a high velocity.

BASE WIDTH — The maximum thickness or width of a dam measured horizontally between upstream and downstream faces, and normal to the axis of the dam, but excluding projections for outlets, etc.

BASE FLOW — The sustained discharge which persists after storm runoff has been depleted. It is usually derived from ground-water discharge or gradual snow or ice melt over extended periods of time, but need not be continuous flow.

BERM — A horizontal step or bench in the sloping profile of an embankment dam.

BLANKET —

DRAINAGE BLANKET — A drainage layer placed directly over the foundation material.

GROUT BLANKET — Consolidating a layer of the foundation to achieve greater impermeability and/or strength by injecting grout.

UPSTREAM BLANKET — An impervious layer placed on the reservoir floor or on the abutments upstream of a dam. In the case of an embankment dam, the blanket may be connected to the impermeable element in the dam.

CONDUIT — A closed channel to convey the discharge through or under a dam.

CONDUIT FILTER DRAIN — A pervious filter drain around a conduit for the purpose of seepage control. The filter drain is often tied into other drain systems in the foundation or embankment. It is an alternative to anti-seep collars.

CONSERVATION STORAGE — The water that is impounded for consumptive uses such as municipal, industrial, irrigation, stockwater and non-consumptive uses such as lake evaporation and seepage. Conservation storage does not include flood or sediment storage.

COFFERDAM — A temporary structure enclosing all or part of the construction area so that construction can proceed in the dry. A diversion cofferdam diverts a river into a pipe, channel, or tunnel.

CONTROL SECTION — The section where flow passes through critical depth.

CORE (IMPERVIOUS CORE) (IMPERVIOUS ZONE) — A zone of material of low permeability in an embankment dam; hence the terms central core, inclined core, puddle clay core, and rolled clay core.

CREST LENGTH — The developed length of the top of the dam.

DAM — An artificial barrier, together with any associated spillways and appurtenant works, across a watercourse or natural drainage area, which does or may impound or divert water.

DAM HEIGHT — The distance between the stream channel bottom at the centerline of the dam to the top of the settled embankment.

DAMAGE REACH — A length of floodplain or valley selected for damage evaluation.

DEAD STORAGE — The storage that lies below the invert of the lowest outlet and that, therefore, cannot be withdrawn from the reservoir without pumping.

DESIGN LIFE — A period of time during which a dam is designed to perform its assigned functions satisfactorily.

DIAPHRAGM — A cutoff wall, or core wall, made of relatively impervious material such as asphaltic concrete, concrete, or earth.

DRAINAGE AREA (WATERSHED) — The area that drains naturally to a particular point on a river, stream or creek.

DRAINAGE WELLS (PRESSURE RELIEF WELLS) — Vertical wells or boreholes usually downstream of impervious cores, grout curtains, or cutoffs, designed to collect and control seepage through or under a dam, so as to reduce uplift pressures under or within a dam. A line of such wells forms a drainage curtain.

DRAWDOWN — The lowering of water surface level due to release of water from the reservoir.

DRAWDOWN PIPE — A pipe through the embankment that allows for water releases below the principal spillway level.

DRY DAM (DETENTION DAM) — A dam that has an ungated outlet positioned so that essentially all stored water will be drained from the reservoir by gravity. The reservoir will normally be dry.

ECONOMIC LIFE — The period of time during which economic benefits accrue to a dam.

EARTHFILL DAM — A dam constructed of excavated natural earth material obtained from a borrow area.

HOMOGENEOUS EARTHFILL DAM — A dam constructed of similar earth material throughout, except for possible inclusion of internal drains or drainage blankets. Used to differentiate from a zoned earthfill dam.

ZONED EARTHFILL DAM — A dam, the thickness of which is composed of zones of selected material having different degrees of porosity, permeability, and density.

EMERGENCY ACTION PLAN — A predetermined plan of action to be taken to reduce the potential for property damage and loss of lives in an area affected by a dam break.

EMERGENCY SPILLWAY (SECONDARY) — The spillway designed to convey excess water through, over or around a dam.

EMERGENCY SPILLWAY SYSTEM — A single emergency spillway or combination of emergency spillways designed to work together.

EXIT CHANNEL — An open channel spillway, located downstream from the control section, which conducts the flow to a point where it may be released without jeopardizing the dam.

FACE — With reference to a structure, the external surface that limits the structure, e.g., the face of a wall or a dam.

FETCH — The straight line distance between a dam and the farthest reservoir shore. The fetch is one of the factors used in calculating wave heights in a reservoir.

FILTER (FILTER ZONE) — A band or zone of granular material that is incorporated in a dam and is graded (either naturally or by selection) so as to allow seepage to flow across or down the filter without causing the migration of material from zones adjacent to the filter.

FLASHBOARDS — Lengths of timber, concrete, or steel placed on the crest of a spillway to raise the retention water level but that may be quickly removed in the event of a flood, either by a tripping device or by a deliberately designed failure of the flashboards or their supports.

FLOOD FREQUENCY — An expression or measure of how often a hydrologic event of a given size or magnitude should, on an average, be equaled or exceeded. For example, a 50-year frequency flood (two percent chance) should be equaled or exceeded, on the average, once in 50 years.

FLOODPLAIN — An area adjoining a body of water or natural stream that has been or may be covered by floodwater.

FLOOD ROUTING — Computation of the changes in the rise and fall in stream flow as a flood moves downstream. The results provide hydrographs of flow versus time at given points on the stream or in a reservoir.

FLOOD STAGE — The stage or elevation in which overflow of the natural banks of a stream or body of water begins in the reach or area.

FLOOD STORAGE — Floodwater storage in a reservoir. In a floodwater retarding reservoir, the temporary storage between the crests of the principal and emergency spillways.

FOUNDATION OF DAM — The natural material on which the dam structure is placed.

FREEBOARD HYDROGRAPH — The hydrograph used to establish the minimum settled elevation of the top of the dam. It is also used to evaluate the structural integrity of the spillway system.

GROIN — That area along the contact (or intersection) of the face of a dam with the abutments.

GROSS STORAGE CAPACITY — The gross capacity of a reservoir from the river bed up to maximum controlled retention water level. It includes active, inactive, and dead storage.

GROUT CAP — A concrete pad or wall constructed to facilitate subsequent pressure grouting of the grout curtain beneath the grout cap.

GROUT CURTAIN — A barrier to reduce seepage under a dam, produced by injecting grout into a vertical zone, usually narrow in horizontal width, in the foundation.

HYDROGRAPH — A graphical representation of discharge, stage, volume, or other hydraulic property (with respect to time) for a particular point on a stream.

HYDROLOGIC SOIL-COVER COMPLEX (CURVE NUMBER) — A combination of hydrologic soil group and a type of cover. Each complex is assigned a runoff curve number (CN) that indicates that runoff potential.

HYDROLOGIC SOIL GROUP — A group of soils having the same runoff potential under similar storm and cover conditions.

INLET CHANNEL — An open channel in a spillway system upstream from the control section.

JOINT EXTENSIBILITY — The amount a pipe joint can be extended from the fully engaged position without losing strength or watertightness. In case of rubber gasket joints, it is measured from the center of the gasket to the point of flare of the bell ring (or collar) when the joint is fully closed.

JOINT GAP — The longitudinal dimension between the end face of the spigot end of a pipe joint and the corresponding face of the bell end of the connecting pipe. It does not include the beveled portion designed for sealing compounds.

LAG (OR LAG TIME) — The time from the centroid of rainfall to the peak of the hydrograph. It can be estimated from time of concentration as $0.6T_C$.

LOW-LEVEL OUTLET — A gated opening from the reservoir, generally used for lowering the reservoir or for providing downstream releases.

MAXIMUM WATER LEVEL — The maximum water level, including the flood surcharge the dam is designed to withstand.

MINIMUM OPERATING LEVEL — The lowest level to which the reservoir is drawn down under normal operating conditions. The lower limit of active storage.

NAPPE — The free-falling stream from a weir or spillway.

NORMAL WATER LEVEL — For a reservoir with a fixed overflow sill, it is the water level at the lowest ungated spillway sill. For a reservoir which is controlled wholly or partly by movable gates, or by other means, it is the maximum water level under normal operation conditions.

PEAK FLOW — The maximum instantaneous discharge that occurs during a flood. It is coincident with the peak of a flood hydrograph.

PERMANENT STORAGE — Water impounded for consumptive uses such as municipal, industrial, irrigation, stockwater; and non-consumptive uses such as recreation, and fish and wildlife, including the storage lying below the lowest ungated outlet.

PERVIOUS ZONE — A part of the cross section of an embankment dam comprising material of high permeability.

PHREATIC SURFACE — The free surface of ground water at atmospheric pressure.

PIEZOMETER — An instrument for measuring pore water pressure within soil, rock, or concrete.

PIPING — The progressive development of internal erosion by seepage, appearing downstream as a hole or seam discharging water that contains soil particles.

PLUNGE BASIN (PLUNGE POOL) — A natural or sometimes artifically created pool that dissipates the energy of free-falling water.

PRINCIPAL SPILLWAY — The lowest ungated spillway designed to convey water from the reservoir at uncontrolled release rates.

PRINCIPAL SPILLWAY HYDROGRAPH — The hydrograph used to determine the minimum crest elevation of the emergency spillway. It is used to establish the principal spillway capacity, and to determine the associated minimum floodwater retarding storage.

PROBABLE MAXIMUM FLOOD (PMF) — The flood that may be expected from the most severe combination of critical meteorologic and hydrologic conditions that are possible in the region.

PROBABLE MAXIMUM PRECIPITATION (PMP) — The maximum amount of precipitation that can be expected to occur on a drainage basis for varying durations.

RETARDING OR DETENTION POOL — The portion of the reservoir allotted to the temporary impoundment of floodwater. Its upper limit is the elevation of the crest of the emergency spillway.

RESERVOIR AREA — The surface area of a reservoir when filled to a controlled retention water level.

RIPRAP — A layer of large stones, broken rock, or precast blocks placed in random fashion on the upstream slope of an embankment dam, on a reservoir shore, or on the sides of a channel, as a protection against wave and ice action.

RISK ASSESSMENT — As applied to dam safety, the process of identifying the likelihood and consequences of dam failure to provide the basis for informed decisions on a course of action.

RUNOFF YIELD — The portion of precipitation (including snowmelt) that flows across the land surface and contributes to stream or flood flow.

SEDIMENT STORAGE — The portion of the reservoir allotted to the accumulation of submerged sediment during the design life of the dam.

SLOPE PROTECTION — The protection of an embankment slope against wave action or erosion.

SLURRY TRENCH — A narrow excavation whose sides are supported by a slurry made of mud, clay, or cement and mud, filling the excavation. Sometimes used to describe the cutoff itself.

SPILLWAY — An open or closed channel, conduit or drop structure used to convey water from a reservoir. It may contain gates, either manually or automatically controlled, to regulate the discharge of water.

STILLING BASIN — A basin constructed so as to dissipate the energy of fast-flowing water, e.g., from a spillway or bottom outlet, and to protect the river bed from erosion.

STOPLOGS — Large logs or timbers or steel beams placed on top of each other with their ends held in guides on each side of a channel or conduit.

STORAGE — The capacity of the reservoir below the elevation of the crest of the emergency spillway.

STORAGE INDICATION METHOD — A name often given to a flood-routing method also often called the Puls method (after Louis G. Puls) — though it is actually a variation of the method devised by Puls.

STREAM REACH — A length of stream channel selected for use in hydraulic or other computations.

STRUCTURAL HEIGHT — The distance between the lowest point in the excavated foundation (excluding narrow fault zones) and the top of the dam.

TIME OF CONCENTRATION (T_c) — The time it takes water from the most distant point (hydraulically) to reach a watershed outlet. T_c varies, but it is often used as a constant.

TOE OF DAM — The junction of the dam with the ground surface. For an embankment dam, the junction of the upstream face with ground surface is called the upstream toe, and the junction of the downstream face with the ground is referred to as the downstream toe.

TOP OF DAM — The elevation of the uppermost surface of a dam.

TOP WIDTH — The thickness or width of the top of the dam.

TRASH RACK — A screen located at an intake to prevent the ingress of floating or submerged debris.

UNGATED OUTLET — The outlet that allows uncontrolled flow through, around or over a dam, e.g., the crest of a weir box, the invert of a pipe inlet, or the crest of the emergency spillway on a dam without a principal spillway.

UPLIFT — (a) The upward water pressure in the pores of a material or on the base of a structure, (b) An upward force caused by frost heave or wind force.

VELOCITY SPILLWAY HYDROGRAPH — The hydrograph used to establish the dimensions of the emergency spillway.

VEGETATED SPILLWAY — The vegetated open channel spillway in earth materials.

WATERSHED COMPUTER MODEL — A mathematical representation of a drainage basin within which flood flows are computed with the aid of a computer. Represents the flow process over time using time steps.

WEIR — A wall structure built across a stream or incorporated into the inlet portion of the principal spillway of a dam to maintain an upstream water level.

APPENDIX A

1. Application for Permit to Construct or Enlarge a Dam or Reservoir

2. Application for Conditional Water Permit

APPLICATION / NOTIFICATION TO CONSTRUCT OR MODIFY DAM, DIKE, RING DIKE OR OTHER WATER RESOURCE FACILITY

Office of State Engineer
900 East Boulevard - Bismarck, ND 58505
SFN 51695 (6-98)

OFFICIAL USE ONLY

I,the undersigned, do hereby submit the following information to the Office of the State Engineer for their determination and use as a filing of information required under North Dakola Century Code 61-04-02 or as an application to construct or modify a facility under NDCC 61-16.1-38.

No._____

A. GENERAL INFORMATION:

(1) This Application/Notification must include a map from an actual survey, aerial photo or topographic map. The size of the map shall be 8 1/2 by 11 inches. The map shall have a north arrow and approx. scale. If in the opinion of the State Engineer, the map does not contain information to properly evaluate the project, it will be returned.

(2) The proposed facility is:

- ❒ Dam (Complete Section A & B)
- ❒ Dike (Complete Section A & C)
- ❒ Ring Dike (Complete Section A & C)
- ❒ Diversion Ditch (Complete Section A & E)
- ❒ Restoration (Complete Section A & D)
- ❒ Stock Pond (Complete Section A & E
- ❒ Lagoon/waste storage ponds (Complete Section A & E)
- ❒ Sediment Pond (Complete Section A & E)
- ❒ Creations (Complete Section A & B)
- ❒ Other (Complete Section A & E)

(3) Is this Application/Notification for modification of an existing structure? ❒ Yes ❒ No

If so, when was existing structure constructed? _____ By whom_____

(4) Project Located in_____Water Resource District.

(5) Legal description to the nearest forty-acre tract:_____1/4_____1/4 Sec._____Twp. _____Rge._____

(Optional) Latitude_____Longitude_____

(6) Is the dam and reservoir, dike, diversion ditch, lagoon/pond entirely on Applicant's land? ❒ Yes ❒ No

(if not, applicant must have landowner's permission to construct facility or structure.

Copies of all easements should be filed with these application/notification sheets.)

(7) The facility will be built under the supervision of _____

and will conform to the attached.

(8) Waterway on which structure is or will be located:_____

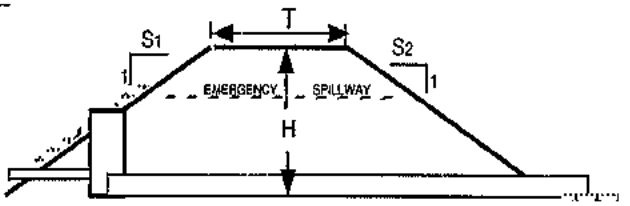
(9) A tributary to:_____, _____

NDCC:

61-16.1-38. Permit to construct or modify dam, dike, or other device required - Penalty - Emergency.

No dikes, dams, or other devices for water conservation, flood control regulation, watershed improvement, or storage of water which are capable of retaining, obstructing, or diverting more than twelve and one-half acre-feet [15416.52 cubic meters] of water may be constructed within any district except in accordance with the provisions of this chapter. An application for the construction of any dike, dam, or other device, along with complete plans and specifications, must be presented first to the state engineer. After receipt, the state engineer shall consider the application in such detail as the state engineer deems necessary and proper. The state engineer shall refuse to allow the construction of any unsafe or improper dike, dam, or other device which would interfere with the orderly control of the water resources of the district, or may order such changes, conditions, or modifications as in the judgment of the state engineer may be necessary for safety or the protection of property. Within forty-five days after receipt of the application, except in unique or complex situations, the state engineer shall complete the state engineer's initial review of the application and forward the application, along with any changes, conditions, or modifications, to the water resource board of the district within which the contemplated project is located. The board thereupon shall consider, within forty-five days, the application, and suggest any changes, conditions, or modifications to the state engineer. If the application meets with the board's approval, the board shall forward the approved application to the state engineer. The state engineer shall make the final decision on the application and forward that decision to the applicant and the local water resource board. The state engineer may issue temporary permits for dikes, dams, or other devices in cases of an emergency. Any person constructing a dam, dike, or other device, which is capable of retaining, obstructing, or diverting more than twelve and one-half acre-feet [15418.52 cubic meters] of water, without first securing a permit to do so, as required by this section, is liable for all damages proximately caused by the dam, dike, or other device, and is guilty of a class B misdemeanor.

61-04-02. Permit for beneficial use of water required.



Any person, before commencing any construction for the purpose of appropriating waters of the state or before taking waters of the state from any constructed works, shall first secure a water permit from the state engineer unless such construction or taking from such constructed works is for domestic or livestock purposes or for fish, wildlife, and other recreational uses or unless otherwise provided by law. However, immediately upon completing any constructed works for domestic or livestock purposes or for fish, wildlife, and other recreational uses the water user shall notify the state engineer of the location and acre-feet [1233.48 cubic meters] capacity of such constructed works, dams, or dugouts. Regardless of proposed use, however, all water users shall secure a water permit prior to constructing an impoundment capable of retaining more than twelve and one-half acre-feet [15418.52 cubic meters] of water or the construction of a well from which more than twelve and one-half acre-feet [15418.52 cubic meters] of water per year will be appropriated. In those cases where a permit is not required of a landowner or the landowner's lessee to appropriate less than twelve and one-half acre-feet [15418.52 cubic meters] of water from any source for domestic or livestock purposes or for fish, wildlife, and other recreational uses, those appropriators may apply for water permits in order to clearly establish a priority date; the state engineer may waive any fee or hearing for such applications. An applicant for a water permit to irrigate need not be the owner of the land to be irrigated.

B. DAMS:

(1) Drainage area above dam _____ sq. mi.,_____acres

(2) Purpose: _____

(3) Geometric description of dam

a. Maximum height (H)_____ ft.,_____ msl

b. Top width (T)_____ ft.

c. Side slope: upstream (S_1)_____:1

downstream (S_2)_____:1

d. Dimensions of principal spillway _____

e. Dimensions of emergency spillway _____

f. Type and dimensions of control gate _____

g. Type of outlet protection _____

h. Size of draw down pipe _____

	ELEVATION	RESERVOIR SURFACE AREA (acres)	RESERVOIR CAPACITY (acre-feet)
TOP OF DAM			*
EMERGENCY SPILLWAY			
PRINCIPAL SPILLWAY			
DRAWDOWN PIPE			
STREAMBED AT DAM			

* If Reservoir Capacity is 12 1/2 acre feet or greater at top of Dam, a complete set of plans and specifications must be submitted with and made part of this application/notification. The filing of this application/notification and its approval in no way relieves the landowner(s) from any responsibility or liability for damages from the construction, operation or failure of this structure.

C. DIKE:

(1) Is this application/notification for the construction of a ring dike? ☐ Yes ☐ No

If so, will the ring dike tie into existing? ☐ dike ☐ roadway ☐ high ground ☐ other _____

(2) Purpose: _____

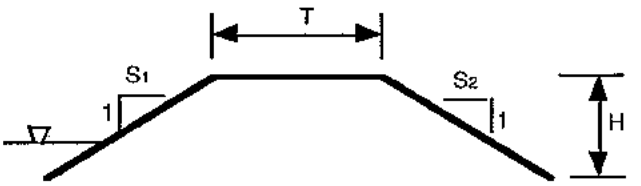
(3) Area of land to be protected by dike: _____ Acres

(4) Description of Dike:

a. Dike length_____feet

b. Dike design:

1. Top width (T) _____feet



2. Side slope upstream (S_1) _____:1

downstream (S_2) _____:1

3. Maximum height (H) _____feet.

Minimum height _____feet

4. Embankment erosion protection_____

(5) Will the dike flood or adversely affect adjacent, upstream or downstream land? ☐ Yes ☐ No

If so, have flowage easements been obtained? ☐ Yes ☐ No (If flowage easements have been obtained, attach copies and describe provisions of easements, and names of grantors)

(6) Is the proposed dike a result of a township-wide, county-wide, or other water management plan? ☐ Yes ☐ No If so, please describe on attached sheet.

D. WETLAND RESTORATION:

(1) The proposed wetlands are _____ Temporary _____ Permanent

(2) Drainage area above the structure _____ Acres

(3) Are the dam/ditch plug and restored wetland entirely on the applicants land? ☐ Yes ☐ No

If not, land rights are needed to construct dam/ditch plug and flood land. Copies of all easement should be included.

(4) Is this project mitigation for another project? ☐ Yes ☐ No (if yes, describe project)_____

_____

(5) Describe the proposed operation plan for the wetland. _____

_____

(6) If restored wetland volume is less than 12.5 acre-feet at top of structure, provide heights and length of structure in feet, surface area in acres, and volume in acre-feet for each restored wetland within each section.

(7) If restored wetland is greater than 12.5 acre-feet at top of structure provide information below for each restored wetland and complete Section B.

	OVERFLOW ELEVATION (feet)	VOLUME (acre-feet)	SURFACE AREA (acres)
EXISTING			
NATURAL			
PROPOSED			
TOP OF STRUCTURE			

E. OTHER WATER RESOURCE FACILITY:

(1) Design Data:

a. Pond, Lagoon or Dugout

1. Surface area_____ acres
2. Maximum storage _____ acre-feet
3. Maximum depth of water_____ feet
4. Maximum height of embankment above ground _____ feet

b. Diversion Ditch

1. Length of ditch _____feet
2. Bottom width _____feet
3. Side slope _____feet
4. Maximum cut _____feet
5. Gradient _____foot/foot

(2) Description of other project, if not a Pond, Lagoon, Dugout, or Diversion ditch:_____

_____

_____

(3) Waterway into which resevoir would discharge, if drained: _____

ADDITIONAL INFORMATION AND COMMENTS

_____

_____

_____

_____

A permit is granted only upon final decision by the state engineer after review by the water resource district in which the dam, dike, or other device is located. The following definitions apply:

1. Waterway-- include any natural or artificial lake, pond, slough, river,stream, brook,coulee, creek, rill, swale, canal, channel, or ditch.
2. Dam - a structure built across a waterway capable of retaining water.
3. Dike - a structure built along or adjacent to a waterway capable of diverting water.
4. Ring Dike - a structure built around an area such as a farm site or village.
5. Other Device - Includes but is not limited to a division ditch, dugout, lagoon, and holding ponds.

If failure of the project will result in substantial damage to property or loss of life the affidavit of Design Engineer Section will need to be completed.

AFFIDAVIT OF DESIGN ENGINEER

I, _____, a registered professional engineer in the State of North Dakota, designed or directly supervised the design of the dam and reservoir as described in this application and on attached sheets, and construction will be approved by me according to the specifications and data shown in this application and data sheets attached hereto. Dated this _____day of _____ 19____.

The filing of this application/notification in no way relieves the landowner from any responsibility or liability for damages from the construction, operation or failure of the project.

Date Submitted:_____ Name (Print or Type): _____

(Land Owner)

Signed:_____ Address: _____

(Owner of the land on which the project / is located or legal entity sponsoring project)

_____

Phone No. (___)-_____

Application No._____

STATE OF NORTH DAKOTA
APPLICATION FOR CONDITIONAL WATER PERMIT

NOTE: Use one application for each type of source (ground water, surface water). Check all appropriate boxes and fill in each blank line. If the question is not applicable to your proposed development, enter NA (not applicable). If more space is necessary, attach additional sheets.

(PLEASE TYPE OR PRINT IN INK)

1. Name of Applicant _____

Mailing Address _____

City _____ State _____ Zip _____

Home Phone _____ Other Phone _____

2. Source of water supply: ☐ ground water ☐ surface water

If surface water: (a) stream _____ a tributary of _____

_____

(b) If new impoundment — _____1/4_____1/4 Sec._____, Twp._____, Rge. ____

(c) If existing impoundment, give name _____

3. Point of diversion:

(1) _____1/4 of Section_____Township_____N., Range_____W.,_____County

Additional points of diversion, if any:

(2) _____1/4 of Section_____Township_____N., Range_____W.,_____County

(3) _____1/4 of Section_____Township_____N., Range_____W.,_____County

(4) _____1/4 of Section_____Township_____N., Range_____W.,_____County

4. Amount of water requested:

(a) Annual use from points listed in Item 3 above, rate of diversion, and period of use:

_____acre-feet at_____ cfs / gpm from_____to_____inclusive
(AMOUNT) (RATE) (MONTH-DAY) (MONTH-DAY)

(b) If Impoundment:_____acre-feet storage out of which_____acre-feet will be used to offset evaporative losses.

(c) Total annual use requested (sum of annual use from 4a and evaporation from 4b):

_____acre-feet

5. Proposed construction:

Proposed starting date _____

Anticipated completion date _____

6. Description of proposed beneficial water uses:

(a) Irrigation (if applicable)

(1) Method of irrigation: ☐ gravity ☐ sprinkler ☐ waterspreading

(2) Project will involve new irrigated land: ☐ Yes ☐ No

(3) Project will involve supplemental water to existing irrigation: ☐ Yes ☐ No

(4) Description of land to be irrigated (show lot numbers where applicable):

SEC.	TWP.	RGE.	NE1/4				NW1/4				SW1/4				SE1/4				TOTAL
			NE1/4	NW1/4	SW1/4	SE1/4	NE1/4	NW1/4	SW1/4	SE1/4	NE1/4	NW1/4	SW1/4	SE1/4	NE1/4	NW1/4	SW1/4	SE1/4	
TOTAL NUMBER OF ACRES TO BE IRRIGATED:																			

(b) Non-irrigation use (if applicable):

Municipal _____ Recreation _____

Rural-Domestic _____ Fish and Wildlife _____

Industrial _____ Other (please specify) _____

7. Ownership:

(a) Property owner at the point of diversion: _____

(b) Property owner at the place of use: _____

(c) If either (a) or (b) above are other than the applicant, describe the arrangement enabling the applicant to make this filing: _____

_____

_____

8. State law requires that cities and landowners within a one-mile radius of the proposed point of diversion be advised of this application. A completed "Notice of Application" will be forwarded to you upon receipt of this application. Therefore, please indicate the number of landowners and cities which you must notify:

_____

9. *THE APPLICANT CERTIFIES THAT THE STATEMENTS APPEARING HEREIN ARE TO THE BEST OF HIS KNOWLEDGE TRUE AND CORRECT:*

_____
(SIGNATURE) (DATE)

_____
(SIGNATURE) (DATE)

_____
(SIGNATURE) (DATE)

Signature of the applicant(s) must be exactly as in item 1. If more than one applicant is shown, all must sign.

NOTE: Mail the completed application, along with the required map and application fee to:

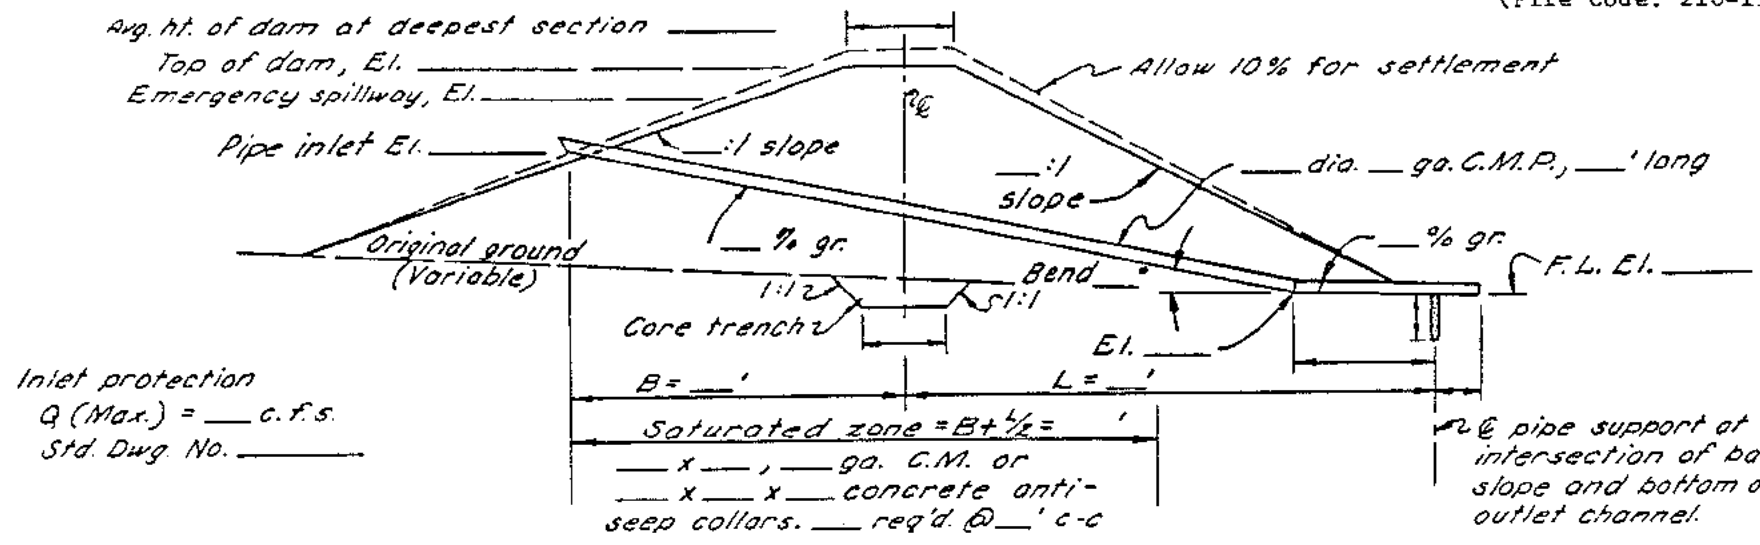
1. Category I: required capacity = $\frac{\text{drainage area (ac.)}}{640}$ x 7 = _____c.f.s.
2. Category II: peak discharge (Q)* _____c.f.s. (required capacity)
3. Type of spillway: hood_____ hood with weir box_____ drop inlet_____
4. Weir length_____ft. (riser diameter_____ inches)
   (weir box_____ ft. x _____ ft.)
5. Barrel diameter _____ inches; length _____ ft.
6. H_w = _____ ft. Q_w = _____c.f.s.
7. Hor = _____ ft. Qor = _____ c.f.s.
8. H_{ob} = _____ ft. Q_{ob} = _____ c.f.s.
9. H_b = _____ ft. Q_b = _____ c.f.s.
10. Principal spillway capacity _____c.f.s. (must equal or exceed 1 or 2)
    (lesser of 6, 7, 8 or 9)



EMERGENCY SPILLWAY

1. Peak discharge (Q) _____ c.f.s.*
2. Shaped spillway design
   a. Depth of water above ES crest H_p = _____ ft.
   b. Total length of spillway L = _____ ft.
   c. Length of level section _____ft.
   d. S_o = _____
   e. Discharge per foot of width** q = _____ c.f.s.
   f. Design width W=Q/q = _____ ft.
   g. SS = _____ : 1
3. Natural spillway design
   a. Top width of spillway at design flow depth _____ ft.
   b. Cross sectional area at flow depth _____ sq.ft.
   c. Mean depth = $\frac{\text{cross sectional area}}{\text{top width}}$ = _____ ft.
   d. S_o = _____
   e. Crest length (approx. level section) _____ ft.
   f. Design capacity (Q)* _____ c.f.s.

INSTRUCTIONS

The JOB DIARY is the pertinent history of the project beginning with the showing of the site to prospective bidders and concluding with the completion of the job. Keep the diary at hand at all times; make complete, legible entries as events occur and sign them.

Pages are provided in the front of the diary for (1) listing the information in the bid schedule, (2) listing the data for material certification and (3) keeping the equipment operating record. Note: To keep the "Type and size of unit" column visible for the pages following it, fold the right-hand sheet back on itself to expose that page in two half-page segments.

Use one numbered page for each shift in which the contractor performs work. Make appropriate entries to record weather, rainfall, duration of work, force used, quantities of work accomplished, and the narrative record. Include in the narrative record, instructions given the contractor, notation of stakes set, measurements taken, tests made, equipment and material delivered to or removed from the site, time lost, cause of delays, rejected work, problems, etc. Show the time of other Service employees on the site and the work they performed. Record the names and purpose of job related visitors. Note pertinent points of discussions between landowners and contractors or their supervisory personnel.

Additional ruled pages are provided in the back for supplemental narrative. Cross-reference the supplemental entries; date and sign them. See Chapter 7 of the Watershed Protection Handbook for more detailed instructions.

1. Spalling			
2. Cracking			
3. Erosion			
4. Scaling			
5. Exposed reinforcement			
B. Do joints show:			
1. Displacement or offset			
2. Loss of joint material			
3. Leakage			
C. If spillway is earth cut			
1. Are slopes eroding			
2. Are slopes sloughing			
3. Is crest eroding			
D. If controlled spillway			
1. Are gates bent/broken			
2. Are they corroded/rusted			
3. Are controls, hoists, etc. in need of repair			
4. Not maintained			
5. Not Operated Periodically			
6. Date last operated			
7. When closed, do they leak			
E. Is weir in poor condition			
F. Where is control structure			

ITEM	YES	NO	REMARKS
3. CONVEYANCE STRUCTURE (SPILLWAY CONT)			
A. If structure is concrete			
1. Do concrete surfaces show:			
a. Spalling			
b. Cracking			
c. Erosion			
d. Scaling			
e. Exposed reinforcement			
2. Do joints show:			
a. Displacement or offset			
b. Loss of joint material			
c. Leakage			
B. For an unlined channel			
1. Does channel show erosion			
2. Side slopes show sloughing			
3. Is channel poorly protected with vegetation/riprap			
4. TERMINAL STRUCTURE			
A. Do concrete surfaces show:			
1. Spalling			
2. Cracking			
3. Erosion			
4. Scaling			
5. Exposed reinforcement			
B. Do joints show:			
1. Displacement			
2. Loss of joint material			
3. Leakage			
C. Do energy dissipators show:			
1. Signs of deterioration			
2. Are they covered w/debris			
3. Signs of inadequacy			
5. OUTLET CHANNEL			
A. Is the channel:			
1. Eroding or backcutting			
2. Sloughing			
3. Obstructed			
4. Inadequately riprapped			

ITEM	YES	NO	REMARKS
OUTLET WORKS			
1. APPROACH CHANNEL			
A. Eroding or backcutting			
B. Sloughing			
C. Restricted by vegetation			
D. Obstructed with debris			
E. Silted in			
2. INTAKE STRUCTURE			
A. Do concrete surfaces show:			
1. Spalling			
2. Cracking			
3. Erosion			
4. Scaling			
5. Exposed reinforcement			
B. Do joints show:			
1. Displacement or offset			
2. Loss of joint material			
3. Leakage			
C. Metal Appurtenances			
1. Corrosion present			
2. Breakage present			
3. Anchor system poorly secured			
D. Obstructed by silt & debris			
3. CONVEYANCE STRUCTURE			
A. If structure is concrete			
1. Do concrete surfaces show:			
a. Spalling			
b. Cracking			
c. Erosion			
d. Scaling			
e. Exposed reinforcement			
2. Do joints show:			
a. Displacement or offset			
b. Loss of joint material			
c. Leakage			
B. If conduit is metal			
1. Is corrosion present			
2. Protective coating deficient			
3. Is the conduit misaligned			

ITEM	YES	NO	REMARKS
4. CONTROL STRUCTURE (OUTLET WORKS CONT)			
A. Are service gates in need of repair			
B. Emergency gates/stop logs in need of repair			
C. Are control valves in need of repair			
D. Are they bent/broken			
E. Are they corroded/rusted			
F. Not maintained			
G. Unoperational			
H. When closed, do they leak			
I. Date last operated			
J. Is cold water return not operational			
K. Is the low level outlet not operational			
5. TERMINAL STRUCTURE			
A. Do concrete surfaces show:			
1. Spalling			
2. Cracking			
3. Erosion			
4. Scaling			
5. Exposed reinforcement			
B. Do joints show:			
1. Displacement			
2. Loss of joint material			
3. Leakage			
C. Do the energy dissipators:			
1. Show signs of deterioration			
2. Covered with debris			
3. Show signs of inadequacy			
6. OUTLET CHANNEL			
A. Is the channel:			
1. Eroding or backcutting			
2. Sloughing			
3. Obstructed			
4. Poorly riprapped			

ITEM	YES	NO	REMARKS
DOWNSTREAM AREA			
1. Bridges or culverts that may restrict discharge			
2. Other obstructions which interfere with discharge			
3. Channel headcutting			
4. Downstream floodwalls, levies dikes			
5. Reservoir-connected "springs"			
6. Buildings in flood plain			
7. Overnight recreational sites			
8. Public access sites			
PROJECT AREA			
1. SITE ACCESS			
A. Roads to site inadequate			
B. Unreliable under all weather conditions			
C. Unreliable at all reservoir & river stages			
2. SPILLWAY AND OUTLET CONTROL ACCESS			
A. Are catwalks, ladders, bridges insecurely anchored			
B. Are they unsafe			
C. Are they below elevation of high water			
INSTRUMENTATION			
1. List type(s) of instrumentation			
2. In poor condition			
3. Not read periodically			
4. Is data unavailable			
Notes: List upstream dams			
List downstream dams			
List any high water mark

APPENDIX E

1. Example Categories of Action

2. Emergency Action Plan Directory

EXAMPLE CATEGORIES OF ACTION

CATEGORY I - Failure or Impending Failure Conditions
(THE EMERGENCY ACTION PLAN WILL BE ACTIVATED IF ANY OF THE FOLLOWING CONDITIONS ARE NOTED)

1. embankment is overtopped by flood waters;
2. slides on the embankment slopes and a reservoir water level near the embankment crest;
3. flows through the embankment, foundation, or abutments;
4. large - cloudy seepage;
5. failure of appurtenant structures such as principal outlet works or spillway;
6. mass movement of the dam on its foundation such as spreading or mass sliding failure; and
7. severe erosion in the principal spillway area.

CATEGORY II - Potential Failure Conditions
(AN IMMEDIATE INSPECTION BY A QUALIFIED ENGINEER IS REQUIRED IF ANY OF THE FOLLOWING CONDITIONS ARE NOTED)

1. extremely high water level (a specific level should be determined for each dam);
2. erosion from wave action caused by high winds;
3. landslide, or slides in the upstream or downstream slopes of the embankment;
4. emergency spillway erosion;
5. excessive settlement of embankment;
6. slumping or cracking of dam or abutments;
7. new springs, seeps or boggy areas in the embankment or abutment areas;
8. abnormal instrumentation readings;
9. severe storms; and
10. demonstrations or sabotage.

E.34. Ohio

OHIO DAM SAFETY LAWS AND REGULATIONS 2007

Citation

Ohio Dam Safety Laws are found in the Ohio Revised Code – (ORC) Title XV (enacted Oct. 10, 1963 and last amended March 2007. Administrative rules enacted by the Division of Water of the Department of Natural Resources supplement the permit and inspection laws and reflect Division of Water policy and procedures in carrying out the intent of the law (enacted April 15, 1972, revised Oct. 15, 1981, December 9, 1999, and May 15, 2006).

History

Construction of dams in Ohio dates back to the early 1800s when reservoirs were built to supply water to a state canal system used for agricultural trade and commerce.

Legislation encouraging construction of dams in response to droughts was enacted in 1937, but the forerunner of Ohio's current dam safety laws was enacted in 1963, when the Ohio Department of Natural Resources Division of Water became involved in dam safety. This law required construction permits for new dams.

In 1969, following the failure of several dams in northeast Ohio, the General Assembly revised the law to include periodic inspections of existing structures.

Definitions/Dam Classification

Dams are defined as any artificial barrier together with any appurtenant works, which either does or may impound water or other liquefied material. Upground reservoirs and lagoons are considered to be dams. A fill or structure intended solely for highway or railroad use that does not permanently impound water or other liquefied material as determined by the chief is not considered a dam (Administrative Rules Chapter 3-1501:21-3-01[E]).

Dam height means the vertical dimension as measured from the elevation of the natural stream bed, watercourse, or lowest ground elevation at the downstream or outside toe of a dam to the elevation of the top of the dam (Administrative Rules Chapter 3-1501:21-3-01[I]).

Classification criteria for dams are found in the Administrative Rules Chapter 13-1501:21-13-01.

(1) A dam shall be placed in *class I* when sudden failure of the dam would result in probable loss of human life or structural collapse of at least one residence or one commercial or industrial business. Dams having a total storage volume greater than five thousand acre-feet or a height of greater than sixty feet shall be placed in class I.

(2) Dams having a total storage volume greater than five hundred acre-feet or a height of greater than forty feet shall be placed in *class II*. A dam shall be placed in class II when failure of the dam would result in at least one of the following conditions, but loss of human life is not probable.

(a) Disruption of a public water supply or wastewater treatment facility, release of

health hazardous industrial or commercial waste, or other health hazards.
(b) Flooding of residential, commercial, industrial, or publicly owned structures.
(c) Flooding of high-value property.
(d) Damage or disruption to major roads including but not limited to interstate and state highways, and the only access to residential or other critical areas such as hospitals, nursing homes, or correctional facilities as determined by the chief.
(e) Damage or disruption to railroads~~,~~ or public utilities.
(f) Damage to downstream class I, II or III dams or levees, or other dams or levees of high value. Damage to dams or levees can include, but is not limited to, overtopping of the structure.

(3) Dams having a height of greater than twenty-five feet or a total storage volume greater than fifty acre-feet shall be placed in *class III*. A dam shall be placed in class III when sudden failure of the dam would result in at least one of the following conditions, but loss of human life is not probable.

(a) Property losses including but not limited to rural buildings not otherwise described in paragraph (A) of this rule, and class IV dams and levees not otherwise listed as high-value property in paragraph (A) of this rule. At the request of the dam owner, the chief may exempt dams from the criterion of this paragraph if the dam owner owns the potentially affected property.

(b) Damage or disruption to local roads including but not limited to roads not otherwise listed as major roads in paragraph (A) of this rule.

(4) When sudden failure of the dam would result in property losses restricted mainly to the dam and rural lands, and loss of human life is not probable, the dam may be placed in *class IV*. Dams which are twenty-five feet or less in height and have a total storage volume of fifty acre-feet or less may be placed in class IV. Class IV dams are exempt from the permit requirements of section 1521.06 of the Revised Code pursuant to paragraph (C) of rule 1501:21-19-01 of the Administrative Code.

(B) All pertinent information including any unusual circumstances shall be considered by the chief in establishing an appropriate classification for a dam. Probable future development of the area downstream from the dam that would be affected by its failure shall be considered. Completed downstream hazard mitigation such as acquisition, removal or protection of downstream property may also be considered. However, the above criteria shall in no way preclude the chief's requirement of greater safety in the interest of life, health, or property.

Design Criteria

Hydrologic:

The magnitude of the design flood for each dam shall be set by the chief and determined from actual streamflow and flood frequency records or from synthetic hydrologic criteria based on current publications prepared by the division, the United States army corps of engineers, the United States geologic survey, the national oceanic and atmospheric administration, or others acceptable to the chief.

The minimum design flood will be:

(1) For class I dams, the probable maximum flood or the critical flood;
(2) For class II dams, fifty percent of the probable maximum flood or the critical flood; and,
(3) For class III dams, twenty-five percent of the probable maximum flood or the critical flood.

Seismic:

Seismic design criteria for dams are included in the general design requirements of paragraph (A) of Administrative Rule 1501:21-13-08.

(A) The safety factors for the various elements of the dam shall conform to good engineering practice as approved by the chief. The safety factors and the design standards that are used by the applicant shall agree with the approved design assumptions.

Jurisdiction/Powers of Department

Sections 1521.06-064 of the ORC place the authority for implementation of the dam safety laws within the Division of Water of the Department of Natural Resources.

Section 1521.06 requires that persons or governmental agencies desiring to construct certain dams must obtain a construction permit from the chief of the Division of Water. The Chief has the power to approve or disapprove an application.

Sections 119.01 to 119.13 of the ORC give the Chief of the Division of Water the power to prescribe rules and regulations.

Section 1521.062 of the ORC gives the Chief the power to call for remedial measures, as he deems necessary to safeguard life, health, or property.

If the owner fails to perform such repairs, maintenance, remedial measures, or other measures within the required time period as may have been ordered by the chief, the chief has the right to cite noncompliance and seek judicial measures to have the structure removed or the deficiencies corrected at the expense of the owner. (Administrative Rules 1501:21-21-05).

Permit/Approval Process

Before a construction permit may be issued, three copies of the plans and specifications, including a detailed cost estimate, for the proposed construction, prepared by a registered professional engineer, together with a fee (graduated scale – based on the estimated cost of construction) and the bond or other security required by section 1521.061 of the ORC, shall be filed with the chief. The chief shall within 30 days from the date of the receipt of the application, fee, and bond or other security, issue or deny a permit for the construction or may issue a permit conditioned upon the making of such changes in the plans and specifications for the construction as the chief considers advisable if the chief ~~he~~ determines that the construction of the proposed dam would endanger life, health, or property. If the permit is denied, the bond or other security is returned to the applicant.

After the construction is completed in accordance with the terms of the permit and the plans and specifications, the chief will approve the construction. One year later, if no evidence of non-compliance is evident, the bond is released (ORC 1521.06). As required by Section 1521.063 of the ORC, the owner is then required to pay an annual fee to the Division based on the classification and size of the dam. Owners of pre-permit, Class I, II, and III dams must also pay an annual fee.

Required spillway design standards are found in the Administrative Rules Section 1501:21-13-03 through -05.

Dam construction, including remedial work, is to be paid for by the owner (Administrative Rules 1501:21-21-05).

Repair, Improvement, Alteration, or Removal

Before commencing the repair, improvement, alteration, or removal of a dam or levee, the owner shall file an application including plans, specifications, and other required information, and shall secure written approval of the application by the Chief. Emergency actions by the owner required to safeguard life, health, or property are exempt from this requirement (ORC 1521.062 F).

Fees

Fees on a graduated scale, based on estimated construction costs, are required to obtain construction permits.

Owners of pre-permit, Class I, II, and III dams must also pay an annual fee based on dam classification and size.

Inspection Process

Pursuant to Section 1521.062 of the ORC, periodic inspections will be made by the chief of all class I, II, and III dams to ensure that continued operation and use of the dam does not constitute a hazard to life, health, or property. The chief may make, as deemed necessary, periodic inspections of Class IV dams (Administrative Rules 1501:21-21-01). Section 1521.064 of the ORC provides for the exemption of certain dams from inspection if they meet specific criteria established by the Division of Water. The Rules do not specify any inspection fees to be paid by the owner.

An operation, maintenance and inspection manual is required for all Class I, II and III dams. The manual will include a program for regular inspection, maintenance, and monitoring by the owner or operator (Administrative Rules 1501:21-15-06).

An emergency action plan is required for all class I, II and III structures. The emergency action plan for all class I structures shall include but not be limited to an inundation map of the critical routing reach. An inundation map may also be required for class II and III dams as designated by the chief. The required detail of this map depends upon the complexity of the downstream hazard and shall be acceptable to the chief. (Administrative Rule 1501:21-15-07)

The owner is required to have a licensed, professional engineer perform all inspections

(Administrative Rules 1501-21-3-02).

The chief may make inspections during construction as deemed necessary to insure that the structure is being built in compliance with the approved plans and specifications (Administrative Rules 1501:21-17-01).

Frequency of Inspections

Hazard Classification	*Inspection Cycle*
High	Not to exceed 5 years
Significant	Not to exceed 5 years
Low	Not to exceed 5 years

Violations/Penalties

If the owner fails to perform repairs, maintenance, remedial measures, or other measures as mandated by the chief, the chief shall so notify the owner of the noncompliance and of the chief's intention to remove or correct the unsafe structure, at the expense of the owner, pursuant to section 1521.062 of the ORC. Such cost is a lien upon such lands from the date of entry and shall be collected as other taxes and returned to the division (Administrative Rules 1501:21-21-05). Section 1521.99 of the ORC establishes penalties for violations of Section 1521.06 and 1521.062.

Emergencies

The chief of the Division of Water is empowered to take charge of a dam safety emergency to protect life, property, and health. If the condition of any dam is found, in the judgment of the chief, to be so dangerous to the safety of life, health, or property as not to permit time for the issuance and enforcement of an order relative to repair, maintenance, or operation, the chief shall employ any of the following remedial means necessary to protect life, health, and property.

(1) Lower the water level of the lake or reservoir by releasing water;
(2) Completely drain the lake or reservoir;
(3) Take such other measures or actions as the chief considers necessary to safeguard life, health, and property.

The chief shall continue in full charge and control of the dam or levee until the structure is rendered safe. The cost of the remedy shall be recoverable from the owner of the structure by appropriate action in a court of competent jurisdiction.

Liability

Pursuant to the provisions of section 1521.062 of the ORC, the owner of a dam shall be responsible for the continued safe operation and use of the structure so that it does not constitute a hazard to life, health, or property.

In the interest of safeguarding life, health, or property, the chief may require the owner to prepare a written manual detailing the operation, maintenance, and inspection procedures necessary for the continued safe operation of the dam (Administrative Rules 1501:21-21-04).

Oversight

All orders of the chief are subject to appeal pursuant to sections 1521.06, -.062, and 119.01 to 119.13 of the ORC. Filing of an appeal does not automatically stay the effectiveness of the orders of the chief (Administrative Rules 1501:21-23-01).

Miscellaneous

The following dams are exempt from the construction permit requirement (Administrative Rules 1501:21-19-01):

- Dams constructed under Chapter 1513 ORC (coal mine impoundments).
- Dams, regardless of height, which have a storage capacity of not more than 15 acre-feet.
- Dams less than 10 feet in height, with a storage capacity of not more than 50 acre-feet.
- Dams designed and constructed by the United States Army Corps of Engineers.
- Dams constructed by the state of Ohio, Department of Natural Resources.
- Dams placed by the chief in class IV under rules 1501:21-13-01 of the Administrative Rules.
- Modifications or repairs to existing dams provided that the modifications or repairs do not constitute an enlargement to the structure as defined under rule 1501:21-3-01 of the Administrative Rules.

Ohio Department of Natural Resources
Division of Water Fact Sheet

Fact Sheet 95–37

Dam Safety: Probable Maximum Flood

Uncontrolled flood waters are one of the most powerful and destructive forces in nature. Dams that are not designed to withstand major storms may be destroyed by them, increasing flood damage downstream. This damage is too often catastrophic. In order to protect lives and property downstream, the Ohio Administrative Code requires that dams be constructed to safely handle an appropriate percentage of the Probable Maximum Flood (PMF). This percentage varies according to the height of the dam, size of the impoundment, and extent and severity of damage possible upon failure. The requirements established in Ohio are similar to those used in other states, and historical records of significant storms and dam failures this century verify that the design criteria are reasonable.

Definitions

The Probable Maximum Precipitation (PMP) is the greatest depth (amount) of precipitation, for a given storm duration, that is theoretically possible for a particular area and geographic location.

The Probable Maximum Flood (PMF) is the flood that may be expected from the most severe combination of critical meteorological and hydrologic conditions that are reasonably possible in a particular drainage area.

Historical Storms in Ohio and Dam Failures

Storms which have caused severe flooding and included precipitation amounts that reached a significant percentage of the PMP have occurred in Ohio this century. Flood waters from these storms caused the failure of dams and other structures. Many dam failures are considered disasters because they cause great harm, damage, or serious and sudden misfortune. Because of the rapid and unexpected manner in which dam failures can occur, they are judged to be as serious as earthquakes and tornadoes.

A storm approaching two thirds of the PMP struck north-central Ohio in the summer of 1969. Some small areas within the region were inundated with 14 inches of rain in 12 hours. Three large dams and many small farm-pond dams failed. Almost all the failures were caused by water overtopping the dams.

In 1990, severe flash floods destroyed eighty residences near the town of Shadyside in southeast Ohio. Twenty six people died. In this instance, the amount of precipitation did not constitute a high percentage of the PMP, yet the flood waters which resulted were deep and powerful.

The potential for damage due to dam failures is increasing along with the increase of residential and commercial development downstream of dams. In many cases, existing dams will need to be modified to keep downstream areas safe from disaster.

Recent Notable U.S. Dam Failures

Year	Name	Location	Deaths	Damage
1972	Buffalo Creek Dam	West Virginia	125	$400 million
1972	Canyon Lake Dam	South Dakota	139	$60 million
1976	Teton Dam	Idaho	11	$400 million
1977	Taccoa Falls Dam	Georgia	39	$30 milllion
1982	Lawn Lake Dam	Colorado	3	$21 million

Classification of Ohio Dams

Dams in Ohio are divided into four classes based on the storage volume of the impoundment, dam height and potential downstream hazard (how far downstream the residences are, etc.). These criteria were chosen because they affect the extent and severity of downstream damage possible upon failure. The percentage of the PMF that a dam must be designed to withstand depends upon its classification. Dams that could cause loss of human life if they fail must be designed to handle 100 percent of the PMF. More details about the classification system can be found in the Ohio Administrative Code and Fact Sheet No. 94-29.

Development of the PMP

Scientists use both meteorological methods and historical records to determine the greatest amount of precipitation which is theoretically possible within a region. The historical data consists of point precipitation amounts measured at rain gages throughout the region being studied, or a region with very similar meteorologic and topographic characteristics. These rainfall data are subsequently maximized through "moisture maximization" and other numerical methods. Moisture maximization

Continued on back!

is a process in which the maximum possible atmospheric moisture for a region is applied to rainfall data from a historic storm. This process increases the rainfall depths, bringing them closer to their potential maximum.

Probable maximum precipitation amounts vary slightly throughout Ohio because of variations in topography and meteorology. The PMP is greatest in the southern portion of the state. Furthermore, not all storms have the same duration. Using the methods mentioned above, the PMP has been determined for different storm periods, generally ranging from six to seventy two hours.

Development of the PMF

The Probable Maximum Flood is the flood which is a direct result of the Probable Maximum Precipitation. However, drainage areas with the same PMP may have different PMFs. This is possible because the amount of flooding which results from a given rainfall amount depends upon the characteristics of the drainage basin. For this reason, the PMF, not the PMP, must be used as a design criterion for a dam. Some important characteristics include soil type, land use, size and shape of the watershed, and average watershed slope. Both the volume and rate of runoff are affected. For example, water will run off of steep slopes more quickly than gentle ones. More water will infiltrate sandy soils than clay.

Division of Water Fact Sheet

Fact Sheet 99–60

Dam Safety: Critical Flood Design Criteria

Ohio's Dam Safety Rules require dams to pass floods through their spillways without endangering the safety of the dam. The magnitude of the design flood is directly related to the classification of the dam - which in turn is related to the dam's downstream hazard and/or the dam's height. The greater the downstream hazard, i.e., loss of human life, high-value property, etc., the larger the design flood.

Definitions

The probable Maximum Precipitation (PMP) is the greatest depth (amount) of precipitation for a given storm duration, that is theoretically possible for a particular area and geographic location. The Probable Maximum Flood (PMF) is the flood that may be expected from the most severe combination of critical meteorological and hydrologic conditions that are reasonably possible in a particular drainage area.

Classification of Ohio Dams

Dams in Ohio are divided into four classes based on the storage volume of the impoundment, dam height, and potential downstream hazard (how far downstream residences, businesses are, etc.). More details about the classification system can be found in the Dam Safety: Classification of Structures Fact Sheet No. 94-29.

Critical Flood Design Criteria

Specific guidelines are available for preparing a critical flood engineering analysis. This analysis must be performed by a professional engineer licensed in the State of Ohio. The guidelines can be downloaded from the Division of Water's world wide web site, (http://www.dnr.state.oh.us/odnr/water/temp/dartrlsa.html), or you can request a copy by calling our office directly.

Could the Critical Flood Analysis Make a Difference for My Dam?

The critical flood criteria were developed to make Ohio's Dam Safety Rules more flexible in recognizing that some dams fall outside of the typical parameters used in designing spillway capacity. Specifically, for those circumstances where the size of the dam, its downstream hazard, drainage area, and downstream topography are such that traditional flood design standards do not accurately account for the downstream hazard, critical flood criteria allow for a reduction of up to 60% of the design flood.

For example, let's look at a Class I dam. This type of dam is required to safely pass the 100% PMF through its spillway system without endangering the safety of the dam. As rain falls onto a dam's watershed, some of the rainfall will infiltrate into the ground, some will evaporate, and most of it will runoff across the ground into the pond or lake. The water level in the impoundment will begin to rise while simultaneously flowing through the dam's spillway(s). As water exits the dam's spillway(s), the downstream channel will begin to fill and flow accordingly. For most dams, the downstream channel will likely fill with some water, but most of the water flows downstream without backing up significantly. For those few cases where the downstream channel fills rapidly to the point where water rises dramatically and failure of the dam would have no additional significant increase in elevations of floods downstream, the design flood can be reduced. In other words, there may be a point, say 50% of the PMF (the critical flood in this case), where designing for additional flood capacity for the dam is no longer reasonable. If the dam were to fail, the downstream hazard would not be further adversely effected. In this case, the spillway system may be designed for half of what it would have been originally designed, therefore saving dollars without increasing the hazard to the downstream area.

What is the Maximum Reduction in Design Flood?

The design flood can be reduced approximately up to 60% for each class of dam:

Class I	100% PMF down to no less than 40% PMF
Class II	50% PMF down to no less than 20% PMF
Class III	25% PMF down to no less than 100 Year

Continued on back!

What Factors Should I Consider Before Proceeding With an Analysis?

The cost of the analysis can be thousands of dollars. Let's assume that a dam inspection by our engineers reveals that a dam is deficient in its ability to pass the design flood. It would be beneficial to have an analysis performed if the design flood was reduced enough so that the spillway system did not need to be upgraded or replaced. Let's assume that upgrading the spillway system costs $50,000. If the cost of the critical flood analysis was $5,000, the cost of the critical flood analysis would be warranted.

Sometimes it can be straightforward to predict whether or not an analysis would be beneficial. However, in those cases where it may not be clear, other options should be considered. For example, if room exists in one of the dam's abutments to excavate an emergency spillway or perhaps enlarge an existing emergency spillway, it may be more cost effective to do so. There is always a risk in running an analysis and finding out that the reduction in design flood is insignificant and the spillway system enlargement is still required.

A critical flood analysis approved by our office means that a reduced design flood is acceptable for your dam. Please note that a reduction in the design flood for your dam may increase the risk of failure or damage to your dam. This could result in an economical burden on the dam owner. This risk should be closely considered!

How Can I Apply for the Critical Flood Reduction?

A request for consideration must be submitted to the Chief of the Division of Water. The request must be accompanied by supporting calculations based upon an analysis performed by a professional engineer registered in the State of Ohio. The engineer's analysis must conform to the critical flood guidelines provided by the Division of Water.

Before applying, it is best to call and speak with an engineer in the Division's Dam Safety Engineering Program.

What Restrictions Are There?

A critical flood reduction based upon planned evacuation, probability of inhabitation, or monetary recovery of property damage will not be considered. In other words, guaranteeing that a downstream residence or business will be evacuated during a dam failure will not be considered. In situations where the downstream hazard may or may not be inhabited, such as in the case of a campground, rental property, hotel, and so forth, the probability of inhabitation will not be considered. Also, understanding that failure of a dam will damage downstream property and guaranteeing that the damages will be paid for will also not be considered. Finally, if the downstream hazard were to change, the critical flood exemption could be nullified.

Any other questions, comments concerns, or fact sheet requests, should be directed to the Division of Water at the following address:

Website: http://www.dnr.state.oh.us/water

Critical Flood Guidelines

Purpose of the “critical flood” rule is to recognize that in certain situations, overtopping dam failures may be insignificant in how much damage they cause to downstream areas. It is based on the assumption that if all downstream flood damages occur due to a base-flow flood that is less than the regulatory design flood for the dam, then requiring additional spillway capacity above this flood to satisfy the design flood requirement would therefore, not be necessary. For this outcome, a flood of lesser size may exists that would show a more measurable impact than the regulatory design flood for the dam. The measurable impact that occurs to downstream areas from any hypothetical base-flow flood, given the dam fails, must be greater than the amount occurred for the same flood, given the dam does not fail, before the flood can be labeled as critical. The term “base-flow” flood, used throughout this document, refers to a starting flood condition in which an action or undertaking is made and should not be misinterpreted as groundwater flow.

The importance as to the dam's value and benefits it provides to the owner and the community must always be evaluated before subjecting the dam to possible overtopping and failure by a flood that is less than the required design flood for the structure. An incremental damage analysis may be used to determine the inflow design (critical) flood that is less than the minimum requirements of 1501:21-13-02. The flood will be based upon a comparison of two flood simulations occurring with the dam in question present: one, a base-flow flood that has a size that would cause failure of the dam, but has been modeled without any effects from a dam failure (Condition A), two, the same flood, but modeled to include the dam-break discharges based on the most severe hypothetical dam failure that is possible (Condition B). These flood simulations are routed downstream through a reach that has been determined to be the recipient of the potential floodwater damages. The spillway capacity and inflow design flood will be acceptable where it can be shown that the dam failure flood (Condition B) would cause no expected additional loss of life and would not cause significant incremental flood damages downstream of the dam. Additional potential for loss of life, health or property in the critical routing reach is expected if the incremental depth of flow between the dam failure and non-failure floods is greater than 2.0 feet or the product of the average floodplain flow velocity and the incremental depth is greater than 7.0 feet^2/second.

The design for the critical flood must be for specific site conditions and based on a quantitative and relative impact analysis of the downstream critical routing reach. The owner must submit to the chief, in writing, a request for consideration of the critical flood as the design flood. This request must be accompanied by appropriate supporting calculations. The chief will not consider risk assessment based upon planned evacuation, probability of inhabitation, or monetary recovery of property damage.

The scope of the critical flood analysis will identify the flooding source, upstream and downstream limits of the stream reach to be studied, and the applicable hydrologic and hydraulic methodology to be used. The scope may require completion of any or all of the following work items:

I. Field surveys to obtain data for stream and adjacent floodplain cross sections and other structures that may affect the hydraulics of the study reach.

II. Hydrologic analyses to determine stream peak discharges for the dam's design flood and any floods of a lesser magnitude used in the process of determining the inflow design flood for the dam.

III. Hydraulic analyses to determine dam failure discharges, flood elevations and floodplain stream and channel velocities at critical locations along the study reach.

IV. Development of a flood inundation map for the critical structures within the study reach using topographic work maps of the floodplains.

General Requirements:

1. A critical flood study conducted in accordance with Ohio Administrative Code (OAC) Rule 1501:21-13-02 shall include a written statement of purpose and scope of the analysis.

2. The analysis shall identify the flooding source, recurrence intervals for all flood events that were analyzed, upstream and downstream limits of stream reach to be studied, and the applicable hydrologic and hydraulic methodology to be used. This scope of the study may include, but not be limited to, completion of any or all of the following work items:

    a. Preparation of topographic work maps of the floodplains within the study area. The maps must identify elevations of the critical structures that are affected by the flood study.

    b. Field surveys to obtain data for stream cross sections and other hydraulic parameters (i.e., Manning's "n", Expansion and Contraction coefficients, etc.).

    c. Hydrologic analysis to determine discharge rates used in flood routings for the various flood frequencies used to substantiate the critical flood flows.

    d. Hydraulic analysis to determine dam failure discharges, flood elevations, floodplain boundaries, and stream channel and floodplain velocities. Calculations to determine the dam failure discharges must include a sensitivity study on the set of boundary conditions established for the dam breach analysis. This study is required for obtaining the most severe hydraulic condition during a catastrophic dam failure that is theoretically possible. Dam breach parameters used in the critical flood analysis shall be based on suggested values established by the U. S. Army Corps of Engineers, or the Federal Energy Regulatory Commission, unless otherwise approved by the chief.

e. Compilation of other flood study technical documentation used in the analysis.

f. Preparation of a critical flood report with flood profiles and work maps of the floodplain.

3. A "critical flood" study conducted in accordance with OAC Rule 1501:21-13-02 shall be completed under supervision of a registered professional engineer who is qualified to do flood study work.

Data Acquisition and Mapping

1. Topographic mapping for critical flood studies conducted in accordance with OAC Rule 1501:21-13-02 shall conform to the following standards:

A. Mapping shall be done by photogrammetric methods and/or topographic surveying. If topographic mapping is based solely on field surveys, map accuracy requirements shall be the same as those required by photogrammetric methods.

B. Map scale may vary but should not exceed one inch equals 1000 feet for the study area.

C. Contour intervals shall not exceed 5 feet for the appropriate terrain. Intermediate one-foot contour intervals may be required for special cases such as unusually flat terrain.

D. Elevations used in the flood study shall correspond to the National Geodetic vertical datum of 1929 or, when available, the successor North American vertical datum of 1983. Elevation reference marks and temporary reference points established for the study shall be tied by survey to at least one official bench mark of the datum for which the exact elevation to the nearest hundredth of a foot has been obtained.

Data Standards and Procedures

1. The following standards and procedures shall apply to hydrologic data used in a critical flood determination study conducted in accordance with OAC Rule 1501:21-13-02.

A. Hydrologic data shall be from official government sources except as approved by the chief. Use of unofficial data sources, such as high-water marks, shall be dependent on reliability of the data.

B. Stream flow data used for calibrating the hydrologic model shall be from official government records such as published by the United States Geological Survey.

C. Precipitation data shall be from official government records such as published by the National Weather Service.

D. Watershed data shall be from official maps, survey documents, and aerial photography generated by pertinent government agencies. Sufficient field observations shall be made to interpret maps and photographs and identify any significant changes in watershed conditions since source materials were completed.

2. The following standards and procedures shall apply to channel and valley cross sections used in the critical flood study conducted in accordance with OAC Rule 1501:21-13-02:

A. Each cross section must span the entire floodplain for each of the appropriate discharges used in the flood study. The cross sections must represent the particular stream reach from which it was taken. Local irregularities in ground surface that are not representative of reaches shall be avoided in surveys.

B. Cross-section alignment shall be perpendicular to the direction of flow. Cross-sections may consist of straight, curved or zigzag segments as needed to achieve proper alignment.

C. Horizontal stations for the cross-section shall correspond to the distance measured to the nearest foot along the straight, curved or zigzag alignment of the cross-section.

D. Cross-section elevations shall be determined at all significant breaks in ground slope and at points where significant changes in hydraulic characteristics of the floodplain occur. Additional points shall be included, as appropriate, using the following criteria as a guide:

1. The distance between channel reach stations should be such that the depth of flow at the next neighboring cross-section downstream does not increase more than 20 percent.

2. No adjacent horizontal points in the overbank areas shall be separated by more than 10 percent of the complete valley and channel cross-section width.

3. No adjacent horizontal points in the main channel shall be separated by more than 20 percent of the main channel width or 2 feet, whichever is greater.

4. Elevations of above water portions of cross-sections shall be determined by field surveys or photogrammetric techniques, when reliable data of sufficient accuracy cannot be obtained from available sources. Elevation of below water portion of cross-

sections shall be determined by field survey except where reliable data of sufficient accuracy can be obtained from available sources. Field surveys shall normally be accomplished by differential leveling or a differential global positioning system.

3. The following standards and procedures shall apply to channel and overbank reaches used in the critical flood analysis conducted in accordance with OAC Rule 1501:21-13-02:

A. Channel reach length shall be the distance between cross sections as measured along the principal flow line of the stream channel at the flood stage.

B. Channel and overbank reach lengths between stream cross-sections shall be determined by field surveys or distance measurements on topographic work maps. Design drawings for bridges and hydraulc structures shall be used to obtain reach lengths if available.

4. The following standards and procedures shall apply to roughness coefficients used in the critical flood analysis conducted in accordance with OAC Rule 1501:21-13-02:

A. Roughness coefficients shall be determined by field inspection of channel and overbank areas. Consideration shall be given to variation in roughness at various flood stages. Aerial photographs, when available, shall be used to supplement field observations.

B. Roughness coefficients obtained from any previous work shall be field checked for accuracy and updated, if they do not reflect current conditions.

5. The following standards and procedures shall apply to bridges and hydraulic structures data used in the critical flood analysis conducted in accordance with OAC Rule 1501:21-13-02:

A. Dimensions and elevations of all bridges and hydraulic structures including below water sections shall be obtained from construction drawings and/or by field survey measurements.

B. Bridges and hydraulic structures data obtained from documents shall be field checked in sufficient detail to verify that the data are for the correct structure and match as-built conditions.

C. No dimensions or elevations for bridges and hydraulic structures shall be determined by photogrammetric methods. Photographs shall be used to supplement and document field observations or hydraulic structures.

6. The following standards and procedures shall apply to the dam failure analyses data used in

the critical flood study conducted in accordance with OAC Rule 1501:21-13-02:

A. All boundary conditions used in the dam failure analysis must be supported by sound engineering assumptions and supporting field data obtained for the dam. A sensitivity analysis shall be required by varying the input boundary conditions used in a dam break model as a means of converging on the worst case dam failure modeling scenarios. The maximum discharges obtained from the dam failure analysis shall be used for the basis of determining downstream impact on the critical routing reach.

B. Parameters used to estimate the erosiveness of the soils shall be field checked in sufficient detail to verify their validity in use. Each boundary condition used in the development of the dam failure model shall be supported by sound engineering assumptions.

Hydrologic Requirements

1. Hydrologic analyses for the critical flood determination conducted in accordance with OAC Rule 1501:21-13-02 shall require a determination of the base-flow flood discharges and dam failure discharges at appropriate stream stations downstream of the dam. The criteria used to establish the initial base-flow flood discharge for a class I dam is the probable maximum flood, for a class II dam, 50 percent of the probable maximum flood, and for a class III dam, 25 percent of the probable maximum flood. The dam failure discharges are determined by doing a breach analysis for the dam and combining the resulting breach hydrograph for the worst case failure condition with the base-flow flood hydrograph established for the dam.

A. Flood peak discharge estimates shall be determined for the downstream terminus of the stream reach studied and at all upstream stations where significant changes in peak discharge occur due to reduction in tributary drainage area and other factors.

B. Flood peak discharge estimates established for the study area by previous work shall be acceptable for use in flood studies provided that parameters used to make previous estimates remain valid for existing conditions, methodologies are consistent with standard engineering practices and guidelines, and accuracy of estimate is within confidence limits approved by the chief.

2. Methodology for calculating discharges conducted for critical flood analyses in accordance with OAC Rule 1501:21-13-02 shall conform to the following standards:

A. A rainfall-runoff model (e.g., HEC-1) shall be used to estimate the flood peak discharges used in the critical flood analysis. The model shall be calibrated as

appropriate and conform to the following standards:

1. Models shall normally be based on unit-graph theory as embodied in unit-graph procedures of the Natural Resources Conservation Service, United States Geological Survey, and United States Army Corps of Engineers. Use of an alternate runoff simulation modeling procedure must be approved by the chief.

2. Drainage areas and sub-basin areas for unit graphs shall have reasonable uniform hydrologic characteristics.

3. Durations of storm rainfall shall be the duration resulting in the largest discharges for the stream reach being studied.

4. Rainfall amounts for storm events of different duration and frequency shall be estimates as published by the National Weather Service or other approved source.

5. Point-Rainfall estimates shall be adjusted using area-depth relationships when the area of the modeled drainage basin exceeds ten square miles.

6. Rainfall distribution shall be an appropriate pattern such as national weather service median time distributions, miller distribution, or Natural Resources Conservation Service Type II storm pattern.

7. Methodology used to estimate flood peak discharges shall include procedures that account for urbanization, surface mining, regulation, and valley storage when these are significant factors affecting flood flows. Urbanization and surface mining shall be considered to be significant factors whenever more than 30 percent of the watershed is affected by these land use activities. Allowances for effects of urbanization on flood peaks shall be made by appropriate procedures such as those developed by the United States Geological Survey and the Natural Resources Conservation Service. Effects of Regulation and Valley Storage shall be accounted for by reservoir and stream routing techniques as appropriate.

8. When applicable, flood peak discharge estimates used in the critical flood analysis shall be checked for reasonableness by comparison with other flood peak data such as: actual flood peak discharges recorded for similar drainage basins, peak discharge estimates from other studies of similar basins, and estimates from alternative modeling techniques.

Hydraulic Requirements

Hydrologic analyses for the critical flood determination conducted in accordance with OAC Rule 1501:21-13-02 shall conform to the following standards:

1. Water-surface profiles shall be determined by step-backwater procedure whenever applicable together with other pertinent hydraulic formulae. Computer programs used for water surface profile analysis shall be step-backwater algorithms such as the United States Army Corps of Engineers's HEC-RAS program.

2. Dam failure discharges shall be determined by a flood routing program equipped with dam failure analysis routines and/or a specific dynamic reservoir routing program such as the Boss Dambreak program.

3. Initial water-surface elevation used in step-backwater analysis shall be based on normal depth or determined from stage-discharge rating at a control section. If normal depth is used to determine initial water-surface elevation, the modeling shall include at least three initial cross sections beyond the terminus of the stream reach where actual flood elevations are required to allow for iterative convergence of flood profile.

4. Models shall be calibrated using measured profiles and reliable high-water marks of past floods when such information is available. Models shall match known high-water marks within plus or minus 0.5 foot.

5. Any cases where computation of water-surface profiles may require use of two-dimensional computer modeling, dynamic wave routing or other special analysis shall be approved by the chief.

6. Location, alignment and subdivision of channel and floodplain cross-sections used in stream modeling shall be based on field observations and careful examination of topographic maps and aerial photographs. Cross-sections shall be typical of adjacent upstream and downstream reaches. A minimum of four cross-sections is required for the critical flood analysis.

7. Cross-sections shall be located where needed to account for changes in dimensions and roughness of the channel and floodplain. Cross-sections shall be located at all significant breaks in channel grade. Channel reach length between cross-sections shall be short enough to avoid excessive change in conveyance, velocity head, or energy loss.

8. Alignment of cross-sections shall normally be perpendicular to direction of flow in channels and overbank areas. For streams with severe meanders, where the majority of stream flow deviates from the channel, the alignment of cross-sections shall be perpendicular to the center of mass of the flow.

9. Floodplain and channel cross-sections shall be subdivided into at least channel and overbank

areas for analysis. Additional subdivisions may be required depending on the specific cross-section. Ineffective flow areas shall be excluded from cross-sections as appropriate to insure accurate modeling of stream flow.

10. Modeling of existing channel constrictions shall include a sufficient number of upstream and downstream cross-sections to accurately model flow lines.

11. Modeling of bridges and culverts using routines in step-backwater computer programs shall require at least four cross sections. Sections shall be located at the upstream and downstream sides of the structures and at appropriate distances upstream and downstream of the structures to properly model transitions and ineffective flow areas. Additional cross-sections shall be used as needed to establish starting water elevation and evaluate upstream and downstream impacts. Options in step-backwater programs for direct input of bridge and culvert profiles based on hydraulic charts and other sources may be used when appropriate.

12. Modeling of developed floodplain areas with buildings shall normally be based on adjustment of roughness coefficients by procedures such as those developed by the United States Geological Survey. In cases where it involves a single building or a limited number of buildings, these structures may be modeled using at least four cross-sections to model the blocked portion of the floodplain, ineffective flow areas, and open areas upstream and downstream of the buildings.

13. Split flow analysis shall be considered when stream flows divide around an island or overflow the banks of the main stream and take a different flow path. The analysis shall address the reduction in flow in the downstream reach when overflows leave the main channel and enter another basin. Acceptance of the procedures used in the split flow analysis will be required by the chief on a case by case basis.

14. Modeling of tributary streams shall proceed from initial water-surface elevations determined from normal depth on the main stream unless coincident peak situation applies or tributary flow depth is higher than the corresponding main stream event.

Flood Study Report

1. The critical flood analysis conducted in accordance with OAC Rule 1501:21-13-02 shall be summarized in a flood study report. Contents of the report shall include all applicable narratives and exhibit items detailed under this guideline.

2. Reports of the critical flood analysis shall contain a narrative text that is organized into thefollowing sections: Introduction, Area Studied, Hydrologic Analysis, Hydraulic Analysis, and Summary of Impact.

A. The introductory section of critical flood reports shall state the purpose of the study, cite the authority for the work, summarize the scope of the work, and discuss study requirements.

B. The area studied section of the critical flood report shall describe the location of the study area, flooding source, and define the critical routing reach for the dam.

C. The hydrologic analysis section of the critical flood report shall discuss the following items:

1. Methodology and adequacy for current study of flood discharge estimates for the flooding source.

2. Methodology used to compute peak discharge estimates for flooding source and document sources of hydrologic data.

3. Include a summary of discharges in a table that gives the following information: name of flooding source, location point on stream, drainage area in square miles, and the various flood frequency peak discharges for the with and without dam failure conditions.

4. Review any historical flood information for the flooding source and discuss comparative flood peak estimates based on alternative methodology as appropriate.

C. The hydraulic analysis section of the critical flood report shall discuss the following items:

1. Methodology used to generate flood profiles for the study reach.

2. Discuss methodology, engineering assumptions, and the hydraulic parameters for their adequacy in the development of the dam failure discharges.

3. Discuss methodology and field procedures used to generate flood profiles including: how cross sections were obtained, how channel and overbank reach lengths were determined, how roughness factors were estimated, how dimensions of hydraulic structures were obtained, how water surface elevations were computed, and how starting water elevations were determined.

4. Describe the concepts and procedures used to comply with the no impact requirements for critical flood determination.

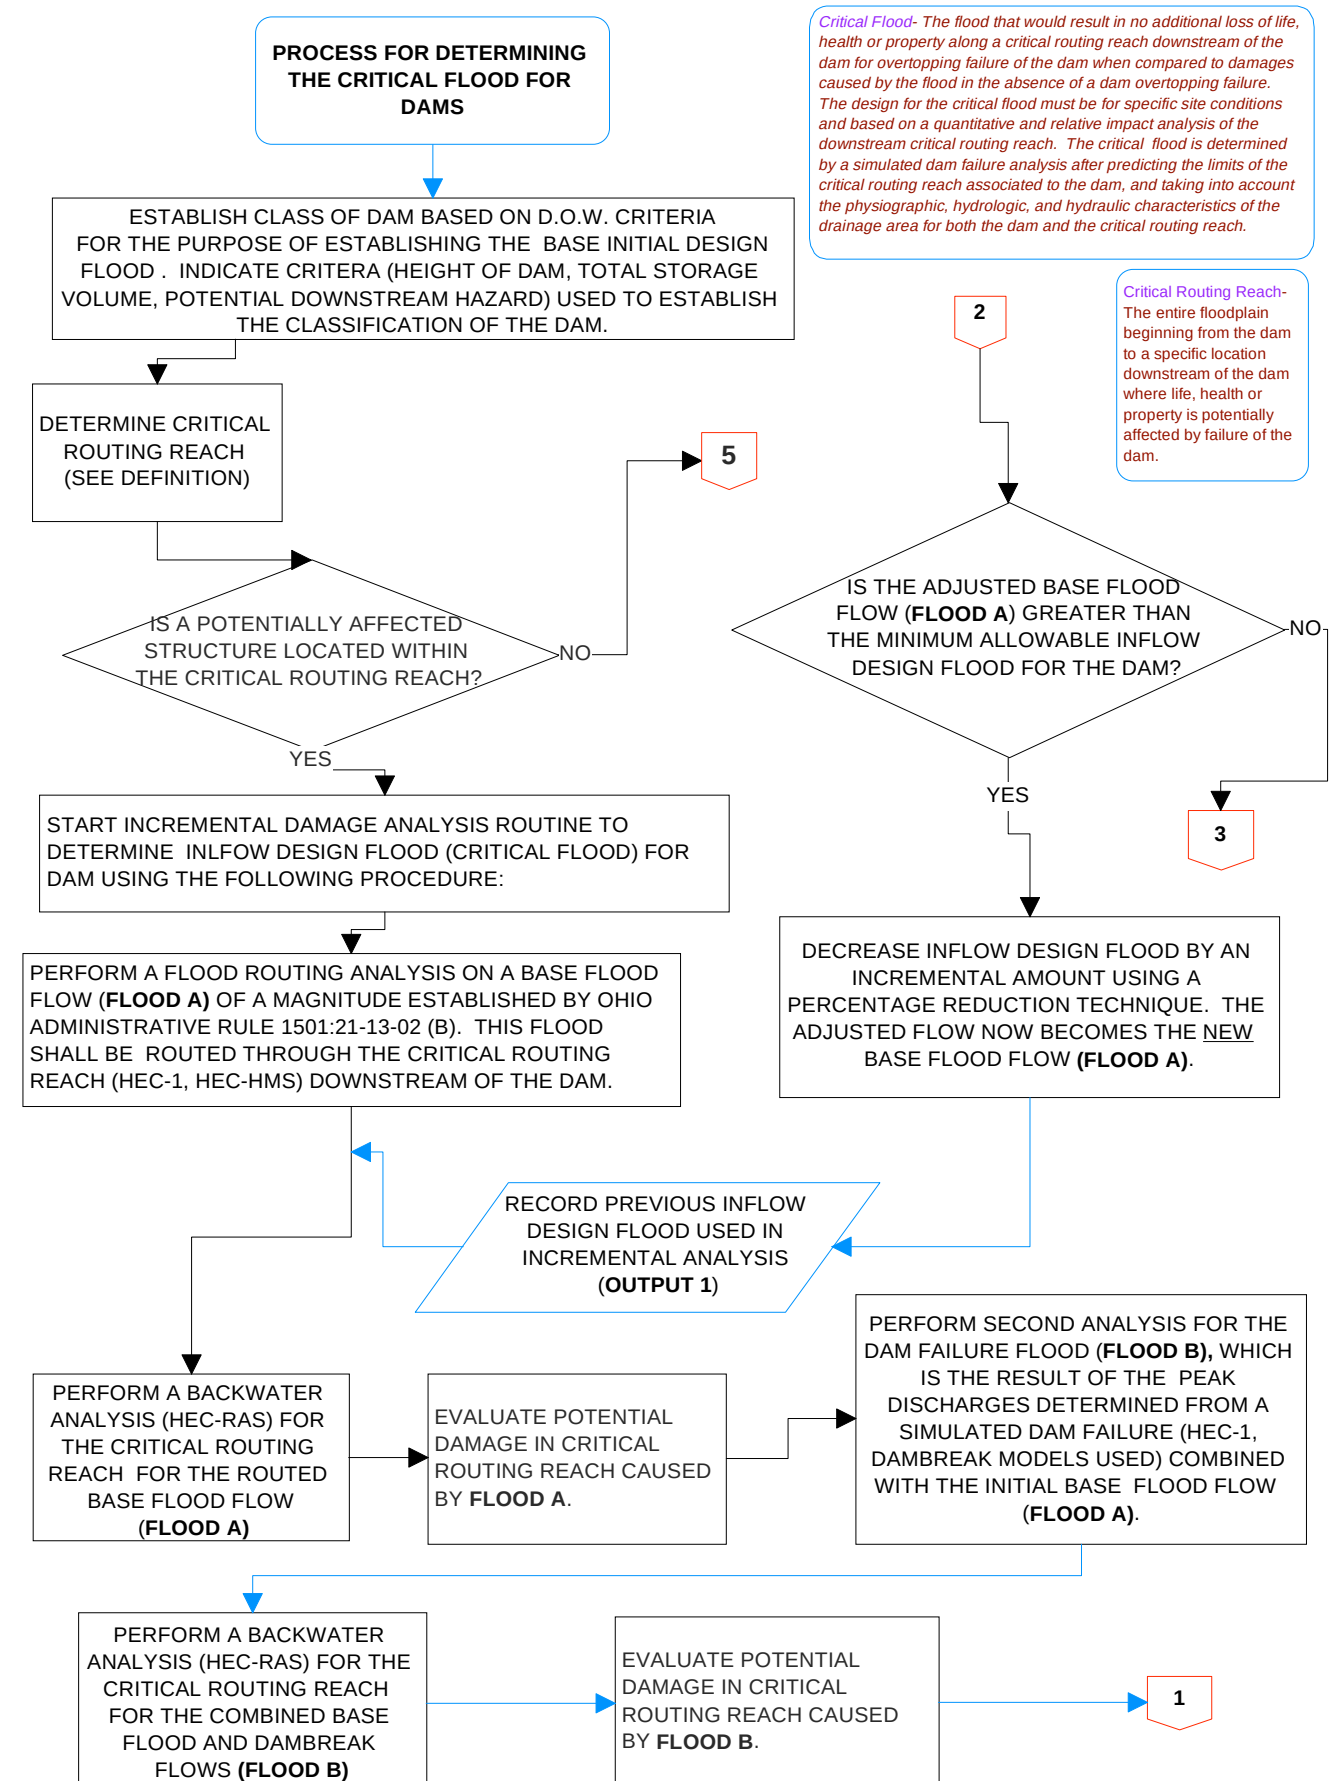
5. Describe methods used to evaluate the hydraulic impact of a dam failure flood on

the critical routing reach, and summarize results of the hydraulic analysis.

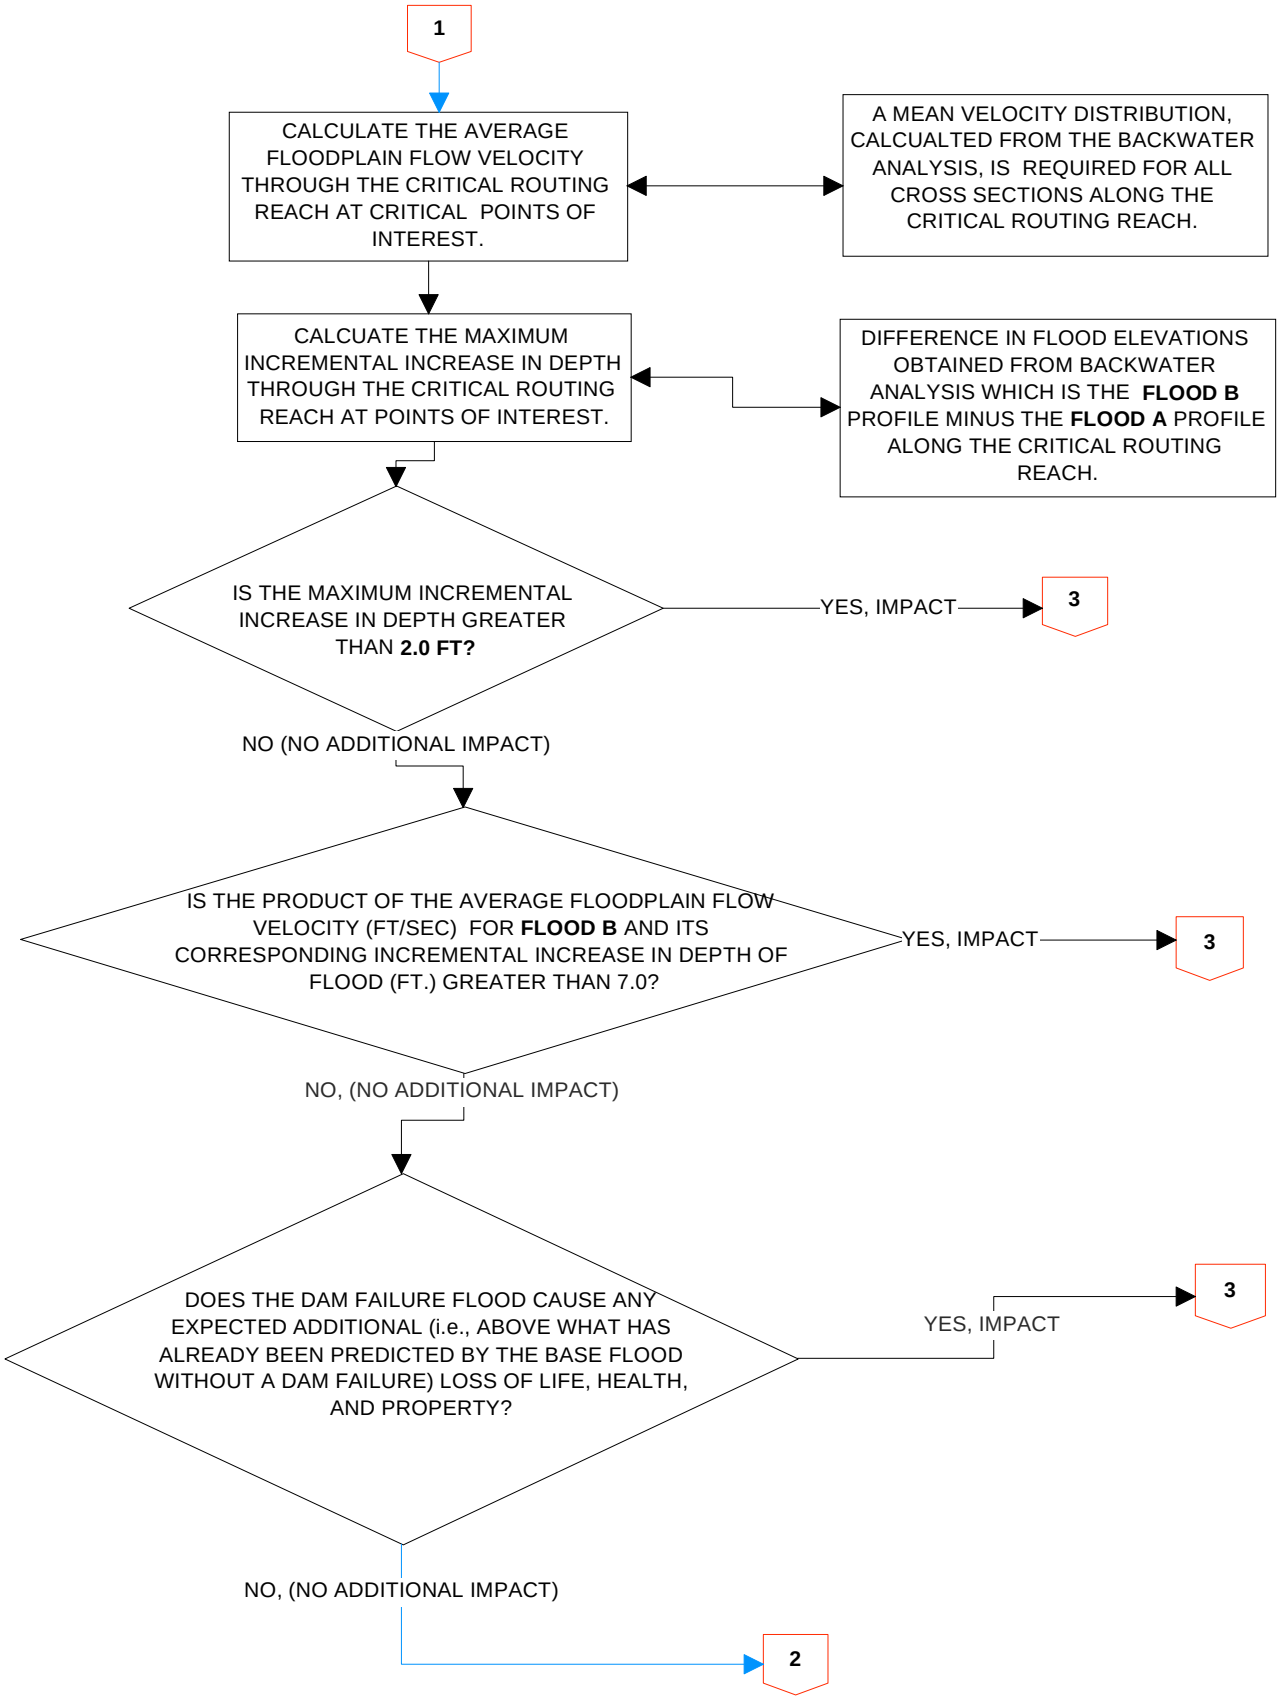
3. Reports of the critical flood analysis, conducted in accordance with OAC Rule 1501:21-13-02 may include, but not be limited to the following exhibits: work maps, flood profiles, and photographs.

A. Work maps shall contain coverage of the critical routing reach and all potential affected structures.

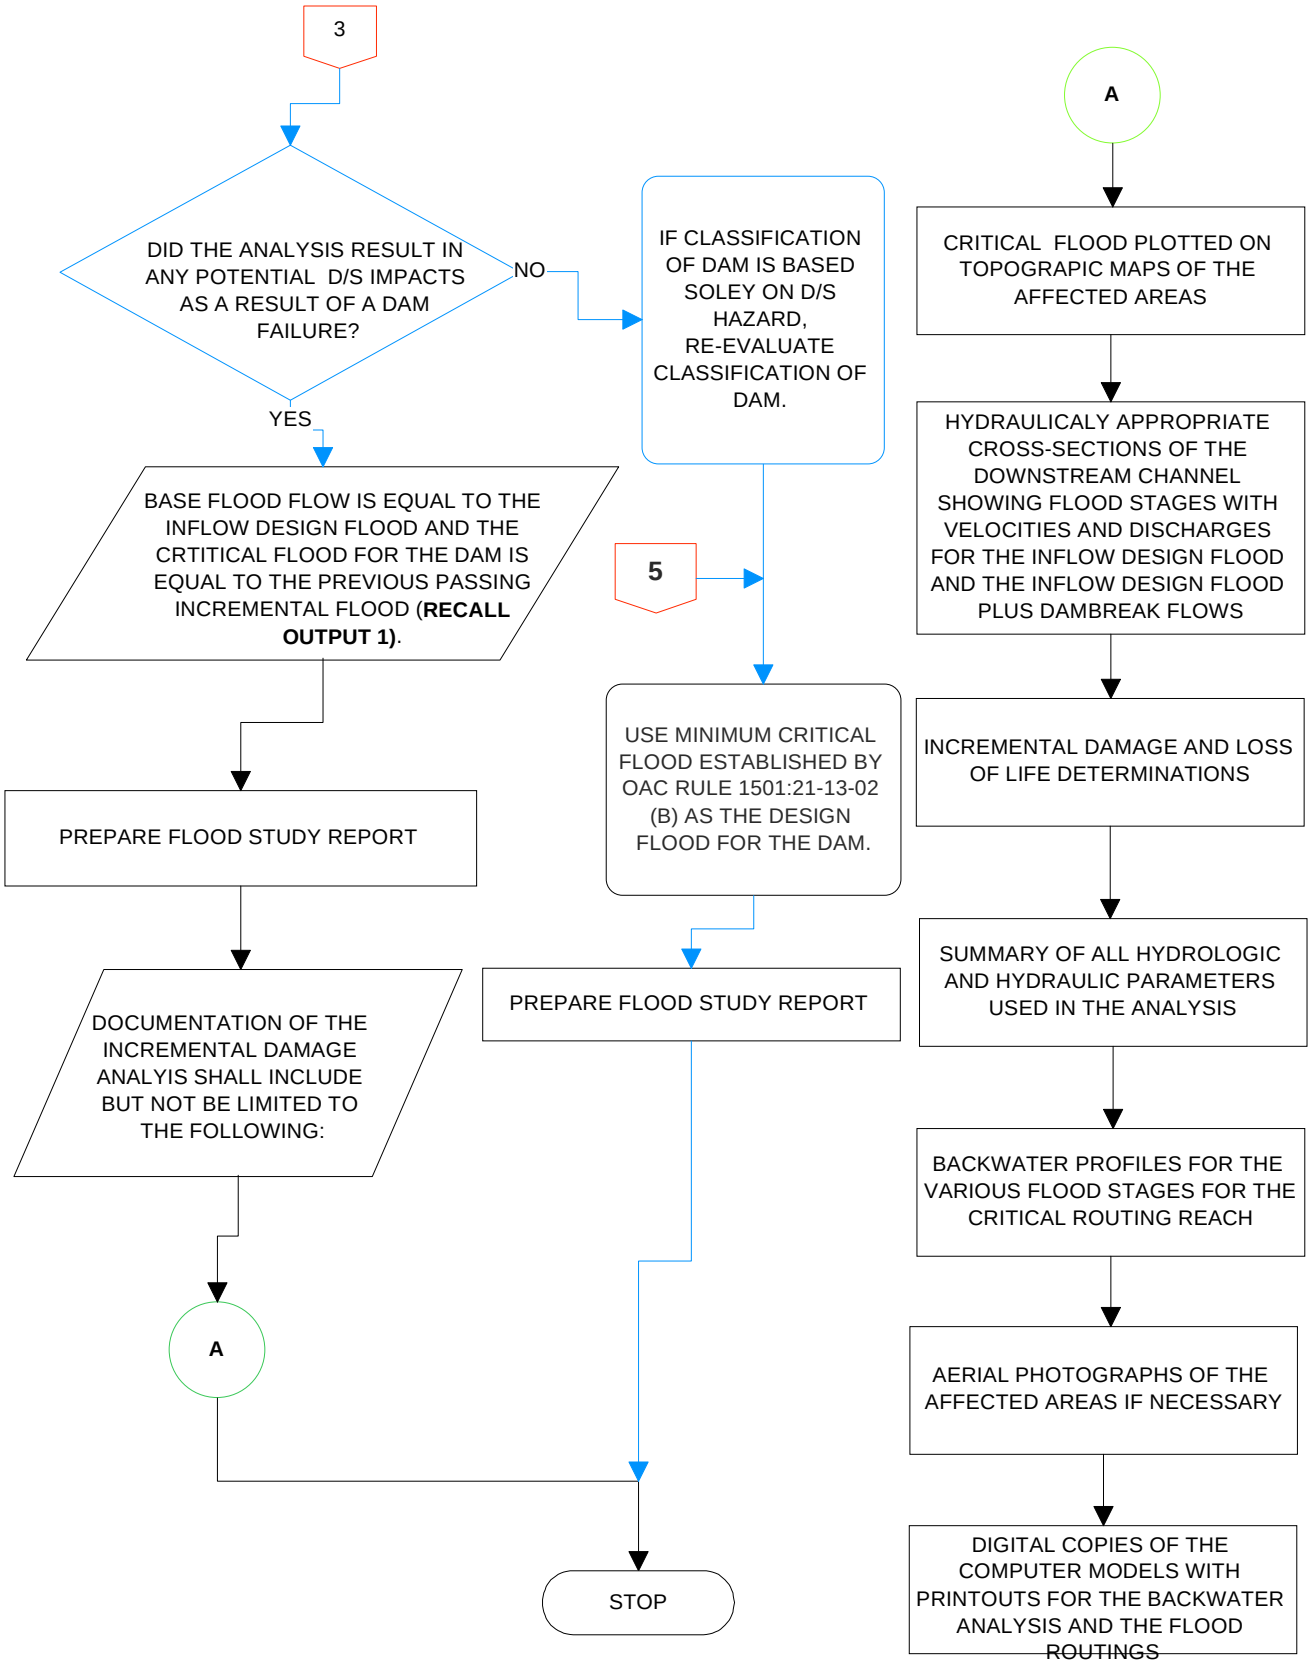
1. Each work map shall be identified with the following information: date map was prepared, map bar scale, north arrow, source of base map and date, whether map is one of several maps, and a legend, if applicable, indicating any symbols used for identifcation purposes on the map.



2. Work maps shall show existing topographic contours, low-water outline of streams and lakes, cross sections, boundaries of floodplains associated with the critical flood discharges.



B. Flood profiles shall be prepared for all flood recurrence interval events studied.



C. Photographs may be used in the critical flood analysis report to supplement text material and provide documentation of observed field conditions at the time of the study. Photographs may include views of the critical routing reach and its overbank areas, hydraulic structures, any structures in the floodplain that are potentially affected by the dam failure discharges, and other significant features of the landscape.

D. A certification page signed and stamped by the registered professional engineer in charge of the study. The engineer shall certify that the data for the physical parameters use in the critical flood study represent actual field conditions.

E. Submittals to the chief of reports and technical documentation of critical flood studies conducted in accordance with OAC Rule 1501:21-13-02 shall be accompanied by a cover letter identifying the report, its purpose, and any action requested of the chief.

PROCESS FOR DETERMINING THE CRITICAL FLOOD FOR DAMS
Critical Flood- The flood that would result in no additional loss of life, health or property along a critical routing reach downstream of the dam for overtopping failure of the dam when compared to damages caused by the flood in the absence of a dam overtopping failure. The design for the critical flood must be for specific site conditions and based on a quantitative and relative impact analysis of the downstream critical routing reach. The critical flood is determined by a simulated dam failure analysis after predicting the limits of the critical routing reach associated to the dam, and taking into account the physiographic, hydrologic, and hydraulic characteristics of the drainage area for both the dam and the critical routing reach.
ESTABLISH CLASS OF DAM BASED ON D.O.W. CRITERIA FOR THE PURPOSE OF ESTABLISHING THE BASE INITIAL DESIGN FLOOD . INDICATE CRITERA (HEIGHT OF DAM, TOTAL STORAGE VOLUME, POTENTIAL DOWNSTREAM HAZARD) USED TO ESTABLISH THE CLASSIFICATION OF THE DAM.
Critical Routing Reach- The entire floodplain beginning from the dam to a specific location downstream of the dam where life, health or property is potentially affected by failure of the dam.
2
DETERMINE CRITICAL ROUTING REACH (SEE DEFINITION)
5
IS A POTENTIALLY AFFECTED STRUCTURE LOCATED WITHIN THE CRITICAL ROUTING REACH?
NO
YES
IS THE ADJUSTED BASE FLOOD FLOW (FLOOD A) GREATER THAN THE MINIMUM ALLOWABLE INFLOW DESIGN FLOOD FOR THE DAM?
NO
YES
3
START INCREMENTAL DAMAGE ANALYSIS ROUTINE TO DETERMINE INLFOW DESIGN FLOOD (CRITICAL FLOOD) FOR DAM USING THE FOLLOWING PROCEDURE:
PERFORM A FLOOD ROUTING ANALYSIS ON A BASE FLOOD FLOW (FLOOD A) OF A MAGNITUDE ESTABLISHED BY OHIO ADMINISTRATIVE RULE 1501:21-13-02 (B). THIS FLOOD SHALL BE ROUTED THROUGH THE CRITICAL ROUTING REACH (HEC-1, HEC-HMS) DOWNSTREAM OF THE DAM.
DECREASE INFLOW DESIGN FLOOD BY AN INCREMENTAL AMOUNT USING A PERCENTAGE REDUCTION TECHNIQUE. THE ADJUSTED FLOW NOW BECOMES THE NEW BASE FLOOD FLOW (FLOOD A).
RECORD PREVIOUS INFLOW DESIGN FLOOD USED IN INCREMENTAL ANALYSIS (OUTPUT 1)
PERFORM A BACKWATER ANALYSIS (HEC-RAS) FOR THE CRITICAL ROUTING REACH FOR THE ROUTED BASE FLOOD FLOW (FLOOD A)
EVALUATE POTENTIAL DAMAGE IN CRITICAL ROUTING REACH CAUSED BY FLOOD A.
PERFORM SECOND ANALYSIS FOR THE DAM FAILURE FLOOD (FLOOD B), WHICH IS THE RESULT OF THE PEAK DISCHARGES DETERMINED FROM A SIMULATED DAM FAILURE (HEC-1, DAMBREAK MODELS USED) COMBINED WITH THE INITIAL BASE FLOOD FLOW (FLOOD A).
PERFORM A BACKWATER ANALYSIS (HEC-RAS) FOR THE CRITICAL ROUTING REACH FOR THE COMBINED BASE FLOOD AND DAMBREAK FLOWS (FLOOD B)
EVALUATE POTENTIAL DAMAGE IN CRITICAL ROUTING REACH CAUSED BY FLOOD B.
1

1
CALCULATE THE AVERAGE FLOODPLAIN FLOW VELOCITY THROUGH THE CRITICAL ROUTING REACH AT CRITICAL POINTS OF INTEREST.
A MEAN VELOCITY DISTRIBUTION, CALCUALTED FROM THE BACKWATER ANALYSIS, IS REQUIRED FOR ALL CROSS SECTIONS ALONG THE CRITICAL ROUTING REACH.
CALCUATE THE MAXIMUM INCREMENTAL INCREASE IN DEPTH THROUGH THE CRITICAL ROUTING REACH AT POINTS OF INTEREST.
DIFFERENCE IN FLOOD ELEVATIONS OBTAINED FROM BACKWATER ANALYSIS WHICH IS THE FLOOD B PROFILE MINUS THE FLOOD A PROFILE ALONG THE CRITICAL ROUTING REACH.
IS THE MAXIMUM INCREMENTAL INCREASE IN DEPTH GREATER THAN 2.0 FT?
YES, IMPACT
3
NO (NO ADDITIONAL IMPACT)
IS THE PRODUCT OF THE AVERAGE FLOODPLAIN FLOW VELOCITY (FT/SEC) FOR FLOOD B AND ITS CORRESPONDING INCREMENTAL INCREASE IN DEPTH OF FLOOD (FT.) GREATER THAN 7.0?
YES, IMPACT
3
NO, (NO ADDITIONAL IMPACT)
DOES THE DAM FAILURE FLOOD CAUSE ANY EXPECTED ADDITIONAL (i.e., ABOVE WHAT HAS ALREADY BEEN PREDICTED BY THE BASE FLOOD WITHOUT A DAM FAILURE) LOSS OF LIFE, HEALTH, AND PROPERTY?
YES, IMPACT
3
NO, (NO ADDITIONAL IMPACT)
2

3
DID THE ANALYSIS RESULT IN ANY POTENTIAL D/S IMPACTS AS A RESULT OF A DAM FAILURE?
NO
YES
IF CLASSIFICATION OF DAM IS BASED SOLEY ON D/S HAZARD, RE-EVALUATE CLASSIFICATION OF DAM.
BASE FLOOD FLOW IS EQUAL TO THE INFLOW DESIGN FLOOD AND THE CRTITICAL FLOOD FOR THE DAM IS EQUAL TO THE PREVIOUS PASSING INCREMENTAL FLOOD (RECALL OUTPUT 1).
5
PREPARE FLOOD STUDY REPORT
USE MINIMUM CRITICAL FLOOD ESTABLISHED BY OAC RULE 1501:21-13-02 (B) AS THE DESIGN FLOOD FOR THE DAM.
DOCUMENTATION OF THE INCREMENTAL DAMAGE ANALYIS SHALL INCLUDE BUT NOT BE LIMITED TO THE FOLLOWING:
PREPARE FLOOD STUDY REPORT
A
STOP
A
CRITICAL FLOOD PLOTTED ON TOPOGRAPIC MAPS OF THE AFFECTED AREAS
HYDRAULICALY APPROPRIATE CROSS-SECTIONS OF THE DOWNSTREAM CHANNEL SHOWING FLOOD STAGES WITH VELOCITIES AND DISCHARGES FOR THE INFLOW DESIGN FLOOD AND THE INFLOW DESIGN FLOOD PLUS DAMBREAK FLOWS
INCREMENTAL DAMAGE AND LOSS OF LIFE DETERMINATIONS
SUMMARY OF ALL HYDROLOGIC AND HYDRAULIC PARAMETERS USED IN THE ANALYSIS
BACKWATER PROFILES FOR THE VARIOUS FLOOD STAGES FOR THE CRITICAL ROUTING REACH
AERIAL PHOTOGRAPHS OF THE AFFECTED AREAS IF NECESSARY
DIGITAL COPIES OF THE COMPUTER MODELS WITH PRINTOUTS FOR THE BACKWATER ANALYSIS AND THE FLOOD ROUTINGS

Ohio Department of Natural Resources
Division of Water Fact Sheet

Fact Sheet 99–60

Dam Safety: Critical Flood Design Criteria

Ohio's Dam Safety Rules require dams to pass floods through their spillways without endangering the safety of the dam. The magnitude of the design flood is directly related to the classification of the dam - which in turn is related to the dam's downstream hazard and/or the dam's height. The greater the downstream hazard, i.e., loss of human life, high-value property, etc., the larger the design flood.

Definitions

The probable Maximum Precipitation (PMP) is the greatest depth (amount) of precipitation for a given storm duration, that is theoretically possible for a particular area and geographic location. The Probable Maximum Flood (PMF) is the flood that may be expected from the most severe combination of critical meteorological and hydrologic conditions that are reasonably possible in a particular drainage area.

Classification of Ohio Dams

Dams in Ohio are divided into four classes based on the storage volume of the impoundment, dam height, and potential downstream hazard (how far downstream residences, businesses are, etc.). More details about the classification system can be found in the Dam Safety: Classification of Structures Fact Sheet No. 94-29.

Critical Flood Design Criteria

Specific guidelines are available for preparing a critical flood engineering analysis. This analysis must be performed by a professional engineer licensed in the State of Ohio. The guidelines can be downloaded from the Division of Water's world wide web site, (http://www.dnr.state.oh.us/odnr/water/temp/dartrlsa.html), or you can request a copy by calling our office directly.

Could the Critical Flood Analysis Make a Difference for My Dam?

The critical flood criteria were developed to make Ohio's Dam Safety Rules more flexible in recognizing that some dams fall outside of the typical parameters used in designing spillway capacity. Specifically, for those circumstances where the size of the dam, its downstream hazard, drainage area, and downstream topography are such that traditional flood design standards do not accurately account for the downstream hazard, critical flood criteria allow for a reduction of up to 60% of the design flood.

For example, let's look at a Class I dam. This type of dam is required to safely pass the 100% PMF through its spillway system without endangering the safety of the dam. As rain falls onto a dam's watershed, some of the rainfall will infiltrate into the ground, some will evaporate, and most of it will runoff across the ground into the pond or lake. The water level in the impoundment will begin to rise while simultaneously flowing through the dam's spillway(s). As water exits the dam's spillway(s), the downstream channel will begin to fill and flow accordingly. For most dams, the downstream channel will likely fill with some water, but most of the water flows downstream without backing up significantly. For those few cases where the downstream channel fills rapidly to the point where water rises dramatically and failure of the dam would have no additional significant increase in elevations of floods downstream, the design flood can be reduced. In other words, there may be a point, say 50% of the PMF (the critical flood in this case), where designing for additional flood capacity for the dam is no longer reasonable. If the dam were to fail, the downstream hazard would not be further adversely effected. In this case, the spillway system may be designed for half of what it would have been originally designed, therefore saving dollars without increasing the hazard to the downstream area.

What is the Maximum Reduction in Design Flood?

The design flood can be reduced approximately up to 60% for each class of dam:

Class I	100% PMF down to no less than 40% PMF
Class II	50% PMF down to no less than 20% PMF
Class III	25% PMF down to no less than 100 Year

Continued on back!

What Factors Should I Consider Before Proceeding With an Analysis?

The cost of the analysis can be thousands of dollars. Let's assume that a dam inspection by our engineers reveals that a dam is deficient in its ability to pass the design flood. It would be beneficial to have an analysis performed if the design flood was reduced enough so that the spillway system did not need to be upgraded or replaced. Let's assume that upgrading the spillway system costs $50,000. If the cost of the critical flood analysis was $5,000, the cost of the critical flood analysis would be warranted.

Sometimes it can be straightforward to predict whether or not an analysis would be beneficial. However, in those cases where it may not be clear, other options should be considered. For example, if room exists in one of the dam's abutments to excavate an emergency spillway or perhaps enlarge an existing emergency spillway, it may be more cost effective to do so. There is always a risk in running an analysis and finding out that the reduction in design flood is insignificant and the spillway system enlargement is still required.

A critical flood analysis approved by our office means that a reduced design flood is acceptable for your dam. Please note that a reduction in the design flood for your dam may increase the risk of failure or damage to your dam. This could result in an economical burden on the dam owner. This risk should be closely considered!

How Can I Apply for the Critical Flood Reduction?

A request for consideration must be submitted to the Chief of the Division of Water. The request must be accompanied by supporting calculations based upon an analysis performed by a professional engineer registered in the State of Ohio. The engineer's analysis must conform to the critical flood guidelines provided by the Division of Water.

Before applying, it is best to call and speak with an engineer in the Division's Dam Safety Engineering Program.

What Restrictions Are There?

A critical flood reduction based upon planned evacuation, probability of inhabitation, or monetary recovery of property damage will not be considered. In other words, guaranteeing that a downstream residence or business will be evacuated during a dam failure will not be considered. In situations where the downstream hazard may or may not be inhabited, such as in the case of a campground, rental property, hotel, and so forth, the probability of inhabitation will not be considered. Also, understanding that failure of a dam will damage downstream property and guaranteeing that the damages will be paid for will also not be considered. Finally, if the downstream hazard were to change, the critical flood exemption could be nullified.

Any other questions, comments concerns, or fact sheet requests, should be directed to the Division of Water at the following address:

TITLE 785. OKLAHOMA WATER RESOURCES BOARD
CHAPTER 25. DAMS AND RESERVOIRS

Introduction:

This document contains permanent amendments to Chapter 25 adopted by the Oklahoma Water Resources Board that became effective May 27, 2010. Also, this document was prepared by Oklahoma Water Resources Board staff as a convenience to the reader, and is not a copy of the official Title 785 of the Oklahoma Administrative Code. The rules in the official Oklahoma Administrative Code control if there are any discrepancies between the Code and this document.

SUBCHAPTER 1. GENERAL PROVISIONS

Section
785:25-1-1. Purpose
785:25-1-2. Definitions
785:25-1-3. Violations and penalties
785:25-1-4. Variances and waivers

785:25-1-1. Purpose

The rules of this Chapter on reservoir requirements and safety of dams set forth minimum standards for construction and maintenance of dams based on size and hazard classification, application requirements for approval of plans and specifications, and inspection requirements. These rules are adopted pursuant to 82 O.S. 1981, §§105.27, 110.1 et seq. (Oklahoma Dam Safety Act) and 1085.2(7), and Public Law 92-367, 92nd Congress, H.R. 15951, approved August 8, 1972 (33 U.S.C. 467 et seq.). Under no circumstances shall the rules in this Chapter be construed to deprive or limit the Oklahoma Water Resources Board of any exercise of powers, duties, and jurisdiction conferred by law nor to limit or restrict the amount or character of data or information which may be required from any owner of any dam for the proper administration of the law.
[**Source**: Amended at 10 Ok Reg 3287, eff 6-25-93]

785:25-1-2. Definitions

The following words and terms, when used in this Chapter, shall have the following meaning, unless the context clearly indicates otherwise:

"Alteration" means only such alteration as may affect the safety of a dam or reservoir.

"Application" means a formal request to the Board and the first step required by law to acquire the right to perform or engage in activities regulated by the Board.

"Board" means and refers to the Oklahoma Water Resources Board or any employee or agent or staff member thereof.

"Breach analysis" means an engineering analysis to determine the area that would be inundated by the failure of a dam.

"Dam" means any artificial barrier, together with appurtenant works, which does or may impound or divert water.

"Enlargement" means any change in or addition to an existing dam or reservoir which raises or may raise the water storage elevation of the water impounded by the dam or reservoir.

"Failure" with respect to a dam means any uncontrolled release of water.

"Gully plug" means any grade stabilization structure that has less than five acre-feet of water storage available below the principal spillway elevation and less than 50 acre-feet of storage volume below the emergency spillway elevation.

"Interested party" means party.

"Loss of human life" means the human fatalities that would result from a failure of the dam, excluding the occasional passer-by or recreationist and without considering evacuation or other emergency actions.

"Notice by publication" means unless otherwise specifically provided, publication in a daily or weekly newspaper of general circulation once a week or two (2) consecutive weeks (minimum seven day interval).

"Owner" *means any person who, jointly or severally, owns, controls, maintains, manages, or proposes to construct a dam or reservoir, and includes those shown by records of the county registrar of deeds to have some interest, fee, easement, or otherwise, in the land on which the dam and lake lie and may also include those persons who may derive a direct pecuniary benefit from the existence of the lake* [82:110.3].

"Party" means a person or agency named and participating, or properly seeking and entitled by law to participate, in hearings other than hearings on Board rules, regulations and standards.

"Person" *means any individual, firm, partnership, association, corporation, any trust formed for the benefit of an individual, business or any public entity, federal agency, state agency, the State or any political subdivision thereof, municipalities, and any other legal entity* [82:110.3].

"Repairs" means only such repairs as may affect the safety of a dam or reservoir.

"Reservoir" means any surface depression which contains or will contain the water impounded by a dam.

"Statistical twenty-four (24) hour, fifty (50) year storm" means a storm of twenty-four (24) hour duration with a probable recurrence interval of once in fifty (50) years as defined by the National Weather Service in Technical Paper Number 40, "Rainfall Frequency Atlas of the United States," May 1961, and subsequent amendments, or equivalent regional or state rainfall probability information developed therefrom.

"Water storage elevation" means that elevation of water surface which may be obtained by the temporary or permanent storage of water. This elevation is normally the lowest point on the top of the dam.

[**Source**: Amended at 10 Ok Reg 3287, eff 6-25-93; Amended at 11 Ok Reg 2931, eff 6-13-94]

785:25-1-3. Violations and penalties

(a) Under Section 105.20 of Title 82 of the Oklahoma Statutes, the continued use of works which are unsafe, after receiving notice to repair, and the refusal to change unsafe works when directed to do so, or the injury or obstruction of waterworks shall be a misdemeanor and each day such violation continues shall be a separate violation.

(b) Under the Oklahoma Dam Safety Act (82 O.S. Supp. 1992, §§110.1 et seq.), the Board is authorized to issue emergency orders without prior notice and hearing and orders after notice and hearing requiring an owner to take action as necessary to put a dam in safe condition. In addition, the Board may impose administrative penalties against owners of dams who fail,

refuse or neglect to comply with the provisions of the Oklahoma Dam Safety Act. Procedures for imposition of such penalties are found in Subchapter 11 of this Chapter.
[**Source**: Amended at 10 Ok Reg 3287, eff 6-25-93]

785:25-1-4. Variances and waivers

Applicants who request a variance or waiver to rules specified in this chapter must demonstrate, and shall bear the burden of demonstrating that operations under the variance will equal or exceed the protections accorded by the particular rule for which the variance is sought. The variance may also be granted if the Board finds that the cost of compliance with the rule without a variance would impose significant expense without providing for additional safety of the construction for which the variance or waiver is sought, and integrity of the dam will not be adversely affected. The Board may require that a registered professional engineer certify that the variance or waiver being requested will not adversely affect the integrity of the dam.

SUBCHAPTER 3. RESPONSIBILITY, CLASSIFICATION AND DESIGN STANDARDS

Section

785:25-3-1. Dams subject to Board's jurisdiction
785:25-3-2. Owner's responsibility
785:25-3-3. Classification of size and hazard potential
785:25-3-4. Dams considered unsafe and menace to life and property
785:25-3-5. Minimum design standards (other than spillway)
785:25-3-6. Minimum spillway performance standards
785:25-3-7. Minimum outlet conduit capacities
785:25-3-8. Measuring devices
785:25-3-9. Prohibited construction
785:25-3-10. Prohibited vegetation
785:35-3-11. Minimum safety factors

785:25-3-1. Dams subject to Board's jurisdiction

(a) *Dams, together with appurtenant works, which meet the following alternative criterion are subject to the provisions of* [82:110.4] the Oklahoma Dam Safety Act and this Chapter of the Board's rules:

(1) *Dams which are or will be twenty-five (25) feet or more in height from the natural bed of the stream or watercourse at the downstream toe of the barrier or from the lowest elevation of the outside limit of the barrier or from the lowest elevation of the outside limit of the barrier if it is not across a stream channel or watercourse, to the top of the dam* [82:110.4]; or

(2) Dams which have or will have an impounding capacity of fifty (50) acre-feet or more [82:110.4];

provided, however, any barrier to the flow of water which does or may impound water and which is or will be not in excess of six (6) feet in height, regardless of storage capacity, or which has or will have a storage capacity not in excess of fifteen (15) acre-feet, regardless of height, shall not be subject to regulation . . . unless it is determined to have a high hazard potential classification under these rules [82:110.4] or except as hereinafter provided. The figure in Appendix A of this Chapter presents a graphic illustration of the height and storage criteria reviewed to determine the Board's authority relating to dams.

(b) *No barrier to the flow of water determined by the Board to be designated primarily for roadfill shall be subject to regulation under this* [82:110.4] Chapter.

(c) *Gully plugs are not subject to regulation under this* [82:110.4] chapter of the Board's rules.

(d) *Dams constructed by any agency of the United States Government shall not be subject to regulation under this Chapter during or after construction while such dams remain under the supervision of any officer or agency of the United States* [82:110.4]
[**Source**: Amended at 10 Ok Reg 3287, eff 6-25-93; Amended at 11 Ok Reg 2931, eff 6-13-94]

785:25-3-2. Owner's responsibility

(a) **General**.

(1) Owners of dams to which the provisions of this Chapter apply shall have the responsibility to provide for the safety of such works by making any necessary changes to put the works in a safe condition.

(2) Such responsibility includes but is not necessarily limited to the following: the filing of an application to construct, enlarge, alter or repair the dam pursuant to Subchapter 5, the modification of the dam to meet applicable minimum requirements in this Subchapter, and the adequate maintenance, operation, and inspection of an existing dam.

(b) **Multiple owners.**

(1) When there is more than one owner of a dam, the Board shall consider all such owners responsible for the safety of such dam unless evidence to the contrary shows otherwise.

(2) The Board shall provide copies of inspection reports to at least one owner of record at the Board and shall provide notice of hearing on dam safety related matters to such owner with an instruction that the notice shall be delivered or mailed to all owners.

(3) Unless otherwise agreed by all the owners and the Board, the Board may, after such notice and hearing, order all the owners to take whatever remedial action is necessary to put the dam in a safe condition.

(4) The Board will not attempt to delineate levels of responsibility or allocate particular items of action among the owners.

(c) **Transfer of ownership**. Upon transfer of ownership of the works, the new owner shall notify the Board of such transfer.

[**Source:** Amended at 9 Ok Reg 1675, eff 5-11-92; Amended at 14 Ok Reg 2766, eff 7-1-97]

785:25-3-3. Classification of size and hazard potential

(a) All dams shall be classified as to size and for potential hazards as follows:

(1) **Size Classification of Dams**. The size classification shall be based on the following chart:

(A) Small:
(i) Storage – less than10,000 Ac-Ft.
(ii) Height – less than 50 Ft.

(B) Intermediate:
(i) Storage – between 10,000 and 50,000 Ac-Ft.
(ii) Height – between 50 and 100 Ft.

(C) Large:
(i) Storage – over 50,000 Ac-Ft.
(ii) Height – over 100 Ft.

(2) **Hazard-Potential Classification of Dams**. The hazard-potential classification of a dam is determined by the downstream risk in the event of a failure, without regard to the physical condition of the dam, as follows:

(A) **Low.** Dams assigned the low hazard-potential classification are those where failure would result in no probable loss of human life and low economic losses.

(B) **Significant.** Dams assigned the significant hazard-potential classification are those dams where failure would result in no probable loss of human life but can cause economic loss or disruption of lifeline facilities.

(C) **High.** Dams assigned the high hazard-potential classification are those where failure will probably cause loss of human life.

(b) **Hazard classification subject to regulation and change.**

(1) For dams which were inventoried in the National Safety of Dams program authorized under 33 U.S.C. 467 et seq., and for which "Phase I" reports pursuant to said inventory were prepared, the hazard classifications set forth in such "Phase I" reports shall be presumed accurate. If the owner of the dam disagrees with the hazard classification, the owner shall have the burden to show that such hazard classification is inaccurate and should be changed.

(2) At the discretion of the Board, any proposed or existing dam considered to have classification of a high hazard potential may be subject to regulation regardless of size or impounding capacity.

(3) The hazard potential classification may change as the area downstream from a dam develops and the dam may be reclassified from time to time under the provisions of 785:25-9-10 and 785:25-9-11.

[**Source**: Amended at 11 Ok Reg 2931, eff 6-13-94]

785:25-3-4. Dams considered unsafe and menace to life and property

(a) In determining whether a dam is *unsafe and a menace to life and property* [82:105.27] under the provisions of Section 105.27 of Title 82 of the Oklahoma Statutes and the corrective actions necessary to put a dam in a safe condition, the Board shall review the requirements set forth in rules of this Chapter, and recommendations on matters which directly affect the integrity of dams set forth in DESIGN OF SMALL DAMS (1977) and DESIGN OF GRAVITY DAMS (1976), published by the U.S. Department Interior Bureau of Reclamation (BOR), ENGINEERING AND DESIGN MANUALS, SERIES EM-1110, published by the U.S. Department of the Army, Corp of Engineers (COE), the ENGINEERING FIELD MANUAL and TECHNICAL RELEASE NO. 60, published by the U.S. Department of Agriculture, Natural Resources Conservation Service, or equivalent recommendations.

(b) Existing dams which are in imminent peril of failure shall be considered *unsafe and a menace to life and property* [82:105.27] under the provisions of Section 105.27 of Title 82 of the Oklahoma Statutes.

[**Source**: Amended at 9 Ok Reg 1676, eff 5-11-92; Amended at 10 Ok Reg 3287, eff 6-25-93; Amended at 14 Ok Reg 2766, eff 7-1-97]

785:25-3-5. Minimum design standards (other than spillway)

(a) The construction of the downstream embankment slope shall not be steeper than 3 horizontal units to each 1 vertical unit (3:1) to provide adequate factors of safety against sliding, sloughing or rotation in the embankment and foundation, unless a stability analysis is performed which shows a steeper slope provides an adequate factor of safety.

(b) Except as otherwise provided in this Chapter, all dams must be designed by methods, procedures and criteria that meet or exceed acceptable dam safety engineering practices, including those found in the federal agency publications referenced in 785:25-3-4.

785:25-3-6. Minimum spillways performance standards

(a) **General performance standards**

(1) Except as otherwise provided in this Chapter, all dams must meet or exceed the following performance standards as determined by analysis of plans and specifications for the dam and existing site conditions.

(2) Owners of existing dams which do not meet the following performance standards must make necessary changes in the dam to meet the applicable performance standards.

(3) The discharge capacity and/or storage capacity of the project shall be capable of passing the indicated spillway design flood without infringing on the minimum freeboard requirements, provided that a design which includes overtopping of the dam may be authorized if specifically approved by the Board.

(4) The minimum performance standards expressed as magnitude of spillway design flood and minimum freeboard will be assigned to the various size and hazard potential classification determined under 785:25-3-3 as follows:

(b) **Minimum Performance Standards**

MINIMUM SPILLWAY

SIZE	HAZARD	DESIGN FLOOD	MINIMUM FREEBOARD
Small	Low	25% PMF	0 Feet
Small	Significant	40% PMF	0 Feet
Small	High	50% PMF	1 Foot
Intermediate	Low	25% PMF	1 Foot
Intermediate	Significant	50% PMF	1 Foot
Intermediate	High	75% PMF	3 Feet
Large	Low	50% PMF	1 Foot
Large	Significant	75% PMF	1 Foot
Large	High	100% PMF	3 Feet

(c) **Amending minimum freeboard**. The minimum freeboard requirements may be amended by the Board on a case-by-case basis for good cause shown by the owner.

(d) **Probable maximum flood.**

(1) PMF means and refers to the Probable Maximum Flood and is defined as the flood that may be expected from the most severe combination of critical meterorologic and hydrologic conditions that are reasonably possible in the region as listed in Hydrometeorological Report No. 51, National Weather Service.

(2) Since design floods are usually determined by using mathematical computations through computer modeling and since several different acceptable models are available, flood design calculations must fall within plus/minus 5% PMF of the Board's current model results.

(3) The PMF storm should be of appropriate duration to adequately reflect the size and hydrologic characteristics of the watershed in which the dam is located.

(e) **PMF on dam designated for regulation.** A dam which the Board has determined is subject to regulation because of its high hazard potential, although otherwise considered too small, shall be required to safely pass 25% PMF with no minimum freeboard.
(f) **Dams constructed prior to June 13, 1973.** Any dam constructed prior to June 13, 1973 and which is classified as intermediate size and high hazard potential according to 785:25-3-3 shall be required to pass a minimum design of 50% of the PMF. Any dam constructed prior to June 13, 1973 and which is classified as large size and high hazard potential according to 785:25-3-3 shall be required to pass a minimum design flood of 75% of the PMF.
[**Source**: Amended at 9 Ok Reg 1676, eff 5-11-92; Amended at 12 Ok Reg 2687, eff 7-1-95]

785:25-3-7. Minimum outlet conduit capacities
(a) **Requirements for outlet conduit capacity shall be as follows:**
(1) All dams subject to the Board's jurisdiction shall have at least one outlet conduit of sufficient capacity to prevent interference with natural streamflow and injury of downstream appropriators and domestic users. Absent evidence to the contrary, the minimum size of the outlet conduits shall be as set forth in subsection (d) of this section.
(2) The height of the outlet conduit shall be no more than five feet (5') above the natural stream channel unless otherwise ordered by the Board. The capacity of the reservoir below the outlet conduit shall be designated as the inactive pool.
(b) **Conduit operation**. All conduits shall be gate- or valve-operated on the upstream side and shall be maintained in an operable condition at all times.
(c) **Conduit design life.** The design life expectancy of the conduit shall be equal to or greater than the design life of the dam.
(d) **Minimum size outlet conduit requirements.** The outlet conduit must be of sufficient size to draw down the entire reservoir to the inactive pool within twenty (20) days, provided that minimum size outlet requirements are as follows:
(1) For less than 100 acre-feet normal pool capacity (at principal spillway), the minimum size of conduit is 6-inch pipe.
(2) For 101 to 150 acre-feet normal pool capacity (at principal spillway), the minimum size of outlet conduit is 8-inch pipe.
(3) For 151 to 200 acre-feet normal pool capacity (at principal spillway), the minimum size of outlet conduit is 10-inch pipe.
(4) For 201-250 acre-feet normal pool capacity (at principal spillway), the minimum size of outlet conduit is 12-inch pipe.
(5) For 251-300 acre-feet normal pool capacity (at principal spillway), the minimum size of outlet conduit is 14-inch pipe.
(6) For 301-350 acre-feet normal pool capacity (at principal spillway), the minimum size of outlet conduit is 15-inch pipe.
(7) For 351-500 acre-feet normal pool capacity (at principal spillway), the minimum size of outlet conduit is 16-inch pipe.
(8) For more than 500 acre-feet normal pool capacity (at principal spillway), the minimum size of outlet conduit is 24-inch pipe.
(e) **Amendments of minimum requirements for good cause.** Minimum size requirements may be amended by the Board for good cause. However, conduit must be of sufficient size to draw down the entire reservoir to the inactive pool within a period of not more than twenty (20) days.
[**Source**: Amended at 21 Ok Reg 2625, eff 7-1-2004]

785:25-3-8. Measuring devices
When required by the Board, measuring devices capable of providing an accurate water measurement must be provided to measure the flow of the stream above and below the

reservoir. Permanent staff gages may be required to be placed near the outlet of the reservoir and such other locations as specified by the Board and such gages shall be plainly marked in feet and tenths of feet.

785:25-3-9. Prohibited construction

No construction or excavation other than that necessary for the operation, maintenance, investigation and monitoring of the dam and reservoir, shall be allowed on a dam or spillway structure or within fifty (50) feet from the line where such dam or spillway structure meets the natural grade unless otherwise ordered by the Board after a showing by substantial, competent evidence that the proposed construction will not affect the integrity of the dam or spillway structure.

[**Source**: Amended at 9 Ok Reg 1676, eff 5-11-92]

785:25-3-10. Prohibited vegetation and erosion

Trees and heavy vegetation shall be removed from the slopes and crest of earthen embankments and emergency spillway area. Trees and heavy vegetation shall also be removed from an area a minimum distance from the toe of the embankment of 30 feet. Dams shall be maintained such that internal or external erosion is prevented. If erosion is present it shall be repaired utilizing appropriate engineering practices.

785:25-3-11. Minimum safety factors

As a guide for use by the Board and by engineers designing new dams, assessing the condition of existing dams or proposing modifications to existing dams, the following safety factors shall be utilized for:

(1) Embankment dams:

LOADING CONDITION	MINIMUM FACTOR OF SAFETY*
Steady seepage at emergency spillway crest	1.5
Rapid drawdown from principal spillway	1.2
Earthquake – reservoir at emergency spillway crest for downstream slope, reservoir at principal spillway for upstream slope	1.0

*The minimum factor of safety is calculated by the ratio of available shear strength stress required for stable equilibrium

(2) Concrete dams or concrete portions thereof.

LOADING	MINIMUM

CONDITION	FACTOR OF SAFETY ** (by hazard classification of dam)	
Principal spillway level	High and Significant 2.25	Low 2.0
Inflow design flood at maximum pool level	1.75	1.25
Principal spillway level with earthquake	greater than 1.0	greater than 1.0

** These minimum factors of safety apply to the calculations of stress and the shear friction factor of safety within the structure of the rock/concrete interface and foundation
[**Source**: Amended at 11 Ok Reg 2931, eff 6-13-94]

SUBCHAPTER 5. APPLICATIONS AND APPROVAL OF CONSTRUCTION

Section
785:25-5-1. Application and fee required
785:25-5-2. Plans to be prepared by registered professional engineer
785:25-5-3. Content of plans and specifications
785:25-5-4. Additional report information
785:25-5-5. Notice of hearing
785:25-5-6. Affidavit of notice publication
785:25-5-7. Protest
785:25-5-8. Approval or denial of application

785:25-5-1. Application and fee required

(a) **General**.

(1) Any person who shall desire to construct, enlarge, alter, remove or repair any dam under the Board's jurisdiction shall submit an application upon printed forms which will be furnished by the Board upon request.

(2) For the purposes of this subchapter, repair shall not be deemed to include routine normal maintenance.

(3) The maps, plans, drawings, and specifications of the proposed work along with the required fee shall form a part of the application.

(4) The application and attachments shall be filed in duplicate.

(5) Notwithstanding the provisions of paragraph (1) of this subsection, *an owner who proposes to construct a new dam classified as having a low hazard potential that will be used primarily for agriculture purposes, and will be designed or constructed with the assistance of a local conservation district or federal agriculture related agency, shall be required only to notify the Board of such construction* and file a notice of completion in accordance with 785:25-7-6 [82:110.5].

(b) **Signature of applicant.** The application shall be signed as follows:

(1) If the applicant is an individual, the application shall be signed by the applicant or his duly appointed agent, who shall present satisfactory evidence of his authority to represent the applicant.

(2) A joint application shall be signed by each applicant or his duly authorized agent, provided that a joint application by husband and wife may be signed by either party (joint applicants are required to select one among them to act for and represent the others in dealing with the Board).

(3) If the application is by a partnership, the applicant shall be designated by the firm name followed by the words "A Partnership" and the application shall be signed by each of the general partners or, if signed by one partner or other agent, a written statement of the agent's authorization to make the application, signed by the other parties of interest, shall be attached to the application.

(4) In the case of an estate or guardianship, the application shall be signed by the duly appointed guardian or representative of the estate, and a certified copy of the letter issued by the court shall be attached to the application.

(5) In the case of a water district, county, municipality, etc., the application shall be signed by a duly authorized official, and a certified copy of the resolution or other authorization to make the application shall be attached.

(6) In the case of a private corporation, the application shall be signed by a duly authorized person and, if not attested by the secretary or assistant secretary, a copy of the authorization shall be attached to the application.

(c) **Notary public required**. All applicants shall subscribe and swear to the application before a Notary Public, who shall also sign his name and affix his seal to the application.

(d) **Water rights**. Water rights requested or required in connection with a planned dam or reservoir may be approved based on preliminary information, however, no construction, enlargement, alternation or repair shall proceed until the application required by this Section has been submitted and approved in accordance with the rules of this subchapter and until the water rights required are approved.

[**Source**: Amended at 10 Ok Reg 3287, eff 6-25-93; Amended at 14 Ok Reg 2766, eff 7-1-97]

785:25-5-2. Plans to be prepared by registered professional engineer

Plans and specifications shall be prepared by a Registered Professional Engineer (59 O.S. 1981, §§475.1 and 475.15) who shall have training and/or experience concerning the analysis, design, and/or construction of dams and reservoirs, or by an engineer of any United States governmental agency acting in his official capacity (82 O.S. 1981, §105.27). However, if it is found that a project does not concern or involve the public welfare or the safeguarding of life, health or property, this requirement may be waived by the Board.

785:25-5-3. Content of plans and specifications

(a) The plans and specifications shall, as a minimum, include the following:

(1) A topographic map of the dam site showing the location of spillway and outlet works. The map shall also show all contiguous property and the owners thereof. The topographic maps for low hazard dams are not required to show test borings, test pits and borrow pits.

(2) A profile along the dam axis showing the location, elevation, depth of borings or test pits including logs or bore holes and/or test pits, provided that plans and specifications for low hazard dams are not required to contain such a profile.

(3) A maximum cross-section of the dam showing elevation and width of crest, slopes of upstream and downstream faces, thickness of riprap, zoning of earth embankment, location of cutoff and bonding trenches, elevations, size and type of outlet conduit, valves and operating mechanism.

(4) Area and capacity curves of the proposed reservoir.
(5) Detailed drawings showing plans, cross and longitudinal sections of the outlet conduits, valves and controls for operating the same, and trash racks.
(6) The discharge capacity in cubic feet per second of the spillway for each foot in water depth above the spillway crest up to the maximum high water level and the formula used in making such determinations.
(7) Detailed plans of spillway structures, cross-section of the channel leading to and from the spillway, spillway profile, and procedures for operation of the spillway structure.
(8) For high hazard potential classified dams, a breach analysis, and a map showing the breach inundation area utilizing guidelines provide by the Board.
(9) A requirement, during the period of construction, for supervision by an engineer as required in 785:25-7-2.
(10) A provision that the plans and specifications may not be substantially changed or changed in any material respect without prior written consent of the Board.
(11) A provision stating in detail all matters necessary to ensure that construction is accomplished in a responsible manner and that needed control is exercised by an engineer as required in 785:25-7-2 to ensure construction of a safe structure.

(b) The size of all plans and maps filed shall not be more than 11" x 17" and shall be drawn with an adequate number of views, in proper dimensions, and to a sufficiently large scale so that the plans and maps may be readily interpreted and studied. In addition to the plans and maps required to be filed, if plans and maps larger than 11" x 17" are submitted for review purposes, the larger plans and maps will not be retained by the Board.

785:25-5-4. Additional report information

An engineer's report giving details necessary for analysis of the structure and appurtenants shall be submitted with the plans and specifications. Included as a part of the report shall be the following:

(1) Formula and assumptions used in design:
(2) Hydrologic data used in determining runoff from the drainage areas including copies of any records that the applicant has of flood flows and precipitation for the region;
(3) Foundation and materials investigations; and
(4) All other information which would aid in evaluating the design.

785:25-5-5. Notice of application

(a) **Notice preparation**

(1) After an application has been duly filed and accepted, the Board may require that applicants for permits involving significant and high hazard-potential dams publish notice as it instructs. If such notice is required, a notice will be prepared by the Board and include information describing the application, the name and address of the applicant and opportunities for public comment.
(2) The notice will be mailed to the applicant with a letter of instructions as to the publication. Prior to publication the applicant shall check the notice for any errors.

(b) **Publication in newspaper**

(1) The notice of application, if required, shall be published once a week for two (2) consecutive weeks on the dates designated by the Board in a newspaper having general circulation in the county where the dam is located.
(2) The last notice shall be published at least ten (10) days prior to the hearing date.
(3) The applicant shall bear the cost of publication and shall see that the notice is reproduced accurately in the newspaper.
(4) If the Board instructs the applicant to mail notice, such mailing shall be by certified mail, return receipt requested.

[**Source**: Amended at 9 Ok Reg 1677, eff 5-11-92]

785:25-5-6. Affidavit of notice publication and mailing

(a) **Affidavit of publication required.** If the Board has required publication of notice, then the applicant shall file the sworn statement of the publisher with the Board before the application is considered by the Board. The affidavit shall state the dates on which the notice was published in the newspaper.

(b) **Failure to furnish affidavit.** Failure to furnish evidence of publication or of mailing of the notice in the manner required on or before the date the Board considers the application or may be deemed evidence of abandonment of the application.

[**Source**: Amended at 9 Ok Reg 1677, eff 5-11-92]

785:25-5-7. Public Comment

(a) Any interested person may submit written comments on any application.

(b) If the Board determines there is significant public interest in an application, it may schedule a public meeting to receive oral comments. Any interested person may appear and present comments.

(c) The Board shall consider the public comments when evaluating the application, and shall respond or prepare and publish a response to those comments, and may direct the applicant to respond.

[**Source**: Amended at 9 Ok Reg 1677, eff 5-11-92]

785:25-5-8. Approval or denial of application.

(a) After evaluating the application, if it is determined that the proposed construction, enlargement, alteration, or repair of any dam is safe and not a menace to life and property and is in conformity with all statutory requirements and the rules in this Chapter, said application shall be approved by the Board upon such conditions as the Board may prescribe.

(b) If it is determined that the proposed construction, enlargement, alteration, or repair of any dam is *unsafe and a menace to life and property*, [82:105.2] said application shall be denied by the Board.

(c) The applicant shall be notified in writing of the Board's decision

(d) If the application is approved, no impoundment of water by the dam may be made until all additional requirements of these rules and regulations are met unless the approved construction is for an existing dam and the construction may be carried out without emptying the water in the reservoir.

(e) The applicant shall commence construction within two (2) years after the date of approval of the plans and specifications or the approval will be deemed to have lapsed and shall thereafter be null and void, provided that the applicant may request an extension of time to commence such construction and if the extension is granted, the approval will not be deemed to lapse during the time extended.

SUBCHAPTER 7. POST APPROVAL ACTIONS

Section

785:25-7-1. Inspection during construction
785:25-7-2. Inspection fee
785:25-7-3. Deficiencies during and after construction
785:25-7-4. Supervision of construction by owner
785:25-7-5. Changes to plans and specifications after approval
785:25-7-6. Notice of completion and filing of supplementary drawings or descriptive matter
785:25-7-7. Warning and evacuation plans
785:25-7-8. Certificate of completion

785:25-7-1. Inspection during construction

During the construction, enlargement, repair, alteration, or removal of any dam or reservoir, periodic inspections may be made by the Board and the owner shall be required to perform at his expense such works or tests as necessary to disclose information sufficient to enable the Board to determine that substantial conformity with approved plans and specifications is being secured, which shall include adequate inspection, at owner's expense, to satisfy the Board of substantial compliance to approved plans, drawings, and specifications.

785:25-7-2. Inspection fee

(a) Fees for any such inspection must be paid by the owner upon submission of an itemized statement by the Board.

(b) Fees for inspections not paid by the owner within thirty (30) days after notice by the Board, *shall be a lien against any property of such owner, to be recovered by suit instituted by the District Attorney of the county at the request of the Board.* Such liens *shall be superior in right to all mortgages or other encumbrances, except ad valorem tax liens, placed upon the land and the water appurtenant thereto or used in connection therewith*. [82:105:27]

785:25-7-3. Deficiencies during and after construction

(a) If, after any inspections, investigations, or examinations, or at any time after completion, it is found that amendments, modifications, or changes to the work performed pursuant to the approved plans and specifications are necessary to protect life and insure safety of the dam or to meet acceptable dam safety engineering practices, including those found in references set forth in 785:25-3-4, the owners shall be required to submit a revised application.

(b) If conditions are revealed which will not permit the construction of a safe dam or reservoir, the prior approval may be revoked or modified by the Board after notice and hearing.

(c) After the inspection, investigation, or examination, the Board shall, in a report to the owner, specify the deficiencies and allow a reasonable time for correcting the deficiencies.

[**Source**: Amended at 9 Ok Reg 1677, eff 5-11-92]

785:25-7-4. Supervision of construction by owner

After receiving approval of plans and specification, supervision of construction by the owner shall be as follows:

(1) The work of construction, enlargement, repair, alteration or removal of dam or reservoir, for which approved application, plans, drawings, and specifications are required, shall be under the responsible charge of an engineer as defined in 785:25-5-2 who shall certify, upon completion and prior to impoundment of any waters, that such construction, enlargement, repair, alteration, or removal was done in accordance with approved plans, drawings, and specifications.

(2) Final approval in writing by a United States governmental agency shall be required for those structures designed by and/or constructed under the supervision of personnel of that agency.

785:25-7-5. Changes to plans and specifications after approval

(a) If during construction, enlargement, repair, alteration, or removal of any dam or reservoir, it is found that amendments, modifications, or changes that increase the normal or maximum water elevations, increase spillway releases or discharges, or that increase potential damages downstream will need to be made to the plans and specifications as previously approved by the Board, an amended application including maps, plans, drawings, and specifications shall be submitted to the Board for approval.

(b) The owner may be required to publish notice of the date, place and time when the Board will consider the matter as was done for the original application.
(c) Other amendments, modifications or changes shown in as-built plans and specifications may be accepted by Board staff.
[**Source**: Amended at 9 Ok Reg 1677, eff 5-11-92]

785:25-7-6. Notice of completion and filing of supplementary drawings or descriptive matter

Immediately upon completion of a new dam or reservoir or enlargement or repair of a dam or reservoir, the owner shall give notice of completion and as soon thereafter as possible shall file supplementary drawings or descriptive matter showing or describing the dam or reservoir as actually constructed, including the following:

(1) A record of all grout holes and grouting;
(2) A record of permanent location points and bench marks;
(3) A record of tests of concrete soils, or other materials used in the construction of the dam or reservoir; and
(4) Any other items which may be of permanent value and have a hearing on the safety and performance of the dam or reservoir.

785:25-7-7. Emergency action plans

(a) Owners of existing or proposed dams classified as high hazard potential, regardless of the size of such dams, and any other dam as determined by the Board, shall create and maintain an EAP that utilizes the recommendations, as determined by the Board, of the "Federal Guidelines for Dam Safety, Emergency Action Planning for Dam Owners," published August 2004 by the Federal Emergency Management Agency. The owner shall submit a copy of the EAP to the Board.
(b) Owners shall annually review their EAPs to assure they are still accurate and applicable, and submit any updates to the EAPs to the Board.

785:25-7-8. Certificate of completion

(a) **Issuance; revocation; amendments.**
Certificates of completion shall be issued and may be revoked or amended as follows:

(1) Upon filing of notice of completion of works by the applicant, the Board shall, within sixty (60) days, inspect or cause the dam to be inspected. The Executive Director shall approve the issuance of a certificate of completion if, based on the certification from the engineer in the Notice of Completion, the dam or reservoir is safe to impound water within the limitations prescribed in the certificate. However, no certificate of completion shall be issued until receipt of fee for certificate and all invoiced filing and inspection fees.
(2) Every certificate of completion issued shall contain *the date of approval of plans and specifications for the dam, date construction was completed on said dam, and* [82:110.8] any such terms and conditions as the Board may prescribe. The Board may revoke any such certificate whenever it is determined that the dam constitutes a danger to life and property. Whenever such action is necessary to safeguard life and property, the terms and conditions of any such certificate may be amended and a new certificate issued containing the revised terms and conditions.
(3) *Certificates of completion of works from the . . . Board shall be required before any water may be impounded by a new dam or before water may be impounded at an elevation higher than that previously authorized by the Board at an existing dam which has been modified* [82:110.8]

(b) **Notice and action.** After the issuance of the certificate of completion, the Board shall provide notice to the owner, allowing opportunity for a hearing, prior to the issuance of any order revoking or modifying the previous Board certificate.
[**Source**: Amended at 10 Ok Reg 3287, eff 6-25-93]

SUBCHAPTER 9. ACTIONS AFTER CONSTRUCTION

Section
785:25-9-1. Inspections of dams
785:25-9-2. Records and reports of owner
785:25-9-3. Correcting deficiencies (not creating imminent peril)
785:25-9-4. Notice and action (Revoked)
785:25-9-5. Correction of deficiencies creating imminent peril
785:25-9-6. Request for inspection of dams by other parties
785:25-9-7. Recovery of costs and expenses
785:25-9-8. Emergency repairs

785:25-9-1. Inspections of dams

(a) **Oversight vested in Board.** Oversight of the maintenance and operation of constructed dams and reservoirs insofar as necessary to safeguard life and property from injury by reason of the failure thereof is vested in the Board.
(b) **Periodic inspections.** Except for low hazard potential dams, owners are required to have their dams inspected by qualified persons periodically according to a schedule prepared by the Board to meet the requirements of paragraphs (1) and (2) of this subsection and shall include review of the Emergency Action Plan and of the operation and maintenance manual to assure they are still accurate and applicable. Periodic inspections of dams shall be scheduled according to hazard potential classifications as follows:

(1) High hazard. High hazard potential dams shall be inspected at least once annually.

(2) Significant hazard. Significant hazard shall be inspected at least once every three years.

(3) Low hazard. Low hazard potential dams shall be inspected at least once every five years, which inspection shall be conducted by the owner and shall consist of a review of the hazard classification on forms provided by the Board.

(c) **Expense of periodic inspections.** Periodic inspections shall be at the owner's expense (except for low hazard potential periodic inspections) and shall be conducted by a Registered Professional Engineer hired by the owner who shall have training and/or construction of dams and reservoirs, or by an engineer of any United States governmental agency acting in his official capacity. Provided that inspections of low hazard classification dams may be conducted by persons who are not Registered Professional Engineers but who are trained in inspecting dams. If a periodic inspection is conducted by the owner or his representative, a written inspection report shall be submitted to the Board not later than 30 days after the inspection and shall contain information as set forth in a Board's hazard verification report.
(d) **Unscheduled inspections.** Unscheduled (non-periodic) inspections such, as those conducted in response to complaints, after major heavy precipitation events or in emergency situations, may be conducted by Board staff, or the Board may require the owner to conduct and unscheduled inspection at the owner's expense. No fee for such inspection shall be due, provided that a request for inspection by other parties shall be governed by 785:25-9-6.
(e) **United States dams not subject to inspection**. Any dam *constructed by the United States or its duly authorized agencies shall not be subject to inspection while under the supervision of officers or the United States.* [82:105.27]
(f) **Board to notify when inspection due; violation.** The Board shall notify persons shown by its records to own the dam of the date the periodic inspection of the dam is due. Such notice

shall require the owner to advise the Board by a date specified when an engineer retained by the owner will conduct the inspection. Failure to so notify the Board or to have the inspection completed shall constitute a violation of Board rules.
[**Source:** Amended at 10 Ok Reg 3287, eff 6-25-93; Amended at 11 Ok Reg 2931, eff 6-13-94; Amended at 12 Ok Reg 2687, eff 7-1-95]

785:25-9-2. Records and reports of owner
(a) The owner of a dam or reservoir or his agent shall fully and promptly advise the Board by telephone or any sudden or unprecedented flood or unusual or alarming circumstances or occurrence affecting the safety of the dam or reservoir. Within ten (10) days after such flood event or circumstance, the owner or owner's agent shall provide a written report of any damages to the dam and of the need to make any repairs.
(b) The Board may require owners to keep records of and to report on maintenance, and staffing of any dam or reservoir if, in the opinion of the Board, such records and reports are necessary to safeguard life and property.
[**Source:** Amended at 10 Ok Reg 3287, eff 6-25-93]

785:25-9-3. Correction of deficiencies (not creating imminent peril)
(a) *When an owner fails, neglects or refuses to comply with* the Oklahoma Dam Safety Act, rules of this chapter, *or orders of the . . . Board, and there is no imminent peril to the public health or welfare shown* the Board *may, after notice and opportunity for hearing, issue an order requiring such owner to take whatever action the Board deems necessary to place the dam in a safe condition, meet the requirements of* the Oklahoma Dam Safety Act, *rules of the Board, or the previous orders of the Board* [82:110.10].
(b) Actions which can be ordered *may include but are not limited to lowering the level of or removing all water in the reservoir, providing an adequate warning to the public downstream, repair or modification of the existing dam after having the appropriate application for approval of plans and specifications granted, cease all construction work on a dam, and implementation of an appropriate operation and maintenance plan* [82:110.10].
(c) If after such hearing it shall be determined to order such amendments, modifications or changes, the owner shall submit, if necessary under 785:25-5-1, plans and specifications for Board approval. Upon approval of the plans and specifications, the Board shall direct the time within which such modification, alteration, or construction shall be completed.
(d) In determining whether amendments, modifications or changes are necessary to protect life and insure safety of the dam, the Board shall take into consideration the possibility that the dam and reservoir might be endangered by overtopping, seepage, settlement, erosion, cracking, earth movement, or other conditions which exist in any area in the vicinity of the dam or reservoir.
(e) Amendments, modifications or changes may include routine maintenance items that do not require plans and specifications, such as removal of trees on an earthen embankment, establishing vegetation cover to prevent erosion, or updating a warning and evacuation plan, etc. Amendments, modifications or changes may also include alterations or repairs which require submittal and approval of plans and specifications, including but not limited to changing the spillway design capacity, rebuilding embankments, etc.
[**Source:** Amended at 9 ok Reg 1678, eff 5-11-92; Amended at 10 Ok Reg 3287, eff 6-25-93]

785:25-9-4. Notice and action (Revoked)
[**Source**: Revoked at 10 Ok Reg 3287, eff 6-25-93]
Agency Note (1): The language in 785:25-9-4 has been moved to 785:25-7-8(c).

785:25-9-5. Correction of deficiencies creating imminent peril

(a) *When an owner fails, neglects or refuses to comply with* the Oklahoma Dam Safety Act, rules of this Chapter, *or orders of the Board, and there is an imminent peril to the public health or welfare shown, the Executive Director of the Board, or Assistant Director in the absence of the Executive Director, may, without notice or opportunity for hearing, issue an emergency order requiring such owner to take actions the Board deems necessary to place the dam in a safe condition. Such emergency order shall indicate the finding of imminent peril and shall specify the actions that are to be taken immediately. The order shall also specify a time and place for hearing to be held after such actions are taken.* [82:110.10]. In determining whether an imminent peril to the public health or welfare exists, the Board may consider the following:

(1) The condition of any dam or reservoir is so dangerous to the safety of life or property as not to permit time for the issuance and enforcement of an order after notice and hearing relative to maintenance or operation;

(2) Passing imminent floods threaten the safety of any dam or reservoir.

(b) The Board may, if the owner cannot be served or is otherwise unable to act, immediately employ remedial measures. The remedial measures the Board may take in such an emergency include but is not limited to any of the following:

(1) Lower the water level by releasing water from the reservoir;

(2) Completely empty the reservoir, or

(3) Take such other steps as may be essential to safeguard life and property.

(c) The cost and expenses of the remedial measures taken by the Board, including cost of any work done to render a dam or reservoir or its appurtenances safe, shall be recoverable by the State from the owner by action brought by the Board in the district court of the district wherein the dam or reservoir or any part thereof is situated.

[**Source**: Amended at 10 Ok Reg 3287, eff 6-25-93]

785:25-9-6. Request for inspection of dams by other parties

Upon the request of any party, accompanied by the estimated cost of inspection, the Board shall cause any alleged unsafe works to be inspected. If the works are *found to be unsafe, the money deposited by such party shall be refunded and the fee for inspection shall be paid by the owner of such works*. [82:105.27]

[**Source:** Amended at 11 Ok Reg 2931, eff 6-13-94]

785:25-9-7. Recovery of costs and expenses

The costs and expenses incurred by the Board for inspection of any dam found to be unsafe *shall be paid by the owner of such works and if not paid by the owner of the dam within thirty (30) days after the decision of the Board shall be a lien against any property of such owner and be recoverable by the State from the owner by suit instituted by the District Attorney of the county at the request of the Board.* Such *liens shall be superior in right to all mortgages or encumbrances, except ad valorem tax liens placed upon the land and the water appurtenant thereto or used in connection therewith*. [82:105.27]

785:25-9-8. Emergency repairs

(a) If conditions exist which may cause loss of life if repairs are not made immediately, emergency repairs may be made by the owner without prior submittal of the plans and specifications required under 785:25-5-1.

(b) The Board shall be notified of the emergency and the repairs to be made within 48 hours and plans and specifications shall be furnished to the Board for review as required in 785:25-5-1 as soon as possible.

785:25-9-9. Breach analysis for existing dams

If an existing dam does not have a breach analysis, and a failure might put lives at risk downstream, then after the next regularly scheduled inspection the Board's Engineer may direct the owner to provide a breach analysis and breach inundation map, utilizing modeling and analysis guidelines provided by the Board, and according to a reasonable schedule of compliance.

785:25-9-10. Reclassification of the hazard-potential class of a dam

(a) The Board may reclassify the hazard-potential classification of a dam at any time based on an inspection and downstream hazard evaluation.

(b) If the Board determines that the hazard-potential class of a dam should be increased to a greater hazard-potential classification, then the Board shall notify the owner of that finding and of the upgrade options that are available, and set a reasonable deadline, based on the circumstances, for the owner to:

(1) file an application to upgrade the dam to meet the requirements for a greater hazard-potential classification; or

(2) seek an individual proceeding to contest the finding: or

(3) perform a breach analysis and inundation mapping or, for existing dams that lack a breach analysis, through the use of acceptable mathematical computations applied to the downstream area from the dam to a point where the necessary design flood and breach is contained within the main stream channel, utilize modeling and analysis guidelines provided by the Board to show the dam should not be reclassified to the greater hazard-potential classification.

785:25-9-11. Upgrading dams due to downstream development

(a) **Alternatives.** Instead of upgrading the dam using structural methods, an owner may seek to implement alternative methods. Such alternative methods shall include but is not limited to the following:

(1) a current breach analysis and hydrologic study that demonstrates a lesser hazard-potential classification is correct; or

(2) a current breach analysis and design flood analyses that demonstrate existing downstream developments would not be adversely affected by more than one foot difference between breach and non-breach simulations in the affected area, or records showing the downstream development has been dedicated to non-residential and non-commercial use; or

(3) a plan to permanently remove the dam.

(b) **Schedule of Compliance.** An owner may seek a compliance schedule with the Board that sets the timeframes for various stages of work to be performed. In considering such applications to upgrade on a compliance schedule the Board shall evaluate whether the current dam will not significantly affect the public safety during the compliance period.

SUBCHAPTER 11. ADMINISTRATIVE PENALTIES AND PROCEDURES

Section

785:25-11-1. Applicability and authority
785:25-11-2. Notice of violation and proposed assessment
785:25-11-3. Determined amount of penalty
785:25-11-4. Procedures for penalty assessment

785:25-11-1. Applicability and authority

(a) *The Board may impose administrative penalties against owners of dams who fail, refuse or neglect to comply with the provisions of* the Oklahoma Dam Safety Act, rules of the Board

promulgated pursuant to the Oklahoma Dam Safety Act, and *orders of the Board. Such administrative penalties shall be imposed only after notice and opportunity for hearing on the proposed imposition of such penalties* [82:110.10].
(b) *The notice and opportunity for hearing required by this* Section *may be combined with the notice and hearing required in* [82:110.10] 785:25-9-3.
(c) The penalties *shall not exceed Five Hundred Dollars ($500.00) per day for each violation* [82:110.10].
(d) *Each day a violation continues shall constitute a separate violation* [82:110.10]
[**Source**: Added at 10 Ok Reg 3287, eff 6-25-93]

785:25-11-2. Notice of violation and proposed assessment

The notice of proposed assessment of administrative penalties shall inform the respondent of the provisions of the Oklahoma Dam Safety Act or of the rule or order of the Board at issue and the proposed amount of the penalty. A letter, petition, notice of violation, consent order or final order may constitute a notice of proposed assessment for purposes of initiating administrative penalty proceedings if it meets the requirements of this section.
[**Source:** Added at 10 Ok Reg 3287, eff 6-25-93]

785:25-11-3. Determining amount of penalty

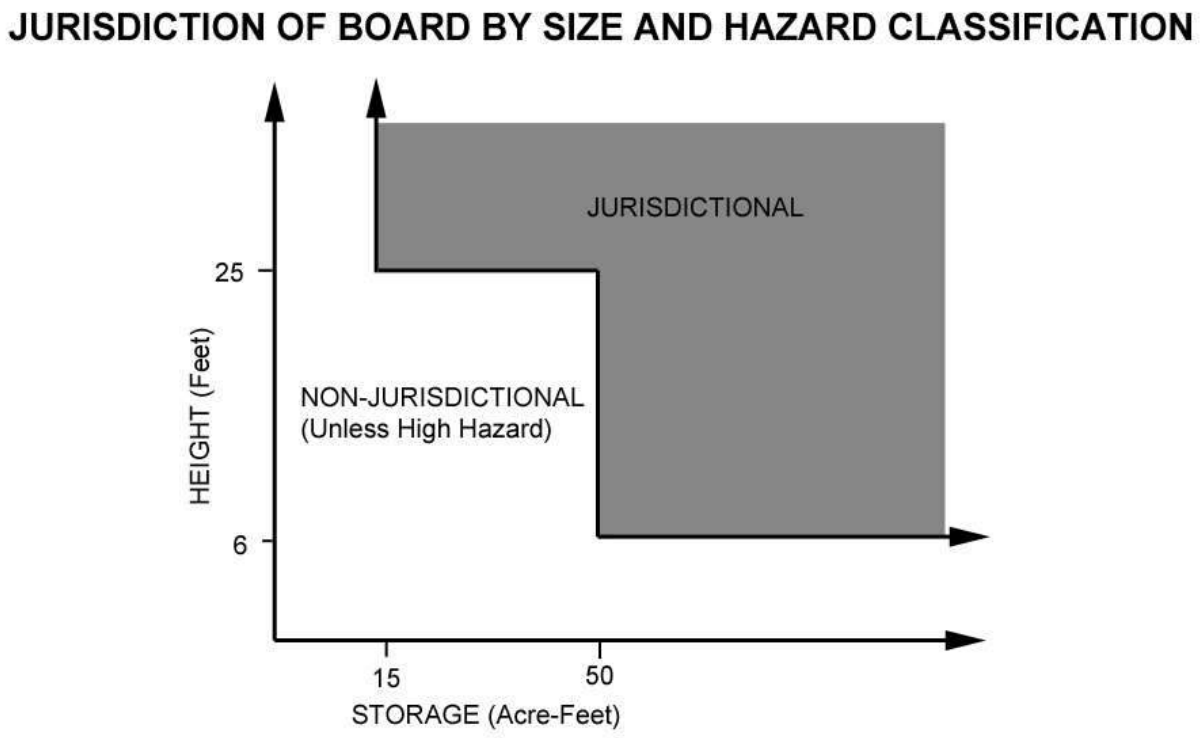
In setting the administrative penalty amount, the Board may consider the following:

(1) The nature, duration and number of previous instances of failure by respondent to comply with requirements of law relating to dam safety and requirements of Board rules and orders.

(2) The efforts of the owner to correct deficiencies or other instances of failure to comply with the requirements of Board rules and orders subject of the proposed penalty.

(3) The cost of carrying out actions required to meet the requirements of law and Board rules and orders;

(4) The size and hazard classification of the dam;



(5) Other factors deemed appropriate by the Board.

[**Source**: Added at 10 Ok Reg 3287, eff 6-25-93]

785:25-11-4. Procedures for penalty assessment

(a) The notice of proposed assessment of administrative penalties shall specify a time, date and place of a hearing.
(b) Failure of respondent to appear at the hearing shall be deemed to constitute an agreement with the imposition of the penalty in the amount proposed as set forth in the notice, and proposed findings, conclusions and order shall not be prepared in that instance. The Board and respondent may also agree to an informal disposition of the matter. In either situations, the matter shall be presented to the Board for consideration of entering a final order assessing the administrative penalty.
(c) The administrative penalty is due and payable immediately upon issuance of the final order, unless otherwise provided therein.
(d) If the Board believes that violations are continuing after issuance of the administrative penalty order, it may seek the issuance of additional orders to assess penalties occurring in the period after issuance of the previous assessment orders.
[**Source**: Added at 10 Ok Reg 3287, eff 6-25-93]

APPENDIX A.
JURISDICTION OF BOARD BY SIZE AND HAZARD CLASSIFICATION

Dam Safety • FACT SHEET

OWRB
the water agency

The Oklahoma Water Resources Board (OWRB) coordinates the state's Oklahoma Dam Safety Program to ensure the safety of more than 4,600 of our dams in the state, especially those that could impact downstream life and property. The most common requirements of the Dam Safety Program are:

* Yearly inspections for "High-hazard" dams (likely to cause loss of human life)
* Inspections every 3 years for "Significant-hazard" dams (likely to cause high economic loss)
* Inspections every 5 years for "Low-hazard" dams (likely to cause minimal economic loss)
* Application to construct a new dam
* Approval of plans for modification of an existing dam
* Emergency Action Plan for High-hazard dams (see below)

Training - The Dam Safety Program coordinates periodic training sessions and workshops on dam safety issues and regulations for dam owners and engineers. OWRB strongly encourages such persons to attend these valuable sessions (schedules are posted on our website*)

Liability - It is important to be aware that any person or company that owns, operates, or maintains a dam is liable for some or all damages due to a failure of that dam even if an unsafe condition existed prior to a new dam owner's term of ownership. Thus, the potential owner must carefully inspect the structural integrity of any dam prior to purchase and then inspect, maintain, and repair it thereafter.

Small Dams - Construction application may not be necessary if the dam will be less than 25 feet in height above the stream bed or if the lake impounded by the dam will less than 50 acre-feet of water; however, approval is required irregardless of size if there are houses or habitable structures located below the dam.

If you plan to construct a dam always check with a professional engineer, the NRCS, or with the OWRB Dam Safety Program engineer before you begin construction to determine if you need to file an application with the State.

Emergency Action Plans

It is the responsibility of each high-hazard dam owner to develop an Emergency Action Plan (EAP) tailored specifically to that dam. The EAP assigns critical roles including surveillance, notification, and identification of the dam break flood zone as well as develop a critical contact list in order to protect downstream lives and property. A written EAP must be submitted to and approved by the OWRB and subsequently filed with the local Civil Defense authorities. The OWRB publication, "Emergency Action Plan Guidelines for High Hazard–Potential Dams" is strongly recommended for dam owners. The Guideline and a fillable EAP form are available on OWRB's website*.

Dam Safety Inspections

The regular inspection of dams is the heart of your care and maintenance program. Early detection and remedy are essential for preserving the integrity of the dam. Technical inspections must be performed by professional engineers familiar with the design and construction of dams and should include assessments of structure safety.

Maintenance inspections are performed more frequently than technical inspections in order to detect, at an early stage, any developments that may be detrimental to the dam. Downstream hazard verification inspections must also be performed to determine if there has been any construction of homes, building, or other structures downstream of their dam which could raise the dam's hazard classification. This has important implications for the dam owner as it could result in a change of how often the dam must be inspected and require structural modifications to the dam.

NRCS Sugar Creek Site # 44 dam, Caddo Cnty, OK washed out from heavy rains

OKLAHOMA

Citation

Oklahoma dam safety laws are contained in 82 O.S. § 110, last amended in 1992. Regulations are found in the Oklahoma Water Resources Board Rules, Chapter 25, originally adopted in 1973 and last revised in 1997.

Definitions/Dam Classifications

Dam means any artificial barrier, together with appurtenant works, which does or may impound or divert water (Rules 785:25-1-2). A dam is regulated if it is 25 feet or more in height or has an impounding capacity of 50 acre-feet or more. No obstruction determined to be designated primarily for road fill shall be considered a dam (Rules 785:25-3-1[6]).

Dam height is measured from the natural bed of the stream or watercourse at the downstream toe of the barrier or from the lowest elevation of the outside limit of the barrier if it is not across a stream channel or watercourse, to the maximum possible water storage elevation.

Dam classifications are based on size of the structure and the potential for hazards (Rules 785:25-3-3).

Size Classification

Size	Maximum Storage (ac-ft)	Maximum Height (ft)
Small	less than 10,000	less than 50
Intermediate	between 10,000 - 50,000	between 50 - 100
Large	greater than 50,000	greater than 100

Hazard Potential Classification

Category	Loss of Life	Economic Loss
Low	none	minimal
Significant	none	appreciable
High	yes	excessive

Jurisdiction/Powers of Department

State dams fall under the jurisdiction of the Oklahoma Water Resources Board, hereafter referred to as "the Board". Title 82 of the Oklahoma Statutes 1981, section 1085.2, as amended, requires the Board to adopt rules and regulations deemed necessary to the exercise of any powers conferred upon it.

The Board is empowered to issue permits and review and approve applications for the construction, enlargement, alteration, or repair of any dam (Rules 785:25-5-1). The Board's responsibility over dams shall be limited to dams with a height of twenty-five feet or more, or those with an impounding capacity of fifty acre-feet or more (Rules 785:25-3-1).

The Board is empowered to inspect dams during construction (Rules 785:25-7-1) and after construction is completed (Rules 785:25-7-3). The Board has the power to cite noncompliance and call for remedial work (Rules Chapter VII730.4) and may invoke judicial actions if necessary (Rules 785:25-11-1).

The Board has the power to immediately employ remedial measures in the event of a dam emergency (Rules 785:25-9-5).

Permit/Approval Process

A filing fee must be submitted with each application to construct, enlarge, alter, or repair a dam, based on estimated cost of construction (Rules Chapter III305.5).

Estimated Cost	Filing Fee
$20,000 or less	$ 100.00
$20,001-$99,999	$200.00
$100,000-$999 999	$500.00
$1,000,000 or more	$1,000.00

Plans and specifications are to be prepared by a registered professional engineer (Rules 785:25-5-2).

Applicants for a permit must submit an application upon printed forms, which will be furnished by the Board upon request. The maps, plans, drawings, and specifications of the proposed work along with the filing fee shall form part of the application (Rules 785:25-5-1).

In addition, an engineer's report giving details necessary for analysis of the structure and appurtenances shall be submitted with the plans and specifications (Rules 785:25-5-4). After an application has been filed, a notice will be prepared by the Board setting forth the time, date, and place for hearing the application. Protests regarding the application may be heard at this time. The Board will then render its decision (Rules 785:25-5-7).

Rules 785:25-3-5 and 785:25-3-6 establish minimum design standards as well as minimum spillway performance standards which all dams are required to meet. The owner is required to pay all fees and is responsible for any remedial work (Rules 785:25-9-5).

Inspection Process

State

Supervision over the maintenance and operation of constructed dams and reservoirs insofar as necessary to safeguard life and property is vested in the Board (Rules 785:25-9-1). The rules give the Board responsibility for carrying out routine inspections of every dam under their jurisdiction. Periodic inspections of dams shall be scheduled according to hazard classification as follows:

High Hazard - At least once annually
Significant Hazard - At least once every three years
Low Hazard - At least once every five years

Costs and expense incurred by the Board for inspecting a dam found to be unsafe are the responsibility of the owner. A lien shall be placed on the property if the owner does not pay within 30 days of the Board's decision and expenses shall be recovered by suit.

Owner

Periodic inspections shall be at the owner's expense and shall be conducted by Board staff, a registered professional engineer, or an engineer of any United States governmental agency acting in his official capacity. Some low hazard dams may be exempt from the periodic inspection (Rules 785:25-9-1). Rule 785-25-9-2 requires the owner or his agent to "fully and promptly advise the Board of any sudden or unprecedented flood or unusual or alarming circumstances or occurrence affecting the safety of the dam or reservoir".

During the construction, enlargement, repair, alteration, or removal of any dam, periodic inspections may be made by the Board and the owner shall be required to perform at his expense such works or tests as necessary to disclose information sufficient to enable the Board to determine that substantial conformity with approved plans and specifications is being secured (Rules 785:25-7-1).

Violations/Penalties

Every person shall be guilty of a misdemeanor who violates any of the provisions of the laws or of any order, rule, or regulation of the Board issued pursuant thereto, where a copy of the order, rule, or regulation has been served upon said person by certified mail and said person fails to comply therewith within the time provided, or within ten days of such service if not otherwise provided. In the event of a continuing violation, each day that the violation continues constitutes a separate offense (Rules 785:25-1-3).

Emergencies

The Board may, without notice and hearing issue an emergency order requiring remedial measures to be taken necessary to protect life and property. If the owner cannot be served or is otherwise unable to act, the Board may immediately employ remedial measures. In applying remedial measures, the Board may in emergency do or cause to be done any of the following:

(a) Lower the water level by releasing water from the reservoir,

(b) Completely empty the reservoir, or

(c) Take such other steps as may be essential to safeguard life and property.

The cost and expenses of the remedial means, including cost of any work done to render a dam safe, shall be recoverable by the State from the owner by action brought by the Board in the district court of the district wherein the dam is situated (Rules 785:25-9-5).

Rule 785:25-7-7 requires owners of existing or proposed dams classified as high hazard to provide an adequate warning system and evacuation plan to protect downstream lives and property. The plan is to be approved by and filed with the local Civil Defense authorities. The plan must also be filed with the Board.

Liability

Owners of dams have the responsibility to provide for the safety of such works by making any necessary changes to put the works in a safe condition (Rule 785:25-11-1).

Title 51.05 Supp. 1990 Section 155 exempts the state from liability if a loss or claim results from inspection power including the failure to make an inspection or the completion of an inadequate or negligent inspection.

Oversight

As allowed by and subject to compliance with the requirements imposed under the Oklahoma Administrative Procedures Act (75 O.S. 1981, Sections 301326), any interested party may request rehearing, reopening or reconsideration of any final Board action, decision or Order (Rule 785:4-9-3).

Miscellaneous

Dams constructed by the United States or its duly authorized agencies shall not be subject to inspection while under the supervision of the officers of the United States (Rules 785:25-9-1).

The Oregon Administrative Rules contain OARs filed through October 15, 2010

WATER RESOURCES DEPARTMENT

DIVISION 20

DAM SAFETY

690-020-0000

Purpose and Applicability

(1) These rules describe the standards and requirements under which the department will administer and enforce the design, construction, maintenance, inspection, and fees regarding dams in Oregon. The purpose is to provide the guidance necessary for dams to be constructed and operated in a manner that will ensure the protection of life and property and to provide the department with the resources necessary to manage and support the construction and safe operation of dams in accordance with these rules.

(2) These rules apply to:

(a) Dams that are not subject to ORS 540.350–540.390 as described in 540.400.

(b) Dams that are subject to ORS 540.350–540.390 and which exceed the statutory limits as described in ORS 540.400(1) & (2).

(3) These rules do not apply to metal or reinforced concrete water storage tanks or various types of tanks that are part of water treatment facilities.

Stat. Auth.: ORS 540.350 - 540.400, 536.050
Stats. Implemented: ORS 183, 540, 536
Hist.: WRD 12-1986, f. & ef. 10-3-86; WRD 12-1994, f. & cert. ef. 11-7-94; Renumbered from 690-020-0021, WRD 7-2009, f. 12-7-09, cert. ef. 1-1-10

690-020-0022

Definitions

The following definitions apply in OAR 690, Division 20:

(1) “Abutment” means a natural valley or canyon side against which the dam is built;

(2) “Acre-foot” means the equivalent volume of one acre covered with one foot of water (325,900 gallons);

(3) “Conduit” means a closed conveyance used to release water through a dam;

(4) “Cutoff Trench” means a trench excavated beneath the dam foundation and backfilled with low permeability material to retard water seepage;

(5) “Dam” means a hydraulic structure built above the natural ground grade line that is used to impound water. Dams include wastewater lagoons and other hydraulic structures that store water, attenuate floods, and divert water into canals;

(6) “Dam Crest” means the top of the dam;

(7) “Department” means the Oregon Water Resources Department;

(8) “Director” means the Director of the Oregon Water Resources Department;

(9) “Embankment” means an engineered earth fill;

(10) “Emergency Spillway” means an overflow structure constructed to bypass flood water and prevent overtopping the dam crest. Often, dams have two spillways. The lower elevation spillway that spills first is referred to as the principle spillway. The higher elevation spillway is referred to as the emergency spillway;

(11) “Foundation” means the ground surface upon which a dam is constructed;

(12) “Freeboard” means the vertical distance between the designed high-water level in the reservoir and the dam crest;

(13) “Gate” or “Valve” means a permanent device for regulating water flow through the dam;

(14) “Hazard Rating” means the rating established by the department for a large dam that pertains to the potential level and degree of damage to life and property downstream of a dam in the event dam failure results in a catastrophic release of water;

(15) “Large Dam” for dam safety purposes, means a dam with a height of 10 feet or more and impounding 3,000,000 gallons (9.2 acre-feet) or more of water;

(16) “Significant dam work” means an activity to repair, rehabilitate, enlarge or otherwise alter a dam in which: 1) at least 30% of the fill material is impacted by the activity, 2) a spillway is being enlarged or repaired that affects the height or hydraulics of the spillway, 3) dam height and/or reservoir size is being increased, 4) a low level outlet conduit or inlet gate is being reworked with excavation or 5) any other activity that could affect the integrity of the dam or its auxiliary works;

(17) “Small dam” for dam safety purposes, means a dam with a height of less than 10 feet or impounding less than 3,000,000 gallons (9.2 acre-feet) of water; and

(18) “Tank” means a fully-enclosed (bottom and sides) hydraulic structure made from metal, reinforced concrete, rigid fiberglass, or plastic that provides its own water-sealing and structural stability.

Stat. Auth.: ORS 183 & 540
Stats. Implemented: ORS 183 & 540, 536

690-020-0025

General Requirements for all Dams

(1) The director may require any information or data in addition to that outlined herein which the director finds necessary for determining the safety of the proposed structure.

(2) Whenever possible, precipitation and runoff records shall be submitted as part of the design for new or significant dam work on existing dams. If records are not available for the basin in which the dam is located, the hydrological/hydraulic criteria used in the design shall be submitted.

(3) The director may include as part of any permit to construct a dam limitations and conditions that pertain to construction, operation, maintenance, and the protection of lives and property. These limitations and conditions become, by reference, part of the certificate and remain in effect throughout the life of the water right.

(4) Approved plans and specifications for construction are, by reference, considered limitations and conditions placed on the water right permit and water right certificate. The director retains the authority to place additional limitations and conditions on the water right relative to operation and maintenance.

(5) Dams constructed or operated in violation of limitations and conditions included in the permit or certificate are subject to

restricted use and permit cancellation procedures. The certificate affirms the applicant's right to store water subject to the limitations and conditions therein.

(6) An outlet conduit with a minimum diameter of 8" must be installed in any instream reservoir to permit drainage of the reservoir and for passage of flow to downstream prior rights. The director may waive this requirement if the director determines that the conduit is not needed for dam safety and will not be needed to pass flow for the benefit of other water rights, minimum perennial streamflows, or if the director determines an adequate alternative for passing flow is provided. Adequate alternatives must be capable of passing flow in sufficient quantity to satisfy downstream needs, and can include pumps, by-pass channels and siphons. Conduit material should be chosen based on design and site condition requirements. Acceptable conduit materials include reinforced concrete cylinder pipe; cast-in-place, reinforced concrete; appropriate PVC; concrete-encased corrugated metal pipe or plastic pipe; ductile iron; and cast iron. All joints should be water tight. The conduit valve should be installed at the upstream end and should be industry-manufactured with specifications consistent to the applied usage. Special provisions should be made for pressure conduits gated on the downstream end.

(7) The department shall determine the height of a dam by calculating the vertical distance (measured in feet) between the center point of the dam crest relative to and above the stream channel and the lower of either the natural soil surface that was in place prior to the construction of the dam or where a channel incision exists, the bottom of the channel incision. This measurement is to be taken at the maximum section along the dam’s longitudinal axis.

(8) The department shall determine water impoundment volumes (in acre-feet or millions of gallons) as follows:

(a) For dams impounding water for an authorized beneficial use, the impoundment volume indicated in the area-capacity curve from the bottom of the reservoir to the spillway crest. For dams with multiple spillways, ‘spillway crest’ is referring to the crest of the principle or lower elevation spillway.

(b) For wastewater treatment lagoons, the impoundment volume indicated in the wastewater lagoon plans and specifications, and

(c) For diversion or flood control dams, the impoundment volume calculated at full reservoir at the dam emergency (highest elevation) spillway crest level.

690-020-0029

Small Dams, Recommended Minimum Standards

The following information is presented for the applicant's assistance in constructing small earthfill dams:

(1) It is recommended that the crest width of the dam be not less than 8 feet.

(2) It is recommended that the upstream slope of the dam be no steeper than 3:1.

(3) It is recommended that the downstream slope of the dam be no steeper than 2:1.

(4) It is recommended that the spillway channel be constructed around the dam, not over the top of the fill. The spillway is commonly excavated in natural material and, if necessary, lined to prevent erosion. The spillway should be large enough to pass the 50-year flood flow without overtopping the dam. Assistance is available from the department in sizing the spillway. Flow passing through the spillway should be returned to the creek channel at a sufficient distance downstream to prevent erosion of the dam’s embankment.

(5) It is recommended that all brush, stumps, roots, and organic matter should be cleared from the area to be occupied by the dam. All such material should also be removed from the borrow area.

(6) It is recommended that the outlet pipe be encased with concrete or other method to allow for proper compaction and the prevention of uncontrolled seepage.

(7) Embankment material should be spread parallel with the dam axis in layers not exceeding eight inches in thickness and adequately compacted with sheepfoot roller or other similar equipment.

(8) It is recommended that prior to construction the dam owner have the dam’s potential hazard to downstream properties studied

using methods listed in 690-020-0100. It is recommended that any dam with a potential significant or high hazard rating be designed by a registered engineer familiar with dam engineering. It is advisable for any dam nearing or surpassing the dam height or storage thresholds for a “large dam” to be designed by a registered engineer.

690-020-0035

Dams Over the Statutory Limits; Minimum Engineering Design Requirements

All maps, plans, and specifications for the construction of new large dams or significant dam work for existing large dams, must be prepared by a professional engineer licensed to practice in the State of Oregon.

(2) Before initiating design, the engineer shall obtain design criteria from the department.

(3) No newly constructed large dam shall be permitted to store water until written approval is received from the department. Approval will be given after construction has been completed and is certified by the supervising engineer to have been constructed in accordance with the approved plans and specifications.

(4) Design documents shall include the following:

(a) Plans:

(A) Plans for dams submitted for approval must accurately portray the work to be accomplished and be of sufficient detail to adequately define all features of the project. Plans must be submitted on good-quality mylar or vellum and must be neatly and accurately drawn to a scale sufficiently large, with an adequate number of views, for the drawing to be readily interpreted. To meet the requirements of this subsection, the director may allow plans for dams to be submitted electronically. The format of the plans in terms of file type, projection and other details must be approved by the department.

(B) Several sheets may be used to eliminate the necessity of large bulky drawings. No map or plan should be larger than 24 x 36 inches. The following information will be required:

(i) A contour map of the reservoir site which will show the location of the dam by quarter-quarter section, township, range and tax lot; and the name and location of the stream flowing through the reservoir. Government survey lines must be indicated on this

map, along with a survey tie to the dam axis from a government land corner. Area and capacity curves and/or tables of the proposed reservoir must be shown;

(ii) A map of the drainage basin showing the location of the dam and reservoir and the streams within the drainage area. This map may be prepared from existing reliable topographical maps and it must include: the number of square miles of drainage area; a brief description of the area; the percentage of bare and timbered lands; and general characteristics of the watershed, whether precipitous, rolling, or comparatively flat. The estimated discharge as well as the spillway capacity at different reservoir water levels should also be provided in the plans or specifications. Extraneous information can also be included in specifications or a separate hydrology report as to not clutter up the map;

(iii) A topographic map of the dam site with contour intervals not to exceed 5 feet. A plan of the dam should be superimposed on this map showing the location of spillways, outlet conduits, and other relevant auxiliary structures;

(iv) A profile of the dam site taken on the axis of the dam and a profile of the spillway along its axis. The profile should also show the location of the outlet conduit and spillway. A log showing the classification of materials encountered below the surface as shown by test pits or borings;

(v) A cross section of the dam at maximum section showing complete details and dimensions;

(vi) Plans showing sections of the outlet conduit, control works, and spillways. These sections should be in sufficient number and detail to make definite all features of the structure.

(b) Specifications. All plans for dams must be accompanied by construction and material specifications:

(A) The specifications shall describe in detail the methods and/or performance criteria to be followed in performing each class of

work and shall set forth the requirements for the various types of material to be used in permanent construction;

(B) The specifications must contain a provision for supervision by the engineer during construction and for inspection by the director or director's authorized representative at any time during the construction period;

(C) The specifications must also contain a provision to the effect that plans or specifications shall not be altered or changed without the written approval of the director or the director's authorized representative.

(5) Construction: Construction should be supervised by an engineer licensed to practice in Oregon. As a minimum the following notices and construction reports shall be submitted to the Department:

(a) Notice of beginning of construction;

(b) Notice of intent to begin placement of fill materials;

(c) Completion report including test results, "as-built" drawings, and certificate of completion in accordance with approved plans and specifications.

(6) During the design process for any newly constructed dams or for significant dam work to existing dams that involves potentially changing the volume or rate of water released during failure, the dam owner or owner's representative must submit to the department an inundation analysis using methods described in 690-020-100. The department shall use this analysis to determine the hazard rating of the dam in accordance with 690-020-100.

(a) If a dam is rated as high hazard, an emergency action plan is required and the plan must be reviewed and approved by the department.

(b) The inundation/evacuation map for the dam must be developed using methods described in 690-020-100(2) and must be reviewed and approved by the department.

Enforcement Procedures

The director shall maintain a program of inspecting existing dams. When any structure is found to be in violation of the terms and conditions of the permit or certificate or directly threatens life or property, or when any structure is found where lack of maintenance or unauthorized alterations could lead to a direct threat to life or property, the department shall notify the owner in writing of the violation and the action necessary to bring the structure up to design, operation, or maintenance standards. Failure by the owner to perform the required action may result in proceedings for one or more of the following:

(1) Notice and opportunity for a contested case hearing as provided for in ORS 540.350(5).

(2) Cancellation of the permit.

(3) Posting of the structure to prevent storage or to limit operation until the owner has complied with the requested action required to fulfill conditions of the permit or certificate.

(4) Instituting legal action by the District Attorney or Attorney General to have the facility declared a public nuisance.

(5) Issuance of an order to prevent storage or to breach the embankment as provided for in ORS 540.370.

(6) Any other enforcement action permitted by law.

690-020-0100

Hazard Rating

(1) Hazard ratings for “large dams” are classified by the department as “high hazard”, “significant hazard”, or “low hazard” as follows:

(a) High Hazard: This rating indicates that if the dam fails there is a strong plausibility for loss of life. The plausibility is established because of inhabited infrastructure (such as homes and business) downstream that would be inundated to such a degree see 690-020-0100(2)(d) for specific criteria that it would put the person who inhabits the structure in jeopardy. Any factor that puts a strong probability of people being downstream in an inundation area of a dam failure shall be considered. The department shall endeavor to inspect this class of dams on an annual basis.

(b) Significant Hazard: This rating indicates that if a dam fails, infrastructure (such as roads, power lines or other largely uninhabited buildings) would be damaged or destroyed due to inundation and flooding. The department shall endeavor to inspect this class of dams at least once every three years.

(c) Low Hazard: This rating indicates that if the dam fails there is little plausibility for loss of life, and human infrastructure that could be affected by inundation downstream is minor or non-existent. The department shall endeavor to inspect this class of dams at least once every six years.

(2) The department shall utilize inundation of infrastructure study results as a primary factor to determine the hazard rating of dams. Methods and modeling acceptable for inundation of infrastructure studies include:

(a) Hydraulic Modeling: Use of one-, two-, or three-dimensional modeling software (such as HEC-RAS, FLO-2D or MIKE) and hydrologic, topographic, and other data to estimate inundation of infrastructure downstream of dams.

(b) Hydrologic Routing Modeling: Use of modeling software such as HEC-HMS with hydrologic routing methods such as the Muskingum and Modified-Puls methods along with hydrologic and topographic data.

(c) Simplified Methods such as SMPDBK and the Washington State Method: “Dam Breach Analysis and Downstream Hazard Classification” may be used. A dam owner may request information on these methods from the department. Use of these or other simplified methods is only to be used in hazard ratings for dams, not for emergency action planning.

(d) Depth of inundation to trigger different hazard ratings: A depth of at least two feet over the finished floors of buildings or road surface of infrastructure is required to establish a “high hazard” rating. Any depth of water over the floorboards of structural buildings such as homes, barns, pump houses or storage sheds can establish a “significant hazard” rating. For roads, a depth of two feet or evidence of depth and velocity capable of creating damage can be used to establish a “significant hazard” rating.

(e) Specific data, methods and results for all methods must be reviewed and approved by the department prior to revising a hazard rating.

(3) The hazard rating of a dam shall remain in effect until the rating is revised by the department using one of the methods described in section 2. A dam owner may request that the department revise a hazard rating. The owner must provide information in support of the request. If the supporting information includes results and/or analysis using the methods described in subsections 2(a) or (b), the information must be prepared by an engineer licensed in Oregon and familiar with hydraulic and hydrologic modeling; if the information includes results and/or analysis using the methods described in subsection 2(c), the information must be prepared by a licensed engineer or a practicing hydrologist familiar with hydraulic and hydrologic calculations.

(4) Exceptions to Hazard rating methods:

(a) Small dams are not assigned a hazard rating.

(b) Situations in which there are heavy recreational or other uses downstream, a dam may be rated as “high hazard” because of probable loss of life regardless of downstream infrastructure presence.

Stat. Auth.: ORS 183 & 540

Hist.: WRD 7-2009, f. 12-7-09, cert. ef. 1-1-10

690-020-0200

Fees for Dams

(1) Owners of a large dam shall submit to the department an annual fee in the amount and on the basis established under ORS 536.050.

(2) Dam owners who fail to pay an annual fee on or before six months after the billing date may be required to pay a late fee in the amount established under ORS 536.050.

(3) If a dam owner fails to pay the annual fee or late fee charged by the department, the department may, after giving the dam owner notice by certified mail, place a lien on the real property where the dam is located for the fees owed by the dam owner.

(4) Dams that are subject to the annual fee include dams partially or wholly in the State of Oregon that meet the definition of ”dam” under OAR 690-020-0020.

(5) Multiple large dams connected together and separated only by embankments or other manmade materials (common with sewage lagoons) will count as one dam for fee purposes.

(6) Owners Exempt from Fee Requirements include:

(a) Owners of a “small dam”,

(b) Owners whose dams that are directly controlled or regulated for safety by an agency of the U.S. Federal Government and the agency that controls or regulates the dam has its own safety program that meets the following criteria:

(A) The program must allow for control of the design and construction process for dams under their control with licensed engineers designing and reviewing any major design or repair. Copies of all design drawings and construction records should be forwarded to the department for tracking and archival purposes.

(B) The program must have a regular dam inspection program that is either conducted by or directly supervised by a licensed engineer with expertise in dam safety. Formal documented dam inspections for high hazard dams should occur at least once per year. For significant hazard dams, inspections shall occur at least once every 3 years and for low hazard dams, once every 6 years. Other more frequent inspections and reports on dam conditions may be necessary depending on the condition of individual dams. Copies of mutually agreed upon inspections and reports should be forwarded to the department for archival and tracking purposes.

(C) The federal agency in charge of the dam via regulation or control must also have a regular maintenance program or be able to require maintenance activity from the regulated party that will address problems discovered in the inspection program.

(D) The federal agency must have a memorandum of understanding or agreement with the department that outlines how the federal agency meets the criteria in paragraphs (b)(A)–(C), and must agree to meet at least annually with the department to review the state of the federal program for continued exemption purposes.

Oregon Water Resources Department

www.wrd.state.or.us - Dam Safety website, forms, and administrative information. The website is updated regularly with news and events.

Federal Emergency Management Agency

www.fema.gov - US government agency dedicated to disaster mitigation, preparedness, and response and recovery planning. Links can be found on their website to Dam Safety and the FEMA Emergency Action Plan. This website is regularly updated with current emergency related news.

Association of State Dam Safety Officials

www.damsafety.org - ASDSO is a non-profit organization of state and federal dam safety regulators, dam owners and operators, engineering consultants, manufacturers and suppliers, and others interested in dam safety. ASDSO's vision is to lead the US dam safety community with a strong, unified voice and effective programs and policies towards furtherance of dam safety.

Bureau of Reclamation

www.usbr.gov - The Bureau of Reclamation is the second largest supplier of wholesale water and hydroelectric power in the American West. They promote water conservation, recycling, and reuse. The Bureau of Reclamation is a contemporary water management agency with a strategic plan outlining numerous programs, initiatives, and activities that will help meet new water needs and balance the multitude of competing uses of water in the west.

US Army Corps of Engineers

www.usace.army.mil - Their mission is to provide quality, responsive engineering services to the nation including planning, designing, building, and operating water resources and other civil works projects. Navigation, flood control, environmental protection, and disaster response links are updated regularly.

Purpose

Dam safety is an important issue of which the public needs to be familiar. This booklet has been designed to cover topics that will benefit the public, engineers, dam owners, and watermasters. This booklet also covers Oregon's laws pertaining to dams and a glossary of commonly used terms.

History

of the Dam Safety Program

Dam safety laws in Oregon were first adopted in 1909, and then modified in 1927, and again in 1929 following the catastrophic failure of California's St. Francis Dam, when the statutes were amended to their present form, more or less. Initially, the review of design plans and specifications was conducted by the State Engineer, and then by a staff engineer in the State Engineer's Office. This one person operation continued until 1956 when the staff was increased to two-full time engineers.

In 1975, further amendments to Oregon water laws merged the State Engineer's Office and the Water Resources Board, forming the Water Resources Department and changing the title of the department head from "State Engineer" to "Water Resources Director". The State Water Policy Review Board and oversight committee was also created, consisting of 7 members from the public appointed by the Governor. As a consequence, the authority to take enforcement actions for protection of human life and property related to Dam Safety was transferred from the State Engineer to the Water Resources Director.

An inspection technician was added to the Dam Safety Program in 1978. Also, Dam Safety added five engineers with funding provided by Congress. A direct result of the increased funding allowed completion of 50 Phase I Inspections Reports for existing high hazard, non-federal dams within the state. In 1982, the program ended as federal funding was eliminated. All but two of the engineering positions and the inspection technician position were also eliminated.

The name of the State Water Policy Review Board was changed to the Water

Resources Commission in 1983, and to it was given new responsibilities for policy decisions, rule making, and management of the agency. Shortly thereafter, the Commission delegated much of its new found authority back to the Director's Office. Until this time, Dam Safety had existed as a separate, stand alone unit.

Later, Dam Safety was combined with the Enforcement Division within the agency. The program was reduced to a single Dam Safety Engineer and one technician. Watermasters were assigned routine inspection duties for existing dams in addition to their other water distribution and regulation assignments. Additionally, other program areas were assigned to the remaining Dam Safety Engineer, including Hydroelectric Facility licensing and Hydrographics.

In 1990, the agency was reorganized so that Dam Safety was combined with Computer Services, GIS, Hydrographics, Hydrology, and Groundwater to form the Technical Services Division. The Hydroelectric Licensing section was moved into the Water Rights Division, however the Dam Safety Engineer was still required to manage a division with about 35 employees.

In 1993, an engineer was hired as Dam Safety Coordinator to upgrade and replace the technician position that was eliminated due to retirement. For a short while, the Technical Services Division was combined with the Field Services Division, but then reverted to the previous arrangement that placed Dam Safety in the Technical Services Division. At present, the Dam Safety Engineer also serves as Division Administrator. The Dam Safety Coordinator is responsible for the management of the Dam Safety Program.

Responsibility

Duties of the Dam Safety Program

The Dam Safety Program is responsible statewide for the review and approval of dam designs, scheduling inspections of existing dams and reservoirs, conducting site inspections of new dam construction, and maintaining both the National Dam Inventory (NID) and the state database.

It is important to realize that the ultimate responsibility for the continued safe operation of any dam or reservoir rests entirely with the dam owner(s). Oregon does not require proof of insurance before a reservoir is filled with water. Typically, water right holders own the land upon which most dams and reservoirs are built. In cases where there are no associated water rights or where the water right holder does not own the real property where the structure is situated, the State presumes the land owner also to be the owner of the dam.

"To serve the public by practicing and promoting responsible water management."
Water Resources Department Mission Statement

The Dam Safety Coordinator provides assistance to watermasters and to owners and operators of dams when questions or situations arise that require engineering advice or training. Other duties include hazard assessment of existing structures, review of emergency management plans, and review of water right transactions (applications, permits, certificates) to assure that appropriate conditions are met that will help to provide safety for downstream life and property.

The Dam Safety Coordinator also performs all regular clerical and office support duties. The state is divided into four regions and twenty watermaster districts. In addition to their duties relating to regulation of water use and distribution, the watermasters assist with performing routine and regularly scheduled inspections of low hazard dams and reservoirs within their respective districts according to a schedule prepared and updated by the Dam Safety Coordinator.

Approximately 8 to 10 percent of each watermaster's time is allocated toward dam and reservoir inspections. At present, nearly 1300 dams and reservoirs are inspected at an interval of 1 to 5 years. Of those, more than 100 structures are owned, operated, or supervised by federal organizations who also maintain active dam safety programs. Some examples of these federal organizations are the Corps of Engineers, Bureau of Reclamation, and certain hydroelectric power generating facilities licensed by the Federal Energy Regulatory Commission (FERC). The Oregon Water Resources Department participates with the respective federal agencies in the inspection of those structures.

Responsibility

For more information about the National Flood Insurance Program (NFIP), visit the website:
www.floodsmart.gov

The National Flood Insurance Program (NFIP) provides federally backed flood insurance in communities that comply with minimum standards for floodplain management. As an incentive, standard homeowners and commercial property located within a designated "flood zone" can receive an insurance premium rate reduction based on various activities that communities voluntarily undertake to reduce flood losses. Once enrolled in the NFIP, each participating community is evaluated based upon the number of credit points earned according to prerequisite activities listed under the NFIP's Community Rating System (CRS). Depending on the total number of credit points, the CRS assigns a community to one of 10 classes. A maximum 45% insurance premium discount is possible if all CRS criteria are satisfied.

For more information about the Association of State Dam Safety Officials (ASDSO), visit the website:
www.damsafety.org

Under CRS Activity 630, a participating community will automatically receive up to 75 credit points if their respective state has a dam safety program that meets certain criteria based on the Model Dam Safety Program recommended by the Association of State Dam Safety Officials (ASDSO). Information and guidelines contained as key components of the

Model State Dam Safety Program are broken into the following chapters:

I. Legislation and Regulations

II. Permitting, Design Approval and Authorization to Impound

III. Inspection

IV. Enforcement

V. Emergency Response

VI. Program Staff and Funding

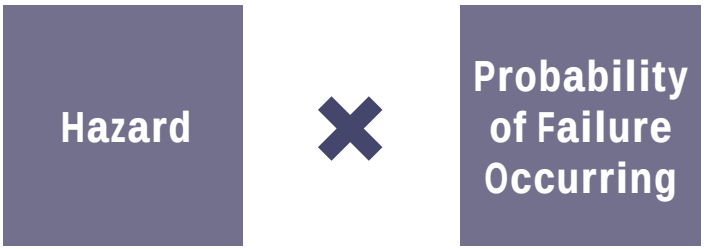
VII. Program Staff and Dam Owner Education and Training

VIII. Dam Safety Program Public Relations Plan

Presently, the Oregon dam safety program does not have authority to take corrective or emergency action if a dam owner fails to comply with an Order. Therefore, Oregon communities participating in the NFIP do not receive any credit points for the state dam safety program. In order for communities to receive this additional credit, all of the elements listed in the Model Dam Safety Program must also be included in the state's program.

What Constitutes a Dam?

"Dam" is not specifically defined in any of Oregon's statutes or rules. Regardless of a legal definition per Oregon law, a dam is taken here to mean: "any artificial barrier, including appurtenant works, that impounds or diverts the flow of water." *(See Glossary)*



Hazard vs. Risk

When considering hazard in terms of dam classification, it is important to realize that the term "Hazard" is not the same as "Risk". For example, a large dam may be rated a high hazard structure because its location is such that a catastrophic failure and sudden release of water could adversely threaten downstream life and property. However, the same dam also could be at low risk for failure because it is conservatively engineered, receives regular inspections, and is exceptionally well maintained. Thus, its probability for failure is very low. In other words, risk is the product of hazard multiplied by the probability that a failure will occur.

Another example to illustrate this concept would be a smaller sized irrigation reservoir located miles from human habitation. In this situation, the dam is rated a low hazard structure because of its location, but it could be at high risk for failure because it was not properly designed by an engineer, it has never been inspected, and it is poorly maintained.

It is important to realize that a dam's hazard rating does not define the physical condition of the structure. Instead, "Hazard" is the definition that is used to estimate the amount of damage that could occur in the event the dam were to suddenly fail and release the contents of its reservoir. For that reason, any dam that is rated a high hazard structure must be properly designed, regularly inspected, and maintained in the best condition at all times because the consequences of a failure are just too great to ignore. All reasonable methods must be implemented to reduce the *risk of failure* for high hazard dams.

Ratings

Hazard Classifications

Oregon Dam Safety has divided existing dams into three hazard classifications. Each rating is an estimate of the potential consequences to downstream life and property that would result from a catastrophic dam failure.

Low

Low hazard dams are scheduled to be inspected every 4 to 5 years depending on the owner's ability to maintain the dam. A sudden or rapidly developing failure of the dam or a sudden uncontrolled release of stored water from the reservoir would not appear to threaten human life. Downstream property damage would be limited primarily to the stream channel.

Significant

Significant hazard dams are scheduled to be inspected every 2 to 3 years depending on the condition of the dam, and the owner's ability to provide upkeep, the maintenance record, or the outward appearance of the dam. A sudden or rapidly developing failure of the dam or a sudden uncontrolled release of stored water would most likely result in significant property damage, and/or the potential for causing the indirect loss of human life.

High

High hazard dams are scheduled to be inspected on an annual basis, alternating between seasons. A sudden or rapidly developing failure of the dam or a sudden uncontrolled release of stored water would likely result in direct loss of human life. Severe and/or widespread property damage would also be expected to occur.

Permits

Reservoir Permits and the Permitting Process

Under Oregon law, all water belongs to the public. With few exceptions, any person wishing to appropriate and store surface water or ground water must first obtain a permit from the Water Resources Department. The water right, once developed, is considered to be a type of property right and is attached to the land where it was established. Consequently, real property with an attached water right may be several miles from the actual source of water. In Oregon, landowners with water flowing past, through, or below their property do not automatically have a right to use that water.

Reservoir applications and other forms can be found on the web: *www.wrd.state.or.us*

Oregon's water laws are based on the Principal of *Prior Appropriation*. This means the first person to obtain a water right on a stream is the last to be shut off in times of low streamflows. In water-short times, the water right holder with the oldest date of priority can demand the water specified in their water right regardless of the needs of junior users. If there is a surplus beyond the needs of the senior right holder, the water right holder with the next oldest priority date can take as much as necessary to satisfy needs under their right and so on down the line until there is no surplus or until all rights are satisfied. The date of application for a permit to use water usually becomes the priority date of the right. Generally, storage water rights have a junior priority date. For that reason, reservoirs are typically filled during the non-irrigation season from excess winter stream flow.

Oregon's Water Code

four fundamental provisions

1. Beneficial purpose without waste
Surface or ground water may be legally diverted for use only if it is used for a beneficial purpose without waste.

2. Priority
The water right priority date determines who gets water in a time of shortage. The more senior the water right, the longer water is available in a time of shortage.

3. Appurtenancy
Generally, a water right is attached to the land described in the right, as long as the water is used. If the land is sold, the water right goes with the land to the new owner.

4. Must be used
Once established, a water right must be used as provided in the right at least once every five years. With some exceptions established in law, after five consecutive years of non-use, the right is considered forfeited and is subject to cancellation.

Applying for a Permit to Use Water

Oregon law requires a Reservoir Permit from the Water Resources Department to store water in an above-ground reservoir. Additionally, a separate permit is needed to apply the stored water to a beneficial use. In most instances, two applications for permits are usually required for above ground reservoirs, those being:

- A *primary* application for reservoir storage of a given volume of water, including both ground water and stream flow and pumped ground water sources.

- A *secondary* application to appropriate surface water or to use water from a reservoir in excess of the amount that was needed to initially fill the reservoir. A secondary application is required to maintain the level of water in the reservoir and to replenish the amount of stored water lost due to evaporation and/or seepage.

Obtaining a permit is a critical hurdle in obtaining a water right. A reservoir permit is the authorization necessary from the State of Oregon via the Water Resources Department to store water. With few exceptions, any existing or proposed hydraulic structure for storage of water requires a permit, regardless of its height or capacity.

- The Alternate Review Application Process for a Water Right Permit pertains to a pond or reservoir of any storage capacity with a dam height less than 10 feet. If the dam is 10 feet or greater, the maximum amount of water stored under the Alternate Review Process must be less than 9.2 acre feet.

- The Standard Review Application Process is for any reservoir that is both greater than or equal to 9.2 acre feet and with a dam height of 10 feet or greater. With few exceptions, engineered plans and technical specifications must be submitted for review and approval before a Reservoir Permit will be issued for these larger sized structures.

Preparing the Reservoir Application

All entries should be typewritten or neatly printed with dark ink. The appropriate filing fee(s) shall accompany each application at the time of submittal. All items must be completed even though portions of the required information may appear on supplemental maps or drawings. Incomplete applications will be returned to the applicant, and will not be assigned a priority date until they are determined to be complete.

How an Application is Processed

Once a completed application has been received, the Department must provide public notice of the application within 60 days. The purpose of the public notice is to allow the public the opportunity to submit detailed, legally obtained information to the Department for consideration as to whether or not the application would be injurious to existing water rights. The Department also notifies other state agencies including the Oregon Department of Fish and Wildlife (ODFW). ODFW provides comments as appropriate regarding potential impact to existing fishery resources. All comments must be submitted within 60 days of the public notice.

Even if there are no fish living in the stream, the Department is required to notify ODFW of all applications.

Within the prescribed 60-day period, if the Department does not find injury to existing water rights or is notified about detrimental impacts to existing fishery resources, then the Department may issue a Final Order that will

allow issuance of a permit within 180 days of the priority date. Because of the processing timelines set forth in ORS 537.409, the Department suggests applicants make certain to file an application prior to scheduling excavation work or expending a large amount of money.

Nonstatutory (Small) Dams Not Subject to Design Review

Nonstatutory dams, those that are less than 10 feet in height or that impound less than 9.2 acre feet, do not require design approval and construction oversight by the Water Resources Department. Nonetheless, a permit to store water is likely required. The local watermaster can assist in filing an application for a permit to store water for these smaller structures.

It is recommended that earthen embankment dams less than 10 feet in height or less than 9.2 acre feet storage capacity have a crest width no less than 8 feet, an upstream slope no steeper than 3:1, and a downstream slope no steeper than 2:1. An emergency spillway channel should be constructed around the dam, not over the top of the fill, and lined to prevent erosion. The spillway should be able to withstand the 50-year flood flow without overtopping the dam. It should also direct the passing flow downstream to prevent erosion of the embankment.

For best results, all brush, stumps, roots, and organic matter should be cleared from the borrow area and beneath the dam. Only fill materials consisting of non-organic and cohesive soils adjusted in moisture to optimum water content should be used for construction of the dam. Individual layers should not exceed 8 inches in thickness and should be compacted with a sheepsfoot roller or similar equipment. Fill material should be placed in thin layers parallel with the long axis of the dam.

Statutory Sized (Large) Dams

The following list is a summary of the minimum requirements for examination and approval of design plans and technical specifications for construction of dams greater than or equal to 10 feet in height and that impound 9.2 acre feet or more of storage. **A licensed professional engineer must prepare these design documents and submit them for approval prior to construction.**

1. Vicinity Map

- Location of dam and reservoir in relation to township, range, and quarter-quarter section, together with a survey tie (bearing and distance) from a benchmark on the dam to an established government land corner.
- Watershed map that delineates the contributing drainage area into the reservoir.
- Access roads, significant land features, urban areas, or downstream development.
- Borrow areas, quarries, utilities, and property lines within project boundaries.

2. Plan View of Dam and Appurtenances

- Topographic contour map, maximum 2-foot interval.
- Locate by station the primary outlet and auxiliary or emergency spillway; if applicable, include toe drains, filters, log boom, or fish by-pass facilities.
- Area/Capacity Diagram or stage/storage data tabulating hydraulic depth versus corresponding surface area and reservoir storage capacity.
- Locations of field exploration or subsurface investigation including bore holes, test pits, excavations, trenches, monitoring wells, and other invasive methods.

3. Profile Parallel to Centerline Axis of Dam

- Existing ground surface and thickness of stripping or grubbing.
- Grade line for cutoff trench and/or excavation for foundation.
- Bedrock or foundation material contacts.
- Crest elevation of dam; include camber if applicable.
- Locate by station the primary outlet and auxiliary or emergency spillway; if applicable, include toe drains, filters, log boom, or fish by-pass facilities.

4. Sectional View of Dam at Maximum Section

- Upstream and downstream slopes, including erosion control or armoring.
- Dam dimensions and elevations; X (width) and Y (height) coordinates.
- Emergency spillway crest elevation and spillway channel grade line(s).
- Water surface elevations, including normal pool and flood maximum.
- Interior material zones and/or internal filters.
- Invert elevations of outlet conduit, toe drains, and other internal piping.
- Existing ground surface and thickness of stripping or grubbing.
- Cutoff trench and/or excavation for foundation, with dimensions.

5. Emergency Spillway Detail Drawing

- Both a sectional and profile view.
- Elevations and dimensions at all stations where channel configuration or grade lines transition or otherwise change.
- Dimensions and elevations for stilling basin or other flow and energy dissipaters, including both formed-in-place concrete or constructed channel armoring.
- Elevations and dimensions of flow control mechanisms such as flash boards, stop logs, lift or tainter gates, or channel splitters.

6. Outlet Conduit and/or Primary Spillway Detail Drawing

- Cross section showing sizes, dimensions, and type(s) of material, including concrete encasement and/or pipe bedding.
- Draw down curve, flow rating information, or discharge capacity data.
- Longitudinal section (profile) illustrating configuration and position of conduit and all joints, flanges, or other connections.

7. Outlet Works Detail Drawing

- Operating gates or valves, and guard gates or valves; if manufactured, list the name, model number, supplier, etc.
- Base block or anchor, pedestals, operating stem and/or lift mechanism.
- Fish screen, trash rack, or other clog prevention device.

8. Technical Data

- All elevations referenced to established benchmark, such as MSL or NGVD.
- Hydrologic report or calculations verifying adequacy of emergency spillway at 100-year storm (1% flow) or PMF as appropriate.
- Summary report of foundation investigation which may include site geology, ground water hydrology, drill logs, test pits, laboratory test results and geotechnical stability analysis for rapid drawdown, flood loading and/or seismic analysis as appropriate.
- Bid package or a complete set of technical specifications for design, manufacture, placement, and testing of construction materials or material components as appropriate.

9. Operation and Maintenance Manual

(Significant and High Hazard Dams)

- Preventative maintenance schedule, contact information, storage/release schedule.

10. Emergency Action Plan

(High Hazard Dams)

- Dam failure/breach analysis for both sunny day and storm scenario.
- Downstream inundation maps for sunny day and storm failure scenarios.
- Monitoring and/or warning systems, notification charts, and evacuation procedure(s).

Inspection

Process of Inspecting Dams

No person shall construct any dam that is 10 feet or greater in height and stores 9.2 acre feet or more, unless the Department has made an examination of the site and of the plans and specifications and other features involved in the construction of such works, and has approved them in writing. (ORS 540.350; amended 1981)

Periodic inspection of existing hydraulic structures for protection of public safety is part of the Oregon Dam Safety Program. However, Oregon laws do not specify the frequency of inspections. The inspections are made under the supervision of the Dam Safety Coordinator.

Many dam owners do not realize their responsibility and liability toward the downstream public and environment.

If a person residing on or owning land in the neighborhood of any dam after completion, or in the course of construction, applies to the Director desiring inspection of the works, the Director may order an inspection, or he may make such order on his own motion. If the inspection is deemed justified by the Director, he may require that the owner pay all or part of the expenses for the inspection. (ORS 540.390)

If a potential risk is discovered during an inspection or the structure is determined to be unsafe, the owner of the dam is notified and requested to take necessary action to prevent failure of the dam. Owners are expected to maintain their hydraulic structure in a safe and responsible manner and make proper repairs to keep it operational.

Rating Criteria

Very Good Condition

a. No apparent problems; new or newly replaced.
b. Well maintained and supervised.
c. No need for increased maintenance or monitoring activities.

Acceptable Condition

a. Fully functional and trouble-free operation.
b. Increased maintenance or monitoring may be necessary.
c. Letter to owner may be appropriate to advise of maintenance/monitoring.

Unsatisfactory Condition

a. Marginally functional under normal conditions, but could be a potential problem under extreme loading or operating conditions not routinely experienced.
b. Intensive maintenance program necessary to prevent further deterioration.
c. Minor repair, rehabilitation, or restoration may be necessary in addition to increased maintenance or monitoring activities.

Repair or Replace

a. Non-functional, defective, or missing component.
b. Deterioration has progressed beyond ability of maintenance program or owner's willingness to adequately restore to design conditions.
c. Major repair or rehabilitation necessary to restore dam, spillway, or appurtenant works to original design or to standards acceptable to OWRD Dam Safety.

Enforcement

Enforcement Procedures

The Dam Safety Program maintains an inventory of existing hydraulic structures that exceed statutory height and storage criteria. When, during the course of inspection of any of the inventoried dams, a particular structure is discovered to be in violation of safety conditions that would adversely affect or threaten downstream life and property, the Director may act to cause the dam owner to remedy the situation.

Upon discovery of a safety hazard that poses a threat to life or property, the Department may notify the owner in writing of the hazard and action(s) necessary to return to the project and appurtenant works to safe design, mechanical operational, or maintenance standards. Failure by the owner to perform the required action may result in proceedings for one or more of the following scenarios:

1. Notice and opportunity for a contested case hearing. [As provided for in ORS 540.350(5).]
2. Cancellation of the permit for failure to make a satisfactory Claim of Beneficial Use.
3. Posting of the structure to prevent storage or to limit operation until the owner has complied with the requested action.
4. Instituting legal action by the District Attorney or Attorney General to have the facility declared a public nuisance.
5. Issuance of an order to prevent storage or to breach the dam. [As provided for in ORS 540.370.]
6. Any other enforcement action permitted by law.

Check out **ORS 183** and **ORS 540** for more information about dam safety enforcement.

Glossary

Abutment: That part of the valley wall against which a dam is constructed. The left and right abutments of dams are defined with the observer viewing the dam looking in the downstream direction, unless otherwise indicated.

Acre foot: The volume or amount of water needed to cover 1 acre (43,560 square feet) 1 foot deep (325,851 gallons).

Breach: An eroded opening through a dam or spillway that drains the reservoir. A controlled breach is a constructed opening. An uncontrolled breach is an unintentional opening which allows uncontrollable discharge from the reservoir.

Channel: A general term for any natural or artificial facility for conveying water.

Cohesionless Soil: A soil possessing little or no shear strength when unconfined (sand).

Cohesive Soil: A soil that exhibits considerable shear strength when unconfined (clay).

Collar: A thin collar placed at uniform intervals along an outlet conduit to retard water seepage.

Compaction: Mechanical action to increase the density of a soil by reducing the number or size of internal voids.

Conduit: A closed conveyance pipe used to release water through a dam.

Contested Case: A legal proceeding before an agency.

Core: A zone of low permeability material in an embankment dam. The core is sometimes referred to as central core, rolled clay core, or impervious zone.

Cutoff Trench: A trench excavated beneath the dam foundation and backfilled with impermeable material to retard water seepage under the dam.

Dam: An artificial barrier across a watercourse or valley for creating a reservoir, diverting water from a channel, or creating hydraulic head. "Any artificial barrier, including appurtenant works, that impounds or diverts the flow of water."

Dam Crest: The top surface of the dam.

Glossary

Dam Failure: Catastrophic type of failure characterized by the sudden, rapid, and uncontrolled release of impounded water.

Dike: An artificial protective barrier or obstacle designed to prevent flooding of adjacent land surrounded by water.

Drain: A pipe or similar feature that collects and directs water to a specified location.

Embankment: An engineered earth fill.

Emergency Action Plan: A formal plan of procedures to alleviate risk during construction of or after completion of a dam, or to reduce the consequences to life and property that would result from a dam failure. Also, a plan of action to be taken to reduce the potential for property damage and loss of life in an area affected by a dam failure or large flood.

Filter: A material or zone of materials designed to provide drainage without causing movement or erosion of the individual particles comprising the filter.

Final Order: Final agency action expressed in writing.

Flashboard (Stoplogs): Planed timber or steel beams that are physically placed on top of each other in a channel or an outlet so as to adjust the flow of water. Flashboards often are an alternative to gates or valves in low-head situations.

Flood: A temporary rise in water levels resulting in inundation of areas not normally covered by water. May be expressed in terms of probability of exceedance per year, such as 1 percent chance flood, or expressed as a fraction of the probable maximum flood or other referenced flood of record.

Flood Frequency: Refers to the probability (expressed in percentage) that a flood will occur in a given year, example 20%, 10% ,or 1%.

Flood, Probable Maximum (PMF): The largest flood that is estimated for a selected location on a stream resulting from the probable maximum precipitation storm (PMP) in combination with extreme runoff conditions.

Flood Surcharge: The storage volume between the top of the active reservoir storage and the design maximum water level.

Foundation: The ground surface upon which a dam is constructed.

Freeboard: The vertical distance between the design high-water level in the reservoir and the dam crest.

Gate: A movable, watertight barrier for the control of water flowing through a pipe or channel. (See Valves)

Groin: The area along the contact (or intersection) of the face of a dam with the abutments.

Hazard Classification: The rating for a dam based on the potential consequences of failure. The rating considers the aggregate damage to downstream life and property that failure of the dam could cause.

Height: The maximum vertical distance from natural ground surface to the top of a dam.

Hydrograph: A graph showing, for a given point on a stream or conduit, the discharge, stage, velocity, available power, or other properties of water with respect to time.

Hydrologic Connection: Condition where water can move between a surface water source and an adjacent sub-surface aquifer.

Impervious: Not allowing liquid to pass through; waterproof.

Instream Flow: Minimum quantity of water necessary to support the public use requested by an agency.

Inundation Map: A map delineating the area that would be flooded by a particular flood event. It includes the ground surfaces downstream of a dam showing the estimated encroachment by water released because of failure of a dam or from abnormal flows released through a dam's spillway.

Invert: Elevation at the bottom of a pipe, conduit, or culvert.

Levee: An artificial protective barrier built adjacent to a waterway to prevent flooding of bordering land.

Maximum Water Surface: The highest acceptable water surface elevation with all factors affecting the safety of the structure considered. It is the highest water surface elevation resulting from a computed routing of the inflow design flood through the reservoir under established operating criteria. This surface is also the top of a surcharge capacity.

Glossary

Minimum Streamflow: A rate of flow established by administrative rule necessary to support aquatic life or minimize pollution.

Normal Water Surface: The highest elevation at which water is normally stored, or the design surface elevation which the reservoir is expected to be operated.

Order: Agency action expressed orally or in writing directed to a named person or persons; includes any agency decision issued in connection with a contested case hearing.

Outlet Works: A device to provide controlled releases from a reservoir.

Piping: A characteristic type of erosion of embankment or foundation material (soil) due to leakage. The action of water passing through a soil mass resulting in removal of particles leading to the development of channels or "pipes".

Precipitation, Probable Max (PMP): The greatest amount of precipitation possible resulting from a specified size storm occurring during a distinct period of time at a particular geographic location.

Reservoir: A body of water impounded by a dam or other artificial construction in which water can be stored.

Reservoir Surface Area: Ground surface area covered by water when a reservoir is filled to a specified level.

Risk: The relationship between the consequences resulting from an adverse event and its probability of occurrence.

Seepage: The slow movement or percolation of water through a permeable medium; specifically, flow through small cracks, voids, or interstices in a dam, abutment, or foundation.

Soil: Sediments or other unconsolidated and non-cemented aggregations of particles produced by the chemical/mechanical disintegration of rocks.

Spillway: A structure over or through which flow is discharged from a reservoir. If the rate of flow is controlled by mechanical means such as gates, it is considered a controlled spillway. If the geometry of the spillway is the only control, then it is defined as an uncontrolled spillway.

Spillway, Auxiliary: Any secondary spillway that is designed to be operated very infrequently or only in anticipation of extreme climactic events.

Spillway, Emergency: A spillway that is designed to provide additional protection against overtopping of dams and is intended for use under extreme conditions such as misoperation or malfunction of the service spillway or other emergency conditions.

Spillway, Primary: A spillway that is designed to provide continuous or frequent regulated or unregulated releases from a reservoir without significant damage to either the dam or its appurtenant structures.

Storage: The retention of water or delay of runoff either by planned operation, as in a reservoir, or by temporary filling of overflow areas, as in the progression of flood wave through a natural stream channel.

Storage, Active (Normal): The volume of the reservoir that is readily available for beneficial use such as power generation, irrigation, flood control, water supply, fish culture, and others.

Storage, Dead: The volume of water that lies below the invert of the lowest outlet and that cannot readily be withdrawn from the reservoir.

Toe of Dam: Those portions of a dam slope that intersect natural ground surface, either upstream or downstream.

Top of Dam (Crest): The elevation of the uppermost surface of a dam, usually a road or walkway excluding any parapet wall, railing, etc.

Valves: Valves, as distinguished from gates, are constructed so that the closing member remains in the water passageway for all operating positions.

Void: Open spaces inside soil, rock or concrete that may be filled with air or water or some other gas or liquid.

Watermaster: Field representative (1 of 20 statewide) authorized by statute to regulate established water rights according to Oregon's water laws, based on the principle of prior appropriation.

Authority

The provisions of this Chapter 105 issued under section 7 of the act of June 14, 1923 (P. L. 704, No. 294) (32 P. S. § 597); sections 514, 1901-A, 1908-A, 1917-A and 1920-A of The Administrative Code of 1929 (71 P. S. §§ 194, 510-1, 510-8, 510-17 and 510-20); sections 5 and 402 of The Clean Streams Law (35 P. S. §§ 691.5 and 691.402); sections 302 and 402 of the Flood Plain Management Act (32 P. S. §§ 679.302 and 679.402); and sections 5, 7, 10, 11 and 17 of the Dam Safety and Encroachments Act (32 P. S. §§ 693.5, 693.7, 693.10, 693.11 and 693.17), unless otherwise noted.

Source

The provisions of this Chapter 105 rescinded and readopted September 26, 1980, effective September 27, 1980, 10 Pa.B. 3843, unless otherwise noted. Immediately preceding text appears at serial pages (38843), (47970) to (47983), (38854) to (38859), (47990) to (47994), (38864), (38865), (47996) to (47998), (38868) to (38891) and (49597) to (49598).

Notes of Decisions

The Department regulations providing for exception to maximum peak particle velocity and noise requirements during surface mining blasting operations in close proximity to certain structures were unreasonable since they made a distinction between ownership of the structure at the location of the blasting. *Department of Environmental Resources v. Croner, Inc.*, 618 A.2d 1135 (Pa. Cmwlth. 1992).

ponds); 25 Pa. Code § 297.202 (relating to areas where incinerators and other processing facilities are prohibited);
25 Pa. Code § 297.213 (relating to access roads); 25 Pa. Code § 297.232 (relating to soil erosion and sedimentation control); 25 Pa. Code § 299.141 (relating to scope); 25 Pa. Code § 299.142 (relating to general requirements); 58 Pa. Code § 51.61 (relating to permits required for disturbance of waterways or watersheds); and 67 Pa. Code § 459.10a (relating to bridge occupancy).

Subchapter A. GENERAL PROVISIONS

GENERAL

Sec.
105.1. Definitions.
105.2. Purposes.
105.3. Scope.
105.4. Delegations to local agencies.

PERMIT APPLICATIONS

105.11. Permit requirements.
105.12. Waiver of permit requirements.
105.13. Permit applications—information and fees.
105.14. Review of applications.
105.15. Environmental assessment.
105.16. Environmental social and economic balancing.
105.17. Wetlands.
105.18. [Reserved].
105.18a. Permitting of structures and activities in wetlands.
105.19. Complete applications.
105.20. Proof of financial responsibility.
105.20a. Wetland replacement criteria.

PERMIT ISSUANCE, TRANSFER AND REVOCATION

105.21. Criteria for permit issuance and denial.
105.21a. Public notice.
105.22. [Reserved].
105.23. Compliance with other applicable statutes.
105.24. Coordination of permits.
105.25. Transfer of permits.
105.26. Revocation and suspension of permits.
105.27. [Reserved].
105.28. [Reserved].
105.29. [Reserved].
105.29a. Burden of proof.
105.30. [Reserved].

SUBMERGED LANDS OF THE COMMONWEALTH—LICENSES AND ANNUAL CHARGES

105.31. Property rights.
105.32. Projects—proper purpose.
105.33. Licenses for public service corporations.
105.34. Navigation and public trust.
105.35. Charges for use and occupation of submerged lands of this Commonwealth.
105.36. [Reserved].
105.37. [Reserved].
105.38. [Reserved].
105.39. [Reserved].
105.40. [Reserved].

CONSTRUCTION REQUIREMENTS AND PROCEDURES

105.41. Notices and reports.
105.42. Acknowledgement of conditions.
105.43. Time limits.
105.44. Implementation of work according to specifications.
105.45. Inspections.
105.46. Implementation of erosion and sedimentation control plans.
105.46a. Collection and disposal of waste materials.
105.47. Removal of structures.

OPERATION, MAINTENANCE AND INSPECTION

105.51. Operation and maintenance.
105.52. Inspection.
105.53. Inspections by owners and inspection reports.
105.54. Monitoring systems.

INVESTIGATION AND CORRECTION OF UNSAFE CONDITIONS—EMERGENCY PROCEDURES

105.61. Procedures for investigations.
105.62. Correction of unsafe conditions.
105.63. Emergency procedures.
105.64. Emergency permit.

GENERAL

§ 105.1. Definitions.

The following words and terms, when used in this chapter, have the following meanings, unless the context clearly indicates otherwise:

Act—The Dam Safety and Encroachments Act (32 P. S. §§ 693.1—693.27).

Along—Touching or contiguous; to be in contact with; to abut upon.

Copyright © 2010 Commonwealth of Pennsylvania

Appurtenant works—Structures or materials incident to or annexed to dams or water obstructions which are built or maintained in connection with the dams or water obstructions and are essential to their proper functioning. For dams, the term includes, but is not limited to:

(i) Structures such as spillways, either in the dam or separate therefrom.

(ii) Low level outlet works.

(iii) Conduits such as tunnels, pipelines or penstocks through the dam or its abutments.

Archaeological site—A known site of archaeological significance based on the Comprehensive State Plan for Conservation of Archaeological Resources. The Comprehensive State Plan is available from the Historic and Museum Commission, Bureau of Historic Preservation, Box 1026, Harrisburg, Pennsylvania 17108.

Body of water—A natural or artificial lake, pond, reservoir, swamp, marsh or wetland.

Bridge—A structure and its appurtenant works erected over the regulated waters of this Commonwealth.

Commercially navigable waters of the Delaware River and its navigable tributaries—Portions of the Delaware River from the Delaware border in the south to the railroad bridge at Morrisville in the north; the Schuylkill River below Fairmount Dam; Chester Creek below Ninth Street; Crum Creek below the Route 291 (Industrial Highway) Bridge; Darby Creek below 84th Street; Neshaminy Creek below the Route 13 Bridge; Pennypack Creek below the Frankford Avenue Bridge; and Ridley Creek below the Baltimore and Ohio Railroad Bridge in Chester.

Construct—To erect, build, place or deposit including preliminary preparation of a site for construction.

Course—The path taken by a stream, floodway or body of water.

Cross section—The area from the top of the bank to the top of the opposite bank of a stream or body of water as cut by a vertical plane passed at a right angle to the course of the stream.

Culvert—A structure with appurtenant works which carries a stream under or through an embankment or fill.

Current—The rate or velocity of flow of water in a stream, floodway or body of water.

Dam—An artificial barrier, together with its appurtenant works, constructed for the purpose of impounding or storing water or another fluid or semifluid, or a refuse bank, fill or structure for highway, railroad or other purposes which does or may impound water or another fluid or semifluid.

Design flood—A specified discharge for which the hydraulic capacity of a structure is designed.

Discharge of dredged material—An addition, deposit, disposal or discharge of dredged material into the regulated waters of this Commonwealth including, but not limited to, the addition of dredged material to a specific disposal site located in the regulated waters of this Commonwealth and the runoff or overflow of dredged material from a contained land or water disposal area. The term does not include plowing, cultivating, seeding and harvesting for the production of food, fiber and forest products.

Discharge of fill material—

(i) An addition, deposit, disposal or discharge of fill into the regulated waters of this Commonwealth, including, but not limited to, the following types of construction:

(A) Fill that is necessary for the construction of a structure in a regulated water of this Commonwealth.

(B) A structure or impoundment requiring rock, sand, soil or other material for its construction.

(C) Site-development fills for recreational, industrial, commercial, residential and other uses.

(D) Causeways or roadfills.

(E) Dams and dikes.

(F) Artificial islands.

(G) Property protection or reclamation devices, such as riprap, groins, seawalls, breakwaters and revetments.

(H) Levees.

(I) Fill for structures such as sewage treatment facilities.

(J) Intake and outfall pipes associated with power plants and subaqueous utility lines.

(K) Artificial reefs.

(ii) The term does not include plowing, cultivating, seeding and harvesting for the production of food, fiber and forest products.

Dredge—To remove sand, gravel, mud or other materials from the beds of regulated waters of this Commonwealth.

Dredged material—A material that is excavated or dredged from the regulated waters of this Commonwealth.

Encroachment—A structure or activity which changes, expands or diminishes the course, current or cross section of a watercourse, floodway or body of water.

FEMA—The Federal Emergency Management Agency.

Fill—Sand, gravel, earth or other material placed or deposited to form an embankment or raise the elevation of the land surface. The term includes material used to replace an area with aquatic life with dry land or to change the bottom elevation of a regulated water of this Commonwealth.

Copyright © 1996 Commonwealth of Pennsylvania

Flood—A general but temporary condition of partial or complete inundation of normally dry land areas from the overflow of streams, rivers or other waters of this Commonwealth.

Floodplain—The lands adjoining a river or stream that have been or may be expected to be inundated by flood waters in a 100-year frequency flood.

Floodway—The channel of the watercourse and portions of the adjoining floodplains which are reasonably required to carry and discharge the 100-year frequency flood. Unless otherwise specified, the boundary of the floodway is as indicated on maps and flood insurance studies provided by FEMA. In an area where no FEMA maps or studies have defined the boundary of the 100-year frequency floodway, it is assumed, absent evidence to the contrary, that the floodway extends from the stream to 50 feet from the top of the bank of the stream.

Freeboard—The vertical distance between the water surface elevation experienced during the design flood and the crest elevation of a dam levee, floodwall or other embankment.

Height of dam—The vertical measurement expressed in feet as measured from the downstream toe of the dam at its lowest point to the elevation of the top of the dam.

High hazard dam—A dam so located as to endanger populated areas downstream by its failure.

Inundation area—The land area subject to flood waters as the result of failure of a dam.

Levee—An earth embankment or ridge constructed along a water course or body of water to confine water within prescribed limits; the term is also known as a dike.

Limited Power and Water Supply Act—The act of June 14, 1923 (P. L. 700, No. 293) (32 P. S. §§ 621—625); and the act of June 14, 1923 (P. L. 704, No. 294) (32 P. S. §§ 591—600).

Maintenance dredging—Dredging conducted as part of construction of a dam, water obstruction or encroachment, and periodic dredging conducted to accomplish one or more of the following purposes:

(i) Maintain adequate depths for navigation.

(ii) Assure proper passage of ice and flood flows.

(iii) Preserve the safety, stability and proper operation of the dam, water obstruction or encroachment.

Mitigation—

(i) An action undertaken to accomplish one or more of the following:

(A) Avoid and minimize impacts by limiting the degree or magnitude of the action and its implementation.

(B) Rectify the impact by repairing, rehabilitating or restoring the impacted environment.

(C) Reduce or eliminate the impact over time by preservation and maintenance operations during the life of the action.

(ii) If the impact cannot be eliminated by following clauses (A)—(C), compensate for the impact by replacing the environment impacted by the project or by providing substitute resources or environments.

Normal pool elevation—

(i) For bodies of water which have no structural measures to regulate height of water, the height of water at ordinary stages of low water unaffected by drought.

(ii) For structurally regulated bodies of water, the elevation of the spillway, outlet control or dam crest which maintains the body of water at a specified height.

(iii) This term does not apply to wetlands.

100-year frequency flood—The flood magnitude expected to be equaled or exceeded on the average of once in 100 years; it may also be expressed as the flood having a 1.0% chance of being equaled or exceeded in a given year.

Operation—Elements of the use, control and functioning of a dam, water obstruction or encroachment during the lifetime of the dam, water obstruction or encroachment, including its removal, which may affect primarily the storage, release or flow of water; the structural safety of a dam, water obstruction or encroachment; or navigation, with due consideration of the other purposes of the act.

Ordinary low water mark—The water surface elevation at ordinary stages of low water, unaffected by drought and unchanged by artificial means.

Owner—A person who owns, controls, operates, maintains or manages a dam or reservoir, water obstruction or encroachment.

PMF—Probable maximum flood—The flood that may be expected from the most severe combination of critical meteorologic and hydrologic conditions that are reasonably possible in an area. The PMF is derived from the probable maximum precipitation (PMP) as determined on the basis of data obtained from the National Oceanographic and Atmospheric Administration (NOAA).

Parcel—A portion of land formally set forth and described in a conveyance.

Person—A natural person, partnership, association, corporation, public utility, municipality, municipal authority, political subdivision of the Commonwealth, receiver or trustee and a department, board, commission or authority of the Commonwealth.

Political subdivision—A county, city, borough, incorporated town, township, school district, authority or other governmental unit or a combination thereof acting jointly.

Public service corporation or *public utility*—A corporation, association or other corporate body having the powers and privileges of corporations not possessed by individuals or partnerships which entity renders a public utility service. The term does not include a municipality or municipal authority.

Copyright © 1996 Commonwealth of Pennsylvania

Public service line—The term includes, but is not limited to, electric transmission lines, gas pipelines, telephone lines, water lines, railroad trackage and other facilities owned or operated by public service corporations.

Public utility service—The rendering of one or more of the following services for the public:

(i) Gas, electricity or steam production, generation, transmission or distribution.

(ii) Water diversion, pumping, impoundment or distribution.

(iii) Railroad transportation of passengers or property.

(iv) Operation of a canal, turnpike, tunnel, bridge, wharf or similar structure.

(v) Transportation of natural or artificial gas, crude oil, gasoline or petroleum products, materials for refrigeration or other fluid substances by pipeline or conduit.

(vi) Telephone or telegraph communications.

(vii) Sewage collection, treatment or disposal.

Regulated waters of this Commonwealth—Watercourses, streams or bodies of water and their floodways wholly or partly within or forming part of the boundary of this Commonwealth.

Replacement—The construction of a new wetland or restoration of a previously destroyed wetland, or both.

Reservoir—A natural or artificial basin, which contains or will contain the water or other fluid or semifluid impounded by a dam.

Safety—Security from the risk or threat of significant loss or injury to life, health, property and the environment.

Small projects—Water obstructions or encroachments located in a stream or floodplain which will have an insignificant impact on safety and protection of life, health, property and the environment.

Spillway—A device which safely conveys the design flood of a dam without endangering its safety or integrity.

Storage capacity—The volume as expressed in acre-feet of the impounded water to the maximum storage level, that is, the top of the dam.

Stormwater management facilities—anmade measures designed and constructed to convey stormwater runoff away from structures or improved land uses, or to control, detain or manage stormwater runoff to avoid or reduce downstream damages. The term includes, but is not limited to, transportation and related facility drainage systems and manmade stormwater detention basins. The term does not include replacement wetlands or major dams and reservoirs constructed for water supply, recreation, river basin flood control or other regional or basin-wide purposes.

Stream—A watercourse.

Stream crossings—A pipeline, aerial cable or similar structure which is placed in, along, under, across or over the regulated waters of this Commonwealth.

Stream enclosure—A bridge, culvert or other structure in excess of 100 feet in length upstream to downstream which encloses a regulated water of this Commonwealth.

Submerged lands of this Commonwealth—Waters and permanently or periodically inundated lands owned by the Commonwealth, including lands in the beds of navigable lakes and rivers and beds of streams declared public highways which are owned and held in trust by the Commonwealth.

U.S.G.S.—United States Geological Survey.

Watercourse—A channel or conveyance of surface water having defined bed and banks, whether natural or artificial, with perennial or intermittent flow.

Water obstruction—

(i) A dike, bridge, culvert, wall, wingwall, fill, pier, wharf, embankment, abutment or other structure located in, along or across or projecting into a watercourse, floodway or body of water.

(ii) In the case of ponds, lakes and reservoirs, a water obstruction is considered to be in or along the body of water if, at normal pool elevation, the water obstruction is either in the water or adjacent to and abutting the water's edge.

Water Obstructions Act—The act of June 25, 1913 (P. L. 555, No. 355) (32 P. S. §§ 681—691), repealed by section 27 of the act of October 23, 1979 (P. L. 204, No. 70) (32 P. S. § 693.27).

Wetland functions—Include, but are not limited to, the following:

(i) Serving natural biological functions, including food chain production; general habitat; and nesting, spawning, rearing and resting sites for aquatic or land species.

(ii) Providing areas for study of the environment or as sanctuaries or refuges.

(iii) Maintaining natural drainage characteristics, sedimentation patterns, salinity distribution, flushing characteristics, natural water filtration processes, current patterns or other environmental characteristics.

(iv) Shielding other areas from wave action, erosion or storm damage.

(v) Serving as a storage area for storm and flood waters.

(vi) Providing a groundwater discharge area that maintains minimum baseflows.

(vii) Serving as a prime natural recharge area where surface water and groundwater are directly interconnected.

(viii) Preventing pollution.

(ix) Providing recreation.

Wetlands—Areas that are inundated or saturated by surface water or groundwater at a frequency and duration sufficient to support, and that under normal

Copyright © 1996 Commonwealth of Pennsylvania

circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions, including swamps, marshes, bogs and similar areas.

Wild trout streams—A stream classified as supporting naturally reproducing trout populations by the Fish Commission. For a list of wild trout streams, the Fish Commission can be contacted at: Fish Commission, Bureau of Fisheries, Division of Fisheries Management, 450 Robinson Lane, Bellefonte, Pennsylvania 16823-9616.

Authority

The provisions of this § 105.1 amended under the Dam and Safety Encroachments Act (32 P. S. §§ 693.1–693.27); The Clean Streams Law (35 P. S. §§ 691.1—691.1001); section 7 of the act of June 14, 1923 (P. L. 704, No. 294) (32 P. S. § 597); sections 514, 1901-A, 1908-A, 1917-A and 1920-A of The Administrative Code of 1929 (71 P. S. §§ 194, 510-1, 510-8, 510-17 and 510-20); and the Flood Plain Management Act (32 P. S. §§ 679.101—679.601).

Code § 105.14 (relating to review of applications); 25 Pa. Code § 105.20a (relating to wetland replacement criteria); 25 Pa. Code § 105.53 (relating to inspections by owners and inspection reports); and 25 Pa. Code § 105.452 (relating to status of prior converted cropland—statement of policy).

§ 105.2. Purposes.

The purposes of this chapter are to:

(1) Provide for the comprehensive regulation and supervision of dams, reservoirs, water obstructions and encroachments in the Commonwealth in order to protect the health, safety, welfare and property of the people.

(2) Assure proper planning, design, construction, maintenance, monitoring and supervision of dams and reservoirs, including preventive measures necessary to provide an adequate margin of safety.

(3) Assure proper planning, design, construction, maintenance and monitoring of water obstructions and encroachments, in order to prevent unreasonable interference with water flow and to protect navigation.

(4) Protect the natural resources, environmental rights and values secured by PA. CONST. art. I, § 27 and conserve and protect the water quality, natural regime and carrying capacity of watercourses.

Source

The provisions of this § 105.2 adopted September 10, 1971, effective September 11, 1971, 1 Pa.B. 1804; amended August 11, 1978, effective August 28, 1978, 8 Pa.B. 2229; amended September 27, 1980, effective September 27, 1980, 10 Pa.B. 3843. Immediately preceding text appears at serial page (47975).

§ 105.3. Scope.

(a) The following structures or activities are regulated under the act and section 302 of the Flood Plain Management Act (32 P. S. § 679.302):

(1) Dams on a natural or artificial watercourse, other than those licensed under the Federal Power Act (16 U.S.C.A. §§ 791a—825s), where one or more of the following occur:

(i) The contributory drainage area exceeds 100 acres.

(ii) The greatest depth of water measured by upstream toe of the dam at maximum storage elevation exceeds 15 feet.

(iii) The impounding capacity at maximum storage elevation exceeds 50 acre-feet.

(2) Dams used for the storage of water not located on a watercourse and which have no contributory drainage where the greatest depth of water measured at upstream toe of the dam at maximum storage elevation exceeds 15 feet and the impounding capacity at maximum storage elevation exceeds 50 acre-feet.

(3) Dams used for the storage of fluids or semifluids other than water, the escape of which may result in air, water or land pollution or in danger to persons or property.

(4) Water obstructions and encroachments other than dams located in, along or across, or projecting into a watercourse, floodway or body of water, whether temporary or permanent.

(5) Flood control projects constructed, owned or maintained by a governmental unit.

(b) For the purposes of this chapter, the Department's jurisdiction in and along Lake Erie will be defined by the high water elevation of 572.8 feet International Great Lakes Datum (IGLD) and low water elevation of 568.6 IGLD. Dams, water obstructions and encroachments constructed between elevation 572.8 IGLD and elevation 568.6 IGLD require a permit under section 6 of the act (32 P. S. § 693.6). Dams, water obstructions and encroachments constructed lakeward of elevation 568.6 IGLD require both a permit under section 6 of the act and a Submerged Lands License Agreement under section 15 of the act (32 P. S. § 693.15).

(c) The environmental assessment conducted under this chapter is applicable to dams, water obstructions and encroachments for which a permit or approval is required under this chapter.

Notes of Decisions

Fill site must be sufficiently close to wetlands so as to be ''along'' them in order to invoke jurisdiction in action under the Dam Safety and Encroachments Act (32 P. S. §§ 693.1—693.27). *Game Commission v. Department of Environmental Resources*, 509 A.2d 877 (Pa. Cmwlth. 1986); appeal granted 521 A.2d 934 (Pa. 1987); affirmed 555 A.2d 812 (Pa. 1989).

Code § 105.391 (relating to scope).

§ 105.4. Delegations to local agencies.

(a) Under section 17 of the act (32 P. S. § 693.17) and subject to this section, the Department may by written agreement delegate to a county conservation district or other county agency one or more of its regulatory functions including enforcement and the power to permit, inspect and monitor specified categories of water obstructions and encroachments.

(b) No delegation may be made of the authority to issue permits for a water obstruction or encroachment constructed, owned or maintained by the Commonwealth, a political subdivision or a public utility. Delegations may be made of the powers to inspect and monitor the activities, if the Department retains final authority to approve or disapprove permits, and concurrent authority to inspect, monitor and enforce the act.

(c) To the extent delegated by the agreement, the delegations may include the authority to enforce the act and this chapter and to exercise other powers and duties otherwise vested in the Department to implement the act with respect to the categories of water obstructions and encroachments covered by the delegation.

(d) A delegation agreement shall:

(1) Specify the powers and duties to be performed by the delegated agency.

(2) Specify the categories of water obstructions and encroachment activities to be covered by the delegated agency.

(3) Provide for the commitment by the delegated agency of sufficient trained staff and resources to perform the powers and duties to be delegated.

(4) Require the delegated agency to maintain records of activities performed under the delegation.

(5) Provide for monitoring and supervision by the Department of performance by the delegated agency of the functions delegated under the agreement.

(e) A permit for a water obstruction or encroachment issued by a delegated agency is subject to review by the Department, unless the right of review is waived by the Department. A permit issued by a delegated agency shall become effective 30 days following the receipt of notice by the Department of issuance, unless the permit is disapproved by the Department or an appeal is filed with the Department under section 17 of the act (32 P. S. § 693.17).

(f) When the Department delegates one or more of its regulatory functions to a local agency, the Department will retain the concurrent power to inspect and monitor categories of water obstructions and encroachments and to enforce the act and this chapter.

Authority

The provisions of this § 105.4 amended under the Dam Safety and Encroachments Act (32 P. S. §§ 693.1–693.27); The Clean Streams Law (35 P. S. §§ 691.1—691.1001); section 7 of the act of June 14, 1923 (P. L. 704, No. 294) (32 P. S. § 597); sections 514, 1901-A, 1908-A, 1917-A and 1920-A of The Administrative Code of 1929 (71 P. S. §§ 194, 510-1, 510-8, 510-17 and 510-20); and the Flood Plain Management Act (32 P. S. §§ 679.101—679.601).

PERMIT APPLICATIONS

§ 105.11. Permit requirements.

(a) A person may not construct, operate, maintain, modify, enlarge or abandon a dam, water obstruction or encroachment without first obtaining a written permit from the Department.

(b) An existing dam, water obstruction or encroachment constructed under a license or permit issued in compliance with the act of June 8, 1907 (P. L. 496, No. 322) (53 P. S. § 16834 note and 55 P. S. §§ 332.1 and 332.2) or the Water Obstructions Act, shall be deemed to comply with the construction and operating

Copyright © 2008 Commonwealth of Pennsylvania

permit requirements of this section. These projects shall, after September 27, 1980, comply with the operating, maintenance, monitoring and other requirements of this chapter.

(c) The owner of an existing dam, water obstruction or encroachment who does not hold a permit issued under the act of June 8, 1907 (P. L. 496, No. 322) or the Water Obstructions Act shall apply for and receive a permit to operate and maintain the facility under the act on or before January 1, 1981. For purposes of this subsection, a limited power permit issued under the Limited Power and Water Supply Act will be deemed to have been issued under the Water Obstructions Act. These projects shall comply with the operating, maintenance, monitoring and other requirements established under the act.

(d) A permit issued by the Department after July 1, 1979 for the construction and operation of a water obstruction or encroachment shall incorporate authorization for normal repairs and maintenance of permitted structures conducted within the original specifications for the water obstruction or encroachment. A repair or maintenance involving modification of the water obstruction or encroachment from its original specifications and a repair or reconstruction involving a substantial portion of the structure shall require the prior written permit of the Department under subsection (a).

(e) A dam, water obstruction or encroachment or modification thereof, constructed or authorized pursuant to the terms of a permit issued under this chapter prior to October 12, 1991, shall be deemed to comply with the construction permit requirements of this subchapter. These projects shall, after October 12, 1991, comply with the operating, maintenance, monitoring and other requirements of this chapter.

Notes of Decisions

Cause of Action

A builder's allegation that the township approved a subdivision plan in the absence of a permit from the Department of Environmental Protection is not a cognizable cause of action because it is the Department which enforces this regulation, not the local agency; furthermore, this regulation does not create a private cause of action. *Shafer v. Waite*, 43 D. & C. 4th 91 (1999).

Failure to Obtain Permit

Appellant, who placed fill on his land without a permit which constituted an unlawful encroachment on wetlands in violation of the law, could not claim Department of Environment Protection's issuing of compliance order effected an unconstitutional, regulatory taking of property rights because Appellant failed to apply for a permit. *Baehler v. Department of Environmental Protection*, 863 A.2d 57, 59—60 (Pa. Cmwlth. 2004).

Cross References

This section cited in 25 Pa. Code § 105.14 (relating to review of applications); 25 Pa. Code § 105.52 (relating to inspection); and 25 Pa. Code § 105.443 (relating to nature of a general permit; substitution for individual applications and permits).

§ 105.12. Waiver of permit requirements.

(a) Under section 7 of the act (32 P. S. § 693.7), the requirements for a permit are waived for the following structures or activities, regardless of when commenced. If the Department upon complaint or investigation finds that a structure or activity which is eligible for a waiver, has a significant effect upon safety or the protection of life, health, property or the environment, the Department may require the owner of the structure to apply for and obtain a permit under this chapter.

(1) A dam not exceeding 3 feet in height in a stream not exceeding 50 feet in width, except wild trout streams designated by the Fish Commission.

(2) A water obstruction in a stream or floodway with a drainage area of 100 acres or less. This waiver does not apply to wetlands located in the floodway.

(3) An aerial crossing of a nonnavigable stream or wetland by electric, telephone or communications lines which are not located in a Federal wilderness area or watercourse or body of water designated as a wild or scenic river under the Wild and Scenic Rivers Act of 1968 (16 U.S.C.A. §§ 1271—1287) or the Pennsylvania Scenic Rivers Act (32 P. S. §§ 820.21—820.29). This waiver applies to one or more wires attached aboveground to single poles. This does not apply to the maintenance and construction of towers, roads or other water obstructions or encroachments.

(4) A dam subject to the requirements of the Mine Safety and Health Administration, 30 CFR 77.216-1 and 77.216-2 (relating to water, sediment or slurry impoundments and impounding structures; identification; and water, sediment, or slurry impoundments or impounding structures; minimum plan requirements; changes or modifications; certification), if the Department determines on the basis of preliminary data submitted by the applicant that the dam is of Size Classification C and Hazard Potential Classification 3 as defined in § 105.91 (relating to classification of dams and reservoirs) and is not located in a watercourse or body of water designated as a wild and scenic river under the Wild and Scenic Rivers Act of 1968 or the Pennsylvania Scenic Rivers Act.

(5) A water obstruction or encroachment located in, along, across or projecting into a wetland or impoundment, constructed and maintained for the purpose of treating acid mine drainage, sewage or other waste, if the wetland or impoundment is a treatment facility constructed under a valid permit issued by the Department under the Surface Mining Conservation and Reclamation Act (52 P. S. §§ 1396.1—1396.31), The Clean Streams Law (35 P. S. §§ 691.1—691.1001), the Noncoal Surface Mining Conservation and Reclamation Act (52 P. S. §§ 3301—3326), the Solid Waste Management Act (35 P. S. §§ 6018.101—6018.1003), the Oil and Gas Act (58 P. S. §§ 601.101—601.605) and the Pennsylvania Sewage Facilities Act (35 P. S. §§ 750.1—750.20).

Copyright © 2008 Commonwealth of Pennsylvania

(6) A water obstruction or encroachment located in, along, across or projecting into a stormwater management facility or an erosion and sedimentation pollution control facility which meets the requirements in Chapter 102 (relating to erosion and sediment control), if the facility was constructed and continues to be maintained for the designated purpose.

(7) Maintenance of field drainage systems that were constructed and continue to be used for crop production. Crop production includes:

(i) Plowing, cultivating, seeding, grazing or harvesting.

(ii) Crop rotation.

(iii) Government set aside programs.

(8) Plowing, cultivating, seeding or harvesting for crop production.

(9) Construction and maintenance of ford crossings of streams for individual private personal use which require only grading of banks for approach roads and the placement of not more than 12 inches of gravel for roadway stability. Fords may not be used for commercial purposes and shall cross the regulated waters of this Commonwealth in the most direct manner. This waiver does not apply in exceptional value streams as listed under Chapter 93 (relating to water quality standards) or in wild trout streams.

(10) A navigational aid or marker, buoy, float, ramp or other device or structure for which a permit has been issued by the Fish Commission under 30 Pa.C.S. § 5123(a)(7) (relating to general boating regulations).

(11) The removal of abandoned dams, water obstructions and encroachments if the Department determines in writing on the basis of data, information or plans submitted by the applicant that the removal of the abandoned dam water obstruction or encroachment cannot imperil life or property, have significant effect on coastal resources or have an adverse impact on the environment, and the plans provide for restoration and stabilization of the project area.

(12) The construction, operation or removal of staff gages, water recording devices, water quality testing devices, including, but not limited to, sensors, intake tubes, weirs and small buildings which contain required instruments and similar scientific structures.

(13) A bridge or culvert purchased from an operating railroad company subsequent to the abandonment of the railroad line, track, spur or branch pursuant to the approval of the Interstate Commerce Commission. Major maintenance or reconstruction, or stream dredging may not be undertaken until the new owner obtains a permit under this chapter.

(14) The maintenance of an artificial pond or reservoir to its original storage capacity where:

(i) The contributory drainage area is less than or equal to 100 acres.

(ii) The greatest depth of water at maximum storage elevation is less than or equal to 15 feet.

(iii) The impounding capacity at maximum storage elevation is less than or equal to 50 acre feet.

(15) The construction and maintenance of an encroachment or water obstruction on an abandoned mining site, where the Department has issued a notice of intent to forfeit the bond for a mining activity permitted after July 1982.

(16) Restoration activities undertaken and conducted pursuant to a restoration plan which has been approved, in writing, by the Department.

(b) The requirements for a permit for existing structures or activities, as provided in section 6(c) of the act (32 P. S. § 693.6(c)), are waived for the following structures or activities, if construction was completed prior to July 1, 1979. If the Department upon complaint or investigation finds that a structure or activity which is eligible for a waiver, has a significant effect upon safety or the protection of life, health, property or the environment, the Department may require the owner of the structure or activity to apply for and obtain a permit under this chapter.

(1) A dam not exceeding 5 feet in height in a nonnavigable stream operated and maintained for water supply purposes.

(2) A dam which the Department determines, on the basis of preliminary data submitted by the applicant, is of Size Classification C and Hazard Potential Classification 3, as defined in § 105.91 and does not have a significant effect on coastal resources or an adverse impact on the environment.

(3) A fill not located on navigable lakes and navigable rivers.

(4) A streambank retaining device.

(5) A stream crossing other than a crossing located on submerged lands of this Commonwealth and a crossing by pipelines for conveyance of petroleum products and gas.

(6) An outfall, headwall or water intake structure.

(7) A culvert, bridge or stream enclosure on a watercourse where the drainage area above the culvert, bridge or stream enclosure is 5 square miles or less.

(c) Structures and activities shall meet the construction, operation, maintenance, monitoring and other requirements of this chapter. No other permits which may be required under a law other than the act are waived by this section.

Authority

The provisions of this § 105.12 amended under the Dam Safety and Encroachments Act (32 P. S. §§ 693.1–693.27); The Clean Streams Law (35 P. S. §§ 691.1—691.1001); section 7 of the act of June 14, 1923 (P. L. 704, No. 294) (32 P. S. § 597); sections 514, 1901-A, 1908-A, 1917-A and 1920-A of The Administrative Code of 1929 (71 P. S. §§ 194, 510-1, 510-8, 510-17 and 510-20); and the Flood Plain Management Act (32 P. S. §§ 679.101—679.601).

§ 105.13. Permit applications—information and fees.

(a) Application for permits under this chapter shall be submitted to the Department, in writing, upon forms provided by the Department. Applicants are encouraged to request a meeting with the Department prior to submission of their applications.

(b) An application for a permit under this chapter, except applications submitted by Federal, State, county or municipal agencies or a municipal authority for a dam, water obstruction or encroachment shall be accompanied by a check payable to ''Commonwealth of Pennsylvania'' in accordance with the following schedule:

(1) *Dams.*

Class A $3000	(Based on Size Classification as defined in § 105.91)
Class B $2500	
Class C $1500	

(2) *Water obstructions and encroachments.*

Stream enclosures	$350
Channel changes	$300
Commercial dredging	$300
Peat extraction	$750
Fills, levees, floodwalls	$350
Bridges and other water obstructions and encroachments	$200
Small projects	$100

(c) A single application may be submitted or a single permit may be issued for multiple structures and activities which are part of a single project or facility or part of related projects and facilities, located in a single county, constructed, operated or maintained by the same persons. When a single application covers multiple structures or activities other than a single structure and related maintenance dredging, the application fee shall be the sum of fees in subsection (b) for the applicable structures and activities. Stream crossings located within a single county for the installation of a public service line shall be treated as a single structure or activity but the application fee shall be the sum of fees for each stream crossing.

(d) An application for a permit shall be accompanied by information, maps, plans, specifications, design analyses, test reports and other data specifically

required by this chapter and additional information as required by the Department to determine compliance with this chapter.

(1) For all permit applications, except small projects, this information shall include, but is not limited to, the following:

(i) *A site plan.* A site plan shall include:

(A) A complete demarcation of the floodplains and regulated waters of this Commonwealth on the site. The wetlands shall be identified and delineated in accordance with the Department's Wetland Delineation Policy as published at § 105.451 (relating to identification and delineation of wetlands—statement of policy).

(B) Existing roads, utility lines, lots, other manmade structures and natural features such as contour lines and drainage patterns.

(C) Proposed structures or activities included in the project, which shall be identified by labeling.

(D) A scale of one inch equals 200 feet or larger.

(E) A north arrow.

(F) The name of the persons who prepared the plan, and the date and name of the applicants.

(G) A cross sectional view of the regulated waters to be impacted before and after the structure or activity is constructed.

(ii) *A location map.* The location map shall be of a scale factor of 1:24000 (standard U.S.G.S. Topographic Map). The location map shall show all natural features including the names and boundaries of regulated waters of this Commonwealth, natural areas, wildlife sanctuaries, natural landmarks, political boundaries, locations of public water supplies and other geographical or physical features including cultural, archeological and historical landmarks within 1 mile of the site. U.S.G.S. maps may be reviewed at County Conservation District Offices or obtained by writing to: United States Geological Survey Map Distribution, Box 25286 Federal Center, Denver, CO 80225.

(iii) *Project description.* A narrative of the project shall be provided which includes, but is not limited to:

(A) A description of the proposed structure or activity.

(B) The project purpose.

(C) The effect the project will have on public health, safety or the environment.

(D) A statement on water dependency. A project is water dependent when the project requires access or proximity to or siting within water to fulfill the basic purposes of the project.

(iv) *Color photographs.* Color photographs of the proposed site shall be submitted. The photos shall accurately depict the project area and provide a relative scale of the project to the surrounding area and a map showing the location and orientation of each photograph.

Copyright © 1996 Commonwealth of Pennsylvania

(v) *Stormwater management analysis.* If a watershed stormwater management plan has been prepared or adopted under the Stormwater Management Act (32 P. S. §§ 680.1—680.17), an analysis of the project's impact on the Stormwater Management Plan and a letter from the county or municipality commenting on the analysis shall be included.

(vi) *Floodplain management analysis*. If the proposed dam, water obstruction or encroachment is located within a floodway delineated on a FEMA map, include an analysis of the project's impact on the floodway delineation and water surface profiles and a letter from the municipality commenting on the analysis.

(vii) *Risk assessment.* If the stormwater or the floodplain management analysis conducted in subparagraphs (v) and (vi) indicates increases in peak rates of runoff or flood elevations, include a description of property and land uses which may be affected and an analysis of the degree of increased risk to life, property and the environment.

(viii) *Alternatives analysis.* A detailed analysis of alternatives to the proposed action, including alternative locations, routings or designs to avoid or minimize adverse environmental impacts.

(ix) *Mitigation plan.* Actions to be taken in accordance with the definition of mitigation in this chapter.

(x) *Impacts analysis.* A detailed analysis of the potential impacts, to the extent applicable, of the proposed project on water quality, stream flow, fish and wildlife, aquatic habitat, Federal and State forests, parks, recreation, instream and downstream water uses, prime farmlands, areas or structures of historic significance, streams which are identified candidates for or are included within the Federal or State wild and scenic river systems and other relevant significant environmental factors. If a project will affect wetlands the project description shall also include:

(A) A narrative of the delineation process supported by the appropriate data sheets and copies of appropriate soil maps and descriptions from soil conservation service soil surveys. Soil conservation service soil surveys may be obtained from the county conservation district offices.

(B) An analysis of whether the wetland is exceptional value as classified in § 105.17 (relating to wetlands).

(C) A statement on water dependency. A project is water dependent when the project requires access or proximity to or siting within water to fulfill the basic purposes of the project.

(2) An application for a project which will affect less than 1 acre of wetland where the wetland is not exceptional value wetland shall also include a description of functions and values of the existing wetlands to be impacted by the project, as defined in § 105.1 (relating to definitions).

(3) An application for a project which may have an affect on an exceptional value wetland or on 1 or more acres of wetland shall also include an

assessment of the wetland functions and values using a methodology accepted by the Department and a survey, conducted by a licensed professional land surveyor, of the wetland boundary as delineated and of the property lines of the parcel where the project is located.

(e) A permit application for small projects located in streams or floodplains shall be accompanied by the following information. This permit application may not be used for projects located in wetlands. If upon review the Department determines that more information is required to determine whether a small project will have an insignificant impact on safety and protection of life, health, property or the environment, the Department may require the applicant to submit additional information and processing fees required by this chapter.

(1) *A site plan.* A site plan shall include:

(i) The floodplains and regulated waters of this Commonwealth on the site, including wetlands, existing roads, utility lines, lots, other manmade structures, natural features such as slopes and drainage patterns, proposed structures or activities included in the project.

(ii) The names of the persons who prepared the plan.

(iii) The date and the name of applicants.

(iv) A north arrow.

(2) *A cross sectional view.* A cross sectional view of the affected regulated waters of this Commonwealth before and after the structure or activity is constructed.

(3) *A location map.* A map showing the geographic location of the project. U.S.G.S. topographic maps, FEMA maps or municipal maps are acceptable. FEMA and municipal maps may be obtained from local government offices. U.S.G.S. maps may be reviewed at county conservation district offices or obtained by writing to: United States Geological Survey Map Distribution, Box 25286 Federal Center, Denver, CO 80225.

(4) *Project description.* A narrative of the project shall be provided which includes, but is not limited to:

(i) A description of the proposed structure or activity.

(ii) The project purpose.

(iii) The effect the project will have on public health, safety or the environment.

(iv) The project's need to be in or in close proximity to water.

(5) *Color photographs.* Color photographs of the proposed site shall be submitted. The photos shall accurately depict the project area and provide a relative scale of the project to the surrounding area and a map showing the location and orientation of each photograph.

(f) Except for small projects, an application for a permit under this chapter shall be accompanied by proof of an application for an Earth Disturbance Permit or an erosion and sedimentation control plan for activities in the stream and earthmoving activities. The plan shall conform to the requirements contained in

Copyright © 1996 Commonwealth of Pennsylvania

Chapter 102 (relating to erosion and sediment control) and shall include a copy of a letter from the conservation district in the county where the project is located indicating that the district has reviewed the erosion and sediment control plan of the applicant and considered it to be satisfactory, if applicable. Earthmoving activities, including small projects, shall be conducted pursuant to an earth disturbance plan.

(g) An application shall be submitted by the person who owns or has primary responsibility for the proposed dam or reservoir, water obstruction or encroachment. If an application is submitted by a person with primary responsibility for the structure or activity, the owner of a dam or reservoir, water obstruction or encroachment will not thereby be relieved of legal duties or responsibilities for the structure or activity as imposed by the act or this chapter.

(h) An application shall be signed by the owners of the dam or reservoir, water obstruction or encroachment, or the persons exercising primary responsibility for the dam or reservoir, water obstruction or encroachment. In the case of a partnership, one or more members of the partnership authorized to sign on behalf of the entire partnership shall sign the application. In the case of a corporation, it shall be signed by the president, vice president or other responsible official empowered to sign for the corporation. In the case of a political subdivision, it shall be signed by the chief officers of the political subdivision or other responsible official empowered to sign for the political subdivision, with the seal affixed and attested by the clerk.

(i) Plans, specifications and reports accompanying applications for any category of dams, or for bridges and other water obstructions or encroachments which would pose a threat to human life or substantial potential risk to property shall be affixed with the seal of a registered professional engineer and a certification, signed by the registered professional engineer, which shall read as follows:

> ''I (name) do hereby certify pursuant to the penalties of 18 Pa.C.S.A. Sec. 4904 to the best of my knowledge, information and belief, that the information contained in the accompanying plans, specifications and reports has been prepared in accordance with accepted engineering practice, is true and correct, and is in conformance with Chapter 105 of the rules and regulations of the Department of Environmental Resources.''

(j) The Department may waive the specific information requirements of this section in writing, in the record of decision, if upon review of the permit application, the Department finds that specific information is not necessary to review the application.

Authority

The provisions of this § 105.13 amended under the Dam Safety and Encroachments Act (32 P. S. §§ 693.1–693.27); The Clean Streams Law (35 P. S. §§ 691.1—691.1001); section 7 of the act of June 14, 1923 (P. L. 704, No. 294) (32 P. S. § 597); sections 514, 1901-A, 1908-A, 1917-A and 1920-A of The Administrative Code of 1929 (71 P. S. §§ 194, 510-1, 510-8, 510-17 and 510-20); and the Flood Plain Management Act (32 P. S. §§ 679.101—679.601).

Notes of Decisions

Needs Analysis

Where the applicant failed to submit a proper alternatives/justification analysis and parking needs could have been met elsewhere, the Environmental Hearing Board concluded that petitioner did not justify the need to fill wetlands. *Hatchard v. Department of Environmental Resources*, 612 A.2d 621 (Pa. Cmwlth. 1992).

Code § 105.302 (relating to permit applications for existing stream crossings by pipelines for conveyance of petroleum products and gas); 25 Pa. Code § 105.331 (relating to permit applications); 25 Pa. Code § 105.371 (relating to permits: content of application); and 25 Pa. Code § 105.401 (relating to permit applications).

§ 105.14. Review of applications.

(a) An application will be reviewed to determine the proposed project's effect on health, safety and the environment, in accordance with prevailing practices in the engineering profession and in accordance with current environmental principles.

(b) In reviewing a permit application under this chapter for construction or substantial modification of a dam or reservoir, water obstruction or encroachment, the Department will use the following factors to make a determination of impact:

(1) Potential threats to life or property created by the dam, water obstruction or encroachment.

(2) Potential threats to safe navigation created by the dam, water obstruction or encroachment.

(3) The effect of the dam, water obstruction or encroachment on the property or riparian rights of owners above, below or adjacent to the project.

Copyright © 2005 Commonwealth of Pennsylvania

(4) The effect of the dam, water obstruction or encroachment on regimen and ecology of the watercourse or other body of water, water quality, stream flow, fish and wildlife, aquatic habitat, instream and downstream uses and other significant environmental factors.

(5) The impacts of the dam, water obstruction or encroachment on nearby natural areas, wildlife sanctuaries, public water supplies, other geographical or physical features including cultural, archaeological and historical landmarks, National wildlife refuges, National natural landmarks, National, State or local parks or recreation areas or National, State or local historical sites.

(6) Compliance by the dam, water obstruction or encroachment with applicable laws administered by the Department, the Fish Commission and river basin commissions created by interstate compact.

(7) The extent to which a project is water dependent and thereby requires access or proximity to or siting within water to fulfill the basic purposes of the project. The dependency shall be based on the demonstrated unavailability of any alternative location, route or design and the use of location, route or design to avoid or minimize the adverse impact of the dam, water obstruction or encroachment upon the environment and protect the public natural resources of the Commonwealth.

(8) Present conditions and the effects of reasonably foreseeable future development within the affected watershed above and below the dam, water obstruction or encroachment:

(i) A dam, water obstruction or encroachment shall be designed, constructed and operated to assure adequacy and compliance with this chapter, taking into account reasonably foreseeable development within the watershed.

(ii) In assessing the impact of future development upon a dam, water obstruction or encroachment, the Department may require the applicant to submit data regarding estimated development potentials and municipal, county and regional planning related to the affected watershed.

(9) Consistency with State and local floodplain and stormwater management programs, the State Water Plan and the Coastal Zone Management Plan.

(10) Consistency with the designations of wild, scenic and recreational streams under the Wild and Scenic Rivers Act of 1968 (16 U.S.C.A. §§ 1271—1287) or the Pennsylvania Scenic Rivers Act (32 P. S. §§ 820.21—820.29), including identified 1-A candidates.

(11) Consistency with State antidegradation requirements contained in Chapters 93, 95 and 102 (relating to water quality standards; wastewater treatment requirements; and erosion and sediment control) and the Clean Water Act (33 U.S.C.A. §§ 1251—1376).

(12) Secondary impacts associated with but not the direct result of the construction or substantial modification of the dam or reservoir, water obstruction or encroachment in the area of the project and in areas adjacent thereto and

future impacts associated with dams, water obstructions or encroachments, the construction of which would result in the need for additional dams, water obstructions or encroachments to fulfill the project purpose.

(13) For dams, water obstructions or encroachments in, along, across or projecting into a wetland, as defined in § 105.1 (relating to definitions), the Department will also consider the impact on the wetlands values and functions in making a determination of adverse impact.

(14) The cumulative impact of this project and other potential or existing projects. In evaluating the cumulative impact, the Department will consider whether numerous piecemeal changes may result in a major impairment of the wetland resources. The Department will evaluate a particular wetland site for which an application is made with the recognition that it is part of a complete and interrelated wetland area.

(c) In reviewing a permit application under § 105.11(c) (relating to permit requirements) and section 6(c) of the act (32 P. S. § 693.6(c)) for the operation and maintenance of an existing dam, water obstruction or encroachment, the Department will use the following factors:

(1) Potential threats to life, property or safe navigation created by the continuing operation or maintenance of the project.

(2) Adverse impact on stream flow, water quality or the environment which might be reduced or mitigated by reasonable changes in the operation of the project.

(3) Compliance of the operation and maintenance of the project with applicable laws administered by the Department, the Fish Commission and river basin commissions created by interstate compact.

(d) The Department may review a permit application for the operation and maintenance of existing projects without regard to the design criteria and construction requirements in Subchapters B—J. If the Department finds that an existing dam, water obstruction or encroachment is unsafe or adversely affects property or the environment, it may consider application of criteria and requirements reasonably necessary to correct the conditions.

Notes of Decisions

Reservoir was not an ''available'' alternative supplemental cooling water source within the meaning of 25 Pa. Code § 105.14(b)(7) where there was substantial evidence to support conclusion that such use of the reservoir was technically not feasible, there were legal impediments to such use and it would be unfair to give all unallocated water to one consumptive user. *Del-Aware Unlimited, Inc. v. Department of Environmental Resources*, 508 A.2d 348 (Pa. Cmwlth. 1986); appeal denied 523 A.2d 1132 (Pa. 1986).

Cross References

This section cited in 25 Pa. Code § 105.15 (relating to environmental assessment); 25 Pa. Code § 105.18a (relating to permitting of structures and activities in wetlands); 25 Pa. Code § 105.82 (relating to permit applications for operation and maintenance of existing dams and reservoirs); and 25 Pa. Code § 105.442 (relating to authorization for general permits).

§ 105.15. Environmental assessment.

(a) A person may not construct, operate, maintain, modify, enlarge or abandon the following categories of structures or activities until an environmental assessment has been approved in writing by the Department. The environmental assessment shall be on a form provided by the Department and shall include the following information:

(1) For dams, water obstructions or encroachments permitted under this chapter, the Department will base its evaluation on the information required by § 105.13 (relating to permit applications—information and fees) and the factors included in § 105.14(b) (relating to review of applications) and this section.

(2) For dams, water obstructions or encroachments located in, along or projecting into a wetland for which a permit is not otherwise required under this chapter, the Department will base its evaluation on the information required by § 105.13(d) and the factors included in § 105.14(b) and this section.

(3) For dams located in, along or projecting into an exceptional value water as defined in Chapter 93 (relating to water quality standards) for which a permit is not otherwise required under this chapter, the Department will base its evaluation on the information required by the factors included in § 95.1 (relating to general requirements) and §§ 105.13(d) and 105.14(b) and the following information submitted by the applicant:

(i) The surface area of the impoundment.

(ii) The height of the dam.

(iii) The mean depth and maximum depth of the stream at the location of the dam.

(iv) A description of the release structure.

(v) The rate of a conservation release.

(vi) The design of bypass structures.

(vii) The use of the dam.

(viii) The material used for construction of the dam.

(b) For structures or activities where water quality certification is required under section 401 of The Clean Water Act (33 U.S.C.A. § 1341), an applicant requesting water quality certification under section 401 shall prepare and submit to the Department for review, an environmental assessment containing the information required by subsection (a) for every dam, water obstruction or encroachment located in, along, across or projecting into the regulated water of this Commonwealth.

(c) Based on the results of the environmental assessment required under subsection (a), the Department may require the applicant to undertake further studies and submit additional information, analyses and reports as found necessary by the Department.

(d) The environmental assessment has been conducted by the Department for all general permits, categories of structures and activities listed in § 105.12(a)(1)—(10) and (12)—(15) (relating to waiver of permit requirements). The environmental assessment has also been conducted for the structures or activities listed in § 105.12(b) or for which water quality certification has been granted for a Nationwide permit regulating the structure or activity and the environmental assessment requirements have been deemed satisfied.

§ 105.16. Environmental, social and economic balancing.

(a) If the Department determines that there may be an impact on natural, scenic, historic or aesthetic values of the environment, the Department will consult with the applicant to examine ways to reduce the adverse environmental impact. If, after consideration of mitigation measures, the Department finds that the adverse environmental impact will occur, the Department will evaluate the public benefits of the project to determine whether the public benefits outweigh the environmental harm.

Copyright © 2008 Commonwealth of Pennsylvania

(b) An application for a permit for a structure or activity which the Department determines will have an adverse impact on the environment or public natural resources will not be approved by the Department unless the applicant demonstrates and the Department finds that the public benefits of the proposed project outweigh the harm to the environment and public natural resources. Public benefits include, but are not limited to:

(1) Correction and prevention of pollution.

(2) Protection of public health and safety.

(3) Reduction of flood damages.

(4) Development of energy resources.

(5) Creation or preservation of significant employment.

(6) Provision of public utility services.

(7) Other essential social and economic development which benefits a substantial portion of the public.

(c) An application for a permit will not be approved by the Department in the following areas unless the applicant demonstrates and the Department finds that the project will not have an adverse impact upon the public natural resources:

(1) A project located in or within 100 feet of a watercourse or body of water that has been designated as a National or State wild or scenic river in accordance with the Wild and Scenic Rivers Act of 1968 (16 U.S.C.A. §§ 1271—1287) or the Pennsylvania Scenic Rivers Act (32 P. S. §§ 820.21—820.29).

(2) A project located in or within 100 feet of a Federal wilderness area designated in accordance with the Wilderness Act (16 U.S.C.A. §§ 1131—1136) or the Federal Eastern Wilderness Act of 1975 (16 U.S.C.A. § 1132).

(3) A project located within an area which serves as a habitat of a threatened or endangered species protected by the Endangered Species Act of 1973 (7 U.S.C.A. § 136; 16 U.S.C.A. §§ 4601-9, 460k-1, 668dd, 715i, 715a, 1362, 1371, 1372, 1402 and 1531—1543) or for a species which has been designated as a threatened or endangered species under the Wild Resource Conservation Act (32 P. S. §§ 5301—5314), 30 Pa.C.S. (relating to the Fish and Boat Code) or 34 Pa.C.S. (relating to the Game and Wildlife Code).

(4) A project located in waters designated as exceptional value in Chapter 93 (relating to water quality standards).

(d) In reviewing permit applications, it will be the policy of the Department to encourage activities that protect the natural condition of the watercourses or other body of water.

(e) This section does not apply to dams, water obstructions or encroachments located in, along, across or projecting into wetlands. These structures or activities will be evaluated under §§ 105.17 and 105.18a—105.20.

Authority

The provisions of this § 105.16 amended under the Dam Safety and Encroachments Act (32 P. S. §§ 693.1–693.27); The Clean Streams Law (35 P. S. §§ 691.1—691.1001); section 7 of the act of June 14, 1923 (P. L. 704, No. 294) (32 P. S. § 597); sections 514, 1901-A, 1908-A, 1917-A and 1920-A of The Administrative Code of 1929 (71 P. S. §§ 194, 510-1, 510-8, 510-17 and 510-20); and the Flood Plain Management Act (32 P. S. §§ 679.101—679.601).

Notes of Decisions

Because the petitioner failed to utilize available alternatives, the Department was not required to consider the petitioner's proposed mitigation measures. *Hatchard v. Department of Environmental Resources*, 612 A.2d 621 (Pa. Cmwlth. 1992).

Cross References

This section cited in 25 Pa. Code § 105.442 (relating to authorization for general permits).

§ 105.17. Wetlands.

Wetlands are a valuable public natural resource. This chapter will be construed broadly to protect this valuable resource.

(1) *Exceptional value wetlands.* This category of wetlands deserves special protection. Exceptional value wetlands are wetlands that exhibit one or more of the following characteristics:

(i) Wetlands which serve as habitat for fauna or flora listed as ''threatened'' or ''endangered'' under the Endangered Species Act of 1973 (7 U.S.C.A. § 136; 16 U.S.C.A. §§ 4601-9, 460k-1, 668dd, 715i, 715a, 1362, 1371, 1372, 1402 and 1531—1543), the Wild Resource Conservation Act (32 P. S. §§ 5301—5314), 30 Pa.C.S. (relating to the Fish and Boat Code) or 34 Pa.C.S. (relating to the Game and Wildlife Code).

(ii) Wetlands that are hydrologically connected to or located within 1/2-mile of wetlands identified under subparagraph (i) and that maintain the habitat of the threatened or endangered species within the wetland identified under subparagraph (i).

(iii) Wetlands that are located in or along the floodplain of the reach of a wild trout stream or waters listed as exceptional value under Chapter 93 (relating to water quality standards) and the floodplain of streams tributary thereto, or wetlands within the corridor of a watercourse or body of water that has been designated as a National wild or scenic river in accordance with the Wild and Scenic Rivers Act of 1968 (16 U.S.C.A. §§ 1271—1287) or designated as wild or scenic under the Pennsylvania Scenic Rivers Act (32 P. S. §§ 820.21—820.29).

Copyright © 1996 Commonwealth of Pennsylvania

(iv) Wetlands located along an existing public or private drinking water supply, including both surface water and groundwater sources, that maintain the quality or quantity of the drinking water supply.

(v) Wetlands located in areas designated by the Department as ''natural'' or ''wild'' areas within State forest or park lands, wetlands located in areas designated as Federal wilderness areas under the Wilderness Act (16 U.S.C.A. §§ 1131—1136) or the Federal Eastern Wilderness Act of 1975 (16 U.S.C.A. § 1132) or wetlands located in areas designated as National natural landmarks by the Secretary of the Interior under the Historic Sites Act of 1935 (16 U.S.C.A. §§ 461—467).

(2) *Other wetlands.* This category includes wetlands not categorized as exceptional value wetlands.

(3) *Permits.* The Department will maintain a list of permit decisions involving wetlands. This list will be a matter of public record and will be available for inspection at the Department's offices.

Authority

The provisions of this § 105.17 amended under the Dam Safety and Encroachments Act (32 P. S. §§ 693.1–693.27); The Clean Streams Law (35 P. § 105.18. [Reserved].

Source

The provisions of this § 105.18 adopted September 26, 1980, effective September 27, 1980, 10 Pa.B. 3843; reserved February 18, 1983, February 19, 1983, 13 Pa.B. 781. Immediately preceding text appears at serial pages (59026) to (59027).

§ 105.18a. Permitting of structures and activities in wetlands.

(a) *Exceptional value wetlands.* Except as provided for in subsection (c), the Department will not grant a permit under this chapter for a dam, water obstruction or encroachment located in, along, across or projecting into an exceptional value wetland, or otherwise affecting an exceptional value wetland, unless the applicant affirmatively demonstrates in writing and the Department issues a written finding that the following requirements are met:

(1) The dam, water obstruction or encroachment will not have an adverse impact on the wetland, as determined in accordance with §§ 105.14(b) and 105.15 (relating to review of applications; and environmental assessment).

(2) The project is water-dependent. A project is water-dependent when the project requires access or proximity to or siting within the wetland to fulfill the basic purposes of the project.

(3) There is no practicable alternative to the proposed project that would not involve a wetland or that would have less effect on the wetland, and not have other significant adverse effects on the environment. An alternative is practicable if it is available and capable of being carried out after taking into consideration construction cost, existing technology and logistics. An area not presently owned by the applicant which could reasonably be obtained, utilized, expanded or managed to fulfill the basic purpose of the project shall be considered as a practicable alternative.

(4) The project will not cause or contribute to a violation of an applicable State water quality standard.

(5) The project will not cause or contribute to pollution of groundwater or surface water resources or diminution of resources sufficient to interfere with their uses.

(6) The cumulative effect of this project and other projects will not result in the impairment of the Commonwealth's exceptional value wetland resources.

(7) The applicant shall replace affected wetlands in accordance with § 105.20a (relating to wetland replacement criteria).

(b) *Other wetlands.* Except as provided for in subsection (c), the Department will not grant a permit under this chapter for a dam, water obstruction or encroachment in, along, across or projecting into the wetland which is not an exceptional value wetland, or otherwise affecting the wetland, unless the appli-

Copyright © 2005 Commonwealth of Pennsylvania

cant affirmatively demonstrates in writing and the Department issues a written finding that the following requirements are met:

(1) The project will not have a significant adverse impact on the wetland, as determined in accordance with §§ 105.14(b) and 105.15. The determination of whether an adverse impact is significant includes an evaluation of the following factors:

(i) The areal extent of the wetland impacts.

(ii) The wetland's values and functions.

(iii) Whether the affected wetlands values and functions are unique to the area or region.

(iv) Comments from other State and Federal environmental agencies concerning the scope and effect of the impact.

(2) Adverse environmental impacts on the wetland will be avoided or reduced to the maximum extent possible.

(3) There is no practicable alternative to the proposed project that would not involve a wetland or that would have less adverse impact on the wetland, and that would not have other significant adverse impacts on the environment. An alternative is practicable if it is available and capable of being carried out after taking into consideration construction cost, existing technology and logistics. An area not presently owned by the applicant which could reasonably be obtained, utilized, expanded or managed to fulfill the basic purpose of the proposed project shall be considered as a practical alternative.

(i) It shall be a rebuttable presumption that there is a practicable alternative, not involving a wetland, to a nonwater-dependent project, and that the alternative would have less adverse impact on the wetland.

(ii) To rebut the presumption, an applicant for a permit under this chapter shall demonstrate with reliable and convincing evidence and documentation and the Department will issue a written finding that the following statements are true:

(A) The basic project purpose cannot be accomplished utilizing one or more other sites that would avoid, or result in less, adverse impact on the wetland.

(B) A reduction in the size, scope, configuration or density of the project as proposed and alternative designs to that of the project as proposed that would avoid, or result in fewer or less severe, adverse impacts on a wetland will not accomplish the basic purpose of the project.

(4) The project will not cause or contribute to a violation of an applicable State water quality standard.

(5) The project will not cause or contribute to pollution of groundwater or surface water resources or diminution of the resources sufficient to interfere with their uses.

(6) The cumulative effect of this project and other projects will not result in a major impairment of this Commonwealth's wetland resources.

(7) The applicant will replace the affected wetlands to compensate for unavoidable impacts, in accordance with § 105.20a.

(c) The Department will not grant a permit under this chapter for a dam, water obstruction or encroachment which has a significant adverse impact on a wetland unless the applicant affirmatively demonstrates and the Department finds in writing that a project is necessary to abate a substantial threat to the public health or safety and that the requirements of subsection (b)(2)—(7) are met.

§ 105.19. Complete applications.

(a) An application for a permit is not complete until the necessary information and requirements under the act and this chapter, including proof of financial responsibility, have been satisfied by the applicant.

(b) When the Department determines that an application is incomplete or contains insufficient information to determine compliance with this chapter, it will notify the applicant in writing. The applicant shall then have 60 days to complete the application or the Department will consider the application to be withdrawn by the applicant. Requests for a specific extension may be sought by the applicant in writing. The applicant will be notified in writing when an application is considered withdrawn. When an application is considered withdrawn, the Department will close the application file and take no further action to review the file, unless the applicant requests the file to be reopened after submitting the previously identified information to complete the application and a new fee. Fees will not be refunded after an application is withdrawn.

§ 105.20. Proof of financial responsibility.

(a) Prior to the approval of a permit under this chapter for construction or modification of a dam, water obstruction or encroachment which may present a substantial potential risk to life or property, the Department will require proof of financial responsibility or security for continued operation and maintenance during the lifetime of the facility. Dams, water obstructions or encroachments which may be subject to the proof of financial responsibility include, but are not limited to, Category 1 dams, Hazard Potential Classification, as defined in § 105.91 (relating to classification of dams and reservoirs) stream enclosures, bridges, levees, fills and floodwalls.

(b) As proof of responsibility or security, the Department may require one or more of the following:

(1) A certificate of public convenience from the Pennsylvania Public Utility Commission if the owner of the proposed facility is subject to regulation under 66 Pa.C.S. (relating to the Public Utility Code).

(2) Ownership or management of the facility by an agency of the Federal, State, county or municipal government or of an interstate compact.

(3) A bond or other legal device of a form acceptable to the Department, payable to the Commonwealth, which guarantees proper construction, repair, operation and maintenance, inspection and monitoring, and removal if necessary of the facility. The amount of bond or legal device shall be sufficient to cover the costs of entry, repair, correction, operation, maintenance, inspection, monitoring or removal of the facility by the Commonwealth in the event of failure of the owner to comply with orders of the Department, terms and conditions of the permit, this chapter and the act and section 302 of the Flood Plain Management Act (32 P. S. § 679.302).

Cross References

This section cited in 25 Pa. Code § 105.16 (relating to environmental, social and economic balancing); 25 Pa. Code § 105.21 (relating to criteria for permit issuance and denial); 25 Pa. Code § 105.25 (relating to transfer of permits); and 25 Pa. Code § 105.442 (relating to authorization for general permits).

§ 105.20a. Wetland replacement criteria.

(a) Wetlands replacement shall meet the following general criteria:

(1) *Area ratio.* The wetland shall be replaced at a minimum area ratio of replacement acres to affected acres of 1:1. The Department may require the area ratio to exceed 1:1 based on a determination of the area affected and the functions and values which will be destroyed or adversely affected by the project. For structures or activities constructed without a permit, and for which mitigation, as defined in § 105.1 (relating to definitions), cannot be achieved, the wetland shall be replaced at a minimum area ratio of 2:1 (replacement acres: affected acres). The Department may require the area ratio to exceed 2:1 based on a determination of the area affected and the functions and values which were destroyed or adversely affected by the project.

(2) *Function and value replacement.* Functions and values that are physically and biologically the same as those that are lost shall be replaced at a minimum ratio of 1:1. The Department may require the functions and values ratio to exceed 1:1 based on the area affected and on the functions and values which will be destroyed as adversely affected by the project and the replacement ratio. For structures or activities constructed without a permit, and for which mitigation, as defined in § 105.1, cannot be achieved, the wetland shall be replaced at a minimum area ratio of 2:1. The Department may require the area ratio to exceed 2:1 based on a determination of the area affected and the functions and values which were destroyed or adversely affected by the project.

(3) *Siting criteria.* Replacement shall be located adjacent to the impacted wetland unless an alternative replacement site is approved by the Department. Alternative replacement sites will generally not be approved unless the replacement site is located within the same watershed as the wetland being replaced or within the designated boundaries of the coastal zone management area where the loss occurs.

(b) In addition to the general criteria in subsection (a), the Department will use its guidelines entitled ''*Design Criteria for Wetlands Replacement*'' in making decisions under this section. These guidelines provide for design, flexibility and utilization of best available technology in environmental engineering. These guidelines are available from the Division of Rivers and Wetlands Conservation, Post Office Box 8761, Harrisburg, Pennsylvania 17105-8761.

PERMIT ISSUANCE, TRANSFER AND REVOCATION

§ 105.21. Criteria for permit issuance and denial.

(a) In addition to the other requirements of this chapter, a permit application will not be approved unless the applicant demonstrates that the following conditions are met:

(1) The application is complete and accurate.

(2) The proposed project or action complies with the standards and criteria of this title and with other laws administered by the Department, the Fish Commission and river basin commissions created by interstate compact.

(3) The proposed project or action will adequately protect public health, safety and the environment.

(4) The proposed project or action is consistent with the environmental rights and values secured by Pa. Const. Art. I, § 27 and with the duties of the Commonwealth as trustee to conserve and maintain public natural resources of this Commonwealth.

(5) The applicant has not been found to be in continuing violation of this title or other laws administered by the Department, the Fish Commission or a river basin commission, including, but not limited to, a violation of an adjudication and order, agreement, consent order or decree, whether or not the applicant's violation resulted in an order or civil penalty assessment.

(6) The applicant has submitted adequate proof of financial responsibility, if required under § 105.20 (relating to proof of financial responsibility).

(b) A permit issued under this chapter shall be subject to the general and special conditions regarding construction, operation, maintenance, inspection and monitoring of a project or action that the Department may deem necessary to assure compliance with the requirements and purposes of this chapter, the act, the Flood Plain Management Act (32 P. S. §§ 679.101—679.601) and other laws

administered by the Department, the Fish Commission and river basin commissions created by interstate compact.

(c) The Department may not issue a permit to operate and maintain a dam, water obstruction or encroachment constructed without a permit unless one of the following is met:

(1) The Department determines that the structure or activity complies with the standards and criteria of this title, including replacement in accordance with § 105.20a (relating to wetland replacement criteria), and with other laws administered by the Department, the Fish Commission and river basin commissions created by interstate compact.

(2) The Department determines that the structure or activity does not comply with the standards and criteria of this title and with other laws administered by the Department, the Fish Commission and river basin commissions created by interstate compact, that the effect on wetlands will be mitigated, and at least one of the following is met:

(i) Restoration would cause destruction of a dwelling occupied by a person who had no role in the planning or construction of the project.

(ii) Restoration may result in more long term damage than would be caused by allowing the project to remain in place.

(iii) Restoration would be unsuccessful due to material changes in the condition of the site and its surrounding area.

(iv) There are extraordinary circumstances which preclude restoration.

(d) The reason for denial of a permit application and appeal procedures shall be communicated in writing to the applicant.

(e) In an appeal from a Department action concerning a permit application to operate and maintain a dam, water obstruction or encroachment, the applicant has the burden of proving that there is no reasonable basis for the Department's action.

§ 105.24. Coordination of permits.

(a) The Department will establish a system to coordinate the application for and issuance of permits under this chapter with permit processes conducted under other statutes and regulations administered by the Department and with permit processes administered by other Federal and State agencies.

(b) When possible, the Department will develop joint permit application forms to facilitate the submission of information on related activities of a project regulated under statutes and regulations administered by the Department and other Federal and State agencies, to reduce duplicate and repetitious application requirements. The joint application forms shall be used in lieu of individual applications for the required permits, except for small projects.

Authority

Immediately preceding text appears at serial page (117658).

§ 105.25. Transfer of permits.

(a) A permit may be transferred to a new owner if there is a change of ownership of the dam, water obstruction or encroachment.

(b) A permit may be transferred only upon application to and approval by the Department. An application for transfer shall be submitted upon forms provided by the Department.

(c) A permit may not be transferred if a violation of this chapter exists at the time of application for transfer unless the transfer will expedite correction of the violation.

(d) The new owner shall expressly agree to abide by the permit conditions and shall, if applicable:

(1) Provide the Department with proof of financial responsibility and security in accordance with § 105.20 (relating to proof of financial responsibility).

Copyright © 1997 Commonwealth of Pennsylvania

(2) Obtain a license, easement, right-of-way or other interest in the submerged lands of this Commonwealth in accordance with §§ 105.31—105.35 (relating to submerged lands of the Commonwealth—licenses and annual charges).

(e) The original permittee will not be relieved of an obligation to comply with this chapter, the terms and conditions of the permit or an order issued by the Department until the transfer has been approved.

(f) Upon receipt of the approved application for transfer, the applicant shall affix the approved application for transfer to the original permit. The approved application for transfer shall become part of, and remain affixed to, the original permit, until the Department issues a new permit.

SUBMERGED LANDS OF THE COMMONWEALTH—LICENSES AND ANNUAL CHARGES

§ 105.31. Property rights.

(a) Except as provided in §§ 105.32 and 105.33 (relating to projects—proper purpose; and licenses for public service corporations), no permit issued under this chapter may give real or personal property rights nor grant exclusive privileges; nor may it be construed to grant or confer a right, title, easement or interest in, to or over lands belonging to this Commonwealth.

(b) No permit for a dam, water obstruction or encroachment to occupy submerged lands of the Commonwealth will be issued by the Department until the applicant has first obtained one of the following:

Copyright © 2005 Commonwealth of Pennsylvania

(1) An easement, right-of-way, license or lease from the Department under section 15 of the act (32 P. S. § 693.15) and § 105.32.

(2) A license under section 514 of The Administrative Code of 1929 (71 P. S. § 194) and § 105.33.

(3) A license, easement, right-of-way or other interest in the submerged lands of this Commonwealth granted under specific statutory authority from the General Assembly.

(c) For purposes of this section, to occupy submerged lands of this Commonwealth includes:

(1) The placement of a physical structure on, under or over submerged lands of this Commonwealth.

(2) The use or control of the space overlying submerged lands of this Commonwealth, associated with use of a structure with the regularity and in a manner that substantially restrict or prevent navigation, fishing, recreation or other public trust uses by the general public on or over the lands.

§ 105.32. Projects—proper purpose.

(a) If the applicant does not have an estate or interest in the submerged lands of this Commonwealth under other specific authority from the General Assembly at the time of application for a permit under the act, the Department may, with the approval of the Governor, grant an easement, right-of-way, license or lease to occupy submerged lands of this Commonwealth in a navigable lake or river or stream declared a public highway for a dam, water obstruction or encroachment regulated under this chapter which is constructed for the purpose of:

(1) Improving navigation or public transportation.

(2) Recreation, fishing or other public trust purposes.

(3) Protecting public safety or the environment.

(4) Providing water supply, energy production or waste treatment.

(5) Providing a public utility service by a government agency or subdivision, public utility or electric cooperative.

(6) Other activities which require access to water.

(b) The total area of land which any such project may occupy under one or more easements, rights-of-way, licenses or leases granted by the Department under this section may not exceed 25 acres.

§ 105.35. Charges for use and occupation of submerged lands of this Commonwealth.

(a) Except as provided in subsections (b) and (c), the following charges apply to the granting of an easement, right-of-way, license or lease to occupy submerged lands of this Commonwealth issued under section 15 of the act (32 P. S. § 693.15) and § 105.32 (relating to projects—proper purpose):

Copyright © 2005 Commonwealth of Pennsylvania

(1) For commercial utility and other dams, water obstructions and encroachments except as listed in subsection (c), annual license charges:

(i) For areas occupied by facilities, $50 per tenth of an acre.

(ii) For barge fleeting and mooring areas, $10 per tenth of an acre.

(iii) Minimum annual charge, $250.

(2) For private recreation docks, owned and used solely by the owners of adjacent riparian property, unless the project is otherwise authorized by a general permit issued under section 7 of the act (32 P. S. § 693.7), an annual charge of $250.

(b) Licenses for public service lines crossing or occupying submerged lands of this Commonwealth, issued under section 15 of the act or section 514 of The Administrative Code of 1929 (71 P. S. § 194) are subject to the following schedule of annual charges:

Length of Crossings (in feet)	*Charges (in dollars)*
Less than 500	$250
500 to 999	500
1000 to 1499	1000
1500 to 1999	1500
2000 to 2499	2000
2500 to 2999	2500
3000 to 3499	3000
3500 to 3999	3500
4000 to 4499	4000
4500 to 4999	4500
5000 and over	5000

(c) Charges may not be imposed under section 15 of the act or section 514 of The Administrative Code of 1929 for the following categories of activities and structures:

(1) An activity or structure constructed, owned or operated by a department, commission or agency of the Commonwealth or the Federal government.

(2) A project or activity constructed, or operated primarily for the benefit of a State building or a State institution.

(3) A flood control project constructed, owned or operated by an agency of the Commonwealth, the Federal government or a municipality.

(4) A project or activity constructed, owned or operated by a political subdivision of the Commonwealth which provides potable water supply, sewage disposal or other similar services necessary for public health and welfare, or in connection with a service for which no fees or charges other than general taxes are imposed.

(5) A facility to provide access to the general public to water for recreational boating, fishing, hunting, swimming or other recreation where the access is provided without charge or on a nonprofit basis.

(6) A structure or facility constructed and operated exclusively to improve fish habitat, under a cooperative agreement with the Fish Commission.

(7) A private recreational dock constructed under a general permit.

(d) The annual charges imposed in subsections (a) and (b) may be revised by the EQB after approval by the Governor and reasonable notice to the holder of a license issued under this section.

(e) This section does not apply to a crossing contiguous to or in a State park or State forest lands. Easements for the crossings shall be administered in accordance with section 514 of The Administrative Code of 1929 and the park and forest land management practices of the Department.

(f) The removal of sand, gravel and other valuable minerals from submerged lands of this Commonwealth are subject to the royalty and agreement provisions established under section 1908-A of The Administrative Code of 1929 (71 P. S. § 510-8).

CONSTRUCTION REQUIREMENTS AND PROCEDURES

§ 105.41. Notices and reports.

(a) The permittee shall notify the Department, in writing, of the proposed time for commencement of work at least 15 days prior to the commencement of construction.

(b) The Department may require submission of the reports as it deems necessary on the status of construction.

Authority

The provisions of this § 105.41 amended under the Dam Safety and Encroachments Act (32 P. S. §§ 693.1–693.27); The Clean Streams Law (35 P. S. §§ 691.1—691.1001); section 7 of the act of June 14, 1923 (P. L. 704, No. 294) (32 P. S. § 597); sections 514, 1901-A, 1908-A, 1917-A and 1920-A of The Administrative Code of 1929 (71 P. S. §§ 194, 510-1, 510-8, 510-17 and 510-20); and the Flood Plain Management Act (32 P. S. §§ 679.101—679.601).

§ 105.42. Acknowledgment of conditions.

(a) Upon receipt of a permit, the permittee shall sign the permit thereby expressly certifying the permittee's acceptance of, and agreement to comply with, the terms and conditions of the permit. The permittee shall return a signed copy of the permit to the Department. The permit will not be effective until the signed copy of the permit is received by the Department.

(b) The permittee shall fully inform the engineer or contractor responsible for the supervision and conduct of work covered by a permit issued under this chapter of the terms, conditions, restrictions and covenants of the permit.

(c) Prior to the commencement of construction, the permittee shall file with the Department in writing, on a form provided by the Department, a statement signed by the permittee and an individual responsible for the supervision or conduct of the construction work acknowledging and accepting the general and special conditions contained in the permit. Unless the acknowledgment and acceptance have been filed, the permit is void.

(d) A copy of the permit and the acknowledgment shall be available at the work site for inspection upon request by an officer or agent of the Department or another Federal, State, county or municipal agency.

§ 105.43. Time limits.

(a) The Department will set time limits for the commencement and completion of work under a permit issued under this chapter that it deems reasonable and appropriate to carry out the purposes of this chapter.

(b) If the work is not completed on or before the dates set by the Department, unless extended by the Department in writing, the permit shall become void without further notification being required.

The provisions of this § 105.43 adopted September 10, 1971, effective September 11, 1971, 1 Pa.B. 1804; reserved August 11, 1978, effective August 28, 1978, 8 Pa.B. 2229; amended effective September 26, 1980, effective September 27, 1980, 10 Pa.B. 3843. Immediately preceding text appears at serial page (4581).

§ 105.44. Implementation of work according to specifications.

(a) Work undertaken under a permit issued under this chapter shall be conducted in accordance with the maps, plans, profiles and specifications as approved by the Department.

(b) No changes in the maps, plans, profiles and specifications for work covered by a permit which would affect the waterway area or structural stability of the project may be made except with the written approval of the Department. Upon written approval by the Department, the changes shall become part of the permit.

(c) The Department will have the right during the progress of work to require changes or modifications in the maps, plans, profiles and specifications for work covered under a permit it may determine are necessary and proper to protect public health, public safety and the environment.

OPERATION, MAINTENANCE AND INSPECTION

§ 105.51. Operation and maintenance.

The permittee or owner of a dam, water obstruction or encroachment shall operate and maintain the facility and appurtenant structures in a safe condition in accordance with permit terms and conditions and the provisions of this chapter so that the facility cannot imperil life, health, safety or property located above or below the facility.

Source

Cross References

This section cited in 25 Pa. Code § 105.131 (relating to operation and monitoring plans).

§ 105.53. Inspections by owners and inspection reports.

The permittee or owner of a dam, water obstruction or encroachment shall inspect the facility and appurtenant works according to the following schedule:

(1) Dams, reservoirs and their appurtenant works shall be inspected at least once every 3 months.

(2) For Category 1 dams and Category 2 dams as classified in § 105.91 (relating to classification of dams and reservoirs), which are defined as high hazard dams in § 105.1 (relating to definitions), annual reports regarding the condition of the dam, certified by a registered professional engineer, shall be submitted to the Department on or before December 31 of each year. More frequent reports of dam conditions may be required by the Department if in its discretion conditions indicate the reports are necessary to assure adequate protection of health, safety and property.

(3) For local flood protection projects, annual reports regarding the condition of the flood protection facility shall be submitted to the Department on or before December 31 of each year.

(4) The owner of a water obstruction or encroachment shall conduct periodic inspections to ensure the safe operation, monitoring and maintenance of the facility in accordance with this title, terms and conditions of the permit and approved operating or monitoring plans.

(5) The owner shall retain records of the inspections, including records of actions taken to correct conditions found in the inspections. Copies of the records shall be provided to the Department on request.

(6) The Department may, through terms and conditions of the permit or by request at any time, require the owner to submit certified reports regarding the condition of the facility to the Department.

(7) In lieu of inspections conducted by the owner and certified reports submitted by the owner, the Department may accept reports of equivalent inspections conducted and prepared by governmental agencies. In addition, the Department may accept equivalent inspection reports certified by the owner and submitted to other governmental agencies.

INVESTIGATION AND CORRECTION OF UNSAFE CONDITIONS—EMERGENCY PROCEDURES

§ 105.61. Procedures for investigations.

The Department may, if it finds there is reasonable cause to suspect the existence of conditions adversely affecting the safety of a dam, water obstruction or encroachment, order the owner to conduct investigations, studies, tests and analyses that may be required to properly evaluate the safety of the structure. The investigations, studies, tests and analyses shall be accomplished under the supervision of a registered professional engineer, experienced in the design, construction, operation and maintenance of the facilities and approved by the Department, and shall be accomplished in accordance with methods the Department may prescribe. Failure to provide the investigation results to the Department on request will constitute adequate grounds for revocation or suspension of a permit.

The provisions of this § 105.61 adopted September 10, 1971, effective September 11, 1971, 1 Pa.B. 1804; amended August 11, 1978, effective August 28, 1978, 8 Pa.B. 2229; amended September 26, 1980, effective September 27, 1980, 10 Pa.B. 3843. Immediately preceding text appears at serial pages (38858) to (38860) and (47990).

§ 105.62. Correction of unsafe conditions.

(a) If the Department determines that a dam, water obstruction or encroachment is unsafe or adversely affects property or the environment or has not been properly constructed, operated, monitored or maintained in compliance with legal requirements, it may require the owner of the facility to repair, alter, maintain or

remove the facility or take other actions necessary to carry out the purposes of this chapter within the time prescribed by the Department.

(b) The Department or its authorized agents may enter and conduct investigations, tests and analyses and take corrective action required to carry out the purposes of this chapter if one or more of the following conditions exist:

(1) The owner cannot be ascertained or found.

(2) The owner refuses or fails to comply with an order issued by the Department under section 14 of the act (32 P. S. § 693.14) or this section.

(3) The condition of the facility is so dangerous as to require immediate remedial action.

(c) The Department may recover from the owner, in the name of the Commonwealth, the expenses incurred in taking the action described in subsection (b) in the same manner as debts are recoverable by law.

Source

Immediately preceding text appears at serial page (4584).

§ 105.63. Emergency procedures.

(a) The permittee or owner of a dam, water obstruction or encroachment shall immediately notify the Department and responsible authorities in adjacent and downstream communities, including emergency management authorities, of a condition which may threaten the safety of the facility and take necessary actions to protect life and property, including action required under an emergency plan or Department order issued under the act.

(b) The permittee or owner of a dam or reservoir shall immediately notify the Department and responsible emergency management authorities in adjacent and downstream communities of conditions which may indicate a potential dam hazard emergency including, but not limited to, one or more of the following conditions:

(1) Sliding of upstream or downstream slopes or abutments contiguous to the dam.

(2) Sudden subsidence of the crest of the dam.

(3) Longitudinal or transverse cracking of the crest of the dam.

(4) Unusual release of water from the downstream face or toe of the dam.

(5) Other unusual conditions at the downstream slope of the dam.

(6) Significant landslides in the reservoir area.

(c) In case of emergency, telephone calls should be directed to the Pennsylvania Emergency Management Agency at (717) 783-8150 or the Department's emergency number at (717) 787-4343.

§ 105.64. Emergency permit.

The Department may issue emergency permits if it finds that immediate remedial action is necessary to alleviate an imminent threat to life, property or the environment.

(1) The emergency permit will be provided in writing, on a form developed for this purpose.

(2) The emergency permit will contain conditions as the Department determines appropriate.

(3) The Department may institute proceedings, legal or administrative, that it deems appropriate for violations of the emergency permit or conditions of the emergency permit.

(4) If the municipality in which the emergency occurs has waived notice, the emergency permit is effective immediately. If notice has not been waived by the municipality, the emergency permit is effective 30 days after notice is sent to the municipality in which the emergency occurred. The emergency permit will expire in 30 days unless extended in writing by the Department.

(*Editor's Note*: The act of August 14, 1991 (P. L. ___ , No. 35) supersedes the first two sentences of § 105.64(4).)

Authority

Subchapter B. DAMS AND RESERVOIRS

GENERAL PROVISIONS

Sec.
105.71. Scope.
105.72. [Reserved].
105.73. [Reserved].
105.74. [Reserved].
105.75. [Reserved].
105.76. [Reserved].
105.77. [Reserved].
105.78. [Reserved].
105.79. [Reserved].

PERMITS

105.81. Permit applications for construction and modification of dams and reservoirs.
105.82. Permit applications for operation and maintenance of existing dams and reservoirs.
105.83—105.87. [Reserved].

CLASSIFICATION AND DESIGN CRITERIA

105.91. Classification of dams and reservoirs.
105.92. Foundations.
105.93. Design stress.
105.94. Spillways.
105.95. Freeboard.
105.96. Outlet works.
105.97. Stability of structure.
105.98. Design flood criteria.
105.99. Dams in subdivision developments.

CONSTRUCTION REQUIREMENTS AND PROCEDURES

105.101. Notices and reports.
105.102. Personnel and supervision.
105.103. Weather and ground conditions.
105.104. Removal and disposal of vegetation.
105.105. [Reserved].
105.106. Activities and facilities on the construction site.
105.107. Completion certificate and final plans.

WATER STORAGE AND DISCHARGE

105.111. Commencement of water storage.
105.112. Stream flow during construction, filling and repair.
105.113. Releases.
105.114. [Reserved].

PROTECTION AND RESTORATION OF AQUATIC LIFE

105.121. Fishways.
105.122. Drawdown of impounded waters.
105.123. Restoration of aquatic life.
105.124. [Reserved].
105.125. [Reserved].

OPERATION, MAINTENANCE AND EMERGENCIES

105.131. Operation and monitoring plans.
105.132. Inspection.
105.133. Directed repairs.
105.134. Emergency warning system and operation plan.
105.135. Dam hazard emergencies.
105.136. Unsafe dams.

GENERAL PROVISIONS

§ 105.71. Scope.

Except as provided in §§ 105.3 and 105.12 (relating to scope; and waiver of permit requirements), this subchapter governs the construction, alteration, enlargement, repair, maintenance, operation and removal of a dam or reservoir regulated under the act.

PERMITS

§ 105.81. Permit applications for construction and modification of dams and reservoirs.

(a) In addition to the information required by § 105.13 (relating to permit applications—information and fees), permit applications under this subchapter for the construction or modification of dams and reservoirs shall give the following information:

(1) The name and address of the applicant.

(2) The location, type, size, height and purpose of the proposed dam and reservoir and appurtenant works.

(3) For projects involving storage of fluids or semifluids other than water, information concerning the chemical content, viscosity and other pertinent physical characteristics of the fluid or semifluid impounded.

(4) The storage capacity and reservoir surface areas for normal pool and maximum high water.

(5) Plans for purposed permanent monitoring of performance by instrument installations in the dam, including the purposes of the instrumentation. If no instrumentation is considered necessary, reasons for this judgment may be stated.

(6) As accurately as may be readily obtained, the area of the drainage basin, pertinent rainfall and streamflow records, and flood flow records and estimates.

(7) The proposed time for commencement and anticipated completion of construction.

(8) The method and schedule of operation of the dam including an emergency warning system and operation plan if required under § 105.134 (relating to emergency action plan).

(9) Plans for control of erosion and water pollution during the anticipated construction operations including plans for adequate measures to limit the erosion of the soil from exposed slopes after completion of construction. The plans shall indicate that adequate control measures will be taken during construction to protect the quality of stream flow below the project site. The application shall include a copy of a letter from the conservation district in the county where the project is located indicating that the district reviewed the erosion and sediment control plan of the applicant and considers it to be satisfactory.

(10) Proof of title or adequate flowage easements for land area below the top of the dam elevation that is subject to inundation.

(11) Other information the Department may require.

(b) The application shall be accompanied by a design report, construction plans and specifications, in sufficient detail to evaluate the safety, adequacy and suitability of the proposed work.

(c) The applicant shall conduct and submit the results of the investigations and tests as the Department, in its judgment, believes are necessary to determine the safety, adequacy and suitability of design, including but not limited to:

(1) Data concerning subsoil and rock foundation conditions and the materials entering into the construction of the dam or reservoir.

(2) Data concerning exploratory pits, drilling, coring and tests to determine seepage rates.

(3) Data concerning the strength tests necessary to measure the physical properties and behavior of foundation and embankment materials at the dam or reservoir site.

(4) Data concerning the geology of the dam or reservoir area, indicating possible hazards such as faults, weak seams and joints.

(5) Data concerning availability and quality of construction materials.

(6) Other information as may be necessary, including the design calculations for the dam, which shall be made available to the Department on request.

(d) Plans and specifications and the results of tests or investigations shall be prepared under the supervision of and certified by a registered professional engineer experienced in dam design and construction and assisted by qualified engineers, geologists and other specialists, when necessary.

The provisions of this § 105.81 adopted September 10, 1971, effective September 11, 1971, 1 Pa.B. 1804; amended August 11, 1978, effective August 12, 1978, 8 Pa.B. 2229; amended September 26, 1980, effective September 27, 1980, 10 Pa.B. 3843. Immediately preceding text appears at serial pages (47994) and (38864).

§ 105.82. Permit applications for operation and maintenance of existing dams and reservoirs.

(a) In addition to information required by §§ 105.13 and 105.14 (relating to permit applications—information and fees; and review of applications), a permit application for the operation and maintenance of existing dams and reservoirs shall give the following information:

(1) The name and address of the applicant.

(2) The location, type, size, height and purpose of the existing dam and reservoir and appurtenant works.

Copyright © 1996 Commonwealth of Pennsylvania

(3) For projects involving storage of fluids or semifluids other than water, information concerning the chemical and physical characteristics of the fluid or semifluid impounded.

(4) The storage capacity and reservoir surface areas for normal pool and maximum high water.

(5) A description of facilities and plans for monitoring the performance of the dam.

(6) Information on the area of the drainage basin, rainfall and stream flow records, and flood flow records and estimates, when available.

(7) Information readily available regarding the foundation, specifications and construction of the dam.

(8) The method and schedule of operation of the dam, if deemed necessary by the Department.

(9) The emergency warning plan for the dam or reservoir, if completed, or work plan to prepare and submit an emergency warning plan in accordance with §§ 105.131 and 105.134 (relating to operation and monitoring plans; and emergency action plan).

(10) Proof of title or flowage easements for land areas below the top of the dam elevation that is subject to inundation.

(11) Reports of the most recent inspections of the dam conducted by the owner or by the State or Federal government agencies.

(12) Other information as the Department may require.

(b) The Department may waive or modify one or more of the application content requirements set forth in subsection (a) if the information required is not available and is not essential to determining the safety of the dam or reservoir or compliance by the dam or reservoir with the requirements of this chapter.

CLASSIFICATION AND DESIGN CRITERIA

§ 105.91. Classification of dams and reservoirs.

(a) A dam or reservoir shall be classified in accordance with size and the hazard potential which might occur in the event of an operational or structural failure. In approving a hazard potential classification, the Department will consider, without limitation:

(1) The height of the dam and storage capacity of the reservoir.

(2) The physical characteristics and extent of actual and projected development of the dam site and downstream areas.

(3) The relationship of the site to existing or projected industrial, commercial and residential areas and other land uses downstream which may be affected by a dam failure.

(b) The following shall be the classifications and descriptions as used in this subchapter:

Copyright © 2005 Commonwealth of Pennsylvania

SIZE CLASSIFICATION*

Class	*Impoundment Storage (Acre Feet)*	*Dam Height (Feet)*
A	Equal to or greater than 50,000	Equal to or greater than 100
B	Less than 50,000 but greater than 1000	Less than 100 but greater than 40
C	Equal to or less than 1000	Equal to or less than 40

*Note: Size classification may be determined by either storage or height of structure, whichever gives the higher category.

HAZARD POTENTIAL CLASSIFICATION

Extent of Development

Category	*Loss of Life*	*Economic Loss*
1	Substantial	Excessive (extensive residential, commercial, agricultural and substantial public inconvenience)
2	Few (no rural communities or urban developments and no more than a small number of habitable structures)	Appreciable (damage to private or public property and short duration public inconvenience)
3	None expected (no permanent structure for human habitation)	Minimal (undeveloped or occasional structures with no significant effect on public inconvenience)

Authority

§ 105.92. Foundations.

(a) The foundation of a dam or reservoir shall be stable under all probable conditions.

(b) In analyzing the stability of the foundation of a proposed or existing dam or reservoir, the applicant shall consider all of the following factors:

(1) The seismic forces at the site.

(2) The shearing strength of the foundation.

(3) Settlement and subsidence.

(4) Leakage, permeability and solubility.

§ 105.93. Design stress.

In the construction of dams and reservoirs, allowable stresses shall conform to the current standards accepted by the engineering profession.

Source

The provisions of this § 105.93 adopted September 10, 1971, effective September 11, 1971, 1 Pa.B. 1804; amended August 11, 1978, effective August 12, 1978, 8 Pa.B. 2229; amended September 26, 1980, effective September 27, 1980, 10 Pa.B. 3843. Immediately preceding text appears at serial page (47996).

§ 105.94. Spillways.

(a) Every dam shall be provided with a spillway system which is capable of safely conveying the design flood of the dam without endangering the safety or integrity of the dam.

(b) Each spillway shall include a satisfactory means of dissipating the energy flow at its outlet to assure conveyance of flow without endangering the safety and integrity of the dam or the natural environment of the stream.

Immediately preceding text appears at serial page (149140).

§ 105.96. Outlet works.

(a) Dams shall include a device to permit the draining of the reservoir within a reasonable period of time as determined by the Department unless the Department determines that an outlet works is not feasible for a specific dam.

(b) In determining the reasonable time period for drainage of the reservoir, the Department may consider, without limitation, the following factors:

(1) The damage potential posed by possible failure of the dam.

(2) The risk and nature of potential failure and the time likely to be available to avert the failure after notice of conditions threatening the safety or stability of the dam.

(3) The purpose of the dam and reservoir.

(4) The capacity and stability of available drainage courses to convey the waters released from the reservoir in the event of emergency drainage.

(5) The influence of rapid drawdown on the stability of the dam, its appurtenant works and the upstream natural slopes of the reservoir.

(c) Each outlet works shall include a means of dissipating the energy of flow at its outlet to assure conveyance of flow without endangering the safety and integrity of the dam or the natural environment of the stream.

The provisions of this § 105.96 adopted September 26, 1980, effective September 27, 1980, 10 Pa.B. 3843.

§ 105.97. Stability of structure.

(a) Dams shall be structurally sound and shall be constructed of sound and durable materials. The completed structure shall be stable under all probable conditions of operation.

(b) In reviewing the stability of a structure, the Department may consider, without limitation, the following:

(1) The physical properties of the materials available for construction.

(2) The seismic and hydraulic forces affecting the structure.

(3) The methods of construction.

(4) The conditions of operation of the dam and reservoir.

The provisions of this § 105.97 adopted September 26, 1980, effective September 27, 1980, 10 Pa.B. 3843.

§ 105.98. Design flood criteria.

(a) The discharge capacity or storage capacity, or both, shall be capable of safely accommodating the recommended design flood for the size and hazard potential classification of the dam as determined by § 105.91 (relating to classification of dams and reservoirs). The design flood is intended to represent the largest flood that need be considered in the evaluation of a given project. When a range of design flood is indicated, the magnitude that most closely relates to the size and hazard potential shall be selected. Design flood criteria shall be as indicated in the following table:

Size and Hazard Potential Classification	*Design Flood*
A-1.A-2.B-1	PMF
A-3,B-2, C-1	1/2 PMF to PMF
B-3, C-2	100 year to 1/2 PMF
C-3	50 year to 100 year frequency

(b) The Department may, in its discretion, require consideration of a minimum design flood for a class of dams or reservoirs in excess of that set forth in subsection (a) when it can be demonstrated that the design flood requirement is necessary and appropriate to provide for the integrity of the dam or reservoir and to protect life and property with an adequate margin of safety.

(c) The Department may, in its discretion, consider a reduced design flood for a class of dams or reservoirs when it can be demonstrated that the design flood provides for the integrity of the dam or reservoir and protects life and property with an adequate margin of safety.

§ 105.99. Dams in subdivision developments.

Whenever a dam or reservoir is proposed to be constructed in or as a part of an existing or proposed subdivision development, the Department will include in the permit the conditions as are necessary to prevent construction of structures on lands which may be subject to flooding caused by the maximum pool of the dam and to require the permittee to adequately inform potential buyers or lessees of the restrictions.

CONSTRUCTION REQUIREMENTS AND PROCEDURES

§ 105.101. Notices and reports.

At least 15 days prior to commencement of construction, the permittee shall notify the Department, in writing, of the proposed time for commencement of work. Thereafter, a detailed report on the status of construction shall be submitted monthly to the Department of Environmental Resources; Division of Dam Safety; Post Office Box 2357, Harrisburg, Pennsylvania 17120, until construction work has been completed.

§ 105.102. Personnel and supervision.

(a) Work shall be conducted under the oversight and supervision of a competent engineer approved by the Department, and the engineer or a competent representative shall be on the work site during significant construction activities until the completion of the dam.

(b) The permittee shall file with the Department at least 15 days prior to the commencement of construction a statement setting forth the name of the contractors conducting the work authorized by the permit and the names and employers of personnel responsible for the supervision of construction.

WATER STORAGE AND DISCHARGE

§ 105.111. Commencement of water storage.

The permittee shall notify the Department, in writing, at least 1 week in advance of the date proposed for the commencement of water storage in the reservoir or pond created by the dam for which the permit is issued. The Department may, at its discretion, require that a representative of the Department be at the site before or during the filling of the pond or reservoir.

§ 105.112. Stream flow during construction, filling and repair.

During the period of construction, alteration, enlargement or repair and during the period that the pond or reservoir is being filled, the permittee shall allow a

sufficient flow of water, as determined by the Department, into the stream below the dam to support fish and other aquatic life and to preserve the water quality in the stream.

Source

The provisions of this § 105.112 adopted September 10, 1971, effective September 11, 1971, 1 Pa.B. 1804; amended August 11, 1978, effective August 28, 1978, 8 Pa.B. 2229; amended September 26, 1980, effective September 27, 1980, 10 Pa.B. 3843. Immediately preceding text appears at serial pages (47998) and (38868).

§ 105.113. Releases.

(a) The Department will impose general and special conditions regarding release rates in a permit for a dam or reservoir that it deems necessary to maintain stream flows for the purposes of protection of public health, water quality control, conservation of fisheries and aquatic habitat, improvement of recreation and protection of instream and downstream water uses. The appropriate release rates for the dams and reservoirs shall be established in accordance with subsections (b) and (c).

(b) For dams or reservoirs constructed after August 28, 1978:

(1) The minimum release rate unless modified in accordance with paragraph (2) shall be the average consecutive 7 day flow having a recurrence interval of once in 10 years (Q 7-10) plus an additional release rate determined by the following formula:

Release rate (csm)	=	Q7-10 + PDF(.25 csm—Q7-10 csm)
where PDF	=	the percentage factor based on the storage capacity of the reservoir measured as percent of average annual runoff retained in the reservoir. This factor is explained in Planning Principles, State Water Plan SWP-1 (March, 1975).
.25 csm	=	.25 cubic feet per second of flow per square mile of watershed.
Q7-10csm	=	The seven-day, ten-year flow, in cubic feet per second per square mile of watershed.

The minimum release rate determined by this formula shall not exceed 0.25 cubic feet per square mile of watershed.

(2) The Department may modify the minimum release rate, or provide variable schedules or releases considering the following factors:

(i) The purposes stated in subsection (a).

(ii) Particular stream requirements, including the particular needs of instream and downstream water uses and riparian rights.

(iii) The particular uses and purposes of the dam or reservoir.

Copyright © 1996 Commonwealth of Pennsylvania

(iv) The particular engineering, hydrologic and economic factors affecting the ability of the dam or reservoir to provide the releases.

(c) For dams and reservoirs constructed prior to August 28, 1978, the Department will determine a reasonable schedule for release rates, considering all of the following:

(1) The purposes stated in subsection (a) and the particular needs of instream and downstream water uses on the affected stream.

(2) The capacity of existing release works at the dam and feasibility of potential modification of the release works.

(3) The yield of the reservoir, and its capability to meet release requirements and satisfy the purposes and uses of the reservoir.

(d) Every dam shall at all times be operated in such manner as to allow the required flow of water into the stream below the dam as established under this section, and as otherwise necessary to support fish and other aquatic life and to assure compliance with the water quality criteria set forth in Chapter 93 (relating to water quality standards) and to provide for other instream uses for the affected stream.

§ 105.123. Restoration of aquatic life.

If the Department finds that construction of a dam or reservoir has so substantially disrupted aquatic life as to preclude natural restoration of the stream ecology within a reasonable period of time, the permittee shall be required to submit and implement a plan to restore the aquatic life of the stream to its prior condition, to the maximum extent possible. The plan shall be subject to review and modification by the Department in consultation with the Fish Commission and shall include but not be limited to:

(1) Placement of bed gravel.
(2) Stabilization of banks and bed.
(3) Installation of stream improvement devices.
(4) Revegetation of stream and banks.
(5) Stocking of fish and other aquatic life.

OPERATION, MAINTENANCE AND EMERGENCIES

§ 105.131. Operation and monitoring plans.

(a) In addition to the requirements of §§ 105.51—105.54 (relating to operation, maintenance and inspection), the permittee or owner of a dam or reservoir shall follow the method and schedule of operation of the dam or reservoir, including the emergency action plan if required by § 105.134 (relating to emergency action plan), as approved by the Department and shall implement a plan approved by the Department for permanent monitoring of performance by instrument installation in the dam.

(b) A permittee or owner of a dam or reservoir may not modify or cease implementation of all or part of the approved plans and methods of operation or monitoring without the prior approval of the Department.

(c) The permittee or owner of a dam or reservoir shall operate and maintain the dam in accordance with the authorized plans and specifications. Normal repairs and maintenance of the dam and the reservoir's design storage capacity will not require further authorization except as provided in § 105.122 (relating to drawdown of impounded waters).

§ 105.134. Emergency action plan.

(a) The owner of a dam or reservoir that may cause loss of life or serious damage to property if a failure of the dam occurs, shall develop an emergency action plan to be followed in the event of a dam hazard emergency. The emergency action plan shall be submitted to and approved by the Department and local emergency management officials prior to commencement of water storage in the reservoir or pond created by the dam during any stage of construction of the dam. The emergency action plan shall, at a minimum, contain the following elements:

(1) An identification of the area below the dam which may be threatened with loss of life or serious damage to property if a failure of the dam occurs.

(2) A listing of key municipal and emergency management officials and their telephone numbers. The list shall be readily available at the dam site near a telephone or other means of communication, if available.

(3) An identification of handicapped or other persons who may have difficulty evacuating the area which may be threatened if a failure of the dam occurs. Procedures for identifying and evacuating these people in a dam hazard emergency shall be developed in cooperation with local and emergency management officials.

(b) For an existing dam or reservoir that may cause loss of life or serious damage to property if failure of the dam occurs, an emergency action plan shall be submitted to and approved by the Department and local emergency management officials.

Copyright © 1996 Commonwealth of Pennsylvania

(c) In addition to the requirements in subsections (a) and (b), the owner of a high hazard dam shall post notices in public places in areas that may be affected by the failure of the dam; for example, areas where public water or sewage service may be interrupted. The notice shall indicate that copies of the emergency action plan are available for review at the appropriate county and municipal emergency management offices. Also, the notice shall be posted by the owner in the following public places within each political subdivision situated within the inundation area downstream of the dam:

(1) The city, borough or township building.
(2) The police department offices.
(3) The fire company halls.
(4) The tax collector's office.

Code § 105.135 (relating to dam hazard emergencies).

§ 105.135. Dam hazard emergencies.

(a) For the purposes of this section, a dam hazard emergency means a condition which the Department, permittee or owner of the dam reasonably finds constitutes an imminent threat to life or property above or below a dam, whether arising from the condition of the dam and appurtenant works or extraordinary natural conditions, affecting the safety and stability of the dam, including, but not limited to, flood, earthquake, fire and ice jam.

(b) The emergency procedures and the emergency warning system and operation plan required by §§ 105.63 and 105.134 (relating to emergency procedures; and emergency action plan) shall be followed by the permittee and owner of a dam or reservoir in the event of an actual or potential dam hazard emergency.

(c) If a dam hazard emergency exists, the Department and the permittee or owner of the dam shall immediately notify appropriate emergency management officials of the existence of the hazard and request the authorities to initiate

appropriate action to assure protection of life and property; and the permittee or owner shall immediately take the steps as are necessary to prevent dam failure or loss of life or property, including, but not limited to, the following:

(1) Draw down of the reservoir.

(2) Reinforcement of the dam structure.

(3) Breach or removal of the dam.

(4) Removal of debris.

(5) Repair or installation of structures necessary to assure the stability and safety of the dam.

(d) The Department, upon determining that a dam hazard emergency exists, will notify the owner immediately to take steps the Department determines are necessary to prevent dam failure or loss of life or property.

Cross References

This section cited in 25 Pa. Code § 105.136 (relating to unsafe dams).

§ 105.136. Unsafe dams.

(a) For purposes of this section, an unsafe dam means a dam which meets one or more of the following criteria:

(1) A dam with deficiencies of such a nature that if not corrected could result in the failure of the dam with subsequent loss of lives or substantial property damage. This determination is based on good engineering judgment or the application of the guidelines established for the National Dam Inspection Program.

(2) A dam classified as unsafe under the National Dam Inspection Program.

(3) A dam declared as unsafe by the Department.

(b) The owner of an unsafe dam shall do the following:

(1) Immediately notify the Department upon receipt of any information indicating the dam is unsafe.

(2) Drain the dam as approved or required by the Department.

(3) Within time limits established by the Department, submit a plan for removal of the dam, a plan for repair of the dam or an application for a permit authorizing modification of the dam under subsection (c).

(4) Following approval of the plan or permit by the Department, undertake and complete actions to remove or repair the dam or implement the modifications to the dam within the time limits set by the Department.

(c) The Department may issue a permit for modification of an unsafe dam, under section 9 of the act (32 P. S. § 693.9), which authorizes the owner of an

Copyright © 1996 Commonwealth of Pennsylvania

unsafe dam to modify the dam within the time prescribed in the permit to meet the requirements of the act and this chapter. The permit shall be conditioned upon:

(1) Compliance by the owner of the dam with a prescribed schedule for correction or modification of the unsafe condition within the shortest time period technically feasible and economically achievable.

(2) Implementation by the owner of the dam of measures deemed necessary by the Department to reduce risks to health and safety pending correction or modification of the unsafe condition, including but not limited to special provisions relating to operation, emergency planning, monitoring and warning systems, and development of an alternative source of water supply if the dam serves as a water supply dam.

(d) In determining whether to require removal of an unsafe dam or to permit the owner to modify the dam, the Department will consider whether there is a substantial adverse impact to the public health and safety which will result from the draining and removal of the dam, and whether that adverse impact outweighs the danger to public health and safety, which outweighing will result in allowing the unsafe dam to remain until it has been modified.

(e) At the discretion of the Department, a public hearing may be held in the affected area prior to the issuance of a permit authorizing modification of an unsafe dam over a period of more than 6 months, to inform affected communities of the risks which may result from allowing the unsafe dam to remain standing or to impound water during the time necessary to complete the modifications.

(f) If the Department finds that conditions upon which the permit authorizing modification was issued have substantially changed or that the owner does not meet the schedule for modification contained in the permit, the Department will review the status of the dam. An extension of the time period for completion of a modification may be issued by the Department if the owner has proceeded in good faith with the previous schedule of modification and the requirements of subsections (c) and (d) are met.

(g) Nothing in this section may be construed to limit the power of the Department to take immediate action, prior to public hearing, to do one or more of the following:

(1) Revoke or suspend a permit where deemed necessary by the Department to protect public health and safety.

(2) Order correction or abatement of a dam hazard emergency under § 105.135 (relating to dam hazard emergencies)

(3) Take another action authorized by law.

PERMITS

§ 105.151. Permit applications for construction or modification of culverts and bridges.

In addition to the information required under § 105.13 (relating to permit applications—information and fees), applications for permits under this subchapter for the construction or modification of culverts and bridges shall contain the following:

(1) Plans showing the location, type, size and height of the proposed bridge or culvert and detailing the topographic features, elevations and structures so as to enable an appraisal of the hazard potential of the structure.

(2) A description of the character of the stream bed and banks and a profile of the stream for a reasonable distance above and below the proposed site, showing slopes of bed, normal water surface and flood water surface.

(3) A hydrologic and hydraulic analysis which shall include: data on size, shape and characteristics of the watershed; the amount and frequency of the design flood; the hydraulic capacity of the structure; the hydraulic capacity of the channel upstream and downstream; and, where flooding is a problem, flood damage and backwater analysis.

(4) Other information as the Department may require.

§ 105.152. Permit applications for operation and maintenance of existing culverts and bridges.

(a) In addition to information required by § 105.13 (relating to permit applications—information and fees), a permit application for the operation and maintenance of existing culverts and bridges shall give the following information:

(1) Plans showing the location, type, size and height of the existing bridge or culvert and detailing the topographic features, elevations and structures so as to enable an appraisal of the hazard potential of the structure.

DESIGN CRITERIA FOR CONSTRUCTION OR MODIFICATION

§ 105.161. Hydraulic capacity.

(a) Bridges and culverts shall be designed and constructed in accordance with the following criteria:

(1) The structure shall pass flood flows without loss of stability.

(2) The structure may not create or constitute a hazard to life or property, or both.

(3) The structure may not materially alter the natural regimen of the stream.

(4) The structure may not so increase velocity or direct flow in a manner which results in erosion of stream beds and banks.

(5) The structure may not significantly increase water surface elevations.

(6) The structure shall be consistent with local flood plain management programs.

(b) In determining flood flows and frequencies for purposes of this subchapter, hydrologic analysis shall be by methods generally accepted in the engineering profession.

(c) The general criteria for design flows are as follows:

(1) Rural area—25-year frequency flood flow.

(2) Suburban area—50-year frequency flood flow.

(3) Urban area—100-year frequency flood flow.

(d) The determination of flood flows for design shall be made with reasonable consideration of development which may alter the runoff characteristics of the watershed during the anticipated life of the structure. Specific design requirements in subsection (c) may be varied to fit the conditions at the site and the requirements of flood plain management regulations and ordinances.

(e) The structures shall pass the 100-year frequency flood with less than a 1.0-foot increase in the natural unobstructed 100-year water surface elevation, except where the structure would be located in a floodway which is delineated on a FEMA map, in which case no increase in the 100-year water surface elevation will be permitted. Exceptions to this criteria may be approved by the Department if the applicant prepares a risk assessment which demonstrates, and the Department finds, that the structure will not significantly increase the flooding threat to life and property or the environment, and if applicable, is consistent with municipal floodplain management programs adopted under the National Flood Insurance

Program and a FEMA Flood Insurance Study. This information may be obtained from the Department of Community Affairs, Floodplain Management Division, Forum Building, Harrisburg, Pennsylvania 17120.

Authority

The provisions of this § 105.161 amended under the Dam Safety and Encroachments Act (32 P. S. §§ 693.1–693.27); The Clean Streams Law (35 P. S. §§ 691.1—691.1001); section 7 of the act of June 14, 1923 (P. L. 704, No. 294) (32 P. S. § 597); sections 514, 1901-A, 1908-A, 1917-A and 1920-A of The Administrative Code of 1929 (71 P. S. §§ 194, 510-1, 510-8, 510-17 and 510-20); and the Flood Plain Management Act (32 P. S. §§ 679.101—679.601).

Source

The provisions of this § 105.161 adopted August 11, 1978, effective August 28, 1978, 8 Pa.B. 2229; amended September 26, 1980, effective September 27, 1980, 10 Pa.B. 3843; amended October 11, 1991, effective October 12, 1991, 21 Pa.B. 4911. Immediately preceding text appears at serial page (117699).

§ 105.162. Multiple pipes and spans.

Multiple pipes and multiple span bridges and culverts which may tend to collect debris, contribute to the formation of ice jams and increase head losses shall be avoided to the maximum practicable extent. Crossings of less than 15 feet shall be by one span, except where conditions make it impractical to effect the crossing without multiple spans.

Source

The provisions of this § 105.162 adopted September 26, 1980, effective September 27, 1980, 10 Pa.B. 3843.

§ 105.163. Bridge piers.

(a) Bridge piers shall be kept to a minimum in number and cross-sectional area and shall be designed to offer the least obstruction to the passage of water and ice, consistent with safety.

(b) Bridge piers in channels subject to unstable or super critical flow shall require special investigation and shall be so designed as to prevent the creation of excessive backwater and waves downstream of the pier.

Source

The provisions of this § 105.163 adopted September 26, 1980, effective September 27, 1980, 10 Pa.B. 3843.

§ 105.164. Bridge abutments.

(a) Bridge abutments shall be set well into the banks in such manner as to assure minimal increase in flood elevations.

(b) Bridge abutments shall be aligned with the flow of the stream. The Department may require, in its discretion, the construction of wing walls at the upstream side of the bridge to assist in directing flood flows through the bridge opening.

Source

The provisions of this § 105.164 adopted September 26, 1980, effective September 27, 1980, 10 Pa.B. 3843.

§ 105.165. Height of bridges and culverts.

Bridges and culverts shall be of sufficient height and clearance to allow the use of the stream or other body of water in its customary manner.

Source

The provisions of this § 105.165 adopted September 26, 1980, effective September 27, 1980, 10 Pa.B. 3843.

§ 105.166. Placement of culverts.

(a) Culverts shall be aligned with the stream flow.

(b) Culverts shall be of sufficient width to minimize narrowing of the stream channel.

(c) The upstream side of culverts shall be protected by wing walls or other structures sufficient to assist in directing flood flows to and through the culvert opening.

Source

The provisions of this § 105.166 adopted September 26, 1980, effective September 27, 1980, 10 Pa.B. 3843.

OPERATION AND MAINTENANCE

§ 105.171. Maintenance.

(a) The owner or permittee of a culvert or bridge is responsible for maintaining the structure opening thereof in good repair and assuring that flood carrying capacity of the structure is maintained. The owner or permittee shall inspect the opening and approach of the culvert or bridge at regular intervals of not less than once each year and shall, after obtaining the verbal or written approval of the Department, remove silt and debris which might obstruct the flow of water through the structure. It shall be assumed that the flow of water is obstructed when there has been a reduction of the effective area of the structure opening of greater than 10%. Debris shall be disposed of in accordance with the Solid Waste Management Act (35 P. S. §§ 6018.101—6018.1003), the Municipal Waste Planning, Recycling and Waste Reduction Act (53 P. S. §§ 4000.101—4000.1904) and The Clean Streams Law (35 P. S. §§ 691.1—691.1001).

Copyright © 1996 Commonwealth of Pennsylvania

(b) Cleaning and maintenance operations shall be conducted to minimize erosion and sedimentation resulting therefrom.

(c) Removal of silt and debris from the stream channel for the purposes of culvert or bridge maintenance shall be accomplished in accordance with the *Standards for Channel Cleaning at Bridges and Culverts*. A copy of this document can be obtained from the Bureau of Dams and Waterway Management, Division of Waterways and Stormwater Management, Post Office Box 8554, Harrisburg, Pennsylvania 17105-8554.

§ 105.172. Inadequate or collapsed structures.

(a) The owner or permittee of a bridge or culvert shall immediately inform the Department of the collapse of the structure or a portion thereof or of the existence of unusual conditions threatening the structural integrity of the bridge or culvert, including, but not limited to, the following:

(1) Undercutting of piers or abutments.

(2) Excessive cracking of bridge or culvert surfacing.

(3) Severe deterioration of piers and supports.

(4) Diversion of all or part of the stream flow through a channel not within the normal span of the structure.

(b) Whenever a bridge or culvert or a portion thereof has collapsed or is in imminent danger thereof, the owner or permittee thereof shall immediately remove the collapsed portions to an area outside the floodplain of the stream and do one of the following:

(1) Completely remove the structure.

(2) Repair the structure in accordance with plans submitted to and approved by the Department.

(c) If the Department finds that the inadequate size, improper placement, collapse or imminent collapse of a bridge or culvert creates an immediate danger of stream obstruction and a hazard to life or property which not to permit the issu-

ance of an order or notice to the owner or permittee or if the owner or permittee cannot be readily contacted in sufficient time to assure adequate protection of life or property, the Department may exercise its powers under section 14 of the act (32 P. S. § 693.14) to remove or repair the conditions and take the actions it deems necessary to protect life and property and recover the cost and expense thereof from the owner or permittee.

GENERAL PROVISIONS

§ 105.181. Scope.

Except as provided in §§ 105.3 and 105.12 (relating to scope; and waiver of permit requirements), this subchapter applies to the construction, alteration, enlargement, repair and removal of a stream enclosure or a culvert in regulated waters of this Commonwealth of upstream to downstream length in excess of 100 feet.

Source

The provisions of this § 105.181 adopted August 11, 1978, effective August 28, 1978, 8 Pa.B. 2229; amended September 26, 1980, effective September 27, 1980, 10 Pa.B. 3843. Immediately preceding text appears at serial pages (38877) to (38878).

§ 105.182. [Reserved].

PERMITS

§ 105.191. Permit applications for construction or modification of stream enclosures.

In addition to the information required by § 105.13 (relating to permit applications—information and fees), applications for permits under this subchapter for the construction and modification of stream enclosures shall contain the following information:

(1) The location, type, size and height of the proposed stream enclosure.

(2) A profile of the stream for a reasonable distance above and below the proposed site showing slopes of bed, normal water surface and flood water surface.

(3) Estimates of flood frequencies and flood flows at the site of the proposed structure, including such information as can be reasonably obtained regarding actual rainfall and flood flow records on the stream.

(4) An analysis of the hydraulic capacity of the proposed structure.

(5) A description of the purposes of the proposed structure.

(6) A complete listing and description of other enclosures and culverts, bridges, dams and other water obstructions located a reasonable distance upstream and downstream of the proposed enclosure.

(7) Proof of title or adequate flowage and other easements for lands included in the site of the proposed structure, including lands which may be subject to flooding by backwater from the structure during a 100-year flood.

(8) Other information as the Department may require.

Source

The provisions of this § 105.191 adopted August 11, 1978, effective August 28, 1978, 8 Pa.B. 2229; amended September 26, 1980, effective September 27, 1980, 10 Pa.B. 3843. Immediately preceding text appears at serial page (38878).

§ 105.192. Permit applications for operation and maintenance of existing stream enclosures.

(a) In addition to information required by § 105.13 (relating to permit applications—information and fees), a permit application for the operation and maintenance of existing stream enclosures shall give the following information:

(1) The location, type, size and height of the proposed stream enclosure.

(2) A profile of the stream for a reasonable distance above and below the existing site.

(3) An analysis of the hydraulic capacity of the existing structure.

(4) A description of the purposes of the existing structure.

(5) Other information the Department may require.

Source

The provisions of this § 105.192 adopted September 26, 1980, effective September 27, 1980, 10 Pa.B. 3843.

CRITERIA FOR APPROVAL OF CONSTRUCTION OR MODIFICATION

§ 105.201. Hydraulic capacity.

(a) A stream enclosure shall be designed and constructed to pass the flows from a flood of 100-year frequency, with no more than a 1.0-foot increase in the 100-year water surface elevation over the water surface elevation of the natural unimpeded 100-year flow, except where the stream enclosure would be located in a floodway which is delineated on a FEMA map in which case no increase in the 100-year water surface elevation will be permitted. The 100-year discharge shall be based upon the degree of development of the contributing watershed projected throughout the lifetime of the structure. The Department may require capacity in excess of that necessary to carry the flows from a 100-year flood if it determines the capacity is necessary to protect the structure or to assure the safety of life and property upstream or downstream of the enclosure.

(b) An exception to the criteria of subsection (a) may be approved by the Department if the applicant prepares a risk assessment which demonstrates, and the Department finds, that the structure will not significantly increase the flooding threat to life, property or the environment, and if applicable, is consistent with municipal floodplain management programs adopted pursuant to the National Flood Insurance Program and a FEMA Flood Insurance Study. CONSTRUCTION AND MAINTENANCE

§ 105.221. Scope.

Except as provided in §§ 105.3 and 105.12 (relating to scope; and waiver of permit requirements), this subchapter applies to channel changes in the regulated waters of this Commonwealth, and to dredging in the regulated waters of this Commonwealth conducted for purposes of construction, operation or maintenance of a dam, water obstruction or encroachment.

PERMITS

§ 105.231. Permit applications for construction or modification of channel changes and dredging for facility construction and maintenance.

(a) *Construction or modification of channel changes.* Construction or modification of channel changes includes the following:

(1) In addition to the information required by § 105.13 (relating to permit applications—information and fees), permit applications under this subchapter for the construction or modification of channel changes shall contain the following information:

(i) The location and length of the proposed channel change.

(ii) A stream profile for a reasonable distance upstream and downstream of the proposed change, showing bed slopes, normal water surface and depths, flood water surfaces, existing obstructions and the location of public and industrial water supply intake.

(iii) Cross-channel sections necessary to indicate the scope of the proposed work.

(iv) Estimates of flood frequencies and flood flows at the site of the proposed channel change, including information reasonably available regarding actual rainfall and flood flow records on the stream.

(v) A description of the purposes of the proposed channel change.

(vi) A plan for the disposal of excavated material.

(vii) Proof of title or adequate flowage and other easements for lands included in the site of the proposed channel change.

(2) The Department may require additional information or waive one or more of the requirements of paragraph (1) in specific cases.

(b) *Dredging.* Dredging includes the following:

(1) In addition to the information required by § 105.13, permit applications for dredging for facility construction and maintenance under this subchapter shall contain the following information:

(i) The location and area of the proposed dredging.

(ii) A stream profile for a reasonable distance upstream and downstream of the proposed dredging showing normal water surface and depths.

(iii) A description of the equipment to be employed in the dredging operation and a plan for the disposal of the dredge soil.

(iv) Proof of title or easements for lands included in the site of the proposed dredging.

(2) The Department may require additional information or waive one or more of the requirements of paragraph (1) in specific cases.

The provisions of this § 105.231 adopted August 11, 1978, effective August 28, 1978, 8 Pa.B. 2229; amended September 26, 1980, effective September 27, 1980, 10 Pa.B. 3843. Immediately preceding text appears at serial page (38882).

Notes of Decisions

Dredging

The terms and conditions attached to a dredging permit are terms and conditions of the permit, rather than rules and regulations. *Warren Sand and Gravel Co. v. Department of Environmental Resources*, 341 A.2d 556 (Pa. Cmwlth. 1975).

Editor's Note: Chapter 105 has been extensively amended since this case was decided. The case actually referred to §§ 105.21 and 105.77.

§ 105.232. Maintenance dredging.

Permits issued for the construction, operation and maintenance of water obstruction or encroachment shall include specific authorization for maintenance dredging.

Source

The provisions of this § 105.232 adopted September 26, 1980, effective September 27, 1980, 10 Pa.B. 3843.

§ 105.233. Removal of sand, gravel and other valuable minerals.

The removal of sand, gravel or other valuable minerals from submerged lands of this Commonwealth in quantities which are commercially usable or marketable, in conjunction with a channel change or dredging permitted under this chapter, shall be subject to the royalty and agreement provisions of the act of July 31, 1970 (P. L. 699, No. 225) and the act of December 3, 1970 (P. L. 834, No. 275) (71 P. S. § 468) (repealed).

CRITERIA FOR APPROVAL FOR CONSTRUCTION OR MODIFICATION

§ 105.241. Flood effect.

No channel change which creates a flooding potential greater than that created by the natural conditions of the existing channel will be approved.

Source

The provisions of this § 105.241 adopted August 11, 1978, effective August 28, 1978, 8 Pa.B. 2229; amended September 26, 1980, effective September 27, 1980, 10 Pa.B. 3843. Immediately preceding text appears at serial pages (3882) to (3883).

§ 105.242. Channel alignment and cross section.

(a) Abrupt bends in channel changes are prohibited, unless necessitated by the alignment of existing bridges or encroachments.

(b) The relocated channel shall rejoin the natural channel of the stream at a point on the permittee's property to insure that alignment of stream flow at the downstream property line is identical to the flow alignment prior to the channel change.

(c) A grade of the changed channel shall not be significantly greater than or significantly less than the grade of the original channel, unless the length of the relocated channel requires.

(d) Where the width of a channel change is greater than the width of the preexisting channel, provision shall be made to assure proper depth and velocity of normal flows, subchannels and installation of stream habitat improvement devices.

(e) In streams having substantial fisheries value, provision shall be made in channel changes to maintain existing pool-riffle ratios.

Source

The provisions of this § 105.242 adopted September 26, 1980, effective September 27, 1980, 10 Pa.B. 3843.

§ 105.243. Temperature of water and shading.

Channel changes shall be so designed and implemented to assure that the water temperature does not substantially increase over that in the preexisting channel. Where necessary, provisions shall be made to provide adequate shading of the relocated channel to duplicate, to the maximum extent possible, the preexisting conditions.

Source

The provisions of this § 105.243 adopted September 26, 1980, effective September 27, 1980, 10 Pa.B. 3843.

§ 105.244. Protection of fish life.

A low flow channel and habitat improvement device will be required when, in the opinion of the Fish Commission, it is necessary to provide a satisfactory channel for maintenance of fish life.

Source

The provisions of this § 105.244 adopted September 26, 1980, effective September 27, 1980, 10 Pa.B. 3843.

§ 105.245. Disposal of waste materials.

(a) Discharge of dredged material into the regulated waters of this Commonwealth shall be subject to Subchapter J (relating to discharges of dredged and fill material).

(b) Dredged spoil and sludge deposits collected during the operation shall be deposited in a location and a manner approved by the Department.

(c) Bilge, ballast or wastewater from dredging operations shall not be discharged to the stream without removal of oils, petroleum products or toxic or hazardous compounds as defined by the Conservation and Recovery Act of 1976 (42 U.S.C.A. §§ 6901—6986) in a manner approved by the Department.

PERMITS

§ 105.261. Permit applications for construction or modification of fills, levees, floodwalls and streambank retaining devices.

In addition to the information required by § 105.13 (relating to permit applications—information and fees), applications for permits for construction or modification of structures under this subchapter shall contain the following information:

(1) A plan detailing the location of the structures and properties 1000 feet upstream and downstream of the proposed fill, levee or similar structure and within the flood plain of the flood of record on both sides of the stream or body of water.

(2) Basement and first floor elevations of structures indicated on the plan required by paragraph (1).

(3) A complete hydraulic and hydrologic report on the proposed project, including, if the Department so requires, a backwater analysis of the project.

Copyright © 1996 Commonwealth of Pennsylvania

(4) Complete cross sections of the stream and floodway of the flood or record.

(5) Stream profiles showing the bed slope and the normal and flood water elevations for points sufficiently upstream and downstream in effect on the project.

(6) The type of materials to be used on the fill, levee or similar structure.

(7) Plans for the protection of the fill, levee or similar structure from erosion, both during and after construction.

(8) The design flood for the fill, levee or similar structure.

(9) A copy of the local flood plain management regulations or ordinances.

(10) Plans for interior drainage.

(11) Other information as the Department may require.

Source

The provisions of this § 105.261 adopted August 11, 1978, effective August 28, 1978, 8 Pa.B. 2229; amended September 26, 1980, effective September 27, 1980, 10 Pa.B. 3843. Immediately preceding text appears at serial page (38884).

§ 105.262. Permit applications for existing fills, levees, floodwalls and streambank retaining devices.

In addition to the information required by § 105.13 (relating to permit applications—information and fees), applications for permits for existing structures under this subchapter shall contain the following information:

(1) A plan detailing the location of the existing fill, levee, floodwall or streambank retaining device.

(2) Cross sections of the stream and floodway.

(3) The type of all materials used in the fill, levee, floodwall or streambank retaining device.

(4) Plans of interior drainage, if available.

(5) Other information as the Department may require.

Source

The provisions of this § 105.262 adopted August 11, 1978, effective August 28, 1978, 8 Pa.B. 2229; amended September 26, 1980, effective September 27, 1980, 10 Pa.B. 3843. Immediately preceding text appears at serial pages (38884) to (38885).

DESIGN CRITERIA FOR APPROVAL FOR CONSTRUCTION OR MODIFICATION

§ 105.271. General criteria.

(a) An application for a proposed levee, fill or similar structure in or along the regulated waters of this Commonwealth will not be approved by the Department where one or more of the following will occur:

(1) It will increase flood heights, either on the opposite bank or upstream and flood easements or flood protection has not been provided.

(2) It will create erosive velocities in the stream and appropriate protection has not been provided.

(3) It will increase flood damages downstream through a loss of flood plain storage.

(b) An application for a proposed levee, fill or similar structure within the floodway of a regulated water of this Commonwealth will not be approved by the Department unless the applicant demonstrates that the project is consistent with local floodplain management programs.

Source

The provisions of this § 105.271 adopted August 11, 1978, effective August 28, 1978, 8 Pa.B. 2229; amended September 26, 1980, effective September 27, 1980, 10 Pa.B. 3843. Immediately preceding text appears at serial page (38885).

§ 105.272. Waste materials.

Waste materials of any type may not be used in the construction of fills, levees or similar structures, except under the Solid Waste Management Act (35 P. S. §§ 6018.101—6018.1003), the Municipal Waste Planning, Recycling and Waste Reduction Act (53 P. S. §§ 4000.101—4000.1904) and related rules and regulations.

Authority

The provisions of this § 105.272 amended under the Dam Safety and Encroachments Act (32 P. S. §§ 693.1–693.27); The Clean Streams Law (35 P. S. §§ 691.1—691.1001); section 7 of the act of June 14, 1923 (P. L. 704, No. 294) (32 P. S. § 597); sections 514, 1901-A, 1908-A, 1917-A and 1920-A of The Administrative Code of 1929 (71 P. S. §§ 194, 510-1, 510-8, 510-17 and 510-20); and the Flood Plain Management Act (32 P. S. §§ 679.101—679.601).

§ 105.274. Top width of levees.

The top width of a levee shall not be less than 10 feet.

Source

The provisions of this § 105.274 adopted September 26, 1980, effective September 27, 1980, 10 Pa.B. 3843.

§ 105.275. Interior drainage.

Adequate facilities shall be provided to drain the interior area behind the levee or floodwall.

Source

The provisions of this § 105.275 adopted September 26, 1980, effective September 27, 1980, 10 Pa.B. 3843.

§ 105.276. Freeboard allowance.

The height of a levee or floodwall shall provide an allowance for freeboard above the design flood of the structure.

Source

The provisions of this § 105.276 adopted September 26, 1980, effective September 27, 1980, 10 Pa.B. 3843.

MAINTENANCE AND REPAIR

§ 105.281. Maintenance and repair of levees or floodwalls.

(a) The owner of a levee or floodwall shall inspect the levee or floodwall and appurtenant structures, including drainage facilities, at least annually and shall comply with § 105.53 (relating to inspections by owners and inspection reports).

(b) Trees and other vegetation with deep roots shall not be allowed on a levee used for flood control purposes, and vegetation shall at all times be controlled.

Source

The provisions of this § 105.281 adopted August 11, 1978, effective August 28, 1978, 8 Pa.B. 2229; amended September 26, 1980, effective September 27, 1980, 10 Pa.B. 3843. Immediately preceding text appears at serial page (38885).

§ 105.282. Maintenance of fills.

Fills shall at all times be maintained in a manner to prevent erosion and to assure the stability of the slopes.

Source

PERMITS

§ 105.301. Permit applications for construction or modification.

In addition to the information required under § 105.13 (relating to permit applications—information and fees), applications for stream crossings shall contain the following, where applicable:

(1) The shore lines of the affected body of water, including both high and low water marks.

(2) Existing structures and stream crossings in the vicinity of the proposed crossings.

(3) The alignment of the proposed pipe or cable.

(4) The depth of the proposed pipe or cable and the clear depth below the data plane to be afforded by the pipe or cable in navigable channels.

(5) A cross section of the stream from bank to bank with the location of the stream crossing to be affixed thereon.

(6) In the case of outfalls, the discharge capacity of the structures.

(7) A statement indicating the purpose of the proposed stream crossing.

(8) The amount and type of cover material.

(9) Adequate provisions for shut-off in the event of break or rupture.

(10) Other information as the Department may require.

Source

The provisions of this § 105.301 adopted August 11, 1978, effective August 28, 1978, 8 Pa.B. 2229; amended September 26, 1980, effective September 27, 1980, 10 Pa.B. 3843. Immediately preceding text appears at serial page (38888).

§ 105.302. Permit applications for existing stream crossings by pipelines for conveyance of petroleum products and gas.

In addition to the information required under § 105.13 (relating to permit applications—information and fees), applications for existing stream crossings by pipelines for conveyance of petroleum products and gas shall contain the following:

(1) The shore lines of the affected body of water, including both high and low water marks.

(2) The alignment and depth of the pipe or cable, and the clear depth below the data plane afforded by the pipe in navigable channels.

(3) A cross section of the stream from bank to bank with the location of the pipeline affixed thereon.

(4) The amount and type of cover material.

(5) Provisions for shut-off in the event of break or rupture.

(6) Other information as the Department may require.

Source

The provisions of this § 105.302 adopted September 26, 1980, effective September 27, 1980, 10 Pa.B. 3843.

CRITERIA FOR APPROVAL OF CONSTRUCTION OR MODIFICATION

§ 105.311. General criteria.

In evaluating applications for stream crossings, outfalls, headwalls, pipelines, aerial crossings and other analogous structures, the Department will not approve an application if one or more of the following is true:

(1) The stream crossings are placed in such a manner as to be displaced by flood waters.

(2) The stream crossing alters the cross section of the stream and its banks.

(3) There is unnecessary paralleling or crossing of streams by pipelines or cables.

(4) Pipelines or cables are placed on the bed of streams.

Source

The provisions of this § 105.311 adopted August 11, 1978, effective August 28, 1978, 8 Pa.B. 2229; amended September 26, 1980, effective September 27, 1980, 10 Pa.B. 3843. Immediately preceding text appears at serial page (38888).

§ 105.312. Cover material.

No waste material of any type may be used as cover material for stream crossings.

Source

The provisions of this § 105.312 adopted August 11, 1978, effective August 28, 1978, 8 Pa.B. 2229; amended September 26, 1980, effective September 27, 1980, 10 Pa.B. 3843. Immediately preceding text appears at serial page (38888).

§ 105.313. Pipelines under stream beds.

(a) Pipelines under stream beds shall be located such that there will be a minimum of 3 feet of cover between the top of the pipe or encasement and the lowest point in the stream bed; provided, that if the pipeline is in rock, it shall have the depth of granular soil plus 6 inches for cover, but never less than 1 foot of total cover.

(b) Pipelines under the stream bed shall be as near to horizontal as possible.

(c) The Department may require additional information or waive the requirements of subsection (a) in specific cases.

Source

GENERAL PROVISIONS

§ 105.321. Scope.

Except as provided in §§ 105.3 and 105.12 (relating to scope; and waiver of permit requirements), this subchapter applies to the construction, operation and maintenance of docks, wharves and bulkheads in the regulated waters of this Commonwealth.

Source

The provisions of this § 105.321 adopted August 11, 1978, effective August 28, 1978, 8 Pa.B. 2229; amended September 26, 1980, effective September 27, 1980, 10 Pa.B. 3843. Immediately preceding text appears at serial page (38889).

PERMITS

§ 105.331. Permit applications.

In addition to the information required under § 105.13 (relating to permit applications—information and fees), applications for new and existing docks, wharves and bulkheads shall contain the following information:

(1) The exact location of the structure.

Copyright © 1996 Commonwealth of Pennsylvania

(2) A plan showing the dimensions of the structure, and if applicable, the dimensions of the mooring area.

(3) A plan indicating the relation of the structure and mooring area to the banks and channel, neighboring structures and mooring areas, the navigation channel and the normal pool elevation or ordinary low water mark.

(4) Cross sections indicating elevations of structures, location of pilings and water depth.

(5) The purposes for which the structure will be used.

(6) Other information the Department may require.

Authority

The provisions of this § 105.331 amended under the Dam Safety and Encroachments Act (32 P. S. §§ 693.1–693.27); The Clean Streams Law (35 P. S. §§ 691.1—691.1001); section 7 of the act of June 14, 1923 (P. L. 704, No. 294) (32 P. S. § 597); sections 514, 1901-A, 1908-A, 1917-A and 1920-A of The Administrative Code of 1929 (71 P. GENERAL PROVISIONS

§ 105.361. Scope.

Except as provided in §§ 105.3 and 105.12 (relating to scope; and waiver of permit requirements), this subchapter applies to dredging in the regulated waters of this Commonwealth for sand, gravel and other minerals for the purposes of commercial exploitation. This subchapter shall not be construed to restrict the Department in managing the Commonwealth's proprietary interests under the act of July 31, 1970 (P. L. 699, No. 225) (71 P. S. § 468) (repealed), repealed by the act of December 3, 1970 (P. L. 834, No. 275); section 15 of the act (32 P. S. § 693.15); and section 1908-A(3) of The Administrative Code of 1929 (71 P. S. § 510-8(3)), from exercising its discretion to issue or not to issue permit agreements or to impose terms and conditions in permit agreements that it deems to be in the best interests of the Commonwealth; in the event, however, that the Department issues a permit agreement conveying the Commonwealth's proprietary interests in a deposit of sand, gravel or other minerals, this subchapter constitutes the minimum requirements for dredging under the Commonwealth's regulatory authority under the act.

Source

The provisions of this § 105.365 adopted August 11, 1978, effective August 28, 1978, 8 Pa.B. 2229; reserved September 26, 1980, effective September 27, 1980, 10 Pa.B. 3843. Immediately preceding text appears at serial page (38893).

PERMITS

§ 105.371. Permits: content of application.

In addition to the requirements of § 105.13 (relating to permit applications—information and fees), applications for commercial dredging permits shall contain the following information:

(1) The delineation of areas to be dredged, with reference to river miles of distances from fixed reference points or sufficient courses and distances referenced to permanent shore points to allow a fix to be made on the boundary points of a dredging area in a lake.

(2) Stream depths in the proposed dredging area if known or approximate estimated depths, if accurate measures are not available.

(3) The equipment to be employed in the dredging operation and its capabilities.

(4) The proposed rate of production.

(5) The location of public and industrial water supply intakes.

(6) A plan for the disposal of solid waste, dredge spoil and sewage from the dredging vessel.

(7) Other information as the Department may require.

Source

The provisions of this § 105.371 adopted September 26, 1980, effective September 27, 1980, 10 Pa.B. 3843.

§ 105.372. Prior requisite approvals.

Provided the other requirements of this subchapter are met, approval by the Department of dredging permit applications is conditioned upon the applicant's obtaining a permit/agreement under the act of July 31, 1970 (P. L. 699, No. 225) (71 P. S. § 468) (repealed), repealed by the act of December 3, 1970 (P. L. 834, No. 275) or an interest in land under section 15 of the act (32 P. S. § 693.15), where the bed of the regulated waters is owned by the Commonwealth.

OPERATIONAL CRITERIA

§ 105.381. Location of dredging.

(a) Dredging may not occur within 500 feet of a bridge pier or abutment.

(b) Dredging may not occur within 5000 feet above a public water supply intake unless the applicant can satisfactorily demonstrate to the Department that drinking water standards for turbidity will not be exceeded and no other adverse effects on the operations of a water user will occur. Water supplies within 5 miles downstream of the dredging operation shall be notified of proposed dredging or start up, or both, of operations. The applicant/permittee shall provide proof of the notification.

(c) Dredging may not occur within a distance of the channel or island shore line at normal pool less than the depth of the dredging, but in no event, less than 125 feet.

(d) Dredging may not occur in reaches of streams where water levels are controlled by dams if the water depth is less than 6 feet at normal pool.

(e) Dredging may not occur in, encroach upon or cause siltation in areas of riffles or shallow pools whenever the areas are contributing to the sustenance of game fish or endangered species in a free-flowing reach of a stream. Game fish includes species and varieties defined as such by 30 Pa.C.S. § 102 (relating to definitions). Endangered species include those species so defined by the Fish Commission, under 30 Pa.C.S. § 102 or defined by 50 CFR 17.12 (relating to endangered and threatened plants). A free-flowing reach of a stream includes a reach, segment or area of a stream except where a pool has been created by a dam.

Authority

The provisions of this § 105.381 amended under the Dam Safety and Encroachments Act (32 P. S. §§ 693.1–693.27); The Clean Streams Law (35 P. S. §§ 691.1—691.1001); section 7 of the act of June 14, 1923 (P. L. 704, No. 294) (32 P. S. § 597); sections 514, 1901-A, 1908-A, 1917-A and 1920-A of The Administrative Code of 1929 (71 P. S. §§ 194, 510-1, 510-8, 510-17 and 510-20); and the Flood Plain Management Act (32 P. S. §§ 679.101—679.601).

Source

The provisions of this § 105.381 adopted September 26, 1980, effective September 27, 1980, 10 Pa.B. 3843; amended October 11, 1991, effective October 12, 1991, 21 Pa.B. 4911. Immediately preceding text appears at serial pages (117724) to (117725).

Notes of Decisions

In remanding and ordering a new trial to determine whether a dredging company violated its permit by dredging too close to shore, the Court noted that the Department of Environmental Resources is authorized to impose conditions which preclude dredging within an established distance from the shore and that such conditions under statute and regulations, 71 P. S. § 510-8 and 25 Pa. Code § 150.381(c), impose a binding duty of care upon parties to a dredging contract. *Hawthorne v. Dravo Corp.* 460 A.2d 266 (Pa. Super. 1983).

§ 105.382. Washing and classification of materials.

Wash water from the classification process may not be returned to the stream, unless a permit in accordance with The Clean Streams Law (35 P. S. §§ 691.1—691.1001) has been obtained.

Source

The provisions of this § 105.382 adopted September 26, 1980, effective September 27, 1980, 10 Pa.B. 3843; amended February 1, 1985, effective February 2, 1985, 15 Pa.B. 361. Immediately preceding text appears at serial page (82601).

§ 105.383. Disposal of waste materials.

(a) The permittee shall not throw, discharge or deposit or cause or permit to be thrown, discharged or deposited from or out of a ship, barge or other floating craft employed in the dredging operation any refuse matter, including oil and petroleum products.

(b) Bilge, ballast or wastewater pumped from barges shall not be discharged to the stream without acceptable removal of oils or toxic compounds in a manner approved by the Department.

(c) Discharge of dredged material into the regulated waters of this Commonwealth is subject to Subchapter J (relating to discharges of dredged or fill material).

(d) Dredge spoil and sludge deposits collected during the operation shall be deposited in a location and a manner approved by the Department.

(e) Litter, refuse and sanitary waste from dredging vessels shall be disposed of in a manner approved by the Department.

Source

The provisions of this § 105.383 adopted September 26, 1980, effective September 27, 1980, 10 Pa.B. 3843.

§ 105.384. Protection of stream users.

(a) A dock or portage shall be constructed around the upstream face of the operation in order to facilitate navigation of small craft where the dredging operation will substantially obstruct the waterway.

(b) The permittee shall post signs 1000 feet upstream of where the dredge is operating and 500 feet from the downstream end of the dredging area warning users of the stream that dredging operations are in progress; the warnings shall be in large block printing, readable at a distance of 300 feet, and contain the warning, ''DANGER, DREDGING 1000 FEET AHEAD'' or ''DANGER, DREDGING 500 FEET AHEAD.''

GENERAL PROVISIONS

Sec.
105.391. Scope.

PERMITS

105.401. Permit applications.

CRITERIA FOR APPROVAL

105.411. General criteria.

OPERATION AND MAINTENANCE

105.421. General.
105.422. Use of heavy equipment.
105.423. Removal of temporary fill.

Cross References

This subchapter cited in 25 Pa. Code § 105.14 (relating to review of applications); 25 Pa. Code § 105.245 (relating to disposal of waste materials); and 25 Pa. Code § 105.383 (relating to disposal of waste materials).

GENERAL PROVISIONS

§ 105.391. Scope.

Except as provided in §§ 105.3 and 105.12 (relating to scope; and waiver of permit requirements), this subchapter applies to the discharge of dredged or fill material into the regulated waters of this Commonwealth.

Source

The provisions of this § 105.391 adopted September 26, 1980, effective September 27, 1980, 10 Pa.B. 3843.

PERMITS

§ 105.401. Permit applications.

In addition to the requirements of § 105.13 (relating to permit applications—information and fees) and other applicable requirements of this chapter, applications for discharges of dredged or fill material into the regulated waters of this Commonwealth shall contain the following information:

(1) The location of a public water supply intake located within 1 mile upstream and 10 miles downstream.

(2) The location of areas of shell-fish production.

(3) The impact of the activity upon a threatened or endangered species as identified under the Endangered Species Act of 1973 (7 U.S.C.A. § 136; 16 U.S.C.A. §§ 460l-9, 460k-1, 668dd, 715i, 715a, 1362, 1371, 1372, 1402 and 1531—1543), and the critical habitat of the species.

(4) The impact of the activity upon those species of aquatic life indigenous to the waterbody.

(5) The amount of percentage of the discharge that will consist of toxic material regulated under section 6 of the Toxic Substances Control Act (15 U.S.C.A. § 2605) or hazardous materials as defined by the Resource Conservation and Recovery Act of 1976 (42 U.S.C.A. §§ 6901—6986) in other than trace quantities.

(6) Other information as the Department may require.

The provisions of this § 105.401 adopted September 26, 1980, effective September 27, 1980, 10 Pa.B. 3843.

CRITERIA FOR APPROVAL

§ 105.411. General criteria.

The Department will not approve an application to discharge dredged or fill material into regulated waters of this Commonwealth, unless the applicant demonstrates to the Department a public benefit which outweighs the damage to the public natural resources, if one or more of the following is true:

(1) The discharge is to a spawning area during spawning season.

(2) The discharge would restrict or impede the movement of aquatic species indigenous to the waters or the passage of normal or expected high flows or cause the relocation of the waters unless the primary purpose of the fill is to impound waters.

Copyright © 1996 Commonwealth of Pennsylvania

(3) The discharge is into regulated waters of this Commonwealth, except wetlands, which are breeding, feeding or nesting areas for migratory water birds.

Subchapter K. DISBURSEMENTS OF MONIES FROM THE DAMS AND ENCROACHMENTS FUND

Sec.
105.431. General provisions.
105.432. Authorization for disbursement.

§ 105.431. General provisions.

(a) Fines collected under the penal provisions of the act and civil penalties collected under the act shall be paid into the treasury of the Commonwealth in a special fund known as the Dams and Encroachments Fund.

(b) Moneys paid into the Dams and Encroachments Fund may be disbursed at the discretion of the Department for use in the elimination of hazards to life, property and the environment resulting from unsafe dams, water obstructions and encroachments. The moneys shall be available for use by the Bureau of Dams and Waterway Management in addition to funds otherwise available to it.

(c) For purposes of this chapter, the full and normal range of activities of the Bureau will be considered to contribute to the elimination of hazards from unsafe dams, water obstructions and encroachments under subsection (b). Disbursement of moneys from the Dams and Encroachments Fund moneys may therefore be made for, but will not be limited to, the following purposes:

(1) Conducting investigations, tests and analyses as required to carry out the purposes of the act, including costs of entry; testing and sampling; and examining books, papers and records.

(2) Undertaking corrective action, repair work or removal to eliminate an actual or potentially dangerous or hazardous condition of a dam, water obstruction or encroachment as provided under section 14(c) of the act (32 P. S. § 693.14(c)).

(3) Purchasing contractual services and consultation from firms and individuals with relevant expertise in the field of safety of dams, water obstructions and encroachments.

(4) Purchasing materials, equipment, services and travel necessary for personnel training and provision of information and educational materials on the safety of dams, water obstructions and encroachments to schools, colleges, institutions and citizens.

(5) Covering extraordinary costs of litigation arising out of the enforcement of dam safety and encroachments laws of the Commonwealth, such as the printing of briefs and records, taking of depositions and expert witness fees.

Authority

Code Chapter 105 Appendix O (relating to private residential construction in wetlands; general permit BDWW-GP-15).

§ 105.442. Authorization for general permits.

(a) In accordance with this subchapter, the Department may issue general permits on a regional or Statewide basis for a category of dam, water obstruction or encroachment if the Department determines the following:

(1) The projects in the category are similar in nature.

(2) The projects in the category can be adequately regulated utilizing standardized specifications and conditions, including reference to specific criteria and requirements adopted by another Federal or State agency which adequately regulate the particular category of dam, water obstruction or encroachment.

(3) The projects which are in the category and meet the specifications and conditions will comply with the requirements for permit issuance in §§ 105.14—105.17 and 105.21 and the standards and requirements for design, construction, operation, maintenance and monitoring in this chapter.

(b) General permits issued under this subchapter may be issued on a Statewide basis or limited to specific watersheds, particular categories of streams or designated geographic regions.

(c) The Department will not issue a general permit for the following:

(1) A dam in size classifications A or B or hazard potential classifications 1 or 2, as defined in § 105.91 (relating to classification of dams or reservoirs).

(2) A dam used for storage of fluids or semifluids other than water the escape of which may result in air, water or land pollution or in danger to persons or property unless the impoundment created by the dam is otherwise adequately regulated by another program requiring individual permits issued by the Department or another Federal or State agency.

(3) A dam, water obstruction or encroachment which may present a substantial risk to life and property, requiring proof of financial responsibility under § 105.20 (relating to proof of financial responsibility).

Code Chapter 105 Appendix O (relating to private residential construction in wetlands; general permit BDWW-GP-15).

§ 105.443. Nature of a general permit; substitution for individual applications and permits.

(a) When the Department issues a general permit for a specified category of dam, water obstruction or encroachment on either a regional or Statewide basis, persons who intend to construct, operate, maintain, modify, enlarge or abandon a dam, water obstruction or encroachment in accordance with the specifications and conditions of the general permit may do so without filing an individual application for, and first obtaining, an individual permit.

(b) Use of an applicable general permit shall satisfy the permit requirements set forth in § 105.11 (relating to permit requirements), so long as:

(1) Activities are conducted in accordance with the specifications and conditions of the applicable general permit.

(2) The owner of the dam, water obstruction or encroachment complies with the registration requirements set forth in the general permits, as authorized by § 105.448 (relating to determination of applicability of a general permit).

eral permit BDWW-GP-10); and 25 Pa. Code Chapter 105 Appendix O (relating to private residential construction in wetlands; general permit BDWW-GP-15).

§ 105.444. Contents of general permits.

Each general permit issued by the Department will include, but not be limited to, the following contents:

(1) A concise description of the category of dam, water obstruction or encroachment covered by the general permit, including exceptions to that category.

(2) A specification of the watersheds, streams or geographic areas where the general permit is effective.

(3) A set of standardized specifications or plans for the particular category of dam, water obstruction or encroachment or a reference to specific criteria and requirements adopted by another Federal or State agency which adequately regulates the particular category of dam, water obstruction or encroachment.

(4) A set of conditions governing the construction, operation, maintenance, inspection and monitoring of the projects covered by the general permit as are necessary to assure compliance with the act and this chapter and with other laws administered by the Department, the Fish Commission and a river basin commission created by interstate compact.

(5) A specification of registration requirements, if any, established under § 105.447 (relating to registration requirements).

§ 105.446. Procedure for issuance.

(a) At least 60 days prior to issuance of a general permit, the Department will:

(1) Publish notice in the *Pennsylvania Bulletin* of intent to issue a general permit, including the text of the proposed general permit and locations for obtaining standardized plans.

(2) Provide written notice of the proposed general permit to the United States Army Corps of Engineers; the United States Coast Guard; the United States Fish and Wildlife Service; the United States Environmental Protection Agency; the Fish Commission; the Game Commission; applicable river basin commissions created by interstate compact; county agencies holding delegations under § 105.4 (relating to delegations to local agencies) and other interested Federal, State or interstate agencies.

(b) An opportunity shall be provided for interested members of the public, Federal and State agencies to provide written comments on a proposed general permit.

(c) The Department may, at its discretion, hold a public hearing on a proposed general permit for the purposes of gathering information and comments.

(d) General permits issued by the Department will be published in the *Pennsylvania Bulletin* at least 30 days prior to the effective date of the permits, as required by section 7(d) of the Dam Safety and Encroachments Act (32 P. S. § 693.7(d)).

§ 105.447. Registration requirements.

(a) The Department will require the registration of a project constructed, operated, maintained, modified or enlarged under a general permit, within a specified time limit.

(b) Registration requirements and time limits, if any, shall be set forth in the general permit governing each category of dam, water obstruction or encroachment.

(c) Registration statements shall set forth:

(1) The name and address of the person responsible for the project.

(2) The location of the project.

(3) The name or number of the general permit being utilized for the project.

(d) For a project requiring registration under this section, an amended registration shall be filed if there is a change of ownership of the dam, water obstruction or encroachment.

§ 105.448. Determination of applicability of a general permit.

(a) A person who desires to utilize a general permit issued under this subchapter, but is uncertain as to the potential application of the general permit to a particular proposed dam, water obstruction or encroachment, should consult with the Department. The Department may issue a determination as to whether the general permit applies to the proposed dam, water obstruction or encroachment.

(b) A request for a determination of the applicability of a general permit may not be considered a permit application for purposes of this chapter, and no application fee will be charged.

Subchapter M. STATEMENTS OF POLICY

WETLANDS

Sec.
105.451. Identification and delineation of wetlands—statement of policy.
105.452. Status of prior converted cropland—statement of policy.

WETLANDS

§ 105.451. Identification and delineation of wetlands—statement of policy.

(a) This section sets forth the policy of the Department as to the methodology to be used for the identification and delineation of wetlands.

(b) The use of some delineation method is necessary in order to administer, implement, enforce and determine compliance with the act, The Clean Streams Law (35 P. S. §§ 691.1—691.1001), the Solid Waste Management Act (35 P. S. §§ 6018.101—6018.1003), the Surface Mining Conservation and Reclamation Act (52 P. S. §§ 1396.1—1396.31), the Pennsylvania Sewage Facilities Act (35 P. S. §§ 750.1—750.20), the Oil and Gas Act (58 P. S. §§ 601.101—601.605) and other applicable statutes administered by the Department and regulations promulgated under these statutes.

(c) The Department adopts and incorporates by reference the 1987 *Corps of Engineers Wetland Delineation Manual (Technical Report Y-87-1)* along with the guidance provided by the United States Army Corps of Engineers, Major General Arthur E. Williams' memorandum dated 6 March 1992, *Clarification and Interpretation of the 1987 Manual* and any subsequent changes as the methodology to be used for identifying and delineating wetlands in this Commonwealth. The 1987 *Corps Wetland Delineation Manual*, Publication No. ADA 176734 is available from the National Technical Information Service (NTIS), Springfield, VA 21161, or telephone: (703) 487-4650. Copies of the Supplemental Guidance issued by the Corps concerning use of the 1987 Manual, (that is, the October 7, 1991, Questions and Answers, and the March 6, 1992, Clarification and Interpretation Memorandum) as well as the Administration's Wetlands Plan of August 24, 1993, may be obtained by contacting the regulatory branch of a local Corps District, or the EPA Wetlands Hotline at (800) 832-7828. For more information, con-

tact Pennsylvania Department of Environmental Protection, Bureau of Dams, Waterways and Wetlands, Post Office Box 8554, Harrisburg, Pennsylvania 17105-8554, telephone (717) 787-6827.

The provisions of this § 105.451 adopted October 27, 1989, effective December 27, 1989, 19 Pa.B. 4612; amended February 2, 1996, effective February 3, 1996, 26 Pa.B. 494. Immediately preceding text appears at serial pages (207778) to (207781).

Cross References

This section cited in 25 Pa. Code § 96.3 (relating to water quality protection requirements); and 25 Pa. Code § 105.13 (relating to permit applications—information and fees).

§ 105.452. Status of prior converted cropland—statement of policy.

(a) This section sets forth the policy of the Department as to the status of prior converted cropland in this Commonwealth.

(b) The use of some procedure for determining wetlands is necessary in order to administer, implement, enforce and determine compliance with the act, The Clean Streams Law (35 P. S. §§ 691.1—691.1001), the Solid Waste Management Act (35 P. S. §§ 6018.101—6018.1003), the Surface Mining Conservation and Reclamation Act (52 P. S. §§ 1396.1—1396.31), the Pennsylvania Sewage Facilities Act (35 P. S. §§ 750.1—750.20), the Oil and Gas Act (58 P. S. §§ 601.101—601.605) and other applicable statutes administered by the Department and regulations promulgated under these statutes.

(c) Naturally occurring events may result in either creation or alteration of wetlands. It is necessary to determine whether alterations to an area have resulted in changes that are now ''normal circumstances'' of the particular area. The Department recognizes ''prior converted cropland,'' as defined in the *National Food Security Act Manual* (180-V-NFSAM, Third Edition, March 1994), as ''normal circumstances'' as the term is used in the definition of wetlands in § 105.1 (relating to definitions). These prior converted croplands are not regulated as wetlands under the Commonwealth's Wetland Protection Program contained in this chapter. Prior converted cropland is defined in the *National Food Security Act Manual*, as wetlands that were drained, dredged, filled, leveled or otherwise manipulated, including the removal of woody vegetation, before December 23, 1985, and have not been abandoned, for the purpose of, or to have the effect of making the production of an agricultural commodity possible, and an agricultural commodity was planted or produced at least once prior to December 23, 1985.

(1) Abandonment is the cessation of cropping, forage production or management on prior converted cropland for 5 consecutive years, so that:

(i) Wetland criteria are met.

(ii) The area has not been enrolled in a conservation set-aside program.

Copyright © 2001 Commonwealth of Pennsylvania

(iii) The area was not enrolled in a State or Federal wetland restoration program other than the Wetland Reserve Program.

(2) Prior converted cropland may also be considered abandoned if the landowner provides written intent to abandon the area and wetland criteria are met.

(d) This policy change does not affect the exemption for plowing, cultivating, seeding and harvesting for the production of food, fiber and forest products or the waiver for maintenance of field drainage systems found at § 105.12(a)(7) and (8) (relating to waiver of permit requirements).

APPENDIX A
FISH ENHANCEMENT STRUCTURES; GENERAL PERMIT BDWW-GP-1

Editor's Note: The following permit was published in the *Pennsylvania Bulletin* as a Notice and is codified under 1 Pa. Code § 3.1(a)(9) (relating to contents of *Code*) as a document which the Legislative Reference Bureau finds to be general and permanent in nature. See §§ 105.441—105.449 (relating to general permits) for the regulations governing this permit.

INSTRUCTIONS FOR USING THE GENERAL PERMIT
BDWW-GP-1
Fish Habitat Enhancement Structures

Prior to Registration to Use:

1. Carefully review the definitions and requirements of the General Permit (Part One and Part Two) to determine if your project can qualify for authorization under this General Permit. Refer to Part One, Section B regarding area restrictions and Part One, Section D regarding criteria. If your project cannot be authorized under the General Permit, you may request approval of an individual permit by submitting an application to the appropriate Soils and Waterways Section in the Regional Office as listed on Exhibit B.

2. Contact the Pennsylvania Fish and Boat Commission, Division of Environmental Services or Division of Property Services at address and telephone number shown on Exhibit A to select a suitable structure and obtain Pennsylvania Fish and Boat Commission approval on Exhibit D. For the Cooperative Adopt-A-Stream Program, the Pennsylvania Fish and Boat Commission will also register the use of the General Permit on behalf of the project sponsor.

3. Locate your project on a United States Geological Survey (U.S.G.S.) 7 1/2 Minute Quadrangle Map (Commonly called ''topographic maps,'' U.S.G.S. Qudarangle may be available from local merchants dealing in books, hunting supplies and camping equipment.) and prepare a project Location Map, utilizing a photocopy of the U.S.G.S. Quadrangle Map.

4. Complete the top portion of the attached Supplement No. 1 (Pennsylvania Natural Diversity Inventory Form). You will not be authorized to use the General Permit until Supplement No. 1 has been processed to check for potential impacts to rare and endangered species. Therefore, to avoid possible project delays or unnecessary design costs, you are advised to submit Supplement No. 1 for processing prior to General Permit registration. To do so, follow the written instructions on the Supplement No. 1 form. The Department will complete the bottom portion of the form and return it to you, generally within a period of 2 weeks. You must have copies of Supplement No. 1 (whether processed or not) for submission as attachments when you register to use the General Permit.

5. For any earthmoving activity (For the definition of earthmoving activity, see Part Two, Section C.) associated with your project, prepare an Erosion and Sedimentation Control Plan which must be reviewed and determined satisfactory by the County Conservation District in the county where your project is located. The required Erosion and Sedimentation Control Plan must be prepared and sub-

Copyright © 1996 Commonwealth of Pennsylvania

mitted to the Conservation District for review prior to or concurrent with your registration to use the General Permit.

The Registration Procedure:

6. Fill in all information on the Notification to Use form (Exhibit D) and make multiple copies. Send one copy each to the municipality and the county in which the project is located.

7. To register use of the General Permit, prepare a complete registration ''package'' consisting of:

—Two Copies of Notification to Use form (Exhibit D)

—Two copies of the Location Map

—Two copies of the Supplement No. 1 form

Send these items to either:

—The County Conservation District for projects located in all counties where there is a delegation agreement (see Exhibit C).

—OR—

—The Soils and Waterways Section having responsibility for the counties where there is no delegation agreement with the County Conservation District (see Exhibit B).

8. If you are also applying for an individual Water Obstruction and Encroachment Permit to authorize related work, you may register to use the General Permit in conjunction with your individual permit application. See Part Two, Section A, Item 2.

Before and During Construction:

9. Do not begin work until:

a. You have received an acknowledgement from the Soils and Waterways Section or County Conservation District that your Exhibit D notification has been received and registered.

b. Your Erosion and Sedimentation Control Plan has been reviewed and determined to be satisfactory by the County Conservation District.

c. You have notified the Pennsylvania Fish and Boat Commission and the County Conservation District 10 days prior to start of construction (see Part Two, Section D).

d. You have obtained any other Federal, State or local permits which may be required.

e. You have complied with any other applicable pre-construction requirements as listed in Part Two, Section E.

f. You have provided written notifications to the municipalities and county where the projects are located prior to the start of construction.

10. During construction of your project, you are responsible for adhering to all terms and conditions of the General Permit, including your approved Erosion and Sedimentation Control Plan and all applicable design and construction criteria in Part One, Section D.

PART ONE

A. General Description and Fees—The Department of Environmental Resources hereby authorizes, by General Permit, subject to the terms and criteria set forth, the installation, operation and maintenance of fish habitat enhancement structures in the regulated waters of this Commonwealth. There is no registration fee required for a project authorized under this General Permit.

B. Sites and Conditions Where this General Permit Does Not Apply—This General Permit does not apply and is not valid in the following sitautions. Where the General Permit is not applicable, you may request approval of an individual permit by submitting an application to the appropriate Soils and Waterways Section in the Regional Office (see Exhibit B).

1. Historic, cultural or archaeological sites as identified in the latest published version of the Pennsylvania Inventory of Historical Places or the National Register of Historical Places. This information is available from the Pennsylvania Historical and Museum Commission, Box 1026, Harrisburg, PA 17108-1026, telephone (717) 787-3362.

2. Sites identified in the latest published version of the National Registry of Natural Landmarks.

3. Construction activities in stocked trout streams from March 1 through June 15, in wild trout streams from October 1 through December 31, and in Lake Erie tributaries from March 1 through June 15 and from September 1 through December 31, unless approval is obtained from the Pennsylvania Fish and Boat Commission's Division of Environmental Services (see Exhibit A). Stocked and wild trout stream locations are compiled by the Commission's Division of Fisheries Management (see Exhibit A).

4. Wetlands.

5. Projects located where there would be an impact on species of special concern listed under the Endangered Species Act of 1973, the Wild Resources Conservation Act, the Fish and Boat Code or the Game and Wildlife Code. Records regarding species of special concern are maintained in a computer database called the ''Pennsylvania Natural Diversity Inventory'' (PNDI). To verify that there will be no such impacts for a specific project, the Department requires submission of the attachment Supplement No. 1 form.

6. Areas in or within 100 feet of a watercourse designated wild in the National or State Scenic Rivers system in accordance with the National Wild and Scenic Rivers Act of 1968 or the Pennsylvania Scenic Rivers Act. For

Copyright © 1996 Commonwealth of Pennsylvania

details on scenic river classifications, contact the DER Pennsylvania Scenic Rivers Program, P. O. Box 8475, Harrisburg, PA 17105-8475, telephone (717) 787-2316.

C. Definitions Applicable to this General Permit—The following words and terms, when used in this General Permit, have the following meanings:

Fish Habitat Enhancement Structures—Structures consisting of deflectors, low flow channel structures, channel blocks, mud sills, boulders, felled shoreline trees, special tire structures, brush structures, rubble reefs, half-log structures, elevated boulder structures and spawning/nursery structures placed in streams, lakes, ponds or reservoirs as developed and approved by the Pennsylvania Fish and Boat Commission.

Reservoir—A natural or artificial basin which contains or will contain the water or other fluid or semifluid impounded by a dam.

D. Project Design and Construction Criteria

1. *Pennsylvania Fish and Boat Commission Approval*—The owner must contact the Pennsylvania Fish and Boat Commission's Division of Property Services or Division of Environmental Services (see Exhibit A) to select a Fish Habitat Enhancement Structure suitable for his individual situation and obtain the required approval of the Pennsylvania Fish and Boat Commission to install the structure as required on the Notification to Use form (Exhibit D).

2. Fish Habitat Enhancement Structures shall be designed and constructed to preclude interference with normal fish migration.

3. Stream flow will not be constructed to a degree greater than the most narrow natural point of the stream in the immediate vicinity of the work within 500 feet upstream or downstream of the project site.

4. Fish Habitat Enhancement Structures located in stream channels shall not extend more than 3 feet above the normal stream bed. Tire structures are prohibited in stream channels.

5. Any archaeological artifacts discovered during the performance of work authorized under this General Permit must be adequately protected and their discovery promptly reported to the Director, Bureau of Historic Preservation, Pennsylvania Historical and Museum Commission, P. O. Box 1026, Harrisburg, PA 17108-1026, telephone (717) 787-2891.

6. Each Fish Habitat Enhancement Structure shall be constructed in such a way so that it does not hinder recreational navigation.

7. Excess fill or excavated and dredged material from the construction of a Fish Habitat Enhancement Structure shall be deposited outside of the adjacent floodplain, wetlands and other regulated waters of this Commonwealth and stabilized immediately in accordance with the Erosion and Sedimentation Control Plan. Waste materials, scrap or excess construction materials shall be collected, stored and disposed of in accordance with the Solid Waste Management Act and related rules and regulations.

8. Fish Habitat Enhancement Structures shall be maintained in a safe and functional condition. This includes the removal of debris. Where maintenance requires excavation or dredging, an Erosion and Sedimentation Control Plan must be reviewed and determined adequate by the County Conservation District in which the activity is located. Disposal of dredged material shall be in accordance with Item 7.

9. Only a clean, nonpolluting, rock material shall be used as fill material in order to minimize excessive turbidity by leaching of fines as well as to preclude the entrance of potentially polluted materials to the watercourse by natural runoff.

10. Slag is not authorized for use under this General Permit unless it qualifies as a co-product which is suitable for the specific use.

11. Construction of a Fish Habitat Enhancement Structure shall take place during periods coinciding with low stream flows.

12. Construction and other activities authorized by this General Permit shall be performed in a manner that minimizes use of equipment within the stream channel or body of water.

13. To the greatest extent possible, the project shall be designed and constructed in a manner which will (a) prevent permanent or long-term adverse changes in water quality, (b) minimize alterations in natural aquatic habitat and (c) maintain natural stream flow velocities and mixing patterns.

E. Cooperative Adopt-A-Stream Program—Special Procedures—The Pennsylvania Fish and Boat Commission is authorized to register the use of this General Permit on behalf of sponsors and landowners who participate in the Commission's Cooperative Adopt-A-Stream Program. To register use of the General Permit for Adopt-A-Stream projects, the Commission shall utilize a modified version of Exhibit D which has been approved by the Department and the U. S. Army Corps of Engineers. The standard attachments to Exhibit D, as specified in Part Two, Section A, are not required to register the use of this General Permit for a Cooperative Adopt-A-Stream Project.

F. Authority and Continuing Authorization—Authorization of this General Permit is under section 7 of the Dam Safety and Encroachments Act (32 P. S. §§ 693.1—693.27) and the rules and regulations promulgated thereunder at 25 Pa. Code §§ 105.441—105.449 (relating to general permits). This General Permit shall authorize the continued operation and maintenance of fish habitat enhancement structures previously authorized by General Permit BDWW-GP-1 (Fish Enhancement Structures) issued on July 25, 1981, and reauthorized on August 29, 1987 and October 7, 1989.

GP _____

NOTIFICATION TO USE
BDWW-GP-1
Fish Habitat Enhancement Structures

1. I/We, _____
(owner name(s))
hereby notify the Department of Environmental Resources of our intent to install

_____
(description of fish habitat enhancement structure)
in accordance with the conditions of this General Permit at a point _____

_____
(describe location)

on _____
(name of stream or body of water)

in _____ , _____
(municipality) (county)

2. I/We have attached a LOCATION MAP (similar to that shown on Drawing No. 1 indicating where the fish habitat enhancement structure will be installed) and a copy of SUPPLEMENT NO. 1.

3. I/We have enclosed duplicate copies of EXHIBIT D, the LOCATION MAP and SUPPLEMENT NO. 1.

4. I/We certify that copies of this notification were sent this day _____(date)_____

to _____ , and _____
(municipality) (County-Commissioner's Office)

5. I/We certify that an EROSION AND SEDIMENTATION CONTROL PLAN for this project has been submitted for review to the _____ County Conservation District on _____(date)_____ .

Signed by: _____ _____
(print name) (owner address)

_____ _____
(owner signature) (city/state/zip code)

_____ _____
(title, if applicable) (owner telephone number)

6. I/We hereby notify the Department also of our intention to install a temporary road crossing in accordance with the terms of BDWW-GP-8, Temporary Road Crossings, during the installation of the fish habitat enhancement structure (if applicable).

Signed: _____

(207787) No. 255 Feb. 96

Approval—The Pennsylvania Fish and Boat Commission hereby approves the installation of the aforementioned fish habitat enhancement structure in this individual situation.

(Signature) (Date)

Send to address on Exhibit B or delegated Conservation District on Exhibit C

PART TWO

A. Registration of Proposed Use of General Permits

1. Standard Procedure

Prior to construction, the owner shall submit the following items to the DER Soils and Waterways Section in the appropriate Regional Office or the delegated County Conservation District where the project is located (see Exhibits B and C).

(a) Two copies of the Notification to Use form (Exhibit D), one copy with original signatures.

(b) Two copies of a location map (see Drawing No. 1).

(c) Two copies of the Supplement No. 1 form.

(d) Two copies of any other items required in the Instructions and Part One (if applicable).

The owner is required to send additional copies of Exhibit D to the municipality and the County Board of Commissioners where the project is located. Also, as part of the registration, the owner shall certify that an Erosion and Sedimentation Control Plan has been submitted for review to the County Conservation District in which the work will be performed. The owner is not authorized to use the General Permit until he has notified the DER Soils and Waterways Section of the appropriate Regional Office or the appropriate delegated County Conservation District and received an acknowledgement of that notification. The Department's acknowledgement serves as registration to use this General Permit. The owner may not begin work until all preconstruction requirements of this General Permit have been completed.

Registration for the use of this General Permit must be sent to the County Conservation District in counties where the District has a delegation agreement with the Department of Environmental Resources. To determine whether this alternate registration procedure currently applies for your location, refer to Exhibit C and/or contact the appropriate DER Soils and Waterways Section or County Conservation District.

2. In Conjunction with a Water Obstruction and Encroachment Permit Application.

When an activity or structure authorized by the General Permit is an integral part of a larger project which requires an individual Water Obstruction and Encroachment permit, intent to use the General Permit may be registered by

Copyright © 1996 Commonwealth of Pennsylvania

attaching copies of the Notification to Use form (Exhibit D) to the individual permit application, and clearly identifying, in the permit application narrative and/or on site plans, any structure or activity which will be constructed in accordance with the terms and conditions of the General Permit. The Department's acknowledgement of the General Permit registration will be included in the individual permit, and upon issuance of the permit the owner may begin work on the structure or activity authorized by the General Permit. Where applicable, this registration procedure is preferred and recommended by the Department, because written authorization for a project can be combined into one action and the associated documentation can be maintained under a single file number.

3. In Conjunction with an Enforcement Action:

The General Permit may also be used, at the discretion of the Department, in conjunction with an enforcement action or settlement of violations, to register regulated activites conducted without prior permit or authorization.

B. Denial of Authorization—The Department shall have the discretion, on a case-by-case basis, to deny, revoke or suspend the authorization to use a General Permit for any project which the Department determines to have a substantial risk to life, health, property or the environment, or otherwise could not be adequately regulated by the provisions of this General Permit.

C. Standard Definitions for General Permits—The terms as used in this General Permit shall have the following meanings:

Body of Water—Any natural or artificial lake, pond, reservoir, swamp, marsh or wetland.

Department—The Department of Environmental Resources.

Earthmoving Activity—Any construction or other activity which disturbs the surface of the land including, but not limited to, excavations, embankments, land development, subdivision development, mineral extraction and the moving, depositing or storing of soil, rock or earth. This includes any excavation or fill within a stream channel.

Erosion and Sedimentation Control Plan—A plan which is designed to minimize accelerated erosion and sedimentation consistent with the requirements of 25 Pa. Code Chapter 102.

Floodway—The channel of the watercourse and portions of the adjoining floodplains which are reasonably required to carry and discharge the 100-year frequency flood. Unless otherwise specified, the boundary of the floodway is as indicated on maps and flood insurance studies provided by the Federal Emergency Management Administration (FEMA). In an area where no FEMA maps or studies have defined the boundary of the 100-year frequency floodway, it is assumed, absent evidence to the contrary, that the floodway extends from the stream to 50 feet from the top of the bank of the stream.

Install—To construct, deposit, place, lay or set in place.

Owner—A person who owns, controls, operates, maintains, or manages a dam or reservoir, water obstruction or encroachment.

Person—A natural person, partnership, association, corporation, public utility, municipality, municipal authority, political subdivision of the Commonwealth, receiver or trustee, and any department, board, commission or authority of the Commonwealth.

Political Subdivision—A county, city, borough, incorporated town, township, school district, authority or other governmental unit or a combination thereof acting jointly.

Regulated Waters of this Commonwealth—Watercourses, streams or bodies of water and their floodways wholly or partly within or forming part of the boundary of this Commonwealth.

Scenic Rivers—Areas in or within 100 feet of a watercourse or body of water designated a component of the Pennsylvania Scenic Rivers System in accordance with the Pennsylvania Scenic Rivers Act (P. L. 1277, Act No. 283 as amended by Act 110, May 7, 1982), or which are 1-A candidate rivers listed in the Pennsylvania Scenic Rivers Inventory.

Stocked Trout Stream—A stream classified as approved trout waters by the Pennsylvania Fish and Boat Commission. For current designations of stocked trout streams, contact the Division of Fisheries Management (see Exhibit A).

Submerged Lands of this Commonwealth—Waters and permanently or periodically inundated lands owned by the Commonwealth, including lands in the beds of navigable lakes and rivers and beds of streams declared public highways which are owned and held in trust by the Commonwealth.

Watercourse—A channel or conveyance of surface water having defined bed and banks, whether natural or artificial, with perennial or intermittent flow.

Wetlands—Areas that are inundated or saturated by surface water or groundwater at a frequency and duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions, including swamps, marshes, bogs and similar areas.

Wild Trout Stream—A stream classified as supporting naturally reproducing trout populations by the Pennsylvania Fish and Boat Commission. For current designations of wild trout streams, contact the Division of Fisheries Management (see Exhibit A).

D. Preconstruction Requirements for All Projects

1. *Other Permits*—Nothing in this General Permit relieves the owner of the obligation of complying with all Federal, Interstate Compact, State and local laws, regulations and standards for the construction, operation or maintenance of the project or activity. The project owner is advised that written authorization from the U. S. Army Corps of Engineers may be required for compliance with Section 404 of the Clean Water Act.

2. *Erosion and Sedimentation Controls*—Work must be done in compliance with Chapter 102 (relating to erosion and sediment control). Prior to construction, an Erosion and Sedimentation Control Plan must be reviewed and determined adequate by the County Conservation District in which the activities are

Copyright © 2000 Commonwealth of Pennsylvania

proposed and implemented prior to, during and after construction. The County Conservation District shall be notified 10 days prior to the start of construction. The project site shall at all times be available for inspection by authorized employees of the County Conservation District. The Erosion and Sedimentation Control Plan shall be available at the site.

3. *Pennsylvania Fish and Boat Commission Notification*—The owners shall notify the Pennsylvania Fish and Boat Commission's Regional Field Office Supervisor (see Exhibit A) responsible for the County where the activities are proposed 10 days prior to start of construction. Written notification is suggested. The project site shall at all times be available for inspection by authorized officers and employes of the Pennsylvania Fish and Boat Commission.

4. *Notification to Operators of Public Water Facilities*—Owners will investigate for drinking water intakes or reservoirs for public water supplies and permitted public bathing beaches within 5 miles downstream of the site of the project. Written notice shall be given at least 10 days prior to construction to the Department and to operators of any such intakes, beaches or reservoirs. This notification shall include expected starting and completion dates for the construction activities. Owners must notify the Department and operators immediately and no longer than 1 hour after the occurrence at the site which results in the release of suspended solids and turbidity to the stream. Public drinking water sources are listed by the DER Bureau of Water Supply and Community Health, and this information is available from each DER Regional Office.

E. Other Preconstruction Requirements Where Applicable

1. *Submerged Lands of this Commonwealth*—This General Permit shall not be effective to authorize any project over, across or occupying submerged lands of this Commonwealth until the owner has obtained a license from the Department authorizing the occupation of such submerged lands issued under section 15 of the Dam Safety and Encroachments Act (32 P. S. § 693.15), section 514 of the Administrative Code of 1929 (71 P. S. § 194), or other applicable laws. Upon receipt of notification from the owner, the Department will review the project to determine if its location is over, across or occupies submerged lands of the Commonwealth. If applicable, the Department will prepare a Submerged Lands License Agreement and forward same to the owner for execution prior to acknowledgement of registration to use the General Permit. No annual charge is required for facilities constructed, owned or operated by a Political Subdivision of the Commonwealth.

2. *Utilization of General Permit BDWW-GP-8, Temporary Road Crossings*—Temporary road crossings of streams and causeways that are necessary for equipment to move back and forth across a stream during construction of a project are authorized by, and must be constructed in accordance with BDWW-GP-8. The owners shall indicate utilization of BDWW-GP-8 on Exhibit D in the space provided. Owners constructing temporary road crossings

in those areas excluded from the application of GP-8 must apply for an individual Water Obstruction and Encroachment Permit for those road crossings.

3. *Use of Explosives*—Prior to the use of explosives in a watercourse or body of water, the permittee shall secure a written permit from the Pennsylvania Fish and Boat Commission, under the Fish and Boat Code, Act 1980-175 Title 30 Pennsylvania Consolidated Statutes, Section 2906. Requests should be directed to the Pennsylvania Fish and Boat Commission, Division of Environmental Services (see Exhibit A).

F. Standard Provisions of the General Permit

1. *Effective Time Period*—This General Permit will remain in effect indefinitely unless specifically modified, suspended or revised by the Department.

2. *Suspension, Modification or Revocation*—The Department may suspend, modify or revoke this General Permit at any time upon notice in the *Pennsylvania Bulletin*.

3. *Project Interference*—This General Permit does not authorize any interference with any existing or proposed local, State, Federal or Federally licensed project, and permittee shall not be entitled to compensation for damage or injury to the work authorized herein which may be caused by or a result of existing or future operations undertaken by the United States or the Commonwealth of Pennsylvania or its Political Subdivisions in the public interest.

4. *Department Inspection*—As a condition of use of this General Permit, and of the owner's authority to conduct the activities authorized by this General Permit, the owner hereby authorizes and consents to allow authorized employes or agents of the Department, without advance notice or a search warrant, at any reasonable time and upon presentation of appropriate credentials, and without delay, to have access to and to inspect all areas where the project is being constructed, operated or maintained. The authorization and consent shall include consent to conduct tests or sampling, to take photographs, to perform measurements, surveys and other tests, to inspect the methods of construction, operation or maintenance, to examine and copy books, papers and records pertinent to any matter under investigation, and to take any other action necessary to assure that the project is constructed, operated or maintained in accordance with the terms and criteria of the General Permit. This General Permit condition is referenced in accordance with Section 16 of the Dam Safety and Encroachments Act, 32 P. S. § 693.16, and in no way limits any other powers granted under the Dam Safety and Encroachments Act.

5. *Activities Not in Accordance with the Terms or Conditions*—If the Department determines, upon inspection, that the construction, operation or maintenance of a project has violated the terms or criteria of this General Permit or of the Chapter 105 Rules and Regulations, the Department may take such actions, legal or administrative, that it may deem to be appropriate.

6. *Structure Removal*—The owners shall remove all or any portion of this project upon written notification to the owner by the Department in the event

Copyright © 2000 Commonwealth of Pennsylvania

the project is causing an adverse impact on public health, safety or the environment, or in any other manner violates the conditions of this General Permit or Chapter 105 Rules and Regulations.

7. *Property Rights*—This General Permit does not authorize trespassing on private property nor convey any property rights, either in real estate or material, or in any exclusive privileges; nor does it authorize any injury to property or invasion of rights or any infringement of Federal, State or local laws or regulations.

8. *Water Quality Certification*—The issuance of this General Permit also constitutes approval of a Water Quality Certification under section 401 of the Federal Clean Water Act (33 U.S.C.A. § 1341).

9. *Other Approvals*—The owners shall secure all other approvals that may be necessary under other Federal, State or local laws or regulations.

10. *Change of Ownership*—If there is a change in ownership of a structure installed in accordance with this General Permit, the new owner is required to register the structure with the Department in accordance with Part Two, Section A, of this General Permit. The new owner shall submit one copy of Exhibit D indicating ''change of ownership'' and one copy of a location map. Additional items required under Part Two, Section A, are not applicable if there are no proposed construction activities.

11. *Signature*—The Notification to Use form for registration to use the General Permit shall be signed by the property owner; the president, vice president or other responsible official of a Corporation; or the chief official for a Government Agency/Political Subdivision. An engineering consultant, contractor or similar agent is not authorized to sign the General Permit registration form on behalf of the owner.

APPENDIX B
PRIVATE RECREATIONAL DOCKS; GENERAL PERMIT BDWW-GP-2

Editor's Note: The following permit was published in the *Pennsylvania Bulletin* as a Notice and is codified under 1 Pa. Code § 3.1(a)(9) (relating to contents of *Code*) as a document which the Legislative Reference Bureau finds to be general and permanent in nature. See §§ 105.441—105.449 (relating to general permits) for regulations governing this permit.

INSTRUCTIONS FOR USING THE GENERAL PERMIT BDWW-GP-2
Small Docks and Boat Launching Ramps

Prior to Registration to Use:

1. Carefully review the definitions and requirements of the General Permit (Part One and Part Two) to determine if your project can qualify for authorization under this General Permit. Refer to Part One, Section B regarding area restrictions and Part One, Sections D and E regarding criteria. If your project cannot be authorized under the General Permit, you may request approval of an individual permit by submitting an application to the appropriate Soils and Waterways Section in the Regional Office as listed on Exhibit B.

2. Locate your project on a United States Geological Survey (U.S.G.S.) 7 1/2 Minute Quadrangle Map (Commonly called ''topographic maps,'' U.S.G.S. Quadrangles may be available from local merchants dealing in books, hunting supplies and camping equipment.) and prepare a project Location Map, utilizing a photocopy of the U.S.G.S. Quadrangle Map.

3. Complete the top portion of the attached Supplement No. 1 (Pennsylvania Natural Diversity Inventory Form). You will not be authorized to use the General Permit until Supplement No. 1 has been processed to check for potential impacts to rare and endangered species. Therefore, to avoid possible project delays or unnecessary design costs, you are advised to submit Supplement No. 1 for processing prior to General Permit registration. To do so, follow the written instructions on the Supplement No. 1 form. The Department will complete the bottom portion of the form and return it to you, generally within a period of 2 weeks. You must have copies of Supplement No. 1 (whether processed or not) for submission as attachments when you register to use the General Permit.

4. Your project may also require a permit from the U. S. Army Corps of Engineers under section 404 of the Federal Clean Water Act, sections 9 and 10 of the Rivers and Harbors Act and/or section 103 of the Marine Protection, Research and Sanctuaries Act. The registration to use this State General Permit does not relieve you of the obligation to comply with, and the State is not authorized to address, these Corps of Engineers' requirements. Therefore, in order to avoid violation of Federal statutes, please contact the appropriate U. S. Corps of Engineers District Office listed below to determine whether a Federal permit is required for your project.

5. For any earthmoving activity (For the definition of earthmoving activity, see Part Two, Section C.) associated with your project, prepare the Erosion and Sedimentation Control Plan which must be reviewed and determined satisfactory by the County Conservation District in the county where your project is located. The required Erosion and Sedimentation Control Plan must be prepared and submitted to the Conservation District for review prior to or concurrent with your registration to use the General Permit.

The Registration Procedure:

6. Fill in all information on the Notification to Use form (Exhibit D) and make multiple copies. Send one copy each to the municipality and the county in which the project is located.

7. To register use of the General Permit, prepare a complete registration ''package'' consisting of:

—Two Copies of Notification to Use form (Exhibit D)

—Two copies of the Location Map

—Two copies of the Supplement No. 1 form

Send these items to either:

—The County Conservation District for projects located in all counties where there is a delegation agreement (see Exhibit C).

—OR—

—The Soils and Waterways Section having responsibility for the counties where there is no delegation agreement with the County Conservation District (see Exhibit B).

8. If you are also applying for an Individual Water Obstruction and Encroachment Permit to authorize related work, you may register to use the General Permit in conjunction with your individual permit application. See Part Two, Section A, Item 2.

Before and During Construction:

9. Do not begin work until:

a. You have received an acknowledgement from the Soils and Waterways Section or County Conservation District that your Exhibit D notification has been received and registered.

b. Your Erosion and Sedimentation Control Plan has been reviewed and determined to be satisfactory by the County Conservation District.

c. You have notified the Pennsylvania Fish and Boat Commission and the County Conservation District 10 days prior to start of construction. (See Part Two, Section D.).

d. You have obtained any other Federal, State or local permits which may be required.

e. You have complied with any other applicable preconstruction requirements as listed in Part Two, Section E.

f. You have provided written notifications to the municipalities and county where the projects are located prior to the start of construction.

10. During construction of your project, you are responsible for adhering to all terms and conditions of the General Permit, including your approved Erosion and Sedimentation Control Plan and all applicable design and construction criteria in Part One, Sections D and E.

PART ONE

A. General Description and Fees—The Department of Environmental Resources hereby authorizes, by General Permit, subject to the terms and criteria set forth below, the installation, operation, modification and maintenance of small docks and boat launching ramps in and along the regulated waters of this Commonwealth. There is no registration fee required for a project authorized under this General Permit.

B. Sites and Conditions Where this General Permit Does Not Apply—This General Permit does not apply and is not valid in the following situations. Where the General Permit is not applicable, you may request approval of an individual permit by submitting an application to the appropriate Soils and Waterways Section in the Regional Office (see Exhibit B).

1. Historical, cultural or archaeological sites as identified in the latest published version of the Pennsylvania Inventory of Historical Places or the National Register of Historical Places. This information is available from the Pennsylvania Historical and Museum Commission, Box 1026, Harrisburg, PA 17108-1026, telephone (717) 787-3362.

Copyright © 1996 Commonwealth of Pennsylvania

2. Sites identified in the latest published version of the National Registry of Natural Landmarks.

3. Areas in or within 100 feet of a watercourse designated wild in the National or State Scenic Rivers system in accordance with the National Wild and Scenic Rivers Act of 1968 or the Pennsylvania Scenic Rivers Act. For details on scenic river classification, contact the DER Pennsylvania Scenic Rivers Program, P. O. Box 8475, Harrisburg, PA 17105-8475, telephone (717) 787-2316.

4. Construction activities in stocked trout streams from March 1 through June 15, in wild trout streams from October 1 through December 31, and in Lake Erie tributaries from March 1 through June 15 and from September 1 through December 31 unless written approval is obtained from the Pennsylvania Fish and Boat Commission's Division of Environmental Services (see Exhibit A). Stocked and wild trout stream locations are compiled by the Commission's Division of Fishery Management (see Exhibit A).

5. Projects located where there would be an impact on species of special concern listed under the Endangered Species Act of 1973, the Wild Resources Conservation Act, the Fish and Boat Code or the Game and Wildlife Code. Records regarding species of special concern are maintained in a computer database called the ''Pennsylvania Natural Diversity Inventory'' (PNDI). To verify that there will be no such impacts for a specific project, the Department requires submission of the attached Supplement No. 1 form.

6. Streams or waterbodies designated as Exceptional Value Waters as defined and listed in Chapter 93 (related to water quality standards).

7. Projects requiring excavation of mudflats in the tidal waters of the Delaware River.

C. Definitions Applicable to this General Permit—The following words and terms, when used in this General Permit, have the following meanings:

Boat Launching Ramp—A sloping stabilized roadway constructed in and along a stream or lake for the purpose of launching boats from vehicular trailers, including associated walkways for boarding boats and on-grade improvements for access, turning and parking.

Dredge—To remove sand, gravel, mud or other materials from the beds of regulated waters of this Commonwealth.

Fill—Sand, gravel, earth or other material placed or deposited to form an embankment or raise the elevation of the land surface. The term includes material used to replace an area with aquatic life with dry land or to change the bottom elevation of any regulated water of this Commonwealth.

Other Private and Commercial Facilities—Docks and boat launching ramps other than those defined as private recreational docks, public access facilities and public service facilities.

Private Recreational Dock—A dock utilized for private recreational purposes by the riparian land owner.

Public Access Facility—A dock or boat launching ramp for public recreational purposes when the facility is open to the general public and maintained on a nonprofit basis or for use without fee.

Public Service Facility—A dock or boat launching ramp constructed, owned or operated by a political subdivision of the Commonwealth which provides services necessary for public health and welfare, or in connection with a service for which no fees or charges other than general taxes are imposed.

Shoreline—The edge of water in a lake or other body of water at normal pool elevation; the edge of water along a waterway at the ordinary low water level.

Small Dock—A single floating, cantilevered or pile structure constructed within a waterway or other body of water and located on lands or adjacent to riparian lands which are owned or leased by the dock owner. Small docks authorized under this General Permit are classified in four categories based on the proposed use and type of ownership. These categories are (1) private recreational dock, (2) public access facility, (3) public service facility and (4) other private and commercial facilities.

D. Project Design and Construction Criteria for Docks

1. Small Docks may be constructed to any configuration but shall not exceed 750 square feet in surface area, except where other limits apply on navigable rivers of the United States and on Scenic Rivers (see items 1a and 1b which follow).

a. A Federal permit is required from the U. S. Army Corps of Engineers for small dock structures located on rivers and other waterways which are designated Navigable Waters of the United States and regulated under Section 10 of the Rivers and Harbors Act. The small dock surface area and configuration on these navigable waters must be in conformance with any applicable Section 10 permit criteria which may be more restrictive than this General Permit. Size and shape limitations may be subject to change and may vary between Corps District Offices.

b. In waterways which are part of the National or Pennsylvania Scenic Rivers System the total surface area of a small dock shall not exceed 250 square feet.

2. A small dock on a lake shall not extend more than 50 feet from the edge of normal pool elevation. In a river or other stream, a small dock shall not extend more than 20% of the width of the stream; however, it shall in no instance extend more than 100 feet from the ordinary low water mark of a stream.

3. Only one small dock shall be constructed on a given riparian parcel under this General Permit, except where the parcel is common property or where multiple parties have deeded access rights or easements. See Section F, Items 2 and 3 for specific terms regarding multiple use of this General Permit on a given riparian parcel.

Copyright © 1996 Commonwealth of Pennsylvania

4. No part of the small dock structure or associated boat mooring area may extend in front of adjacent riparian properties or otherwise interfere with access and use of the water by adjacent riparian land owners.

5. Each small dock shall be constructed in such a way that it does not hinder commercial or recreational navigation and does not interfere with normal fish migration.

6. Construction and other activities authorized by this General Permit shall be performed in a manner that minimizes use of equipment within the stream channel or body of water.

7. Construction of a small dock on a waterway shall take place during periods coinciding with lower stream flows.

8. Each small dock shall be constructed in such a way as not to obscure any navigation aids or lights for bridges in the area.

9. Small docks shall be maintained in a functional condition which includes the periodic removal of debris.

10. Maintenance dredging to restore original depths is permitted only in the mooring area for boats and is limited to 10 feet beyond the edge of the dock.

11. Dredging for construction purposes is not authorized by this General Permit.

12. This General Permit does not authorize the storage of fuel or the construction of fuel servicing facilities on the small dock.

13. This General Permit does not authorize the construction or modification of a small dock for use as a habitable structure with living facilities such as beds, bathrooms or kitchens.

14. The owner shall employ measures to prevent and control spills of fuels or lubricants into the waterway.

15. Flotation devices, if used, shall be securely fastened to the structure to prevent separation from the small dock.

16. Drums to be utilized as flotation devices that have been previously filled with another substance shall be thoroughly cleaned before use to preclude the possibility of pollution.

17. The small dock structure shall be adequately secured to the shoreline to insure the structure's stability to withstand the effects of wind, stream flows and wave action.

18. Anchorages shall be placed so they do not accelerate erosion or cause degradation of the streambanks.

19. The placement of fill or dredged material into a watercourse, floodway or body of water is not authorized under this General Permit.

20. To the greatest extent possible, the project shall be designed and constructed in a manner which will (a) prevent permanent or long-term changes in water quality, (b) minimize alterations in natural aquatic habitat and (c) maintain natural streamflow velocities and mixing patterns.

21. Archaeological artifacts discovered during the performance of work authorized under this General Permit must be adequately protected and their discovery promptly reported to the Director, Bureau of Historic Preservation, Pennsylvania Historical and Museum Commission, P. O. Box 1026, Harrisburg, PA 17108-1026, telephone (717) 787-2891.

E. Project Design and Construction Criteria for Boat Launching Ramps

1. Boat launching ramps authorized by this General Permit are limited to a maximum width of 20 feet.

2. Boat launching ramps shall be located to minimize streambank excavation and wetland impacts. Boat launching ramps are limited to a maximum length of 100 feet measured from the top of the ramp to the shoreline.

3. Only one boat launching ramp shall be constructed on a given riparian parcel under this General Permit, except where the parcel is common property or where multiple parties have deeded access rights or easements. See Section F, Items 2 and 3 for specific terms regarding multiple use of this General Permit on a given riparian parcel.

4. Construction and other activities authorized by this General Permit shall be performed in a manner that minimizes use of equipment within the stream channel or body of water.

5. Construction of a boat launching ramp along a waterway shall take place during periods when the stream is at low flow.

6. To the greatest extent possible, the project shall be designed and constructed in a manner which will (a) prevent permanent or long-term changes in water quality, (b) minimize alterations in natural aquatic habitat and (c) maintain natural streamflow velocities and mixing patterns.

7. Where required to support boat trailers, the portion of a boat launching ramp located in a streambed or lakebed may be stabilized by clean rock and/or gravel, timber, precast concrete planks or precast concrete slabs (formed onshore and pushed or lifted in place). This stabilization of the bed surface shall be limited to the minimum length necessary for boat launching.

8. Exposed bank areas along the approach ramp shall be stabilized and protected from the erosive action of waves and stream currents.

9. For launching ramps which require associated facilities such as parking lots and turn-around driveways in the floodway along a stream, necessary regrading shall be accomplished without the addition of fill within the regulated floodway. Parking facilities shall be built on existing grade or with minimal grade changes not exceeding 12 inches. Surfaces shall be stabilized with gravel, macadam or concrete. There shall be a volume of soil material removed from the floodway equal to or greater than the volume of construction materials to be used, and there shall be no net loss of conveyance area in the floodway cross-section. Along waterways designated Exceptional Value (EV) or High Quality Waters (HQ) under Chapter 93 Rules and Regulations (relating to

Copyright © 1996 Commonwealth of Pennsylvania

water quality), a 50-foot wide vegetated buffer strip is required between parking facilities and the streambank. Access roads which cross wetlands and improved parking areas in wetlands are not authorized by this General Permit.

10. Boat ramps constructed along Lake Erie shall be located near the western edge of a property to allow space to dispose future dredge material. Material from maintenance dredging of a boat ramp along the shoreline of Lake Erie shall be placed on the shoreline to the east of the removal site.

11. Archaeological artifacts discovered during the performance of work authorized under this General Permit must be adequately protected and their discovery promptly reported to the Director, Bureau of Historic Preservation, Pennsylvania Historical and Museum Commission, P. O. Box 1026, Harrisburg, PA 17108-1026, telephone (717) 787-2891.

F. Special Provisions Regarding Property Rights

1. *Submerged Lands License Agreements and Fees*—As explained in Part Two, Section E, Item 1 of this General Permit, a license agreement is required for projects which are located in certain waters designated navigable or public highways and which are held in trust by the Commonwealth. In accordance with Chapter 105 Rules and Regulations, a minimum annual license fee of $250 is assessed except for the following types of facilities and uses:

a. Private recreational docks constructed under a General Permit.

b. Public Access Facilities provided without charge or on a nonprofit basis.

c. Public Service Facilities provided without fees or charges.

There is no annual fee assessed for the facilities listed above. However, other types of docks or boat launching ramps will require an annual fee when located in Submerged Lands of the Commonwealth. Therefore, the user of this General Permit is required to indicate the type of structure on the Notification to Use form (Exhibit D).

2. *Multiple Use of the General Permit on Common Property*—An association of homeowners or similar group (association) holding title to common property with riparian rights may register to construct and maintain docks on behalf of individual members. The association shall assure that adequate spacing for mooring and access is maintained between docks. Each dock shall be registered by the association and constructed in accordance with the General Permit.

3. *Use of the General Permit where Multiple Parties Hold Access Rights on Riparian Land*—In areas where common use of riparian land is reserved by easement or other deed restrictions, and where there is no homeowners association or similar organization with appropriate authority, each holder (owner) of such easement or deed restriction may register and construct one dock and boat launching ramp under the authority of this General Permit. Owners are mutually responsible to assure that adequate spacing for mooring and access is

maintained between structures. Registering the use of this General Permit does not grant the right to interfere with other eligible users or with the riparian rights of others. Users of this General Permit are solely responsible to mutually resolve any problems of interference or other disagreements on riparian lands where access rights are shared.

G. Authority and Continuing Authorization—Authorization of this General Permit is under section 7 of the Dam Safety and Encroachments Act (32 P. S. § 693.7) and the rules and regulations promulgated thereunder at 25 Pa. Code §§ 105.441—105.449 (relating to general permits). This General Permit shall authorize the continued operation and maintenance of private recreational docks authorized by General Permit BDWM-GP-2 (Private Recreational Docks) issued on December 29, 1990.

EXHIBIT D

NOTIFICATION TO USE
BDWW-GP-2
Small Docks and Boat Launching Ramps

FOR DEPT. USE ONLY

ACKNOWLEDGED:
DATE _____
GP _____

1. I/We, _____
(owner name(s))
hereby notify the Department of Environmental Resources of our intent to install

_____
(description of dock or launching ramp)

at a point _____
(describe location)

in _____
(name of stream or body of water)

in _____ , _____
(municipality) (county)

2. Indicate type of use for the facility (see definitions in Part One, Section C):

_____ private recreational dock
_____ public access facility
_____ public service facility
_____ other private or commercial facility

3. I/We have attached a LOCATION MAP (similar to that shown on Drawing No. 1 indicating where the small dock or boat launching ramp will be installed) and a copy of SUPPLEMENT NO. 1.

3. I/We have enclosed duplicate copies of EXHIBIT D, the LOCATION MAP and SUPPLEMENT NO. 1.

5. I/We certify that copies of this notification were sent this day _____ (date)
to _____ , and _____
(municipality) (County-Commissioner's Office)

INSTRUCTIONS FOR USING THE GENERAL PERMIT BDWW-GP-3 Bank Rehabilitation, Bank Protection and Gravel Bar Removal

Prior to Registration to Use:

1. Carefully review the definitions and requirements of the General Permit (Part One and Part Two) to determine if your project can qualify for authorization under this General Permit. Refer to Part One, Section B regarding area restrictions and Part One, Sections D, E and F regarding criteria. If your project cannot be authorized under the General Permit, you may request approval of an individual permit by submitting an application to the appropriate Soils and Waterways Section in the Regional Office as listed on Exhibit B.

2. Locate your project on a United States Geological Survey (U.S.G.S.) 7 1/2 Minute Quadrangle Map (Commonly called ''topographic maps,'' U.S.G.S. Quadrangles may be available from local merchants dealing in books, hunting supplies and camping equipment.) and prepare a project Location Map, utilizing a photocopy of the U.S.G.S. Quadrangle Map.

3. Complete the top portion of the attached Supplement No. 1 (Pennsylvania Natural Diversity Inventory Form). You will not be authorized to use the General Permit until Supplement No. 1 has been processed to check for potential impacts to rare and endangered species. Therefore, to avoid possible project delays or unnecessary design costs, you are advised to submit Supplement No. 1 for processing prior to General Permit registration. To do so, follow the written instructions on the Supplement No. 1 form. The Department will complete the bottom portion of the form and return it to you, generally within a period of 2 weeks. You must have copies of Supplement No. 1 (whether processed or not) for submission as attachments when you register to use the General Permit.

Copyright © 1996 Commonwealth of Pennsylvania

4. Your project may also require a permit from the U. S. Army Corps of Engineers under section 404 of the Federal Clean Water Act, sections 9 and 10 of the Rivers and Harbors Act and/or section 103 of the Marine Protection, Research and Sanctuaries Act. The registration to use this State General Permit does not relieve you of the obligation to comply with, and the State is not authorized to address, these Corps of Engineers' requirements. Therefore, in order to avoid violation of Federal statutes, please contact the appropriate U. S. Corps of Engineers District Office listed below to determine whether a Federal permit is required for your project.

5. For any earthmoving activity (For the definition of earthmoving activity, see Part Two, Section C.) associated with your project, prepare the Erosion and Sedimentation Control Plan which must be reviewed and determined satisfactory by the County Conservation District in the county where your project is located. The required Erosion and Sedimentation Control Plan must be prepared and submitted to the Conservation District for review prior to or concurrent with your registration to use the General Permit.

6. Take color photographs of the project area showing the scope of the project and existing condition of the bank and/or gravel bar. Prepare two sets of these

photos, mount on 8 1/2″x11″ pages and label each photo with a brief description of what is shown and the date photos were taken.

The Registration Procedure:

7. Fill in all information on the Notification to Use form (Exhibit D) and make multiple copies. Send one copy each to the municipality and the county in which the project is located.

8. To register use of the General Permit, prepare a complete registration ''package'' consisting of:

—Two copies of Notification to Use form (Exhibit D)

—Two copies of the Location Map

—Two copies of the Supplement No. 1 form

—Two sets of Color Photographs (mounted with dates and descriptions)

Send these items to either:

—The County Conservation District for projects located in all counties where there is a delegation agreement (See Exhibit C).

—OR—

—The Soils and Waterways Section having responsibility for the counties where there is no delegation agreement with the County Conservation District (see Exhibit B).

9. If you are also applying for an individual Water Obstruction and Encroachment Permit to authorize related work, you may register to use the General Permit in conjunction with your individual permit application (see Part Two, Section A, Item 2).

Before and During Construction:

10. Do not begin work until:

a. You have received an acknowledgement from the Soils and Waterways Section or County Conservation District that your Exhibit D notification has been received and registered.

b. Your Erosion and Sediment Control Plan has been reviewed and determined to be satisfactory by the County Conservation District.

c. You have notified the Pennsylvania Fish and Boat Commission and the County Conservation District 10 days prior to start of construction (Part Two, Section D).

d. You have obtained any other Federal, State or local permits which may be required, including written authorization from the U. S. Army Corps of Engineers for gravel bar removal.

e. You have complied with any other applicable preconstruction requirements as listed in Part Two, Section E.

f. You have provided written notifications to the municipalities and county where the projects are located prior to the start of construction.

Copyright © 1996 Commonwealth of Pennsylvania

11. During construction of your project, you are responsible for adhering to all terms and conditions of the General Permit, including your approved Erosion and Sedimentation Control Plan and all applicable design and construction criteria in Part One, Sections D, E and F.

PART ONE

A. General Description and Fees—The Department of Environmental Resources hereby authorizes, by general permit, subject to the terms and criteria set forth below, the installation, operation, modification and maintenance of bank rehabilitation and protection projects and the removal of gravel bars in and along the regulated waters of this Commonwealth. There is no registration fee required for a project authorized under this General Permit.

B. Sites and Conditions Where this General Permit Does Not Apply—This General Permit does not apply and is not valid in the following situations. Where the General Permit is not applicable, you may request approval of an individual permit by submitting an application to the appropriate Soils and Waterways Section in the Regional Office (See Exhibit B).

1. Historical, cultural or archaeological sites as identified in the latest published version of the Pennsylvania Inventory of Historical Places or the National Register of Historical Places. This information is available from the Pennsylvania Historical and Museum Commission, Box 1026, Harrisburg, PA 17108-1026, telephone (717) 787-3362.

2. Sites identified in the latest published version of the National Registry of Natural Landmarks.

3. Wetlands.

4. Construction activities in stocked trout streams from March 1 through June 15, in wild trout streams from October 1 through December 31, and in Lake Erie tributaries from March 1 through June 15 and from September 1 through December 31, unless approval is obtained from the Pennsylvania Fish and Boat Commission's Division of Environmental Services (See Exhibit A). Stocked and wild trout stream locations are compiled by the Commission's Division of Fisheries Management (see Exhibit A).

5. Projects involving channel relocation, channel realignment or placement of fill to construct berms of levees.

6. Any project having a scope of work which is greater in length than 500 linear feet measured along a single continuous reach of stream channel.

7. Projects involving the installation of tires for bank protection.

8. The removal of vegetated gravel bars.

9. Projects requiring excavation of mudflats in the tidal waters of the Delaware River.

10. Projects located where there would be an impact on species of special concern listed under the Endangered Species Act of 1973, the Wild Resources

Conservation Act, the Fish and Boat Code or the Game and Wildlife Code. Records regarding species of special concern are maintained in a computer database called the ''Pennsylvania Natural Diversity Inventory'' (PNDI). To verify that there will be no such impacts for a specific project, the Department requires submission of the attached Supplement No. 1 form.

11. Areas in or within 100 feet of a watercourse designated wild in the National or State Scenic Rivers system in accordance with the National Wild and Scenic Rivers Act of 1968 or the Pennsylvania Scenic Rivers Act. For details on scenic river classifications, contact the DER Pennsylvania Scenic Rivers Program, P. O. Box 8475, Harrisburg, PA 17105-8475, telephone (717) 787-2316.

12. Gravel bar removal in streams or water bodies designated Exceptional Value Waters as defined and listed in Chapter 93 (related to water quality standards).

C. Definitions Applicable to this General Permit—The following words and terms, when used in this General Permit, have the following meanings:

Bank Rehabilitation and Bank Protection—To restore and/or protect the bank of a stream, lake, pond or reservoir against erosion, scour or sloughing by utilizing any of the following: slope protection, dumped rock protection, cribbing, walls, channel deflectors, vegetative stabilization techniques.

Channel Realignment—Any alteration of the stream channel alignment which involves excavation into an existing stream bank.

Concrete Rubble—Broken concrete in pieces not to exceed 5 feet in length where neither the width or thickness is less than 1/3 its length and all reinforcing is removed flush with the face of the concrete.

Dumped Rock Protection—Sound, durable stone or concrete rubble, insoluble in water and placed by dumping for the purpose of protecting against erosion, scour or sloughing of a bank. To resist transport by flowing water, National Stone Association R-7 is the minimum size rock which shall be used for dumped rock protection.

Filter Layer—Well-graded, hard, durable, non-soluble particles (free from muck, topsoil, organic matter or rubbish) or geotextile fabric, placed under slope protection to prevent the natural soil of the bank from being washed away through the slope protection layer.

Gravel Bars—Alluvial deposits in stream channels, including accumulations of gravel, glacial till, sediment, silt and flood debris, which obstruct and redirect flow, and which are thereby associated with stream bank erosion.

Riprap—A layer, facing or protective mound of stone in random size pieces, selectively placed to prevent erosion, scour or sloughing of a bank.

Slope Protection—A layer or facing of sound, durable rock or similar material (natural or manmade), insoluble in water, selectively placed by hand or machine and sized to resist transport by flowing water.

Copyright © 1996 Commonwealth of Pennsylvania

Vegetated—An area having greater than 50 percent surface coverage of persistent vegetation during the growing season (undisturbed by acts of man). Persistent vegetation is defined as having a predominance of perennial plant species with the exclusion of first year class seedlings of woody vegetation (shrubs and trees). The vegetational groupings to be considered consist of grasslikes, grasses, forbs, vines, shrubs and trees.

D. Project Design and Construction Criteria

1. The use of this General Permit is limited to activities which constitute a single, complete project in and along a continuous reach of stream channel not exceeding 500 feet in length. Multiple registration and use of this General Permit for the purpose of extending a project activity beyond the maximum length is prohibited; however, the Department will consider authorizing more extensive projects upon receipt of an application for an individual Water Obstruction and Encroachment Permit. Because this General Permit authorizes only single, complete projects, repeated projects each require a separate registration of General Permit use.

2. Construction of the bank rehabilitation, bank protection project or removal of a gravel bar should not constrict or increase the normal channel width. The configuration of the shoreline shall remain substantially the same and the work shall align smoothly with, and not project further into the channel than adjacent upstream and downstream banks. The upstream and downstream ends of a bank rehabilitation or bank protection project shall be keyed into the stream bank to ensure stability.

3. Construction and other activities authorized by this General Permit shall be performed in a manner that minimizes use of equipment within the stream channel or body of water.

4. Bank rehabilitation, bank protection and gravel bar removal shall take place during periods when the stream is at low flow.

5. To the greatest extent possible, the project shall be designed and constructed in a manner which will (a) prevent permanent or long-term adverse changes in water quality, (b) minimize alterations in natural aquatic habitat and (c) maintain natural streamflow velocities and mixing patterns.

6. The placement of fill higher than the elevation of the existing stream banks, the construction of levees, the realignment or relocation of the channel, dredging activities in water and excavation below existing water level are not authorized by this General Permit.

7. Bank rehabilitation, bank protection and gravel bar removal projects shall not extend across adjacent property lines without the written permission of all affected property owners.

8. During construction activities, all public and private property including existing vegetation, landscape features and monuments within, along and adjacent to the work area, shall be protected and preserved to the maximum degree

possible. This shall include, but not be limited to, precautions taken to minimize damage, erosion, injury or destruction; prevent pollution; provide protection of all trees and other woody plants; special care being taken to protect the natural vegetation and surroundings to include all natural drainageways, ponds, lakes, wetlands, woods and fields; and storage of materials in such manner to prevent leaching which would be injurious to soils and to plants. Precautions should be taken to prevent damage to pipes, conduits and other underground structures.

9. Archaeological artifacts discovered during the performance of work authorized under this General Permit must be adequately protected and their discovery promptly reported to the Director, Bureau of Historic Preservation, Pennsylvania Historical and Museum Commission, P. O. Box 1026, Harrisburg, PA 17108-1026, telephone (717) 787-2891.

10. As part of the registration to use this General Permit, the owner shall submit duplicate sets of labeled color photographs which show the scope of the project and the existing condition of the bank to be protected and/or the gravel bar to be removed. The two sets of photographs shall be mounted on 8 1/2″x11″ sheets. The date of photography and a written description of what is shown shall be provided for each photograph.

E. Additional Criteria for Bank Rehabilitation and Protection

1. Slope protection and dumped rock protection shall not exceed the placement of a maximum of 1 cubic yard per running foot below the plane of the ordinary high water mark or the high tide line (in order to be consistent with the requirements of the Corps of Engineers). Where slope protection or dumped rock protection is required to be placed in the floodway or floodplain above the plane of the ordinary high water mark or the high tide line, an additional 1 cubic yard per running foot of stream is authorized.

2. Riprap and other types of slope protection, except for vegetative stabilization and dumped stone protection, should be constructed in two layers.

(A) An outer layer of massive particles to resist the forces of moving water.

(1) The outer layer or principal protection layer should consist of well-graded particles. It is recommended that riprap slope protection shall be sized in accordance with the following Table E(2) designated Design Parameters for Riprap.

(2) The protecting layer should be placed to a minimum thickness approximately 6 inches greater than the maximum particle size, or in accordance with the following Table E(2) for riprap design.

(B) An underlying filter layer of fine material or filter fabric.

(1) Satisfactory filter materials are mixtures of gravel and clean sand with about 80% of the material ranging between 2 inches and 1/4 inch. An

Copyright © 1996 Commonwealth of Pennsylvania

alternative is a commercially available geosynthetic filter fabric that will allow drainage without loss of bank material.

(2) The gravel filter layer should be placed to a thickness in accordance with the following Table E(2) for riprap design.

3. Grouting of slope protection or dumped rock protection is not authorized by this General Permit.

Table E(2). Design Parameters for Riprap

NATIONAL STONE ASSOCIATION NUMBER	AVERAGE SIZE OF STONE IN INCHES	RANGE OF STONE SIZE IN INCHES	RECOMMENDED PLACEMENT THICKNESS IN INCHES	RECOMMENDED FILTER THICKNESS IN INCHES	MAXIMUM ALLOWABLE STREAMFLOW VELOCITIES IN FEET PER SECOND	
					1.5 HORIZONTAL TO 1 VERTICAL SLOPE	2 HORIZONTAL TO 1 VERTICAL SLOPE
R-4	6	3 TO 12	15	4	8	10
R-5	9	5 TO 18	24	6	11	12
R-6	12	7 TO 24	30	8	13	14
R-7	15	12 TO 30	36	10	14	16

Copyright © 1996 Commonwealth of Pennsylvania

4. Only clean, nonpolluting materials shall be used for bank rehabilitation and protection projects in order to minimize excessive turbidity by leaching of fines as well as to preclude entrance of undesirable chemical constituents to the watercourse by natural runoff or leaching.

5. Slag is not authorized for use under this General Permit unless it qualifies as a co-product which is suitable for the specific use.

6. Along streams which are classified priority 1-A or designated Scenic Rivers, it is recommended that bank protection and rehabilitation projects shall maintain the natural character of the bank by incorporating vegetation (see Drawing Nos. 11, 12 and 13). However, woody vegetation shall not be incorporated in riprap protection. The use of concrete rubble for dumped rock protection is prohibited along Scenic Rivers.

7. Dumped rock protection shall have a maximum exterior slope of 1.5 horizontal to 1.0 vertical and a minimum top width of 18 inches at the top of the zone to be protected, as shown on Drawing No. 3B. No filter layer is required for dumped rock protection using well-graded rock. National Stone Association R-7 rock is the minimum rock size to be used for dumped rock protection.

8. Slope protection should not be placed with an exterior slope steeper than 1.5 horizontal to 1.0 vertical.

9. For rock riprap installations, a trench must be excavated at the toe of the slope to provide a supporting base. This trench should be extended to an elevation of at least 2 feet below the streambed level and be filled with the same material as the outer protection layer.

10. Immediately following completion of the project all disturbed slopes shall be stabilized to prevent accelerated erosion in accordance with the approved Erosion and Sedimentation Control Plan.

11. Bank rehabilitation and bank protection projects shall be maintained in a functional condition at all times. Periodic removal of debris deposited on the bank project may be necessary.

12. Each bank rehabilitation and bank protection project shall not hinder commercial or recreational navigation nor interfere with the normal migration of fish.

13. Channel deflectors may not extend from the bank into the channel a distance greater than 25% of the total channel width, and may not extend above the normal water flow a distance greater than 6 inches at the streamward tip.

14. The maximum height of a vertical wall authorized under this General Permit is 6 feet measured from the top of wall to the streambed or lakebed adjacent to the wall.

F. Additional Criteria for Removal of Gravel Bars

1. The gravel bar removal shall be completed as a single operation in as short a time period as possible. Such projects shall follow the procedures for

channel restoration projects contained in Chapter 4 of the Department's Erosion and Sediment Pollution Control Program Manual, which is available from the County Conservation District Offices.

2. Removal of a gravel bar shall be limited to periods of low flow; a gravel bar shall be removed only to a depth 6 inches above the water level at time of the project. For streams where there are periods of no flow, depth of gravel bar removal is limited to 6 inches above the elevation of the streambed so as not to disturb the existing low flow channel.

3. The equipment operator or contractor shall be informed of the conditions of this General Permit regarding gravel bar removal and shall be provided with working drawings that clearly show the limits of excavation in accordance with the criteria of this General Permit.

4. Bulldozing of the gravel bar material in or across the stream channel is prohibited. Excavation into a streambed or into a streambank adjacent to a gravel bar is prohibited.

5. Material removed from the stream channel shall be deposited outside regulated waters of the Commonwealth including the floodway and any wetlands adjacent to the project, except when the material is suitable and used for bank reconstruction. When the excavated material is to be used to rebuild opposite streambanks, the material shall be hauled (and not pushed) to the placement location.

6. Clean gravel bar material may be used only as an underlying fill or filter material to reconstruct and stabilize an adjacent streambank where the work can be performed in accordance with Part One, Section E, Item 2 of this General Permit. Gravel bar material used in this manner shall be faced with an outer layer of adequately sized slope protection. Gravel bar material which is removed shall not be used for dumped rock protection as defined in this General Permit.

7. In accordance with § 105.233 of Chapter 105 rules and regulations, the removal of sand, gravel or other minerals from submerged lands of this Commonwealth, in quantities which are commercially usable or marketable, shall require a written agreement from and royalty payments to the Commonwealth.

8. Gravel bar removal on lands owned or administered by the Commonwealth as State Parks, State Game Lands or State Forests shall require prior written approval from the administering agency.

9. Gravel bar removal may have limited long-term benefits where there is a streambank erosion problem. Therefore, the use of bank rehabilitation and bank protection measures in conjunction with gravel bar removal is recommended.

10. The owner is advised that a permit from the U. S. Army Corps of Engineers may be required for gravel bar removal projects (see Instructions, Item 4).

Copyright © 1996 Commonwealth of Pennsylvania

G. Authority and Continuing Authorization—Authorization of this General Permit is under section 7 of the Dam Safety and Encroachment Act (32 P. S. § 693.7) and the rules and regulations promulgated thereunder at 25 Pa. Code §§ 105.441—105.449 (relating to general permits). This General Permit shall authorize the continued operation and maintenance of bank rehabilitation and protection authorized by General Permit BDWM-GP-3 (Bank Rehabilitation and Protection) issued on July 23, 1983, and reauthorized July 23, 1988 and August 20, 1988.

EXHIBIT D

FOR DEPT. USE ONLY

ACKNOWLEDGED:

GP _____

NOTIFICATION TO USE
BDWW-GP-3

Bank Rehabilitation, Bank Protection and Gravel Bar Removal

1. I/We, _____
(owner name(s))
hereby notify the Department of Environmental Resources of our intent to install

_____
(description of bank rehabilitation and protection)
and/or to remove gravel bar material measuring _____ feet by
(length)
_____ feet, in accordance with the terms of this General Permit,
(width, maximum)
across/along _____
(name of stream)
at a point _____
(describe location)
in _____ , _____
(municipality) (county)

2. I/We have attached a LOCATION MAP (similar to that shown on Drawing No. 1 indicating the site of the project and a copy of SUPPLEMENT NO. 1.

3. I/We have enclosed duplicate copies of EXHIBIT D, the LOCATION MAP and SUPPLEMENT NO. 1.

4. I/We have attached two sets (duplicates) of COLOR PHOTOGRAPHS, mounted on 8 1/2″ x 11″ pages, and labeled to show the existing conditions at the project site.

5. I/We certify that copies of this notification were sent this day _____ (date)

to _____ , and _____
(municipality) (County-Commissioner's Office)

6. I/We certify that an EROSION AND SEDIMENTATION CONTROL PLAN for this project has been submitted for review to the _____ County Conservation District on _____ (date) .

Signed by: _____ _____
(print name) (owner signature)

(title, if applicable) (city/state/zip code)

(owner address) (owner telephone number)

7. I/We hereby notify the Department also of our intention to install a temporary road crossing in accordance with the terms of BDWW-GP-8, Temporary Road Crossings, during thebank rehabilitation, bank protection and/or gravel bar removal activities (if applicable).

Signed: _____

Send to address on Exhibit B or delegated County Conservationi District on Exhibit C.

APPENDIX D
BUREAU OF DAMS AND WATERWAY MANAGEMENT; GENERAL PERMIT BDWM-GP-4 (INTAKE AND OUTFALL STRUCTURES)

Editor's Note: The following permit was published in the *Pennsylvania Bulletin* as a Notice and is codified under 1 Pa. Code § 3.1(a)(9) (relating to contents of *Code*) as a document which the Legislative Reference Bureau finds to be general and permanent in nature. See §§ 105.441—105.449 (relating to general permits) for regulations governing this permit.

1. *General Description and Authority*—The Department of Environmental Resources hereby authorizes, by General Permit, subject to the terms and criteria set forth below, the construction, operation and maintenance of intake and outfall structures in, along, across or projecting into the regulated waters of the Commonwealth. This authorization is under section 7 of the Dam Safety and Encroachments Act (32 P. S. § 693.7) and the rules and regulations promulgated thereunder at 25 Pa. Code §§ 105.441—105.449 (relating to general permits).

2. *Denial of Authorization*—The Department shall have the discretion, on a case-by-case basis, to deny, revoke or suspend the authorization to use this general permit for any project which the Department determines to have a substan-

Copyright © 1996 Commonwealth of Pennsylvania

tial risk to life, property or the environment or otherwise could not be adequately regulated by the provisions of this general permit.

3. *Continuing Authorization*—This general permit shall authorize the continued operation and maintenance of outfall structures authorized by general permit BDWM-GP-4 (Outfall Structures) issued on February 4, 1984.

4. *Definitions*—The following terms as used in this General Permit shall have the following meanings:

Body of Water—Any natural or artificial lake, pond, reservoir, swamp, marsh or wetland.

Channel—The bed and banks of a natural stream and/or a man made ditch, canal or conduit which conveys storm water or waste water to a receiving stream or body of water.

Floodway—The channel of the watercourse and those portions of the adjoining floodplains which are reasonably required to carry and discharge the 100-year frequency flood.

Intake—The inlet of a pipe or channel conveying water from a stream or body of water.

Install—To construct, place, lay or set in place.

Outfall—The outlet of a pipe or channel discharging storm water or wastewater into a receiving stream or body of water.

Intake and Outfall Structures—Any intake or outfall in or along a stream or body of water which includes such structures as endwalls, headwalls, splash pads, riprap, ditches, conduits, diffusers and diversions.

Owner—Any person who owns, controls, operates, maintains or manages a dam or reservoir, water obstruction or encroachment.

Person—Any natural person, partnership, association, corporation, public utility, municipality, municipal authority, political subdivision of the Commonwealth, receiver or trustee and any department, board, commission or authority of the Commonwealth.

Regulated Waters of the Commonwealth—All watercourses, streams or bodies of water and their floodways wholly or partly within or forming part of the boundary of this Commonwealth.

Stocked Trout Stream—Streams classified as approved trout waters by the Pennsylvania Fish Commission. Classification may be verified by contacting the Pennsylvania Fish Commission's Regional Office or Division of Environmental Services.

Storm Water—Flows consisting primarily of runoff resulting from a rainfall event and conveyed to a receiving stream or body of water through a pipe or channel.

Submerged Lands of This Commonwealth—All waters and permanently or periodically inundated lands owned by the Commonwealth, including all lands in the beds of navigable lakes and rivers and beds of streams declared public highways which are owned and held in trust by the Commonwealth.

Wastewater—Effluent from a sewage, industrial or water plant, conveyed through a pipe or channel for discharge into a receiving stream or body of water.

Watercourse—Any channel of conveyance of surface water having defined bed and banks, whether natural or artificial, with perennial or intermittent flow.

Wetlands—Those areas that are inundated or saturated by surface or groundwater at a frequency and duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions, including swamps, marshes, bogs and similar areas. The term includes but is not limited to wetland areas listed in the State Water Plan, the United States Forest Service Wetlands Inventory of Pennsylvania, the United States Fish and Wildlife Service Wetlands Inventory Maps, and the Pennsylvania Coastal Zone Management Plan and any wetland area designated by a river basin commission or as defined in this chapter.

Wild Trout Streams—Streams classified as supporting reproducing trout populations by the Pennsylvania Fish Commission. Classification may be verified by contacting the Pennsylvania Fish Commission's Regional Office or Division of Environmental Services.

5. *Submerged Lands of This Commonwealth*—This General Permit shall not be effective to authorize any project occupying submerged lands of this Common-

Copyright © 1996 Commonwealth of Pennsylvania

wealth until the owner has obtained an easement, right of way, license or lease from the Department authorizing the occupation of such submerged lands issued under section 15 of the Dam Safety and Encroachments Act (32 P. S. § 693.15), section 514 of The Administrative Code of 1929 (71 P. S. § 194), or other applicable laws. Upon receipt of notification of proposed use of this general permit from the owner, the Department will review the project for submerged lands and initiate a Submerged Lands License Agreement if applicable.

6. *Specific Areas Where General Permit Does Not Apply*—This General Permit is not authorized in the following areas:

a. Historical, cultural or archaeological sites as identified in the latest published version of the Pennsylvania Inventory of Historical Places or the National Register of Historical Places.

b. Local historical sites officially approved or recognized by a municipality.

c. Sites identified in the latest published version of the National Registry of Natural Landmarks.

d. Areas in or within 100 feet of a watercourse or body of water designated as or nominated for a National or State Wild or Scenic River in accordance with the National Wild and Scenic Rivers Act of 1968 or the Pennsylvania Scenic Rivers Act (32 P. S. §§ 820.21—820.29).

e. Wetlands.

f. These streams or water bodies specified as high-quality (HQ) or Exceptional Value (EV) in Chapter 93 (relating to water quality standards).

g. Stocked trout streams from March 1 through June 15, wild trout streams from October 1 through December 31 and Lake Erie tributaries from September 1 through December 1 unless approval is obtained from the Fish Commission's Division of Environmental Services.

h. Areas within easement lands of any Corps of Engineers or Commonwealth of Pennsylvania constructed local flood protection projects.

7. *Other Permits*—Nothing in this General Permit relieves the owner(s) of the obligation of complying with all Federal, Interstate Compact and State laws, regulations and standards for the construction, operation or maintenance of the intake and outfall structure(s).

8. *Notification of Proposed Use of General Permit*—Prior to construction the owners shall submit Exhibit C along with the required location map to the Bureau of Dams and Waterway Management. A copy of Exhibit C shall also be sent to the municipality and county in which the work will be performed. The owner may not begin work until he has notified the Bureau of Dams and Waterway Management and received an acknowledgement of that notification.

9. *Fees*—There is no fee required for a project authorized under this General Permit.

10. *Effective Time Period*—This General Permit will remain in effect indefinitely unless specifically modified, suspended or revised by the Department.

11. *Suspension, Modification or Revocation*—The Department may suspend, modify or revoke this General Permit at any time upon notice in the *Pennsylvania Bulletin*.

12. *Project Interference*—This General Permit does not authorize any interference with any existing or proposed Local, State, Federal or Federally Licensed Project, and permittee shall not be entitled to compensation for damage or injury to the work authorized herein which may be caused by or a result of existing or future operations undertaken by the United States or the Commonwealth of Pennsylvania or its Political Subdivisions in the public interest.

13. *Criteria*

a. Each intake and outfall structure shall be constructed in such manner so that there is no interference with any navigation on the stream, migration of fish or the passage of flood flows.

b. Intake and outfall structures authorized under this General Permit shall not interfere with stream uses as designated in Chapter 93 of the Department's Rules and Regulations.

c. Intake and outfall structures herein authorized shall be properly maintained which includes the removal of any accumulation of debris.

d. This General Permit is not to be construed as approval of discharges into the receiving stream or body of water which may require certification under section 401(a) of the Federal Water Pollution Control Act (33 U.S.C.A. § 1341(a)) or other relevant State Statutes.

e. This General Permit authorizes the construction only of those outfall structures having a pipe outfall 36 inches in diameter or less.

f. Intake structures shall be properly sized and located so that the intake does not violate the riparian rights of downstream users and does not substantially affect the course, current or cross section of the stream located downstream from the intake structure.

g. Intake structures shall be screened or otherwise properly designed to prevent impingement and entrainment of fish.

h. Any archaeological artifacts discovered during the performance of work authorized under this General Permit must be adequately protected and their discovery promptly reported to the Director, Bureau for Historic Preservation, Pennsylvania Historical and Museum Commission, Post Office Box 1026, Harrisburg, Pennsylvania 17120.

i. Pollution of the waterway with harmful chemicals, fuels, oils, greases, bituminous material, acid and/or other harmful or polluting materials, is prohibited.

j. Owner(s) must investigate for drinking water intakes or reservoirs for public and private water supply users downstream within 5 miles of the site of the intake or outfall structure and other users which may be affected by suspended solids and turbidity increases. Written notice shall be given at least 10 days prior to construction to operators of any such intakes or reservoirs. Own-

Copyright © 1996 Commonwealth of Pennsylvania

er(s) must notify public and private water supply operators immediately and no longer than 1 hour after the occurrence at the site which results in the release of suspended solids and turbidity to the stream.

k. Prior to the use of explosives in a watercourse or body of water the permittee shall secure a written permit from the Pennsylvania Fish Commission, under 30 Pa.C.S. § 2906 (relating to permits for uses of explosives). Requests should be directed to the Pennsylvania Fish Commission, Bureau of Administrative Services, Post Office Box 1673, Harrisburg, Pennsylvania 17120, (717) 657-4522.

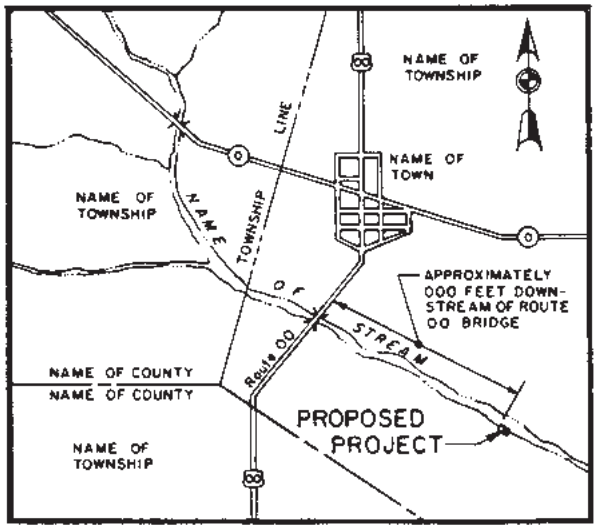
14. *Department Inspection*—As a condition of use of this general permit, and of the owner's authority to conduct the activities authorized by this general permit, the owner hereby authorizes and consents to allow authorized employes or agents of the Department, without advance notice or a search warrant, at any reasonable time and upon presentation of appropriate credentials, and without delay, to have access to and to inspect all areas where the project is being constructed, operated or maintained. The authorization and consent shall include consent to conduct tests or sampling, to take photographs, to perform measurements, surveys and other tests, to inspect the methods of construction, operation or maintainance, to examine and copy books, papers and records pertinent to any matter under investigation, and to take any other action necessary to assure that the project is constructed, operated or maintained in accordance with the terms and criteria of the general permit. This general permit condition is included under section 16 of the Dam Safety and Encroachments Act (32 P. S. § 693.16) and in no way limits any other powers granted under the Dam Safety and Encroachments Act.

15. *Activities not in Accordance with the Terms or Criteria*—If the department determines, upon inspection, that the construction, operation or maintenance of a project has violated the terms or criteria of this general permit or of this chapter, the Department may take such actions, legal or administrative, that it may deem to be appropriate.

16. *Structure Removal*—The owner(s) shall remove all or any portion of the intake or outfall structure upon written notification to the owner by the Department in the event the project is causing an adverse impact on public health, safety or the environment or in any other manner violates the conditions of this general permit or this chapter.

17. *Property Rights*—This General Permit does not convey any property rights, either in real estate or material, or any exclusive privileges, nor does it authorize any injury to property or invasion of rights or any infringement of Federal, State or local laws or regulations.

18. *Other Approvals*—The owners shall secure all other approvals that may be necessary under Federal, State or local laws or regulations.



19. *Fish Commission Notification*—The owners shall notify the Fish Commission's Regional Field Office Supervisor, see Exhibit A, responsible for the County where the activities are proposed 10 days prior to start of construction.

Notification by postcard is suggested. The project site shall at all times be available for inspection by authorized officers and employees of the Pennsylvania Fish Commission.

20. *Erosion and Sediment Pollution Controls*—Work must be done in compliance with Chapter 102 (relating to erosion and sediment control). Prior to construction an Erosion and Sediment Pollution Control Plan must be reviewed and determined adequate by the County Conservation District in which the activities are proposed and implemented prior to, during and after construction. The project site shall at all times be available for inspection by authorized employees of the County Conservation District. The Erosion and Sediment Pollution Control Plan shall be available at the site at all times.

APPENDIX E

UTILITY LINE STREAM CROSSINGS; GENERAL PERMIT BDWM-GP-5

Editor's Note: The following permit was published in the *Pennsylvania Bulletin* as a Notice and is codified under 1 Pa. Code § 3.1(a)(9) (relating to contents of *Code*) as a document which the Legislative Reference Bureau finds to be general and permanent in nature. See §§ 105.441—105.449 (relating to general permits) for regulations governing this permit.

1. *General Description and Authority*—The Department of Environmental Resources hereby authorizes, by general permit, subject to the terms and criteria set forth, the installation, operation and maintenance of utility line stream crossings of the regulated waters of the Commonwealth. This authorization is under section 7 of the Dam Safety and Encroachments Act (32 P. S. § 693.7) and the rules and regulations promulgated thereunder at §§ 105.441—105.449 (relating to general permits).

2. *Denial of Authorization*—The Department shall have the discretion, on a case-by-case basis, to deny, revoke or suspend the authorization to use this general permit for any project which the Department determines to have a substantial risk to life, property or the environment or otherwise could not be adequately regulated by the provisions of this general permit.

3. *Definitions*—The following terms as used in this general permit shall have the following meanings:

Body of Water—Any natural or artificial lake, pond, reservoir, swamp, marsh or wetland.

Floodway—The channel of the watercourse and those portions of the adjoining floodplains which are reasonably required to carry and discharge the 100-year frequency flood.

Install—To construct, deposit, place, lay or set in place.

Owner—Any person who owns, controls, operates, maintains or manages a dam or reservoir, water obstruction or encroachment.

Person—Any natural person, partnership, association, corporation, public utility, municipality, municipal authority, political subdivision of the Commonwealth, receiver or trustee and any department, board, commission or authority of the Commonwealth.

Regulated Waters of the Commonwealth—All watercourses, streams or bodies of water and their floodways wholly or partly within or forming part of the boundary of this Commonwealth.

Reservoir—Any basin, either natural or artificial, which contains or will contain the water or other fluid or semifluid impounded by a dam.

Stocked Trout Stream—Streams classified as approved trout waters by the Fish Commission. Classification may be verified by contacting the Fish Commission's Regional Office or the Division of Environmental Services.

Submerged Lands of this Commonwealth—All waters and permanently or periodically inundated lands owned by the Commonwealth, including all lands in the beds of navigable lakes and rivers and beds of streams declared public highways which are owned and held in trust by the Commonwealth.

Utility Line—Any pipe or pipeline for the transportation of a gaseous, liquid, liquifiable or slurry substance or, any cable, conduit, line or wire for the transmission of electrical energy, telephone, telegraph, radio or television signals, including cathodic corrosion protection.

Watercourse—Any channel of conveyance of surface water having defined bed and banks, whether natural or artificial, with perennial or intermittent flow.

Wetlands—Those areas that are inundated or saturated by surface or groundwater at a frequency and duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation typically adopted for life in saturated soil conditions, including swamps, marshes, bogs and similar areas. The term includes but is not limited to wetland areas listed in the State Water Plan, the United States Forest Service Wetlands Inventory of Pennsylvania, the United States Fish and Wildlife Service Wetlands Inventory Maps, as utilized by the Pennsylvania Coastal Zone Management Program and any wetland area designated by a river basin commission.

Wild Trout Streams—Streams classified as supporting reproducing trout populations by the Fish Commission. Classification may be verified by contacting the Fish Commission's Regional Office or the Division of Environmental Services.

4. *Submerged Lands of this Commonwealth*—This General Permit shall not be effective to authorize any project over, across or occupying submerged lands of this Commonwealth until the owner has obtained a license from the Department authorizing the occupation of such submerged lands issued under section 15 of the Dam Safety and Encroachments Act (32 P. S. § 693.15), section 514 of The Administrative Code of 1929 (71 P. S. § 194), or other applicable laws. Upon receipt of notification from the owner, the Department will review the project to determine if its location is over, across or occupies submerged lands of the Commonwealth.

5. *Specific Areas Where General Permit Does not Apply*—This general permit is not authorized in the following areas:

a. Historic, cultural or archaeological sites as identified in the latest published version of the Pennsylvania Inventory of Historical Places or the National Register of Historical Places.

Copyright © 1996 Commonwealth of Pennsylvania

b. Local historical sites officially approved or recognized by a municipality.

c. Sites identified in the latest published version of the National Registry of Natural Landmarks.

d. Areas in or within 100 feet of a watercourse or body of water designated as or nominated for a National or State Wild or Scenic River in accordance with the National Wild and Scenic Rivers Act of 1968 or the Pennsylvania Scenic Rivers Act (32 P. S. §§ 820.21—820.29).

e. Important wetlands regulated under § 105.17 (relating to wetlands).

f. Wetlands, greater than 10 acres in size.

g. Stocked trout streams from March 1 through June 15, wild trout streams from October 1 through December 31 and Lake Erie tributaries from September 1 through December 1 unless approval is obtained from the Fish Commission's Division of Environmental Services.

h. Reservoirs.

i. Streams or water bodies designated as Exceptional Value Waters as defined and listed in Chapter 93 (relating to water quality standards).

6. *Other Permits*—Nothing in this General Permit relieves the owners of the obligation of complying with all Federal, Interstate Compact and State laws, regulations and standards for the contruction, operation or maintenance of utility lines.

7. *Notification of Proposed Use of General Permit*—Prior to construction the owners shall submit Exhibit B along with the required location map to the Bureau of Dams and Waterway Management. A copy of Exhibit ''B'' shall also be sent to the municipality and county in which the work will be performed. The owner may not begin work until he has notified the Bureau of Dams and Waterway Management and received an acknowledgement of that notification.

8. *Fees*—There is no fee required for a project authorized under this general permit.

9. *Effective Time Period*—This general permit will remain in effect indefinitely unless specifically modified, suspended or revised by the Department.

10. *Suspension, Modification or Revocation*—The Department may suspend, modify or revoke this general permit at any time upon notice in the *Pennsylvania Bulletin*.

11. *Project Interference*—This general permit does not authorize any interference with any existing or proposed Local, State, Federal or Federally Licensed Project; and permittee shall not be entitled to compensation for damage or injury to the work authorized herein which may be caused by or a result of existing or future operations undertaken by the United States, the Commonwealth of Pennsylvania or its Political Subdivisions in the public interest.

12. *Conditions*

a. The maximum size utility line allowed is 36 inches in diameter.

b. All utility lines under streambeds shall be located such that there will be a minimum of 3 feet of cover between the top of the utility line or encasement and the lowest point in the natural contour of the streambed, unless the utility line is in rock, where a minimum cover of 1 foot shall be provided.

c. Trenches excavated for the installation of utility lines shall be the minimum width necessary. As soon as the utility line is installed and tested to ascertain no leakage, appropriate new or previously excavated backfill material shall be placed in the trench and the area restored to its original condition and elevation and stabilized. Backfill material stored in connection with the installation must be properly retained out of the floodway so as to prevent its discharge, washings or runoff from entering the waterway prior to its placement as backfill.

d. Adequate measures shall be used to prevent sedimentation from the trench from entering the stream.

e. The backfilling of the trench in which the pipe will be laid shall be done so as to eliminate the formation of a permanent ridge in the streambed.

f. During construction activities, all public and private property including existing vegetation, landscape features and monuments within, along and adjacent to the work area, shall be protected and preserved to the maximum degree possible. This shall include, but not be limited to, precautions taken to minimize damage, erosion, injury or destruction; prevent pollution; provide protection of all trees and other woody plants; special care being taken to protect the natural vegetation and surroundings to include all natural drainageways, ponds, lakes, swamps, woods and fields; and storage of materials in such a manner to prevent leaching which would be injurious to soils and to plants. Precautions should be taken to prevent damage to pipes, conduits and other underground structures.

g. Archaeological artifacts discovered during the performance of work authorized under this general permit must be adequately protected and their discovery promptly reported to the Director, Bureau of Historic Preservation, Historical and Museum Commission, Post Office Box 1026, Harrisburg, Pennsylvania 17120.

h. Owners shall investigate for drinking water intakes or reservoirs for public and private water supplies within 5 miles downstream of the crossing and written notice shall be given at least 10 days prior to construction to operators of any such intakes or reservoirs. Owners must notify public and private water supply operators immediately and no longer than 1 hour after an occurrence at the crossing site which results in the release of suspended solids and turbidity to the stream.

i. Mats, pads or other similar devices shall be used where crossings of wetland areas by construction equipment cannot be avoided. Original grades through wetlands must be restored after trenching and backfilling. Any excess fill material must be removed from the wetland and not spread onsite. Mound-

Copyright © 1996 Commonwealth of Pennsylvania

ing of fill material to allow for settlement in the trench will be permitted in accordance with best construction methods.

j. Deposition of dredged or excavated materials and all earthwork operations will be carried out in such a way as to minimize erosion of the material and preclude its entering into any wetland adjacent to the utility line crossing.

k. Utility line crossings of streams should be accomplished so that the line is at a right angle to the stream where possible, unless the crossing is installed on an existing bridge.

l. Whenever possible, in accordance with best construction methods utility line crossings are to be made ''in the dry'' by installing sandbag and plastic dams and piping stream flow through the affected area.

m. Prior to the use of explosives in a watercourse or body of water the permittee shall secure a written permit from the Fish Commission, under 30 Pa.C.S. § 2906 (relating to permits for use of explosives). Requests should be directed to the Fish Commission, Bureau of Administrative Services, Post Office Box 1673, Harrisburg, Pennsylvania 17120, (717) 657-4522.

13. *Pollution Incident Prevention and Mitigation*—For projects constructed under the authorization of this general permit which transmit hazardous or toxic material, the owner shall take the following actions to prevent or alleviate the harm from pollution, under the requirements of Chapter 101 (Reserved):

a. Develop and implement a Preparedness, Prevention and Contingency (PPC) Plan in accordance with Departmental guidelines. The Department reserves the right to require the PPC Plan to be revised or amended for any deficiencies subsequently identified by the Department.

b. In the event a pollution incident occurs which causes or threatens to cause surface or groundwater pollution, the owner shall:

(1) Promptly notify the Department by telephone of the location and nature of the danger.

(2) Notify all known downstream users of the water.

(3) Immediately take all necessary steps to prevent injury to property and downstream users and protect waters from pollution or danger of pollution.

(4) Remove any contamination from affected ground or surface water to the extent required by the Department.

14. *Department Inspection*—As a condition of use of this general permit, and of the owner's authority to conduct the activities authorized by this general permit, the owner hereby authorizes and consents to allow authorized employes or agents of the Department, without advance notice or a search warrant, at any reasonable time and upon presentation of appropriate credentials, and without delay, to have access to and to inspect all areas where the project is being constructed, operated or maintained. The authorization and consent shall include consent to conduct tests or sampling, to take photographs, to perform measurements, surveys and other tests, to inspect the methods of construction, operation or maintenance, to examine and copy books, papers and records pertinent to any matter under

investigation, and to take any other action necessary to assure that the project is constructed, operated or maintained in accordance with the terms and criteria of the general permit. This general permit condition is referenced in accordance with section 16 of the Dam Safety and Encroachments Act (32 P. S. § 693.16) and in no way limits any other powers granted under the Dam Safety and Encroachments Act.

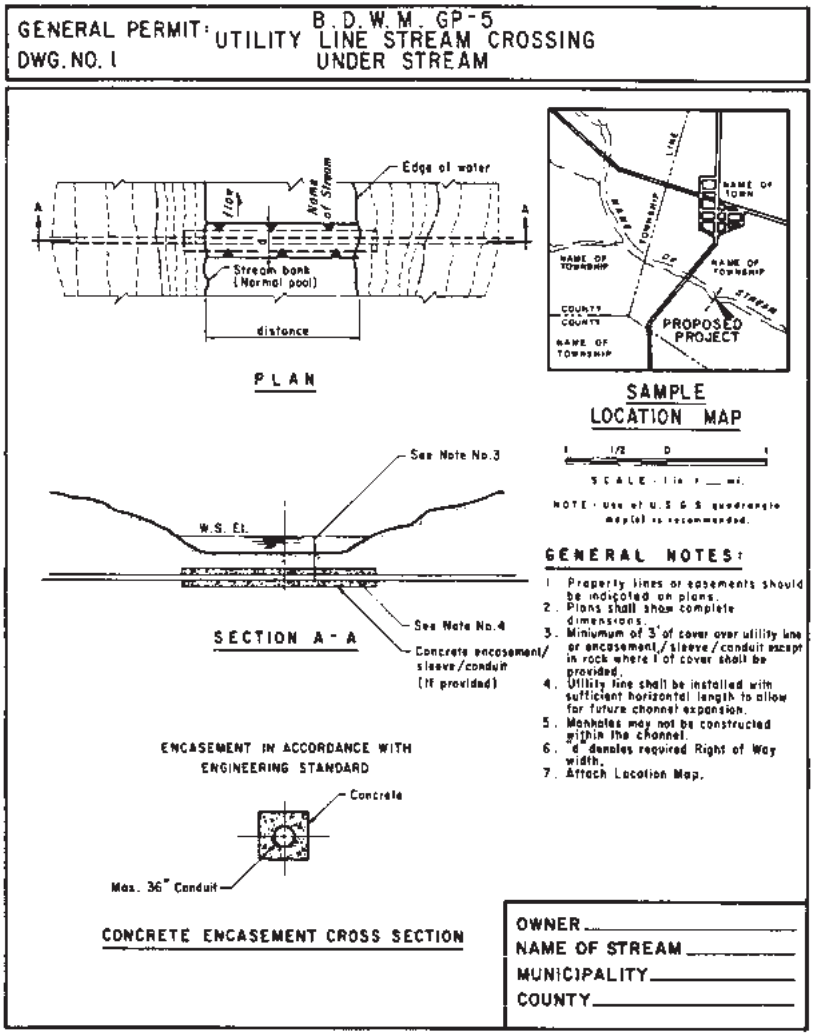
15. *Activities not in Accordance with the Terms or Conditions*—If the Department determines, upon inspection, that the construction, operation or maintenance of a project has violated the terms or conditions of this general permit or of this chapter the Department may take such actions, legal or administrative, that it may deem to be appropriate.

16. *Structure Removal*—The owners shall remove all or any portion of the utility line project upon written notification to the owner by the Department in the event the project is causing an adverse impact on public health, safety or the environment or in any other manner violates the conditions of this general permit or this chapter.

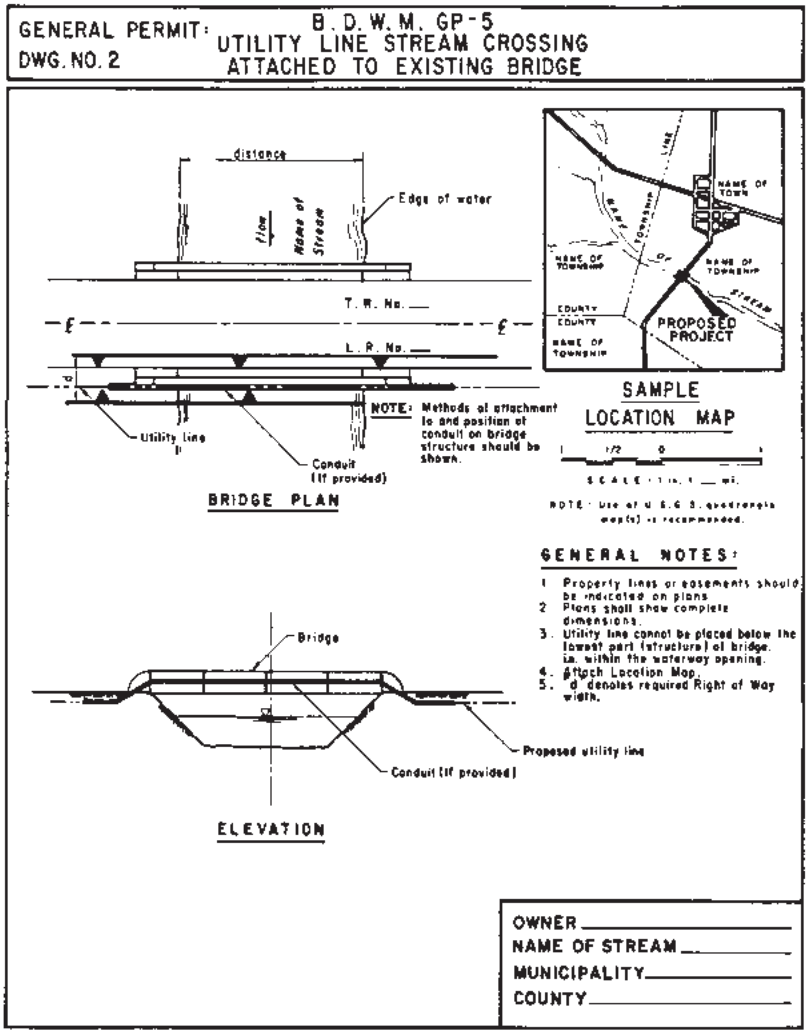
17. *Property Rights*—This general permit does not convey any property rights, either in real estate or material, or any exclusive privileges; nor does it authorize any injury to property or invasion of rights or any infringement of Federal, State or local laws or regulations.

18. *Other Approvals*—The owners shall secure all other approvals that may be necessary under other Federal, State or local laws or regulations, including the specific permission of owners of bridges or other structures to which the utility line may be attached.

19. *Fish Commission Notification*—The owners shall notify the Fish Commission's Regional Field Office Supervisor, responsible for the County where the activities are proposed 10 days prior to start of construction. Notification by postcard is suggested. The project site shall at all times be available for inspection by authorized officers and employes of the Fish Commission.



20. *Erosion and Sediment Pollution Controls*—Work must be done in compliance with Chapter 102 (relating to erosion and sediment control). Prior to construction an Erosion and Sediment Pollution Control Plan must be reviewed and determined adequate by the County Conservation District in which the activities are proposed and implemented prior to, during and after construction. The County Conservation District shall be notified 10 days prior to the start of construction. The project site shall at all times be available for inspection by authorized employes of the County Conservation District. The Erosion and Sediment Pollution Control Plan shall be available at the site.



21. *Utilization of General Permit BDWM-GP-8, Temporary Road Crossings*—Temporary road crossings of streams and causeways that are necessary for equipment to move back and forth across a stream and located adjacent to the utility line crossing are authorized by and must be constructed in accor-

Copyright © 2000 Commonwealth of Pennsylvania

dance with BDWM-GP-8. The owners shall indicate utilization of GP-8 on Exhibit B in the space provided. Owners constructing temporary road crossings in those areas excluded from the application of GP-8 must apply for an individual water obstruction permit for those road crossings.

The provisions of this Appendix E adopted January 15, 1988, effective February 16, 1988, 18 Pa.B. 276.

APPENDIX F
AGRICULTURAL CROSSINGS AND RAMPS; GENERAL PERMIT BDWM-GP-6

Editor's Note: The following permit was published in the *Pennsylvania Bulletin* as a Notice and is codified under 1 Pa. Code § 3.1(a)(9) (relating to contents of *Code*) as a document which the Legislative Reference Bureau finds to be general and permanent in nature. See §§ 105.441—105.449 (relating to general permits) for regulations governing this permit.

1. *General Description and Authority*—The Department of Environmental Resources hereby authorizes, by general permit, subject to the terms and criteria set forth, the installation, operation and maintenance of Agricultural Crossings and Ramps in the regulated waters of the Commonwealth. This authorization is pursuant to section 7 of the Dam Safety and Encroachments Act (32 P. S. § 693.7), and the rules and regulations promulgated thereunder at 25 Pa. Code §§ 105.441—105.449 (relating to general permits).

2. *Denial of Authorization*—The Department shall have the discretion, on a case-by-case basis, to deny, revoke or suspend the authorization to use this general permit for any project which the department determines to have a substantial risk to life, property or the environment or otherwise could not be adequately regulated by the provisions of this permit.

3. *Definitions*—The following terms as used in this general permit shall have the following meanings.

Agricultural ramp—The stabilization of the stream bank with stone or timber to provide protection of the stream bank from livestock and agricultural equipment use.

Agricultural crossing—The stabilization of the bed or banks of a stream to provide protection of the bed and banks from livestock and agricultural equipment use.

Body of water—Any natural or artificial lake, pond, reservoir, swamp, marsh or wetland.

FEMA—The Federal Emergency Management Agency.

Floodway—The channel of the watercourse and those portions of the adjoining floodplains which are reasonably required to carry and discharge the 100-year frequency flood. Unless otherwise specified, the boundary of the floodway is as indicated on maps and flood insurance studies provided by FEMA. In an area where no FEMA maps or studies have defined the boundary of the 100-

year frequency floodway, it is assumed, absent evidence to the contrary, that the floodway extends from the stream to 50 feet from the top of the bank of the stream.

Install—To construct, deposit, lay or set in place.

Owner—Any person who owns, controls, operates, maintains, or manages a dam or reservoir, water obstruction, or encroachment.

Person—Any natural person, partnership, association, corporation, public utility, municipality, municipal authority, political subdivision of the Commonwealth, receiver or trustee and any department, board, commission, or authority of the Commonwealth.

Regulated waters of this Commonwealth—All watercourses, streams or bodies of water and their floodways wholly or partly within or forming part of the boundary of this Commonwealth.

Reservoir—A basin, either natural or artificial, which contains or will contain the water or other fluid or semi-fluid impounded by a dam.

Stocked trout stream—Streams classified as approved trout waters by the Pennsylvania Fish Commission. Classification may be verified by contacting the Pennsylvania Fish Commission's Regional Office, Division of Property Services or Division of Environmental Services.

Submerged lands of this Commonwealth—All waters and permanently or periodically inundated lands owned by this Commonwealth, including all lands in the beds of navigable lakes and rivers and beds of streams declared public highways which are owned and held in trust by the Commonwealth.

Watercourse—Any channel or conveyance of surface water having defined bed and banks, whether natural or artificial, with perennial or intermittent flow.

Wetlands—Those areas that are inundated or saturated by surface or ground water at a frequency and duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions, including swamps, marshes, bogs, and similar areas. The term includes but is not limited to wetland areas listed in the State Water Plan, the United States Forest Service Wetlands Inventory of Pennsylvania, the Pennsylvania Coastal Zone Management Plan, and any wetland area designated by a river basin commission (or as defined in this chapter).

Wild trout streams—Streams classified as supporting reproducing trout populations by the Pennsylvania Fish Commission. Classification may be verified by contacting the Pennsylvania Fish Commission's Regional Office, Division of Property Services or Division of Environmental Services.

4. *Submerged Lands of this Commonwealth*—This general permit shall not be effective to authorize any project over, across or occupying submerged lands of this Commonwealth until the owner has obtained a license from the Department authorizing the occupation of such submerged lands issued under section 15 of the Dam Safety and Encroachments Act (32 P. S. § 693.15), section 514 of The Administrative Code of 1929 (71 P. S. § 194) or other applicable laws. Upon

Copyright © 1996 Commonwealth of Pennsylvania

receipt of notification from the owner, the Department will review the project to determine if its location is over, across, or occupies submerged lands of the Commonwealth.

5. *Specific Areas Where General Permit Does Not Apply*

a. Historic, cultural or archaeological sites as identified in the latest published version of the Pennsylvania Inventory of Historical Places or the National Register of Historical Places.

b. Local historical site officially approved or recognized by a municipality.

c. Sites identified in the latest published version of the National Registry of Natural Landmarks.

d. Stocked trout streams from March 1 through June 15, wild trout streams from October 1 through December 31, and Lake Erie tributaries from September 1 through December 1 unless written approval is obtained from the Pennsylvania Fish Commission's Division of Property Services or Division of Environmental Services.

e. Wetlands except those wetlands that are immediately adjacent to or within a watercourse and are an integral part of the construction of the Agricultural Ramp or Crossing.

f. Streams or water bodies designated as Exceptional Value Waters (EV) as defined and listed in Chapter 93 (relating to water quality standards).

6. *Other Permits*—Nothing in this General Permit relieves the owners of the obligation of complying with all Federal, Interstate Compact and State laws, regulations and standards for installation, operation or maintenance of Agricultural Crossings and Ramps.

7. *Notification of Proposed Use of General Permit*—Prior to construction the owner shall submit Exhibit C along with the required location map to the Bureau of Dams and Waterway Management. A copy of Exhibit C shall be sent to the municipality and county in which the work will be performed. THE OWNER MAY NOT BEGIN WORK UNTIL HE HAS NOTIFIED THE BUREAU OF DAMS AND WATERWAY MANAGEMENT AND RECEIVED ACKNOWLEDGEMENT OF THE NOTIFICATION.

8. *Change of Ownership*—If there is a change in ownership of an agricultural crossing or ramp installed in accordance with this general permit, the new owner is required to register the structure with the Department in accordance with Item 7.

9. *Fees*—There is no fee required for a project authorized under this general permit.

10. *Effective Time Period*—This general permit will remain in effect indefinitely unless specifically modified, suspended, or revised by the Department.

11. *Suspension, Modification or Revocation*—The Department may suspend, modify, or revoke this general permit at any time upon notice in the *Pennsylvania Bulletin*.

12. *Project Interference*—This general permit does not authorize any interference with any existing or proposed Local, State, Federal or Federally License Project, and permittees shall not be entitled to compensation for damage or injury to the work authorized herein which may be caused by or a result of existing or future operations.

13. *Conditions.*

a. The Pennsylvania Fish Commission Division of Property Services, United States Department of Agriculture Soil Conservation Service or respective County Conservation District may be able to provide technical assistance in locating appropriate sites for agricultural crossings and ramps.

b. The agricultural crossing or ramp shall be completed within 30 days from the start of its construction. All disturbed areas shall be stabilized within 5 days.

c. Construction of the crossing or ramp should not alter the normal channel width. The configuration of the stream bank shall remain substantially the same and the work shall blend with adjacent upstream and downstream banks.

d. Each agricultural crossing and ramp shall be installed in such a way that it does not hinder recreational navigation nor interfere with the normal migration of fish.

e. Written notice shall be given to operators of drinking water intakes or reservoirs for public and private water supplies and permitted public bathing beaches within 5 miles downstream of the crossing or ramp at least 10 days prior to construction of the crossing. Owner(s) must notify operators immediately and no longer than 1 hour following the release of suspended solids and turbidity to the stream due to any construction activity.

f. Structures authorized by this general permit shall be maintained in a safe and functional condition including necessary debris removal.

g. Only clean, nonpolluting, granular materials shall be used as fill material in order to minimize excessive turbidity by leaching of fines as well as to preclude the entrance of potentially polluted materials to the watercourse by natural runoff.

h. Slag may not be used as a substitute for stone.

i. Dredged or excavated materials may not be deposited in wetlands or within the limits of the floodway or any area affected by floods.

j. Prior to the use of explosives in a watercourse or body of water the permittee shall secure a written permit from the Pennsylvania Fish Commission, under 30 Pa.C.S. § 2906 (relating to permits for use of explosives). Requests should be directed to the Fish Commission, Division of Environmental Services (See Exhibit A).

k. Agricultural crossings and ramps shall be installed at a right angle to the stream flow.

Copyright © 1996 Commonwealth of Pennsylvania

l. Agricultural crossings and ramps must be keyed into the stream bank(s) or bed which may be accomplished by trenching or by machine weight running on the stone fill.

m. Agricultural crossings and ramps should be no steeper than 4:1.

n. Skidding of timber across ramps and crossings is prohibited.

o. Interior stone for crossings and ramps shall be of a diameter to fill the voids that will encourage livestock use.

p. Exterior frame stone for crossings and ramps shall be of sufficient diameter to resist transport by normal high flows and require deeper keying into the stream bank or bed.

q. Stone placed for agricultural crossings shall not exceed 12 inches in height above the natural streambed.

r. The placement of fill higher than the elevation of the existing stream banks, the realignment of the channel or the dredging of a watercourse is not authorized by this general permit.

s. Grouting of stone is not authorized by this general permit.

t. Agricultural crossings and ramps that are to be utilized by livestock shall include fencing or other barriers to direct the livestock to the crossing or ramp and to control the movement within the crossing or ramp.

u. Roadways leading to or from an agricultural crossing or ramp that are to be constructed in wetlands are not authorized by this general permit.

v. Archaeological artifacts discovered during the performance of the work authorized under this general permit must be adequately protected and their discovery promptly reported to the Director, Bureau of Historic Preservation, Pennsylvania Historical Museum, Post Office Box 1026, Harrisburg, Pennsylvania 17108-1026.

14. *Department Inspection*—As a condition of use of this general permit, and of the owner's authority to conduct the activities authorized by this general permit, the owner hereby authorizes and consents to allow authorized employees or agents of the Department, without advance notice or search warrant, at any reasonable time and upon presentation of appropriate credentials, and without delay, to have access to and to inspect all areas where the project is being constructed, operated or maintained. The authorization and consent shall include consent to conduct tests or sampling, to take photographs, to perform measurements, surveys and other tests, to inspect the methods of construction, operation or maintenance, to examine and copy books, papers and records pertinent to any matter under investigation, and to take any other action necessary to assure that the project is constructed, operated or maintained in accordance with the terms and criteria of the general permit. This general permit condition is referenced in accordance with section 16 of the Dam Safety and Encroachments Act (32 P. S. § 693.16), and in no way limits any other powers granted under the Dam Safety and Encroachments Act.

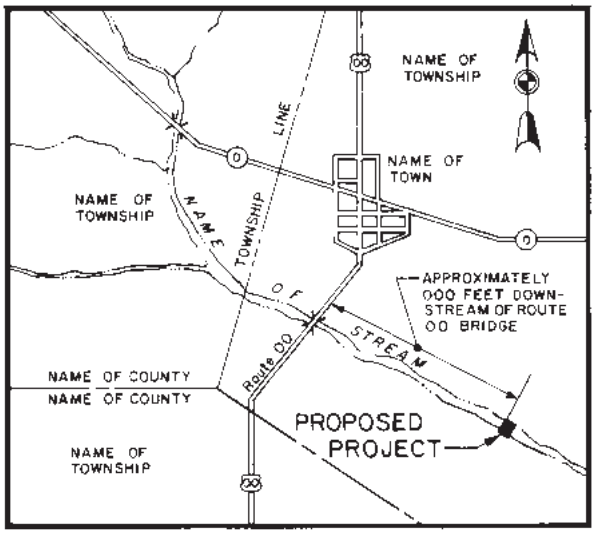
15. *Activities not in Accordance with the Terms or Conditions*—If the Department determines, upon inspection, that the construction, operation, or maintenance of a project has violated the terms or criteria of this general permit or of this chapter, the Department may take such actions, legal or administrative, that it may deem to be appropriate.

16. *Structure Removal*—The owner(s) shall remove all or any portion of the agricultural structures upon written notification to the owner by the Department in the event the project is causing an adverse impact on public health, safety or the environment or in any other manner violates the conditions of this general permit or this chapter.

17. *Property Rights*—This general permit does not convey any property rights, either in real estate or material, or in any exclusive privileges; nor does it authorize any injury to property or invasion of rights or any infringement of Federal, State, or Local laws or regulations.

18. *Other Approvals*—The owner(s) shall secure all other approvals that may be necessary under Federal, State, or Local laws or regulations.

19. *Fish Commission Notification*—The owner(s) shall notify the Pennsylvania Fish Commission's Regional Law Enforcement Field Office Supervisor (see Exhibit ''A'') responsible for the county where the activities are proposed 10 days prior to start of construction. Written notification is suggested. The project site shall at all times be available for inspection by authorized officers and employees of the Pennsylvania Fish Commission.



20. *Erosion and Sediment Pollution Controls*—Work must be done in compliance with Chapter 102 (relating to erosion and sediment control). Prior to construction an Erosion and Sediment Pollution Control Plan must be reviewed and determined adequate by the County Conservation District in which the activities are proposed and implemented prior to, during, and after construction. The County Conservation District shall be notified 10 days prior to the start of construction. The project site shall at all times be available for inspection by authorized employees of the County Conservation District. The Erosion and Sediment Pollution Control Plan shall be available at the site at all times.

21. *Utilization of General Permit BDWM-GP-8; Temporary Road Crossings*—Temporary road crossings of streams and causeways that are necessary for equipment to move back and forth across a stream and located adjacent to an agricultural crossing or ramp are authorized by and must be constructed in accordance with BDWM-GP-8. The owner shall indicate utilization of GP-8 on Exhibit C in the space provided. Owners constructing temporary road crossings in those areas where GP-8 is not authorized must apply for a Water Obstruction and Encroachment Permit for those road crossings.

APPENDIX G
MINOR ROAD CROSSINGS; GENERAL PERMIT BDWM-GP-7

Editor's Note: The following permit was published in the *Pennsylvania Bulletin* as a Notice and is codified under 1 Pa. Code § 3.1(a)(9) (relating to contents of *Code*) as a document which the Legislative Reference Bureau finds to be general and permanent in nature. See §§ 105.441—105.449 (relating to general permits) for regulations governing this permit.

1. *General Description and Authority*—The Department of Environmental Resources hereby authorizes by General Permit, (1) the construction, operation and maintenance of a minor road crossing across wetlands which disturbs less than 0.1 acre of wetlands, (2) the construction, operation and maintenance of a minor road crossing across a stream where the watershed drainage area is 1.0 square mile or less and (3) the removal of an existing minor road crossing across a stream where the drainage area is 1.0 square mile or less. This authorization is pursuant to section 7(b) of the Dam Safety and Encroachments Act (32 P. S. § 693.7(b)) and the rules and regulations promulgated thereunder at 25 Pa. Code §§ 105.441—105.449 (relating to general permits). This General Permit is subject to the terms and conditions set forth below.

2. *Denial of Authorization*—The Department shall have the discretion, on a case-by-case basis, to deny, revoke or suspend the authorization to use this General Permit for any project which the Department determines to present a risk to life, property or the environment or otherwise would not be adequately regulated by the provisions of this General Permit.

3. *Definitions*—The following terms as used in this General Permit shall have the following meaning:

Body of water—Any natural or artificial lake, pond, reservoir, swamp, marsh or wetland.

Bridge—A structure and its appurtenant works erected over the regulated waters of this Commonwealth.

Causeway—A roadway embankment constructed in or across a wetland.

Construct—To erect, build, place or deposit including preliminary preparation of a site for construction.

Culvert—A structure with appurtenant works which carries a stream under or through an embankment or fill.

Dredge—To remove sand, gravel, mud or other materials from the beds of regulated waters of this Commonwealth.

Existing minor road crossing—A bridge or culvert and fill crossing of a stream where the watershed drainage area is 1.0 square mile or less.

FEMA—The Federal Emergency Management Agency.

Fill—Sand, gravel, earth or other material placed or deposited so as to form an embankment or raise the elevation of the land surface. The term includes material used to replace an area with aquatic life with dry land or to change the bottom elevation of a regulated water of this Commonwealth.

Flood—A general but temporary condition of partial or complete inundation of normally dry land areas from the overflow of streams, rivers or other waters of this Commonwealth.

Floodway—The channel of the water course and those portions of the adjoining floodplains which are reasonably required to carry and discharge the 100-year frequency flood. Unless otherwise specified, the boundary of the floodway is as indicated on maps and flood insurance studies provided by FEMA. In an area where no FEMA maps or studies have defined the boundary of the 100-year frequency floodway, it is assumed absent evidence to the contrary, that the floodway extends from the stream to 50 feet from the top of the bank of the stream.

Ford—A road crossing of a stream utilizing the existing streambed.

Maintenance dredging—Dredging conducted as part of the construction of a dam, water obstruction, or encroachment, and periodic dredging conducted in order to:

(i) maintain adequate depths for navigation;

(ii) assure proper passage of ice and flood flows; or

(iii) preserve the safety, stability and proper operation of the facility.

Minor road crossing—A road constructed across a wetland where the length of the crossing is less than 100 feet and the total wetland area disturbed is less than 0.1 acre, or a road constructed across a stream and an adjacent wetland utilizing a bridge, culvert, or ford crossing where the watershed drainage area is 1.0 square mile or less and the total wetland area disturbed is less than 0.1 acre.

Owner—A person who owns, controls, operates, maintains or manages a dam or reservoir, water obstruction or encroachment.

Person—A natural person, partnership, association, corporation, public utility, municipality, municipal authority, political subdivision of the Commonwealth, receiver or trustee and a department, board, commission or authority of the Commonwealth.

Regulated waters of the Commonwealth—Water courses, streams or bodies of water and their floodways wholly or partly within or forming part of the boundary of this Commonwealth.

Copyright © 1996 Commonwealth of Pennsylvania

Replacement wetlands—Artificially created wetlands to replace those wetlands destroyed by the construction of a minor road crossing.

Stocked trout streams—Streams classified as approved trout waters by the Pennsylvania Fish Commission. Classification shall be verified by contacting the Pennsylvania Fish Commission's Regional Office or Division of Environmental Services (see Exhibit A).

Stream—A watercourse.

Stream enclosure—Any bridge, culvert or other structure in excess of 100 feet in length upstream to downstream which encloses any regulated water of this Commonwealth.

Submerged lands of this Commonwealth—Waters and permanently or periodically inundated lands owned by the Commonwealth, including lands in the beds of navigable lakes and rivers and beds of streams declared public highways which are owned and held in trust by the Commonwealth.

Watercourse—A channel or conveyance of surface water having defined bed and banks, whether natural or artificial, with perennial or intermittent flow.

Watershed—A region or area contributing to the supply of a stream or lake; drainage area, drainage basin or catchment area.

Wetlands—Those areas that are inundated or saturated by surface or ground water at a frequency and duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions, including swamps, marshes, bogs and similar areas. The term includes but is not limited to wetland areas listed in the State Water Plan, United States Forest Service Wetlands Inventory of Pennsylvania, the Pennsylvania Coastal Zone Management Plan, and any wetland area designated by a river basin commission.

Wild trout streams—Streams classified as supporting reproducing trout populations by the Fish Commission. Classifications shall be verified by contacting the Fish Commission's Regional Office or the Division of Environmental Services (see Exhibit A).

4. *Submerged Lands of this Commonwealth*—This General Permit shall not be effective to authorize any project over, across or occupying submerged lands of this Commonwealth until the owner has obtained a license from the Department authorizing the occupation of such submerged lands issued under section 15 of the Dam Safety and Encroachments Act (32 P. S. § 693.15), section 514 of The Administrative Code of 1929 (71 P. S. § 194) or other applicable laws. Upon receipt of notification from the owner, the Department will review the project to determine if its location is over, across or occupies submerged lands of the Commonwealth.

5. *Specific Areas and Activities Where General Permit Does Not Apply*—This General Permit does not apply in and is not valid in the following situations:

a. Historic, cultural or archaeological sites as identified in the latest published version of the Pennsylvania Inventory of Historic Places or the National Register of Historic Places.

b. Local historical sites officially approved or recognized by a municipality.

c. Sites identified in the latest published version of the National Registry of Natural Landmarks.

d. Areas in or within 100 feet of a watercourse or body of water designated as a National or State Wild or Scenic river in accordance with the National Wild and Scenic Rivers Act of 1968 or the Pennsylvania Scenic Rivers Act (32 P. S. §§ 820.21—820.29).

e. Stocked trout streams from March 1 through June 15, wild trout streams from October 1 through December 31, and Lake Erie tributaries from September 1 through December 1 unless written approval is obtained from the Fish Commission's Division of Environmental Services. (See Exhibit A).

f. Stream enclosures.

g. Streams or water bodies designated as exceptional value waters as defined in Chapter 93 (relating to water quality standards).

h. Stream channel crossing(s) where the watershed drainage area upstream of the crossing is greater than 1 square mile.

i. A stream channel and the adjoining floodplain which is delineated as a floodway on Flood Insurance Maps that are part of a Flood Insurance Study prepared by FEMA. These maps are available from the local municipality.

j. Wetland crossings where the extent of wetland impact for an individual minor road crossing is greater than .1 acre and the cumulative wetland impact for all minor road crossings installed by an owner on an individual property or project including phased projects is greater than .25 acre. A project shall include the aggregate of all stages of development and all parcels within a subdivision plan, which are under the control of the registrant.

k. Wetland crossings where the wetlands serve as habitat for fauna or flora listed as ''threatened'' or ''endangered'' under the Endangered Species Act of 1973, the Wild Resource Conservation Act, the Fish and Boat Code or the Game and Wildlife Code. Sites for minor road crossings may be checked through the Pennsylvania Natural Diversity Inventory by contacting the Bureau of Forestry, Division of Advisory Services, Post Office Box 8552, Harrisburg, Pennsylvania 17105-8552 or any of the offices listed on Exhibit B.

6. *Other Permits*—Nothing in this General Permit relieves the owner(s) of the obligation of complying with all Federal, Interstate Compacts and State laws, regulations and standards for the construction, operation or maintenance of the minor road crossings.

7. *Registration of Proposed Use of General Permit*—Prior to construction, the owner(s) shall submit Exhibit C along with the wetland delineation data forms completed in accordance with current procedures, the required location map, and

Copyright © 1996 Commonwealth of Pennsylvania

a site plan showing the boundaries of the wetland delineation and the replacement wetlands to the Bureau of Dams and Waterway Management (See Exhibit B). A copy of Exhibit C shall also be sent to the municipality and county in which the work will be performed. The owner may *not* begin work until he has notified the Bureau of Dams and Waterway Management and received an acknowledgement of that notification. The Department's acknowledgement letter serves as registration to use this General Permit.

8. *Change of Ownership*—If there is a change in ownership of a minor road crossing installed in accordance with this General Permit, the new owner is required to register the crossing with the Department in accordance with Item 7.

9. *Fees*—There is no fee required for a project authorized under this General Permit.

10. *Effective Time Period*—This General Permit will remain in effect indefinitely, unless specifically modified, suspended or revised by the Department.

11. *Suspension, Modification or Revocation*—The Department may suspend, modify or revoke this General Permit at any time upon notice in the *Pennsylvania Bulletin*.

12. *Project Interference*—This General Permit does not authorize any interference with any existing or proposed Local, State, Federal or Federally Licensed Project, and permittee shall not be entitled to compensation for damage or injury to the work authorized herein which may be caused by or a result of existing or future operations undertaken by the United States, Commonwealth of Pennsylvania, and its Political Subdivisions in the public interest.

13. *Conditions.*

a. The construction of a minor road crossing shall be completed within 3 years of the date of the Department's acknowledgement letter. If all construction is not completed within this time frame, the owner(s) shall remove all of the minor road crossing and restore the watercourse and floodplain to their former conditions.

b. Minor road crossings shall not create or constitute a risk to life, property or the environment.

c. No fill shall be placed in any floodway, watercourse, or body of water, including approaches to the minor road crossing, except as specifically authorized in this General Permit.

d. Each minor road crossing shall be constructed in such a manner so that there is no interference with the migration of fish.

e. Plans, specifications and reports for bridges and culverts across a stream which are to be used by the general public such as an access to an industrial, commercial or residential development, etc., shall be prepared by a registered professional engineer and shall be affixed with his seal and his certification which shall read as follows:

''I (name) do hereby certify to the best of my knowledge, information and belief, that the information contained in the accompanying plans, specifi-

cations, and reports have been prepared in accordance with accepted engineering practice, is true and correct, and is in conformance with Chapter 105 of the Rules and Regulations of the Department of Environmental Resources.''

f. A project which disturbs wetlands requires (1) a wetland delineation performed in accordance with current procedures and (2) a mitigation plan prepared and affixed with a statement which shall read as follows:

''I (name) do hereby state to the best of my knowledge, information and belief that the information contained in the plans, specifications and reports have been prepared in accordance with accepted environmental practices, is true and correct, and is in conformance with Chapter 105 of the Rules and Regulations of the Department of Environmental Resources.''

g. Bridges and culverts shall be of sufficient width and size so as not to narrow the existing stream channel.

h. The crossing shall be designed to prevent the restriction of and to withstand expected high flows. Bridge and culvert crossings shall have a waterway opening sufficient to adequately discharge, at a minimum, the bank-full flow of the watercourse or stream. The waterway opening shall be large enough to minimize and confine any backwater to the owner's property.

i. Headwalls, wingwalls and riprap shall be installed for bridges and culverts as required to pass flood flows without loss of stability.

j. Bridges and culverts shall not increase velocity or direct flow so as to result in erosion of stream bed and banks.

k. Bridges and culverts shall be inspected by the owner on a regular basis to provide for continued operation and maintenance during the lifetime of the structure.

l. Bridges and culverts shall be kept open and functioning at all times by maintaining the waterway opening free of debris and other obstructions. Maintenance shall be performed in accordance with the ''Standards for Channel Cleaning at Bridges and Culverts''. Copies of this document are available from the offices noted in Exhibit B.

m. Approaches to bridges, culverts and fords should be constructed at original grades where possible. Where necessary, depth of fill in the approaches shall be minimized to allow overflow of the roadway during periods of high water.

n. Bridges shall have abutments set well into the stream banks in such a manner as to assure minimal increase in flood evaluations and no encroachment into the stream.

o. Bridges shall have abutments aligned with the flow of the stream. The use of wing walls at the upstream side of the bridge to assist in directing flood flows through the bridge opening is recommended.

Copyright © 1996 Commonwealth of Pennsylvania

p. Bridges having piers shall be designed and constructed to offer the least obstruction to the passage of water and ice, consistent with safety.

q. Culverts installed in stream channels shall be aligned with the stream flow.

r. Culverts shall be installed with the invert 6 inches below natural streambed and so that the gradient of the invert shall not deviate from that of the natural streambed.

s. The length of culverts installed shall be only that which is necessary to provide adequate road width with stable side slopes.

t. Spacing for multiple culvert installation in a stream channel shall be in accordance with the then current manufacturer's specifications.

u. Depth of fill covering culverts shall not exceed the minimum cover required by the then current manufacturer's specifications for the intended use of the crossing.

v. The removal of existing minor road crossings shall be completed in the following manner: (1) crossing is removed in its entirety, (2) the original stream gradient is restored and (3) the stream banks are stabilized.

w. Fords which are excavated or graded through stream banks must be properly stabilized.

x. Crossings of wetlands shall be avoided if an alternate location is possible. If the crossing of wetlands cannot be avoided, the crossing must be undertaken at the narrowest point of the wetland and shall not exceed 100 feet in length and .1 acre of disturbance.

y. The total wetland impact for all minor road crossings installed by an owner on an individual property or project including phased projects shall not exceed 0.25 acre. A project shall include the aggregate of all stages of development and all parcels within a subdivision plan, which are under the control of the registrant.

z. All wetlands impacted through the use of this General Permit must be replaced adjacent to or in the immediate proximity of the minor road crossing and at a ratio of 1:1 for function, value and areal extent (acreage).

aa. The use of this General Permit shall not prejudice any future Departmental decisions related to regulated activities on this property.

bb. Any archaeological artifacts discovered during the performance of work authorized under this General Permit must be adequately protected and their discovery promptly reported to the Director, Bureau of Historic Preservation, Pennsylvania Historic and Museum Commission, Post Office Box 1026, Harrisburg, Pennsylvania 17108-1026, telephone (717) 787-2891.

cc. Owner(s) shall investigate for drinking water intakes or reservoirs for public water supplies and permitted public bathing beaches within 5 miles downstream of the site of the minor road crossing. Written notice shall be given to operators of any such intakes or reservoirs or public bathing beaches at least 10 days prior to construction of the minor road crossing. Owner(s) must notify

operators immediately and no longer than 1 hour after an occurrence at the crossing site which results in a release of suspended solids and turbidity to the stream.

14. *Department Inspection*—As a condition of use of this General Permit and of the owner's authority to conduct the activities authorized by this General Permit, the owner hereby authorizes and consents to allow authorized employees or agents of the Department, without advance notice or a search warrant, at any reasonable time and upon presentation of appropriate credentials, and without delay, to have access to and to inspect all areas where the project is being constructed, operated or maintained. The authorization and consent shall include consent to conduct tests or sampling, to take photographs, to perform measurements, surveys and other tests, to inspect the methods of construction, operation or maintenance, to examine and copy books, papers and records pertinent to any matter under investigation, and to take any other action necessary to assure the project is constructed, operated or maintained in accordance with the terms and conditions of the General Permit. This General Permit condition is included under section 16 of the Dam Safety and Encroachments Act (32 P. S. § 693.16), and in no way limits any other powers granted under the Dam Safety and Encroachments Act.

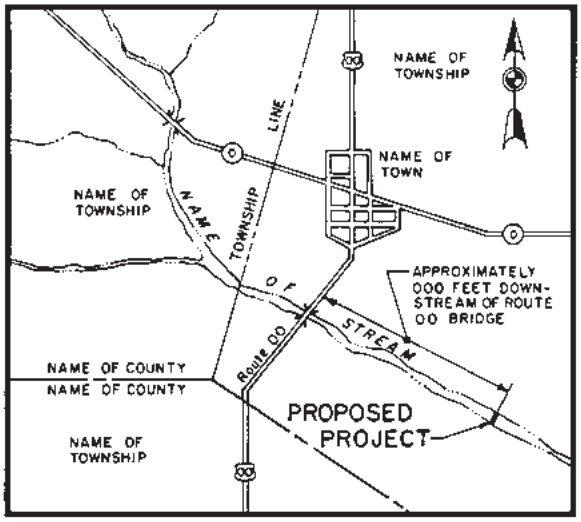
15. *Activities not in Accordance with the Terms or Conditions*—If the Department determines, upon inspection, that the construction, operation or maintenance of a project has violated the terms or conditions of this General Permit or this chapter, the Department may take such actions, legal or administrative, that it may deem to be appropriate, including revocation of the General Permit with regard to the violation.

16. *Structure Removal*—The owner(s) shall remove all or any portion of the minor road crossing upon written notification to the owner by the Department in the event the project is causing an adverse impact on public health, safety or the environment or in any other manner violates the conditions of this General Permit or this chapter.

17. *Property Rights*—This General Permit does not convey any property rights, either in real estate or material, or any exclusive privileges; nor does it authorize any injury to property or invasion of rights or any infringement of Federal, State or local laws or regulations.

18. *Other Approvals*—The owner(s) shall secure all other approvals that may be necessary under Federal, State or local laws or regulations.

19. *Fish Commission Notification*—The owner(s) shall notify the Fish Commission's Regional Field Office Supervisor (see Exhibit A) responsible for the County where the activities are proposed 10 days prior to start of construction. Written notification is suggested. The project site shall at all times be available for inspection by authorized officers and employees of the Pennsylvania Fish Commission.



20. *Erosion and Sedimentation Pollution Controls*—Work must be done in compliance with Chapter 102 (relating to erosion and sediment control). Prior to

Copyright © 2000 Commonwealth of Pennsylvania

construction, an Erosion and Sediment Pollution Control Plan must be reviewed and determined to be adequate by the County Conservation District in which the activities are proposed and implemented prior to, during and after construction. The project site shall at all times be available for inspection by authorized employees of the County Conservation District. The Erosion and Sediment Pollution Control Plan shall be available at the site at all times.

APPENDIX H
TEMPORARY ROAD CROSSINGS; GENERAL PERMIT BDWM-GP-8

Editor's Note: The following permit was published in the *Pennsylvania Bulletin* as a Notice and is codified under 1 Pa. Code § 3.1(a)(9) (relating to contents of *Code*) as a document which the Legislative Reference Bureau finds to be general and permanent in nature. See §§ 105.441—105.449 (relating to general permits) for regulations governing this permit.

1. *General Description and Authority*—The Department of Environmental Resources hereby authorizes, by General Permit, subject to the terms and criteria set forth below, the construction, operation and maintenance of temporary road crossings across regulated waters of this Commonwealth, including wetlands, where no practicable alternatives exist. This authorization is under section 7(b) of the Dam Safety and Encroachments Act (32 P. S. § 693.7(b)), and the rules and regulations promulgated thereunder at §§ 105.441—105.449 (relating to general permits). This General Permit is subject to the terms and conditions set forth below.

2. *Denial of Authorization*—The Department has the discretion, on a case-by-case basis, to deny, revoke or suspend the authorization to use this General Permit for any project which the Department determines to have a significant effect on the safety and protection of life, health, property or the environment or otherwise would not be adequately regulated by the provisions of this General Permit.

3. *Definitions*—The following terms as used in this General Permit shall have the following meanings:

Body of Water—A natural or artificial lake, pond, reservoir, swamp, marsh or wetland.

Bridge—A single span structure erected from top of bank to top of bank carrying a temporary roadway over a stream.

Causeway—An embankment constructed partially across or along a stream.

Culvert—A structure with appurtenant works which carries a stream under or through an embankment or fill.

Exceptional Value Wetlands—Wetlands as defined at § 105.17(1) (relating to wetlands).

Ford—A road crossing of a stream utilizing the existing stream bed.

Install—To construct, place, lay or set in place.

Owner—A person who owns, controls, operates, maintains or manages a dam or reservoir, water obstruction or encroachment.

Person—Any natural person, partnership, association, corporation, public utility, municipality, municipal authority, political subdivisions of the Commonwealth, receiver or trustee and any department, board, commission or authority of the Commonwealth.

Regulated Waters of the Commonwealth—Watercourses, streams or bodies of water and their floodways wholly or partly within or forming part of the boundary of this Commonwealth.

Stocked Trout Stream—A Stream classified as approved trout waters by the Fish and Boat Commission. For a list of stocked trout streams, the Fish and Boat Commission can be contacted at: Fish and Boat Commission, Bureau of Fisheries, Division of Fisheries Management, 450 Robinson Lane, Bellefonte, Pennsylvania 16823-9616.

Stream—A watercourse.

Temporary Road Crossing—A road installed for a period of time not to exceed 1 year across a wetland or across or along a stream utilizing a pipe culvert or a series of culverts, a bridge, a causeway or a ford.

Watercourse—A channel or conveyance of surface water having defined bed and banks, whether natural or artificial, with perennial or intermittent flow.

Wetlands—Those areas that are inundated or saturated by surface or groundwater at a frequency and duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions, including swamps, marshes, bogs and similar areas.

Wild Trout Streams—A stream classified as supporting naturally reproducing trout populations by the Fish and Boat Commission. For a list of wild trout streams, the Fish and Boat Commission can be contacted at: Fish and Boat Commission, Bureau of Fisheries, Division of Fisheries Management, 450 Robinson Lane, Bellefonte, Pennsylvania 16823-9616.

4. *Submerged Lands of this Commonwealth*—This General Permit shall not be effective to authorize any project over, across or occupying submerged lands of this Commonwealth until the owner has obtained a license from the Department authorizing the occupation of such submerged lands issued under section 15 of the Dam Safety and Encroachments Act (32 P. S. § 693.15), section 514 of The Administrative Code of 1929 (71 P. S. § 194), or other applicable laws. Upon receipt of notification from the owner, the Department will review the project to determine if its location is over, across or occupies submerged lands of the Commonwealth.

5. *Specific Areas Where General Permit Does Not Apply*—This General Permit does not apply and is not valid in the following areas:

a. Historic, cultural or archaeological sites as identified in the latest published version of the Pennsylvania Inventory of Historical Places or the National Register of Historical Places.

b. Sites identified in the latest published version of the National Registry of Natural Landmarks.

Copyright © 1996 Commonwealth of Pennsylvania

c. Stocked trout streams from March 1 through June 15, wild trout streams from October 1 through December 31 and Lake Erie tributaries from September 1 through December 1 unless written approval is obtained from the Fish and Boat Commission's Division of Environmental Services. See Exhibit A.

d. Sites which serve as habitat for fauna or flora listed as threatened or endangered under the Endangered Species Act of 1973, the Wild Resource Conservation Act, the Fish and Boat Code or the Game and Wildlife Code. Sites may be checked through the Pennsylvania Natural Diversity Inventory by contacting the Bureau of Forestry, Division of Advisory Services, Post Office Box 8552, Harrisburg, Pennsylvania 17105-8552 or any of the offices listed on Exhibit B.

6. *Other Permits*—Nothing in this General Permit relieves the owners of the obligation of complying with all Federal, Interstate Compact and State laws, regulations and standards for the construction, operation or maintenance of the temporary road crossings.

7. *Registration of Proposed Use of General Permit*—Prior to construction the owners shall submit Exhibit C along with the required location map to the Bureau of Dams and Waterway Management. See Exhibit B. A copy of Exhibit C shall also be sent to the municipality and county in which the work will be performed. The owner may not begin work until he has notified the Bureau of Dams and Waterway Management and received an acknowledgement of that notification.

8. *Change of Ownership*—If there is a change in ownership of a temporary road crossing installed in accordance with this General Permit, the new owner is required to register the crossing with the Department in accordance with Item 7.

9. *Fees*—There is no fee required for project authorized under this General Permit.

10. *Effective Time Period*—This General Permit will remain in effect indefinitely unless specifically modified, suspended or revised by the Department.

11. *Suspension, Modification or Revocation*—The Department may suspend, modify or revoke this General Permit at any time upon notice in the *Pennsylvania Bulletin*.

12. *Project Interference*—This General Permit does not authorize any interference with any existing or proposed Local, State, Federal or Federally Licensed Project, and permittee shall not be entitled to compensation for damage or injury to the work authorized herein which may be caused by or a result of existing or future operations undertaken by the United States, the Commonwealth of Pennsylvania and its political subdivision in the public interest.

13. *Conditions*.

a. Crossings may remain installed for a period of time not to exceed 1 year from the date of the Department's acknowledgement (Item 7) unless extended in writing by the Department.

b. The site of a temporary crossing, except fords, shall be restored to original topography and stabilized within 5 days after termination of its intended use or at the end of the 1 year period, whichever occurs first.

c. Fords used as temporary crossings shall have the approaches adequately blocked and stabilized to prevent future use within 5 days after termination of its intended use or at the end of the 1 year period, whichever occurs first.

d. Roads must cross all watercourses at a right angle to the stream, unless it is physically impossible to cross at a right angle to the stream.

e. Fords are prohibited on all streams within high quality (HQ) and exceptional value (EV) watersheds as specified in Chapter 93 (relating to water quality standards), and in watersheds tributary to drinking water intakes or reservoirs for public water supply users, where the ford is within 2,000 feet upstream of such intake or reservoir.

f. Skidding across fords is prohibited.

g. Whenever the streambed at the site of a ford does not have a rock bottom, a layer of clean rock must be provided. This layer of clean rock must not obstruct the stream flow. In addition, the approaches must: (1) be maintained in a firm and stable condition and (2) enter the stream on less than a 10% grade within 50 feet of the stream with the flow and (3) exit the stream against the flow on the same grade and distance limitation as specified for the entrance.

h. Culverts must provide a waterway area sufficient to adequately discharge the normal flow of the watercourse or stream, and shall be of sufficient length to extend beyond the toe of the clean rock fill.

i. Culverts must be installed in such manner that overtopping of the roadway will occur within the stream channel. This can be accomplished by providing a depressed roadway embankment as shown on attached Drawings No. 3 and No. 4.

j. A culvert having as large a diameter as possible must be provided to minimize placement of excessive fill and excavation of the stream banks. If the bank height prohibits a large diameter pipe culvert, the crossing could consist of a bridge or a series of culverts. The minimum size diameter culvert to be used is 12 inches.

k. Road crossings involving a series of pipe culverts shall be installed with a minimum spacing as specified on attached Drawing No. 4.

l. Road and causeway embankments shall consist of only clean rock material to prevent stream channel sedimentation doing placement, removal and periods of overtopping.

m. Bridges must be single span from top of bank to top of bank and structurally stable.

n. Approach roads to temporary road crossings shall utilize original grades. However, clean rock material or gravel to a depth of 6 inches above original grade shall be utilized for approaches as necessary.

Copyright © 1996 Commonwealth of Pennsylvania

o. Causeways may not extend streamward a distance greater than 1/2 the width of the stream channel.

p. Temporary road crossings shall be kept open and functioning at all times by maintaining the crossings free of debris and other obstructions.

q. The owner shall be responsible for any damages resulting from increased backwater caused by the temporary road crossing. The permittee shall remove the temporary road crossing in the event of high waters to prevent the increased backwater.

r. Wetlands shall be identified and delineated in accordance with the Federal Manual for Identifying and Delineating Jurisdictional Wetlands dated 1989.

s. Crossings of wetlands shall be avoided if an alternate location is possible. If the crossing of wetlands cannot be avoided, the crossing is permissible if it is located at the narrowest practicable point of the wetland and the length of the crossing within the wetland is less than 200 feet.

t. The site of a wetlands crossing shall be stabilized by any appropriate means, including but not limited to, using removable, temporary mats, pads or other similar devices to insure minimization of impact on the wetlands ecology.

u. Embankments for temporary roads across wetlands shall be installed to maintain the hydrology of the wetland.

v. Any archaeological artifacts discovered during the performance of work authorized under this General Permit must be adequately protected and their discovery promptly reported to the Director, Bureau for Historic Preservation, Historical and Museum Commission, Post Office Box 1026, Harrisburg, Pennsylvania 17120.

w. Pollution of the waterway with harmful chemicals, fuels, oils, greases, bituminous material, acid and/or other harmful or polluting materials, is prohibited.

x. Owners shall investigate for drinking water intakes or reservoirs for public water supplies within 5 miles downstream of the site of the temporary road crossing. Written notice shall be given to operators of any such intakes or reservoirs at least 10 days prior to construction of the temporary road crossing. Owners must notify public water supply operators immediately and no longer than 1 hour after an occurrence at the crossing site which results in the release of suspended solids and turbidity to the stream.

y. Access roads should not approach the stream channel directly downslope, but should traverse the slope obliquely to prevent high velocity road drainage flows from directly entering the stream channel. Road drainage shall include proper erosion and sedimentation control measures; as referred to in item 20.

14. *Department Inspection*—As a condition of use of this General Permit, and of the owner's authority to conduct the activities authorized by this General Permit, the owner hereby authorizes and consents to allow authorized employes

or agents of the Department, without advance notice or a search warrant, at any reasonable time and upon presentation of appropriate credentials, and without delay, to have access to and to inspect all areas where the project is being constructed, operated or maintained. The authorization and consent shall include consent to conduct tests or sampling, to take photographs, to perform measurements, surveys and other tests, to inspect the methods of construction, operation or maintenance, to examine and copy books, papers and records pertinent to any matter under investigation, and to take any other action necessary to assure that the projectd is constructed, operated or maintained in accordance with the terms and conditions of the General Permit. This General Permit condition is included under section 16 of the Dam Safety and Encroachments Act (32 P. S. § 693.16), and in no way limits any other powers granted under the Dam Safety and Encroachments Act.

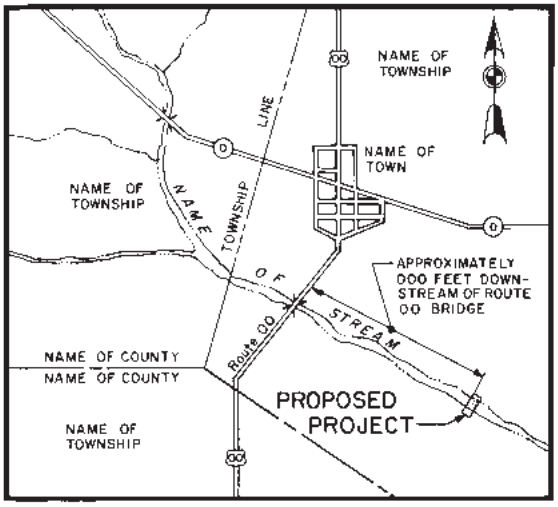
15. *Activities Not in Accordance with the Terms or Conditions*—If the Department determines, upon inspection, that the construction, operation or maintenance of a project has violated the terms or conditions of this General Permit or this chapter, the Department may take such actions, legal or administrative, that it may deem to be appropriate, including revocation of the General Permit with regard to the violation.

16. *Structure Removal*—The owners shall remove all or any portion of the temporary road crossing upon written notification to the owners by the Department in the event the project is causing an adverse impact on public health, safety or the environment or in any other manner violates the conditions of this General Permit or this chapter.

17. *Property Rights*—This General Permit does not convey any property rights, either in real estate or material, or any exclusive privileges, nor does it authorize any injury to property or invasion of rights or any infringement of Federal, State or local laws or regulations.

18. *Other Approvals*—The owners shall secure all other approvals that may be necessary under Federal, State or local laws or regulations.

19. *Fish Commission Notification*—The owners shall notify the Fish and Boat Commission's Regional Field Office Supervisor, see Exhibit A, responsible for the County where the activities are proposed 10 days prior to start of construction. Written notification is suggested. The project site shall at all times be available for inspection by authorized officers and employes of the Fish and Boat Commission.



20. *Erosion and Sediment Pollution Controls*—Work must be done in compliance with Chapter 102 (relating to erosion and sediment control). Prior to construction an Erosion and Sediment Pollution Control Plan must be reviewed and determined to be adequate by the County Conservation District in which the activities are proposed and implemented prior to, during and after construction.

Copyright © 2000 Commonwealth of Pennsylvania

The Project site shall at all times be available for inspection by authorized employes of the County Conservation District. The Erosion and Sediment Pollution Control Plan shall be available at the site at all times.

1. Pipe should extend beyond toe of roadway.
2. Roadway should be depressed over culvert to allow for overflow.
3. Clean rock fill shall be used to guard against erosion and sedimentation. Streambed material is not to be used.
4. Minimum size diameter culvert to be installed is 12 inches.
5. Approaches to crossings are not to exceed a depth of 6 inches above original grade.
6. Proper erosion and sedimentation control measures must be installed, refer to Item 20.
7. Refer to Item 13, Conditions.

APPENDIX I
AGRICULTURAL ACTIVITIES; GENERAL PERMIT
BDWM-GP-9

Editor's Note: The following permit was published in the *Pennsylvania Bulletin* as a Notice and is codified under 1 Pa. Code § 3.1(a)(9) (relating to contents of *Code*) as a document which the Legislative Reference Bureau finds to be general and permanent in nature. See §§ 105.441—105.449 (relating to general permits) for governing this permit.

1. *General Description and Authority*—The Department of Environmental Resources hereby authorizes by General Permit subject to the terms and criteria set forth below the installation, operation, modification and maintenance of certain agricultural activities that encroach into streams and their floodways or bodies of water wholly or partly within or forming part of the boundary of this Commonwealth. These agricultural activities are grassed or lined waterways, terraces, diversions, waste storage facilities, spring development and minor drainage that supports these activities and is necessary for contour strips when engaged in as a part of an existing agricultural operation and shall only be implemented as part of a conservation plan consistent with Chapter 102 (relating to erosion and sediment control) and approved by the County Conservation District. This authorization is under section 7(b) of the Dam Safety and Encroachments Act (32 P. S. § 693.7(b)) and the rules and regulations promulgated thereunder at §§ 105.441—105.449 (relating to general permits). This General Permit is subject to the terms and conditions set forth below.

2. *Denial of Authorization*—The Department has the discretion, on a case-by-case basis, to deny, revoke or suspend the authorization to use this General Permit for any project which the Department determines to present a risk to life, property or the environment or otherwise would not be adequately regulated by the provisions of this General Permit.

3. *Definitions*—The following terms as used in this General Permit shall have the following meanings:

Agricultural Operations—Activities, practices and procedures that farmers adopt, use or engage in for the production of crops and livestock. This does not include practices and procedures related to timber harvesting.

Body of Water—A natural or artificial lake, pond, reservoir, swamp, marsh or wetland.

Conservation Plan—A plan as required by Chapter 102 that includes a map and narrative that identifies conservation practices including an erosion and sedimentation control plan for the identified parcel of land.

Copyright © 2000 Commonwealth of Pennsylvania

Contour Strips—The practice of farming sloped land using alternating crops in such a way that plowing, preparing land, planting and cultivating are done on the contour as part of an agricultural operation. Contour strips without drainage are not regulated.

Diversions—A graded channel with a supporting ridge on the lower side which is constructed as part of an agricultural operation across the slope of a field to intercept surface water runoff and carry it slowly to surface or underground outlets.

Floodway—The channel of the watercourse and those portions of the adjoining floodplains which are reasonably required to carry and discharge the 100-year frequency flood. Unless otherwise specified, the boundary of the floodway is as indicated on maps and flood insurance studies provided by FEMA. In an area where no FEMA maps or studies have defined the boundary of the 100-year frequency floodway, it is assumed, absent evidence to the contrary, that the floodway extends from the stream to 50 feet from the top of the bank of the stream.

Grassed or Lined Waterway—A natural or constructed channel that is shaped or graded to required dimensions and established in suitable vegetation or protection for the stable conveyance of surface water runoff which is part of an agricultural operation.

Install—To construct, deposit, place, lay or set in place.

Minor Drainage—The installation of a water conveying device as necessary for the installation and operation of contour strips and other conservation practices authorized by this General Permit conducted as part of an agricultural operation.

Owner—A person who owns, controls, operates, maintains or manages a dam or reservoir, water obstruction or encroachment.

Person—A natural person, partnership, association, corporation, public utility, municipality, municipal authority, political subdivision of the Commonwealth, receiver or trustee and a department, board, commission or authority of the Commonwealth.

Regulated Waters of This Commonwealth—Watercourses, streams or bodies of water and their floodways wholly or partly within or forming part of the boundary of this Commonwealth.

Spring Development—The practice of intercepting and conveying water to a livestock watering facility that will not be used for a public water supply when conducted as part of an agricultural operation.

Stream—A watercourse.

Terrace—An earthen embankment or a ridge and channel constructed across a slope of a field to intercept surface runoff water and outlet it to a grassed or lined waterway or an underground tile as part of an agricultural operation.

Waste Storage Facility—A structure or basin for temporary storage of animal or other organic agricultural wastes constructed as part of an agricultural operation.

Watercourse—A channel or conveyance of surface water having defined bed and banks, whether natural or artificial, with perennial or intermittent flow.

Wetlands—Those areas that are inundated or saturated by surface or groundwater at a frequency and duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions, including swamps, marshes, bogs and similar areas.

4. *Specific Areas Where the General Permit Does Not Apply*—This General Permit does not apply in and is not valid in the following situations:

a. Historic, cultural or archaeological sites as identified in the latest published version of the Pennsylvania Inventory of Historic Places or the National Register of Historic Places.

b. Sites identified in the latest published version of the National Registry of Natural Landmarks.

c. Wetlands which serve as habitat for fauna or flora listed as threatened or endangered under the Endangered Species Act of 1973, the Wild Resource Conservation Act, the Fish and Boat Code or the Game and Wildlife Code. Sites may be checked through the Pennsylvania Natural Diversity Inventory by contacting the Bureau of Forestry, Division of Advisory Services, Post Office Box 8552, Harrisburg, Pennsylvania 17105-8552 or any of the offices listed on Exhibit C.

d. Watercourses having a drainage area greater than 100 acres.

e. Submerged Lands of this Commonwealth.

f. A spring being developed for public drinking water.

5. *Other Permits*—Nothing in this General Permit relieves the owners of the obligation of complying with all Federal, Interstate Compacts and State laws, regulations and standards for the construction, operation or maintenance of the activities covered by this General Permit.

6. *Registration of Proposed Use of General Permit*—Prior to construction, the owners shall submit Exhibit D containing the required certification along with the required location map to the Bureau of Dams and Waterway Management. A copy of Exhibit D shall also be sent to the municipalities and county in which the work will be performed. The owners may not begin work until he has notified the Bureau of Dams and Waterway Management (Exhibit D) and received an acknowledgement of that notification. The Department's acknowledgement letter serves as registration to use this General Permit.

7. *Change of Ownership*—If there is a change in ownership of the agricultural activities installed in accordance with this General Permit, the new owners are required to register the activities with the Department in accordance with Item 6.

Copyright © 1996 Commonwealth of Pennsylvania

8. *Fees*—There is no fee required for a project authorized under this General Permit.

9. *Effective Time Period*—This General Permit will remain in effect indefinitely, unless specifically modified, suspended or revised by the Department.

10. *Suspension, Modification or Revocation*—The Department may suspend, modify or revoke this General Permit at any time upon notice in the *Pennsylvania Bulletin*.

11. *Project Interference*—This General Permit does not authorize any interference with any existing or proposed Local, State, Federal or Federally Licensed Project, and permittee may not be entitled to compensation for damage or injury to the work authorized herein which may be caused by or a result of existing or future operations undertaken by the United States, Commonwealth of Pennsylvania, or its Political Subdivisions in the public interest.

12. *Conditions*.

a. The use of this General Permit is only authorized as part of a conservation plan approved by the County Conservation District (Exhibit B).

b. Grassed waterways, terraces, diversions, waste storage facilities, spring development and minor drainage must be constructed and maintained according to § 101.8 (relating to pollution control and prevention from agricultural operations) and the design standards and specifications found in the technical guide for Pennsylvania available through the United States Department of Agriculture, Soil Conservation or the County Conservation District (Exhibit B).

c. All excess material from any activity must be deposited and stabilized outside the regulated waters of this Commonwealth.

d. Any archaeological artifacts discovered during the performance of work authorized under this General Permit must be adequately protected and their discovery promptly reported to the Director, Bureau of Historic Preservation, Historical and Museum Commission, Post Office Box 1026, Harrisburg, Pennsylvania 17108-1026, telephone (717) 787-2891.

e. Pollution of the waterway with harmful chemicals, fuels, oils, greases, bituminous material, acid, and/or other harmful or polluting materials, is prohibited.

f. Wetlands shall be avoided if an alternate location is possible. Where wetlands cannot be avoided and the activities are necessary to minimize erosion and sedimentation and improve water quality, the impact shall be minimized.

g. Waste storage facilities constructed within 250 feet of a source of water used as a public water supply source as defined under Pennsylvania Safe Drinking Water Act may need to be relocated due to the geology of the site. Contact the Regional Community Environmental Control Office in your area.

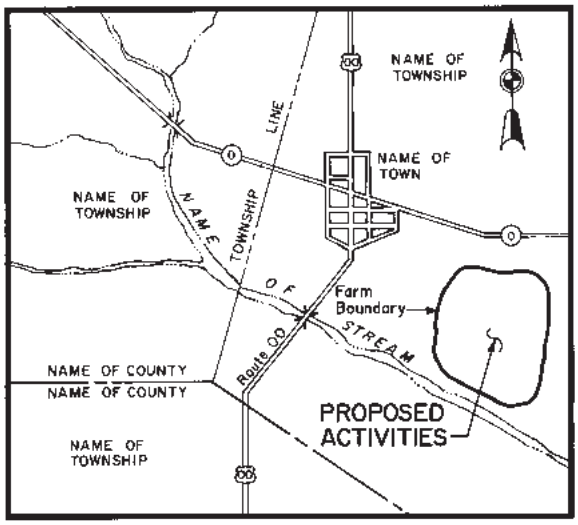
13. *Department Inspection*—As a condition of use of this General Permit and of the owner's authority to conduct the activities authorized by this General Permit, the owners hereby authorizes and consents to allow authorized employes or

agents of the Department, without advance notice or a search warrant, at any reasonable time and upon presentation of appropriate credentials, and without delay, to have access to and to inspect all areas where the project is being constructed, operated or maintained. The authorization and consent shall include consent to conduct tests or sampling, to take photographs, to perform measurements, surveys and other tests, to inspect the methods of construction, operation or maintenance, to examine and copy books, papers and records pertinent to any matter under investigation and to take other action necessary to assure the project is constructed, operated or maintained in accordance with the terms and conditions of this General Permit. This General Permit condition is included under section 16 of the Dam Safety and Encroachments Act (32 P. S. § 693.16) and in no way limits any other powers granted under the Dam Safety and Encroachments Act or The Clean Streams Law (35 P. S. §§ 691.1—691.1001).

14. *Activities Not in Accordance With the Terms or Conditions*—If the Department determines, upon inspection, that the construction, operation or maintenance of a project has violated the terms or conditions of this General Permit or the rules and regulations published in this chapter, Chapter 102 and § 101.8, the Department may take such actions, legal or administrative, that it may deem to be appropriate, including revocation of the General Permit with regard to the violation.

15. *Structural Removal*—The owners shall remove all or any portion of the activities covered by this General Permit upon written notification to the owners by the Department in the event the project is causing an adverse impact on public health, safety or the environment or in any other manner violates the conditions of this General Permit or this chapter.

16. *Property Rights*—This General Permit does not convey any property rights, either in real estate or material, or any exclusive privileges; nor does it authorize any injury to property or invasion of rights or any infringement of Federal, State or local laws or regulations.



17. *Other Approvals*—The owners shall secure all other approvals that may be necessary under Federal, State or local laws or regulations.

18. *Fish and Boat Commission Notification*—The owners shall notify the Fish and Boat Commission's Regional Field Office Supervisor (see Exhibit A) responsible for the County where the activities are proposed 10 days prior to start of construction. Written notification is suggested. The project site shall at all times be available for inspection by authorized officers and employes of the Pennsylvania Fish Commission.

19. *Erosion and Sedimentation Controls*—Work must be done in compliance with a Conservation Plan which meets the requirements of Chapter 102, including erosion control measures for the construction of best management practices installed under that plan. The project shall at all times be available for inspection by authorized employes of the county conservation district. The Conservation Plan shall be available at the site at all times.

APPENDIX J
ABANDONED MINE RECLAMATION; GENERAL PERMIT BDWW-GP-10

1. *General Description and Authority*—The Department of Environmental Resources hereby authorizes, by general permit, subject to the terms and criteria set forth below, the construction, operation or maintenance of an encroachment or water obstruction for reclamation of an abandoned mining site, where the Department has issued a notice of intent to forfeit the bond for a mining activity permitted after August 1977, and before July 1982. This authorization is under section 7 of the Dam Safety and Encroachments Act (32 P. S. § 693.7) and the rules and regulations promulgated thereunder at 25 Pa. Code §§ 105.441—105.449 (relating to general permits).

2. *Denial of Authorization*—The Department shall have the discretion, on a case-by-case basis, to deny, revoke or suspend the authorization to use this general permit for any project which the Department determines to have a substantial risk to life, property or the environment or otherwise could not be adequately regulated by the provisions of this general permit.

3. *Sites and Conditions Where This General Permit Does Not Apply*—This General Permit does not apply and is not valid in the following situations:

a. Projects located where there would be an impact on species of special concern listed under the Endangered Species Act of 1973, the Wild Resources Conservation Act, the Fish and Boat Code or the Game and Wildlife Code. Records regarding species of special concern are maintained in a computer database called the ''Pennsylvania Natural Diversity Inventory'' (PNDI). To verify that there will be no such impacts for a specific project, the Department requires submission of the attached Supplement No. 1 prior to registration for use of the General Permit. The processed Supplement No. 1 is returned to the owner and must be attached to the General Permit notification as verification that the General Permit is applicable.

b. Construction activities in stocked trout streams from March 1 through June 15, wild trout streams from October 1 through December 31 and Lake Erie tributaries from September 1 through December 1, unless approval is obtained from the Fish and Boat Commission's Division of Environmental Services. Stocked and wild trout stream locations are compiled by the Commission's Division of Fisheries Management.

4. *Definitions*—The terms as used in this General Permit shall have the following meanings:

Body of Water—A natural or artificial lake, pond, reservoir, swamp, marsh or wetland.

Copyright © 1996 Commonwealth of Pennsylvania

Owner—Any person who owns, controls, operates, maintains or manages a dam or reservoir, water obstruction or encroachment.

Person—Any natural person, partnership, association, corporation, public utility, municipality, municipal authority, political subdivision of the Commonwealth, receiver or trustee and any department, board, commission or authority of the Commonwealth.

Reclamation—Those actions set forth in the forfeiting operators permit taken to restore the area affected by surface and underground mining activities as required by 25 Pa. Code Chapters 86—89 and for which State and/or Federal reclamation funding is used to perform the reclamation.

Regulated Waters of the Commonwealth—All watercourses, streams or bodies of water and their floodways wholly or partly within or forming part of the boundary of this Commonwealth.

Reservoir—Any basin, either natural or artificial, which contains or will contain the water or other fluid or semifluid impounded by a dam.

Stocked Trout Stream—A stream classified as approved trout waters by the Fish and Boat Commission. For current designations of stocked trout streams contact the Division of Fisheries Management.

Watercourse—Any channel of conveyance of surface water having defined bed and banks, whether natural or artificial, with perennial or intermittent flow.

Wetlands—Those areas that are inundated or saturated by surface or groundwater at a frequency and duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation typically adopted for life in saturated soil conditions, including swamps, marshes, bogs and similar areas.

Wild Trout Streams—A stream classified as supporting reproducing trout populations by the Fish and Boat Commission. For current designations of wild trout streams, contact the Division of Fisheries Management.

5. *Other Permits*—Nothing in this General Permit relieves the owners of the obligation of complying with all Federal, Interstate Compact and State laws, regulations and standards for the construction, operation or maintenance of the activities covered by this General Permit.

6. *Registration for Use*—Prior to construction, the owners shall submit two copies of the completed Notification to Use (Exhibit D) along with two copies of the location map and processed Supplement No. 1 to the Soils and Waterways Section or the County Conservation District (Exhibits B and C). The notification must be sent to the County Conservation District only if there is a delegation agreement between the Department and the District. A copy of Exhibit D shall also be sent to the municipality and county in which the work will be performed. The owners may not begin work until they have received an acknowledgement from the Soils and Waterways Section of County Conservation District that the Exhibit D notification has been received and registered.

7. *Fees*—There is no fee required for a project authorized under this General Permit.

8. *Effective Time Period*—This General Permit will remain in effect indefinitely unless specifically modified, suspended or revised by the Department.

9. *Suspension, Modification or Revocation*—The Department may suspend, modify or revoke this General Permit at any time upon notice in the *Pennsylvania Bulletin.*

10. *Project Interference*—This General Permit does not authorize any interference with any existing or proposed local, State, Federal or Federally licensed project, and permittee shall not be entitled to compensation for damage or injury to the work authorized herein which may be caused by or a result of existing or future operations undertaken by the United States or the Commonwealth of Pennsylvania or its Political Subdivisions in the public interest.

11. *Conditions.*

a. Any archeological artifacts discovered during the performance of work authorized under this General Permit must be adequately protected and their discovery promptly reported to the Director, Bureau of Historic Preservation, Pennsylvania Historical and Museum Commission, P. O. Box 1026, Harrisburg, PA 17101-1026, telephone (717) 787-2891.

b. All excess fill or excavated and dredged material shall be deposited and immediately stabilized outside floodways, floodplains, wetlands and other regulated waters of this Commonwealth. Waste materials, scrap or excess construction materials shall be collected, stored and disposed of in accordance with the Solid Waste Management Act (35 P. S. §§ 6018.101—6018.1003) and the regulations promulgated thereunder.

c. Owners shall investigate for drinking water intakes or reservoirs to public and private water supplies within 5 miles downstream of the reclamation site and written notice shall be given at least 10 days prior to construction to operators of such intakes or reservoirs. Owners shall notify public and private water supply operators and the Department immediately and no longer than 1 hour after an occurrence at the reclamation site which results in the release of suspended solids and turbidity to the drinking water supply, including both surface and groundwater sources, that maintain the quality or quantity of the drinking water supply.

d. Reclamation projects shall not extend beyond the reclamation site.

e. During construction activities, all public and private property including existing vegetation, landscape features and monuments within, along and adjacent to the work area, shall be protected and preserved to the maximum degree possible. This shall include, but not be limited to, precautions taken to minimize damage, erosion, injury or destruction, prevent pollution, provide protection of all trees and other woody plants, special care being taken to protect the natural vegetation and surroundings to include all natural drainageways, ponds, lakes, swamps, woods and fields and storage of materials in such manner to

Copyright © 1999 Commonwealth of Pennsylvania

prevent leaching which would be injurious to soils and to plants. Precautions should be taken to prevent damage to pipes, conduits and other underground structures.

f. The owners shall notify the Fish and Boat Commission's Regional Field Office Supervisor responsible for the County where the activities are proposed 10 days prior to start of construction. Written notification is suggested. The project site shall at all times be available for inspection by authorized officers and employees of the Fish and Boat Commission.

g. Prior to the use of explosives in a watercourse or body of water, the permittee shall secure a written permit from the Fish and Boat Commission, under the Fish and Boat Code, Act 1980-175, 30 Pa.C.S. § 2906 (relating to permits for use of explosives). Requests should be directed to the Fish and Boat Commission, Division of Environmental Services.

h. Prior to construction, approval must be obtained from the Fish and Boat Commission's Division of Environmental Services for use of this project on reclamation sites bordering (1) stocked trout streams from March 1 through June 15 and (2) wild trout streams from October 1 through December 31.

i. All temporary road crossings of the regulated waters of the Commonwealth in areas unaffected by mining activities shall be constructed in accordance with the design standards and conditions of General Permit BDWW-8.

j. Prior to construction, the property owner of the abandoned mine site shall be sent, by certified mail, a questionnaire inquiring whether there are existing facilities on site such as ponds, wetlands or diversion ditches which the property owner wants left in place in their present condition. Construction may not be commenced until receipt of the complete questionnaire.

12. *Department Inspection*—As a condition of use of this General Permit, and of the owner's authority to conduct the activities authorized by this General Permit, the owner hereby authorizes and consents to allow authorized employees or agents of the Department or County Conservation District, without advance notice or a search warrant, at any reasonable time and upon presentation of appropriate credentials, and without delay, to have access to and to inspect all areas where the project is being constructed, operated or maintained. The authorization and consent shall include consent to conduct tests or sampling, to take photographs, to perform measurements, surveys and other tests, to inspect the methods of construction, operation or maintenance, to examine and copy books, papers and records pertinent to any matter under investigation, and to take any other action necessary to assure that the project is constructed, operated or maintained in accordance with the terms and criteria of the General Permit. This General Permit condition is referenced in accordance with section 16 of the Dam Safety and Encroachments Act (32 P. S. § 693.16) and in no way limits any other powers granted under the Dam Safety and Encroachments Act.

13. *Activities Not in Accordance With the Terms or Conditions*—If the Department or County Conservation District determines, upon inspection, that the

construction, operation or maintenance of a project has violated the terms or criteria of this General Permit, the Chapter 105 and 102 Rules and Regulations or the appropriate NPDES permit for discharge of stormwater from construction activities, the Department may take such actions, legal or administrative, that it may deem to be appropriate.

14. *Property Rights*—This General Permit does not convey any property rights, either in real estate or material or in any exclusive privileges; nor does it authorize any injury to property or invasion of rights or any infringement of Federal, State or local laws or regulations.

15. *Other Approvals*—The owners shall secure all other approvals that may be necessary under other Federal, State or local laws or regulations.

16. *Erosion and Sediment Pollution Controls*—Work must be done in compliance with Chapter 102 (relating to erosion and sediment control) and/or under the appropriate NPDES permit for discharge of stormwater from construction activities. Prior to construction, an Erosion and Sediment Pollution Control Plan must be reviewed and determined adequate by the County Conservation District in which the activities are proposed and implemented prior to, during and after construction. The County Conservation District shall be notified 10 days prior to the start of construction. The project site shall at all times be available for inspection by authorized employees of the County Conservation District. The Erosion and Sediment Pollution Control Plan shall be available at the site.

APPENDIX O
GENERAL PERMIT BWQP-GP-15
PRIVATE RESIDENTIAL CONSTRUCTION IN WETLANDS

Editor's Note: The following permit was published in the *Pennsylvania Bulletin* as a Notice and is codified under 1 Pa. Code § 3.1(a)(9) (relating to contents of *Code*) as a document which the Legislative Reference Bureau finds to be general and permanent in nature. See §§ 105.441—105.449 (relating to general permits) for regulations governing this permit.

A. General Description. The Department of Environmental Protection hereby authorizes, by general permit, the placement and maintenance of fill in, or the excavation of, non-tidal wetlands for the construction or expansion of a single family home for the personal residence of the permittee, including reasonable and necessary features such as a driveway, storage shed and utilities on a residential lot purchased by the permitttee prior to November 22, 1991, within established subdivisions approved by the local governing authority where such activities do not impact greater than .50 acre of nontidal wetlands. The issuance of this General Permit also constitutes approval of a Water Quality Certification under section 401 of the Federal Clean Water Act (33 U.S.C.A. § 1341). The monetary

Copyright © 2000 Commonwealth of Pennsylvania

contribution associated with this General Permit is for participation in the Pennsylvania Wetland Replacement Project.

Neither the Department of Environmental Protection nor any County Conservation District which is delegated Chapter 105 permitting authority shall be liable for incidents resulting from subsidence, structure failure, water damage, vector problems or any other hardships that may occur as a result of building in wetlands.

B. Registration Procedure:

1. Complete the registration Form (Exhibit A).

The information requested in Item 2 on the registration form will be used to determine potential impacts to threatened and endangered species. If a potential impact is indicated, the Department will provide assistance to you to address threatened and endangered species concerns. The use of this general permit is not authorized until the potential impact is resolved.

If you desire, to avoid possible project delays, a search for potential impacts can be conducted prior to registration by completing the attached Supplement No. 1, Pennsylvania Natural Diversity Inventory Form (PNDI) and submitting it to the appropriate DEP Regional Office or delegated County Conservation District. The completed search information should be submitted when you register the permit.

2. Prepare a project location map utilizing a photocopy of a 7-1/2 minute U.S.G.S. Quadrangle Map showing the project site.

3. Delineate the wetlands in accordance with established Department procedures. Delineation services for the purpose of registering this general permit will be provided by the U. S. Army Corps of Engineers or the Department of Environmental Protection or its designee, upon request. If you choose to have delineation services provided by the Army Corps of Engineers or the Department, please request this service in writing early in the project planning stage to allow sufficient response and scheduling time to avoid project delays.

4. Prepare an Erosion and Sedimentation control plan. Permit users are encouraged to contact County Conservation Districts for erosion and sedimentation control planning assistance.

5. Prepare a sketch plan (Exhibit B) or attach a copy of a plot plan of the project showing the:

a. dimension of the entire property,
b. location of wetland,
c. location of erosion and sedimentation control measures,
d. dimension of the proposed wetland impact area,
e. location of house/driveways, and the like,
f. location of waterways, drainage ditches, and the like,
g. existing utilities,
h. proposed utilities, water, sewer, telephone, and the like.
i. building setbacks,

j. previously filled wetlands,

k. floodplains,

l. location of replacement wetlands.

6. To register use of the general permit send one copy of the:

a. Location Map,

b. Registration Form (Exhibit A),

c. Sketch Plan (Exhibit B),

d. Wetland delineation,

e. Erosion and Sedimentation Control Plan approval letter, for lots greater than 0.5 acre (see D.8. below),

f. A Wetland Replacement Plan or, a contribution to the Pennsylvania Wetland Replacement Project, as described in Part D.9 of this general permit;

g. Supplement Number 1, PNDI (see B.1); and

h. Corps authorization if the wetland impact is greater than .10 acre;

to the DEP Regional Soils and Waterways Section or the delegated County Conservation District.

7. You may not begin construction until you receive confirmation of registration and Federal authorization from the U. S. Army Corps of Engineers under Section 404 of The Clean Water Act. Please contact the appropriate Corps District for permit information.

C. Definitions Applicable to this General Permit:

Central Sewage—A sewerage system consisting of pipes, lateral lines, trunk lines or mains, which convey waste to a facility that provides treatment for final disposal. The term Central Sewage does not include onlot disposal, community onlot disposal, or any other system that requires a land surface or subsurface absorption area for treatment and disposal purposes.

FEMA—The Federal Emergency Management Agency

Floodplain—The lands adjoining a river or stream that have been or may be expected to be inundated by flood waters in a 100-year frequency flood. Unless otherwise specified, the boundary of the 100-year floodplain is as indicated on maps and flood insurance studies provided by FEMA. In an area where no FEMA maps or studies have defined the boundary of the 100-year floodplain it is assumed, absent evidence to the contrary, that the floodplain extends from the stream to 50 feet from the top of the bank of the stream. Other evidence of the

Copyright © 2000 Commonwealth of Pennsylvania

extent of the floodplain may include local stormwater management plans, local zoning ordinances, subdivision plans and similar land use mapping.

Impact—The loss of nontidal wetlands of the Commonwealth including any filled area previously permitted, the proposed filled area and any other nontidal wetlands of the Commonwealth that are adversely affected by flooding, excavation or drainage as a result of the project.

Individual—A natural person and/or couple but does not include a corporation, partnership or similar entity.

Parcel of Land—The entire contiguous quantity of land in possession of, recorded as property of, or owned (in any form of ownership, including land owned as a partner, corporation, joint tenant, and the like) by the same individual as of November 22, 1991 (and/or his or her spouse), and comprises not only the area of wetlands sought to be filled, but also all land contiguous to those wetlands, owned by the individual and/or his or her spouse in any form of ownership.

Pennsylvania Wetland Replacement Project—A fund managed by the National Fish and Wildlife Foundation from which money is dispersed at the direction of the Department of Environmental Protection, to which Chapter 105 permit applicants can make a monetary contribution, in lieu of creating wetlands.

Subdivision—The division or redivision of a lot, tract or parcel of land into two or more lots, tracts, parcels or other divisions of land including changes in existing lot lines.

Wetlands—Areas that are inundated or saturated by surface water or groundwater at a frequency and duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions, including swamps, marshes, bogs and similar areas.

Emergent Wetland—Wetland areas dominated by nonwoody vegetation.

Forested Wetland—Wetland areas dominated by woody vegetation 20 feet or more in height.

Scrub/Shrub Wetland—Wetland areas dominated by woody vegetation less than 20 feet in height.

D. Conditions:

1. Impacts to wetlands must be avoided and minimized. Nonwetland areas onsite must be utilized whenever practical.

2. Fills or excavations in wetlands, including previously filled areas may not exceed more than 40% of the total lot area, except where lots are less than .25 acre in size where a maximum of .10 acre of fill in wetlands is authorized. In no circumstances may the total impact associated with the fill or excavation exceed 0.50 acre of wetlands.

The following conversion table provides an example of the amount of wetland fill authorized in accordance with the 40% maximum fill condition.

Lot Area in Acres	*x*	*40% of Lot Area*		*Maximum Area of Wetland Fill*
0.25	x	0.40	=	0.10 acre
0.33	x	0.40	=	0.13 acre
0.50	x	0.40	=	0.20 acre
0.75	x	0.40	=	0.30 acre
1.00	x	0.40	=	0.40 acre
1.25	x	0.40	=	0.50 acre

3. Fills, and/or excavations, in wetlands located on floodplains are not authorized by this General Permit. Information on floodplains may be available through local municipalities, home owner associations, county planning offices, FEMA and similar agencies.

4. This permit may only be used once by an individual.

5. This permit may only be used for a single-family home for a personal residence by an individual who purchased the lot prior to November 22, 1991.

6. This permit may only be used on residential lots with access to a central sewage system which is in place and operational at the time of registration, except in instances where the fill is for the expansion of an existing residence. Under no circumstances may fill be used to construct or expand an onlot sewage disposal system.

7. Fill material cannot contain wastes as defined in the Solid Waste Management Act.

8. Appropriate erosion control measures and facilities must be incorporated into all earthmoving activities associated with construction. Upon completion of construction the site shall be stabilized.

a. For lots greater than .50 acre an Erosion and Sedimentation Control Plan must be reviewed and approved by the County Conservation District in the county where your project is located prior to registration.

b. For all other lots equal to or less than .50 acre, an Erosion and Sedimentation Control Plan meeting the requirements of Chapter 102 (relating to erosion and sediment control) must be implemented and must be available at the site for review by the Department and/or the County Conservation District (see Exhibit B, Erosion and Sedimentation Control Notes). Permit users are encouraged to contact County Conservation Districts for erosion and sedimentation control planning assistance.

9. Individuals who wish to use this General Permit for impacts of up to .50 acre of wetlands must provide for the replacement of functions, values and areal extent of the wetlands impacted by:

a. creating a wetland in accordance with the Department's Design Criteria for Wetland Replacement on a 1:1 area ratio, replacement wetlands to filled wetlands. (Copies of the criteria are available at DEP Regional Offices.)

Copyright © 2000 Commonwealth of Pennsylvania

b. participating in the Pennsylvania Wetland Replacement Project by contributing to the National Fish and Wildlife Foundation Fund Project 95-096. The contribution rate is as follows:

Deminimus impact less than or equal to .05 acre	—	$ 0.00
Greater than .05 acre to .10 acre	—	$ 500.00
Greater than .10 acre to .20 acre	—	$ 1,000.00
Greater than .20 acre to .30 acre	—	$ 2,500.00
Greater than .30 acre to .40 acre	—	$ 5,000.00
Greater than .40 acre to .50 acre	—	$ 7,500.00

10. Fills and/or excavations should not increase flood levels or permanently restrict, impede, accelerate, increase or obstruct the passage of normal or expected stormwater flows in such a manner that adversely impacts the property or riparian rights of owners above, below, or adjacent to the project.

11. This permit is not valid for use within the corridor of a watercourse or body of water that has been designated as a National Wild or Scenic River in accordance with the Wild and Scenic Rivers Act of 1968 (16 U.S.C.A. §§ 1271—1287) or designated as wild or scenic under the Pennsylvania Scenic Rivers Act (32 P. S. §§ 820.21—820.29). Information may be obtained by contacting the Department of Conservation and Natural Resources (DCNR), Bureau of Recreation and Conservation, Scenic Rivers Program, P. O., Box 8475, Harrisburg, PA 17105 or calling (717) 787-2316.

E. Activities Not in Accordance with Terms or Conditions—If the Department determines, upon inspection, that the construction, operation or maintenance of a project has violated the terms or criteria of this General Permit or of the Chapter 105 Rules and Regulations, the Department may take such actions, legal or administrative, that it may deem to be appropriate.

F. Denial of Authorization—The Department shall have the discretion to deny, revoke or suspend the use of the General Permit for any project which the Department determines to have a substantial risk to life, health, property or the environment.

G. Authority—Authorization of this General Permit is under section 7 of the Dam Safety and Encroachment Act 32 P. S. § 693.7 et seq., and the rules and regulations promulgated thereunder at 25 Pa. Code §§ 105.441—105.449 (relating to general permits). This General Permit becomes effective April 7, 1997, and will remain in effect indefinitely unless specifically modified, suspended or revoked by the Department.

E.38. Puerto Rico

LexJuris
Puerto Rico

Law Núm. 207 of year 2002

. of C. 2483), 2002, law 207

In order to amend Arts. 4 and 8 of the Law Núm. 133 of 1986: Committee of Supervision and Evaluation of the State Program of Inspection and Regulation of Prey and Dams
LAW NUM. 207 OF 28 OF AUGUST OF 2002

In order to amend Articles 4 and 8 of the Law Núm. 133 of 15 of 1986 July, in order to arrange that the Committee of Supervision and Evaluation of the State Program of Inspection and Regulation of Prey and Dams can be integrated by representatives of the respective agencies, to those who the faculty has been delegated him to act to name of the respective agencies, and to establish a new way to calculate the contribution that corresponds to pay to the Authority of Electrical Energy each organization or person to him owner of a dam or prey, and to other aims.

EXHIBITION OF REASONS

In Puerto Rico several prey and dams with multiple uses exist to give service to the citizenship. Some of these uses consist of the energy generation, irrigation of the agricultural fields, aqueducts, conservation, recreation, fishes and control of floods. The government of the Associated Free State of Puerto Rico, never has scrimped before his responsibility to adopt those measures that he considers necessary or pertinent to protect the life and the security of the citizens, especially, that one that is related to the storage of the water which we consumed.

The State Program of Inspection and Regulation of Prey and Dams was created by means of the Law Núm. 133 of 15 of 1986 July, in order to maintain, to conserve, to inspect and to guard by the security of the prey and dams in Puerto Rico. According to Article 2 of the Law Núm. 133, *supra*, the program before mentioned is administered by the Authority of Electrical Energy through the Unit of Inspection and Regulation for the Security of Prey and Dams.

Article 4 of the Law Núm. 133, *supra*, have the constitution a Committee to the supervision and evaluation of the mentioned Program, which is integrated by the President of the Meeting of Planning, the Executive Director of the Authority of Electrical Energy, the Director of Operations of the Authority of Aqueducts and Sewage systems, the Secretary of the Department of Natural and Environmental Resources and three citizens in representation of the public interest, named by the Governor. It is of general knowledge, that these officials government count on agendas of work extremely loaded. However, this Law nothing arranged to authorize these civil servants to delegate its responsibilities in representatives specifically designated by them to such effects. It brings, consequence, delay in the works of the Committee when, for some reason, three (3) of the civil servants to those who it was designated to them to comprise of the same, cannot attend the meetings properly summoned by the Committee.

In addition, according to Article 8 of the mentioned Law, the created unit is authorized to invoice

to name of the Authority, proportionally, to each agency, person or organization following the number of dams or dams that it owns, independent of the size, the capacity or the structural complexity and the maintenance that the wall requires that dams the water of the same.

The effect of the application of the established formula is unjust. Some prey and dams have needed very little effort and services of the Unit, whereas others have required that the Authority carries out extraordinary inspection and carries out expensive works, complex and continuous in relation to the same. The Legislative Assembly of Puerto Rico understands that it is not reasonable that those facilities that most of receive the services or whose walls of dam are in worse S-state are subsidized by the owners of prey and dams that require minor attention and effort or whose walls are in good state. For example, Represa de Carraízo, that has a capacity of dam of 23.500 acre-feet, has needed extraordinary and complex works, besides a continuous service. Their costs of inspection and maintenance as well as those of conservation of their walls exceed those all the other dams and dams in Puerto Rico, are public and private. He is not reasonable that the costs of operation of the Unit are divided in equal proportion between all the prey and dams, when we considered situations as the one of Represa Carraízo and we compared with Represa the Bronze, that inspects once every three years and has a dam of only 843 acre-feet.

Given the situation that we have indicated, the Government of the Free State Associated of Puerto Rico esteem that this Law, is necessary so that the distribution of expenses between the owners of the prey and dams, is more equitable and suitable, considering, among others factors, the size, material, the age and the conditions in which is the wall that dams the water. In addition, it turns out own to arrange that the civil servants appointed by law to form the Committee for the supervision and evaluation of the State Program of Inspection and Regulation of Prey and Dams, can delegate their responsibilities in representatives specifically designated to act to their name.

IT WOULD DECREE BY THE LEGISLATIVE ASSEMBLY OF PUERTO RICO:

Section 1. - Article 4 of the Law Núm reforms. 133 of 15 of 1986 July, so that it reads as it follows:

"Article 4. -

One forms a Committee for the supervision and evaluation of the Program, which will be integrated by the President of the Meeting of Planning, the Executive Director of the Authority of Electrical Energy, the Director of Operations of the Authority of Aqueducts and Sewage systems, the Secretary of the Department of Natural and Environmental Resources or his respective representatives in those who the faculty has been delegated to act to name of these, and three (3) citizens in representation of the public interest named by the Governor of the Associated Free State of Puerto Rico. The Executive Director of the Authority of Electrical Energy or his authorized representative to act in his name will be the President of the Committee. The first three (3) representing members of the public interest will be named one (1) by three (3) years and two (2) by four (4) years. When expiring the term of each, the subsequent appointments will become all by a term of four (4) years and until their successors are appointed and take possession from the position. In case of happening a vacancy between the members of the Committee in representation of the public interest, the Governor of the Associated Free State of Puerto Rico will send a new appointment by the term nonfulfilled del that caused the vacancy.

Five (5) members of the Committee will constitute quorum."

Section 2. - Article 6 of the Law Núm reforms. 133 of 15 of 1986 July, so that it reads as it follows:

"Article 6. -

When the Unit determines that a prey or dams of an agency or public instrumentality offers danger to the life and property of the citizens of the area in which it is, therefore it will notify the Executive Director of the Authority of Electrical Energy. The Director, as well, will notify the Committee, that in consultation with the Office of Management and Budget and the head or director of the agency or instrumentality owner of the prey or dam will adopt a plan of measures to take, with specification of the necessary bottoms, if some, to carry out them. The Unit will establish the term that will have the organization to correct the indicated deficiencies, of not correcting itself, within the ruled time, the Executive Director of the Authority of Electrical Energy will notify the Secretary of Justice of the breach, for its evaluation and later proceeding according to the Law. The Committee will notify in writing to the Governing one on the situation."

Section 3. - Article 8 of the Law Núm reforms. 133 of 15 of 1986 July, so that it reads as it follows:

"Article 8. -

Annually, the Unit, with the approval of the Committee, will invoice to each public agency, person or private organization that own a prey or a participant dam in the Program, the cost incurred across the Program during every year and the received thing will collect to him to the Authority of Electrical Energy.

The Committee will promulgate a regulation to establish the duties and the obligations of

the possessors of prey and dams that its conservation guarantees, and to determine the way in that the contribution will calculate that corresponds to each public agency, person or deprived organization, taking as it bases the costs incurred across the Program and the size, material, age and conditions in which is the wall of retention in each one of the prey and dams that receive the services that the Unit offers."

Section 4. - This Law will begin to prevail immediately after its approval.

Important note: This law is copy of the original law when it was approved, does not include later amendments to this.

Programa de Reglamentación de Represas

Purpose - The Program's purpose is to provide for a safe design, construction, operation and maintenance of the dams to protect public safety.

Authority - The Puerto Rico Dam Safety **Act 207**. The Dam Safety and Security Act of 2002 (**Public Law 107-310**).

Puerto Rico Dam

¿Which dams are subject to the law? All dams in Puerto Rico are subject to the Dam Safety Act.

“Any artificial barrier, including appurtenant works, which impounds or diverts water, and which:

1) Is 25’ or more in height from the natural bed of the watercourse, measured at the downstream toe, or

2) Has an impounding capacity at the maximum water storage elevation of 50 acre-feet or more.”

National Inventory of Dams	Dams Under State Regulation
35	35

The height of a dam is defined as the vertical distance from the streambed at the downstream toe to the top of the dam.

The capacity of a dam is defined as the volume capable of being impounded at the top of the dam.

Hazard Classification of Dams - Dams are classified with a hazard potential depending upon the downstream losses anticipated in event of failure. Hazard potential is not related to the structural integrity of a dam but strictly to the potential for adverse downstream effects if the dam were to fail.

Hazard Classification	Property Damage	Potential Loss of Life
LOW	Minimal	None
SIGNIFICANT	Appreciable	Unlikely
HIGH	Excessive	Likely

Dams are classified by the hazard they represent to downstream life and property, if they were to fail. The classification does not indicate the state of disrepair or the likelihood of failure.

STATE OF RHODE ISLAND AND PROVIDENCE PLANTATIONS
DEPARTMENT OF ENVIRONMENTAL MANAGEMENT

RULES AND REGULATIONS FOR DAM SAFETY

RULE 1. PURPOSE

The purpose of these Rules and Regulations is to implement the provisions of Chapter 46-19, “Inspection of Dams and Reservoirs” of Rhode Island General Laws (R.I. Gen. Laws) of 1956, as amended and to provide for the safety of dams to protect the public, real property and natural resources by establishing reasonable standards and to create a public record for reviewing the performance of dams.

RULE 2. AUTHORITY

These Rules and Regulations are promulgated pursuant to the requirements and provisions of Chapter 42-17.1, “Department of Environmental Management”, Chapter 42-17.6, "Administrative Penalties for Environmental Violations" and Chapter 46-19, “Inspection of Dams and Reservoirs” in accordance with the provisions of Chapter 42-35 “Administrative Procedures Act”, of the R.I. Gen. Laws of 1956, as amended.

RULE 3. ADMINISTRATIVE FINDINGS

The following administrative findings are made as a basis for these Rules and Regulations:

(A) Rhode Island has approximately 674 dams of varying age, size and state of repair;

(B) Failure or misoperation of high hazard dams or significant hazard dams (both of which represent approximately 30 percent of all dams in the state) will result in a probable loss of human life or cause major economic loss, disruption of lifeline facilities or impact other concerns;

(C) Investigations of dam failures have found that approximately 60 percent were caused by lack of maintenance, resulting in piping, surface erosion, slope protection damage or deterioration of outlet pipes;

(D) Many of these dams, both public and private, have not been properly maintained through the years and pose a significant threat to public safety, real property and natural resources;

(E) Since dam related laws were adopted, the threat to public safety, real property and natural resources has increased due to deterioration of dams and development in downstream areas over which dam owners do not necessarily have control.

(F) It is in the best interest of the state, the cities and towns of the state, and the citizen's thereof, to maintain a safe dam infrastructure; and

(G) In order to maintain a safe dam infrastructure, a collaborative effort is required by state and municipal officials, private dam owners and elected officials.

RULE 4. RESPONSIBILITY OF DAM OWNERS

(A) All owners of high hazard dams and significant hazard dams shall keep their dams and appurtenant works in a safe condition.

(B) All owners or precedent owners are responsible for liability for damage to property of others or injury to persons, including but not limited to loss of life, resulting by the following of the pond raised by the dam, by the stopping or raising of the water either above or below the dam, by the backing of water or by the flowing out of any fall of water by means of the dam.

(C) These regulations shall not be interpreted as relieving any owner or person maintaining or having control of a dam from responsibility, or lessening such responsibility, for any damages to persons or property caused by defects, inappropriate operation or inadequate maintenance or as creating liability on the part of the Department or the Director.

(D) Compliance with these Rules and Regulations does not relieve an owner or person maintaining or having control of a dam of any obligation to comply with any other applicable laws or regulations administered by, through or for the Department or any other government entity.

RULE 5. APPLICATION

(A) The terms and provisions of these Rules and Regulations shall be liberally construed to permit the Department to effectuate the purposes of state law, goals and policies.

(B) Nothing in these Rules and Regulations shall be deemed to prohibit a dam owner or person maintaining or having control of a dam, from seeking assistance from a municipality or prohibit a municipality from assisting a dam owner in complying with these Rules and Regulations.

RULE 6. DEFINITIONS

For the purposes of these Rules and Regulations, the following terms shall have the following meanings:

(A) "**Appurtenant works**" means any ancillary feature of a dam including such structures as dikes, training walls, spillways, either in the dam or separate there from, low level outlet works, and water conduits such as tunnels, channels, pipelines or penstocks, either through the dam or its abutments.

(B) "**Dam**" means any barrier made by humans, including appurtenant works, that impounds or diverts water.

(C) "**Department**" means the Department of Environmental Management and may be used interchangeably with Director.

(D) "**Department dam engineer**" means an individual employed by the Department who possesses a Bachelor of Science degree in engineering and has demonstrated, through a combination of education, experience, and/or training, that he/she is qualified to perform visual inspections.

(E) "**Detailed investigation**" means all studies, investigations and analyses appropriate to evaluate the structural safety and hydraulic capacity of a dam or reservoir and appurtenant works.

(F) "**Director**" means the Director of the Department of Environmental Management, or his or her designee and may be used interchangeably with Department.

(G) "**Embankment**" means the fill material, including but not limited to rock or earth, placed to provide a permanent barrier that impounds water.

(H) "**Freshwater wetlands**" means those areas as defined in Section 2-1-18, et. seq. of the R.I. Gen. Laws of 1956, as amended, and the Wetlands Regulations.

(I) "**Hazard classification**" means a rating for a dam that relates to the probable consequences of failure or misoperation of the dam, which is a determination made by the Director based on an assessment of loss of human life, damages to properties or structures located downstream of the reservoir, or loss of use as a drinking water supply. This rating has no relationship to the current condition of the dam. A higher hazard dam does not imply that it is more likely to fail or be misoperated than a lower hazard dam.

(J) "**Height**" means the vertical distance from the elevation of the uppermost surface of a dam to the lowest point of natural ground, including any stream channel, along the downstream toe of the dam.

(K) "**High hazard dam**" means a dam where failure or misoperation will result in a probable loss of human life.

(L) "**Hydraulic**" means the behavior of water relative to the dam. It is the manner in which water in the reservoir is passed over or through the dam, via an outlet such as a spillway or low level outlet.

(M) "**Hydrologic**" means the volume and speed at which precipitation flows along the earth, combines into streams and discharges into a reservoir.

(N) "**Lifeline facilities**" means essential facilities, the loss of which can result in indirect threats to life. Lifeline facilities may include hospitals, transportation links (highways, bridges, airports, rail lines, waterways, ports and harbor facilities and emergency evacuation routes), and utility systems (electric power plants, gas and liquid fuel pipelines, telecommunication systems, water supply and waste water treatment facilities).

(O) **"Low hazard dam**" means a dam where failure or misoperation results in no probable loss of human life and low economic losses.

(P) "**Maintenance**" means minor work on a dam necessary to maintain the dam in proper working order, including activities such as filling minor erosion areas, mowing or clearing vegetation provided that it does not affect the integrity of the dam, lubricating and exercising equipment and re-pointing masonry areas. Maintenance does not include repair of a dam or substantial alteration of a dam

(Q) "**Owner**" means the person or persons, including any individual, firm, partnership, association, syndicate, company, trust, corporation, municipality, agency, political or administrative subdivision of the state or any legal entity of any kind holding legal title to a dam.

(R) "**Person maintaining or having control of a dam**" means the person or persons, including any individual, firm, partnership, association, syndicate, company, trust, corporation, municipality, agency, political or administrative subdivision of the state or any legal entity of any kind having authority to operate or maintain a dam.

(S) "**Piping**" means the progressive development of internal erosion by seepage through the dam. Piping appears downstream as a hole or a discharging flow of water that includes soil particles from the dam embankment or foundation.

(T) "**Probable loss of human life**" means loss of human life that is likely to occur, or reasonably or realistically expected. This definition does not include persons who are only incidentally in the potential inundation area downstream of a dam. Examples include walking on the dam, driving on lightly traveled roads on or downstream of the dam and recreating downstream of the dam provided the area is not an established recreational area.

(U) "**Qualified engineer**" means a professional engineer fully registered in the State of Rhode Island, who is experienced with dam inspection, design, construction and repair.

(V) "**Registered owner**" means a dam owner who has been issued a certificate of registration by the Department.

(W) "**Regulated dam**" means a low hazard dam that is six (6) feet or more in height or has fifteen (15) acre-feet or more of storage capacity; or a high hazard dam; or a significant hazard dam. An acre-foot is a unit of volume equal to 43,560 cubic feet or 325,830 gallons (a measure that would cover one acre to a depth of one foot).

(X) "**Removal**" means the destruction or breaching of a dam to the extent that the dam no longer impounds or diverts water.

(Y) "**Repair** " means any work performed at a dam that may affect the integrity of the dam, including certain cutting or removal of trees where the resulting decomposition of the tree root system could jeopardize the integrity of the dam, work requiring excavation into the embankment fill or foundation of a dam, work requiring reinforcement of the embankment or work requiring removal or replacement of major structural components of a dam; or any related, new, temporary or permanent access way(s) that may be required within freshwater wetlands.

(Z) "**Reservoir**" means the body of water that is impounded or diverted by a dam.

(AA) "**Significant hazard dam**" means a dam where failure or misoperation results in no probable loss of human life but can cause major economic loss, disruption of lifeline facilities or impact other concerns detrimental to the public's health, safety or welfare. Examples of major economic loss include but are not limited to washout of a state or federal highway, washout of two or more municipal roads, loss of vehicular access to residences, (e.g. a dead end road whereby emergency personnel could no longer access residences beyond the washout area) or damage to a few structures.

(AB) "**Spillway**" means a structure, a low area in natural grade or any part of the dam which has been designed or relied upon to allow normal flow or major flood flow to pass over or through while being discharged from a reservoir.

(AC) "**Substantial alteration**" means any physical modification to a dam that results in a permanent change in the water elevation of the reservoir or in water flow downstream of the dam.

(AD) "**Unsafe dam**" means the condition of a regulated dam, as determined by the Director, is such that an unreasonable risk of failure exists that will result in a probable loss of human life or major economic loss. Among the conditions that would result in this determination are: excessive vegetation that does not allow the Director to perform a complete visual inspection of a dam, excessive seepage or piping, significant erosion problems, inadequate spillway capacity, inadequate capacity and/or condition of control structure(s) or serious structural deficiencies, including movement of the structure or major cracking.

(AE) "**Visual inspection**" means a visual, technical evaluation of the physical conditions of a dam that affect performance of the structure.

(AF) "**Wetlands Regulations**" means the "Rules and Regulations Governing the Administration and Enforcement of the Freshwater Wetlands Act".

RULE 7. PROHIBITIONS

(A) No repair of a high hazard dam or significant hazard dam shall occur until plans and specifications of the proposed work have been filed with and approved by the Director in accordance with these Rules and Regulations.

(B) No repair of a low hazard dam shall occur without approval of the Director in accordance with the Wetlands Regulations unless specifically exempted under the Wetlands Regulations.

(C) No maintenance of a high hazard dam or significant hazard dam shall occur without approval of the Director unless specifically exempted under these Rules and Regulations.

(D) No maintenance of a low hazard dam shall occur without approval of the Director in accordance with the Wetlands Regulations unless specifically exempted under the Wetlands Regulations.

(E) No new construction, substantial alteration, or removal of a dam shall occur without approval of the Director.

RULE 8. REGISTRATION AND NOTIFICATION

(A) The owner of a regulated dam shall file with the Department, within sixty (60) days of promulgation of these Rules and Regulations, a fully completed registration form to be provided by the Director.

(B) The owner of a regulated dam shall notify the Director and the local municipality's emergency management authority having jurisdiction, of the transfer of legal title of such dam or a change in the mailing address, telephone number or emergency contact person not later than thirty (30) days after the date of such transfer or change and provide to the Director the new owner, mailing address, telephone number, or emergency contact person.

(C) The Director, following receipt of a fully completed registration form, shall issue a certificate of registration to the owner of a regulated dam identifying the proper name, registration number and current hazard classification of the dam.

(D) The owner of a regulated dam, upon written request from the Department, shall make available to the Director, all the existing surveys, plans, drawings and reports related to the dam, in possession of or available to the owner, that may be required by the Director for the purposes of dam safety.

(E) The owner of a regulated dam, upon written request from the Department, shall prepare all the necessary surveys, plans, drawings and reports related to the dam that may be required by the Director for the purposes of dam safety.

RULE 9. HAZARD CLASSIFICATION

(A) The Department shall classify each regulated dam in the State as a high hazard dam, significant hazard dam or low hazard dam. The Director shall send a notice of the proposed classification to the registered owner of a dam. The dam owner may contest the proposed classification pursuant to Rule 15 of these Rules and Regulations. The Director shall maintain a list of all classified dams and shall make the list available to the public.

(B) The Director shall examine each regulated dam as often as he or she shall deem necessary to assess whether the dam warrants reclassification.

(C) Any person may petition the Director for reclassification of a dam. The petition must be in writing and must include a written report prepared by a qualified engineer that details the findings and analyses that support the engineer's opinion that the dam should be reclassified.

RULE 10. APPROVALS

(A) MAINTENANCE OF A HIGH OR SIGNIFICANT HAZARD DAM

(1) Maintenance of a high hazard dam or significant hazard dam, except for certain cutting or removal of trees, does not require an approval from the Department. To be exempt from Department approval, the cutting or removal of trees must be limited to those trees with a diameter less than 6 inches (measured 2 feet above the ground level) or that do not affect the integrity of the dam. If trees have a diameter greater than 6 inches (measured 2 feet above the ground level) then the dam owner shall first consult with a qualified engineer who will determine if the cutting or removal could jeopardize the integrity of the dam. The owner shall obtain a written report from the qualified engineer, if the qualified engineer determines that the cutting or removal is not a threat to the integrity of the dam, and keep a copy of the report on file. The report does not have to be filed with the Department. The owner shall file an application for repair of the dam in accordance with these Rules and Regulations if the qualified engineer determines that the cutting or removal is a threat to the integrity of the dam.

Mowing or cutting of vegetation may be performed without an approval from the Department provided it is limited to areas on the dam and adjacent to the dam such that an area does not exceed fifteen (15) feet from the embankment, spillway or low level control structure. All other mowing or cutting of vegetation within freshwater wetlands will require a permit from the Director unless specifically exempted under the Wetlands Regulations. Areas exceeding fifteen (15) feet from the embankment, spillway or low level control structure that have been historically mowed and maintained are specifically exempted under the Wetlands Regulations. These areas can continue to be mowed without a permit from the Director.

(2) All maintenance activities shall comply with the following:

(a) Best management practices for erosion and sediment controls must be used. All controls must be maintained in effective operating condition during the activity, and all exposed soil and other fills must be permanently stabilized at the earliest possible date. (For guidance see *Rhode Island Soil Erosion and Sediment Control Handbook* and *Rhode Island Stormwater Design and Installation Standards Manual.*);

(b) All equipment used for maintenance activities shall be removed from any freshwater wetland upon completion of the maintenance project; and

(c) All maintenance activities shall be protective of water quality and freshwater wetland functions and values so as to prevent pollutants, sediment, direct discharge of stormwater runoff, or any material foreign to waters of the State including freshwater wetlands, or hazardous to life, from entering any waters of the State including freshwater wetlands.

(B) REPAIR OF A HIGH OR SIGNIFICANT HAZARD DAM

The dam owner must submit an application for repair of a high hazard dam or significant hazard dam directly to the Department's Dam Safety Program. Applications shall be in writing and on a form prescribed by the Director and shall contain such documentation and information as the Director may require, which may include but not be limited to the following:

(1) A locus map indicating the location of the dam in relation to other fixed infrastructure in the community such as roads, etc.;

(2) Written justification explaining the need for the work;

(3) Three (3) sets of plans and specifications for the proposed work, prepared and stamped by a qualified engineer. The Department reserves the right to request additional copies for coordination with other State or federal permitting agencies;

(4) Plans drawn in sufficient detail to clearly indicate the extent and complexity of the work, including plan, profile and cross section views, along with any new, temporary or permanent access ways;

(5) Written description of the method of construction;

(6) Supporting computations and field measurements for all assumptions and design work (hydrologic, hydraulic, structural, geotechnical);

(7) Criteria and basis for selection of the design;

(8) Specifications of all material to be used in the repair;

(9) Estimated construction schedule including commencement and completion of the repairs;

(10) Amount (estimated vertical, horizontal and areal) and schedule of reservoir drawdown and schedule of reservoir recovery;

(11) If a temporary water by-pass or diversion is proposed, the dam owner shall provide plans, details and calculations for such by-pass or diversion. The design of the by-pass or diversion shall be capable of accommodating peak flows from a minimum of 95% of all storm events that may be expected to occur within the proposed construction period and contain a contingency provision to safely accommodate a 100-year, 24 hour duration Type III storm event. The design of the by-pass or diversion shall be capable of accommodating, at a minimum, peak flows in accordance with the following table.

Construction Duration	**Required Design Storm**
up to 3 months	5 year
3 months to 6 months	10 year
6 months to 1 year	20 year
1 year to 2 years	50 year

(12) Supporting documentation to demonstrate that there is no practicable alternative to the proposed repair that would have less adverse impact on freshwater wetlands, that addresses the impact avoidance and minimization criteria specified in Appendix I. A practicable alternative is defined as one that is "available and capable of being done after taking into consideration cost, existing technology and logistics in light of the overall project purposes";

(13) Contact name and telephone number of person(s) responsible for repair; and

(14) Statement that a record drawing, certified by the qualified engineer responsible for design that the dam was repaired in conformance with the plan approved by the Director, will be provided to the Director upon completion of the work.

The Director shall provide dam owners with written notice for any additional information the Director requires.

(C) EMERGENCY REPAIR OF A HIGH OR SIGNIFICANT HAZARD DAM

The Director may grant verbal approval of an emergency repair consistent with the following requirements:

(1) Verbal or written request for permission to proceed with an emergency repair must be made by the owner or person maintaining or having control of a dam;

(2) The request must inform the Department of at least the following:

(a) An explanation of the problem necessitating an emergency repair;

(b) The reason why the problem represents an imminent threat to public safety or real property;

(c) The location of the dam on which the repair is required;

(d) The proposed actions necessary to correct the problem and complete the repair;

(e) The person responsible for overseeing the repair, including means of contact; and

(f) The means proposed to restore any wetland areas following the emergency repair that may be required by the Director.

(3) Any emergency repair undertaken shall not result in a significant alteration of any wetland unless authorized by a permit issued by the Director.

(4) Alteration of wetlands shall not exceed work beyond that necessary to abate the emergency;

(5) Unless otherwise informed by the Director, the dam owner must submit a report, a record drawing and a permit application to the Department no later than thirty (30) days following the emergency repair. The report must explain the emergency repair undertaken, and the short-term and long-term effects that the emergency repair had on abating the emergency, any wetlands affected, any permanent, significant alteration which resulted from the activity, and all restoration activities undertaken, or which may still be required;

(6) The time limitation for performance of an emergency repair shall not exceed ten (10) days following initial approval by the Department unless written approval for an extension is obtained from the Department; and

(7) Following submission of the record drawing required above, the applicant is required to comply with any additional activities necessary to prevent significant wetland alterations or to obtain a permit as detailed in writing by the Department.

An emergency repair may be taken by the owner or person maintaining or having control of a dam without prior Department approval in accordance with Rule 12 of these Rules and Regulations. The Department will evaluate the emergency repair to determine if it is consistent with Rule 10(C) of these Rules and Regulations. The Department will consider good faith efforts made by the owner or person maintaining or having control of the dam to obtain prior approval from the Department for the emergency repair.

(D) PROCEDURES FOR REVIEW OF APPLICATIONS

(1) In consideration of the application, the Department may use, but is not limited to, the criteria, manuals and procedures used by the following agencies:

The United States Army Corps of Engineers;
The United States Department of Agriculture, Natural Resources Conservation Services;
The United States Department of Energy, Federal Energy Regulatory Commission;
The United States Department of Homeland Security, Federal Emergency Management Agency; and
The United States Department of the Interior, Bureau of Reclamation.

(2) At any time during the review, the Director may:

(a) Require that the dam owner provide such information as the Director deems necessary for the review of the application;

(b) Issue an approval requiring such terms, conditions, management practices and operation and maintenance requirements as deemed necessary to comply with the requirements of applicable state laws; or

(c) Deny the application for failure to satisfy the requirements of applicable laws and advise the dam owner of the right to appeal under Rule 15 of these Rules and Regulations. A denial may be based on, but is not limited to, any of the following:

(i) Failure to submit any information required by the department; or

(ii) Failure to provide clear and convincing documentation demonstrating, to the satisfaction of the Director, that the project will not violate these Rules and Regulations.

(E) PUBLIC NOTICE

The Director may require the applicant to provide written notice of the planned repair to abutters of the dam and reservoir and to the municipality(s) in which the dam and reservoir are located. In general, an abutter will be limited to a property owner with frontage on the reservoir. The Director may prescribe a form or a format for such notice.

(F) EFFECT OF APPROVAL

(1) The issuance of an approval mandates compliance with all terms, conditions, management practices and operation and maintenance requirements set forth in the approval.

(2) The issuance of an approval does not relieve any person of the continuing responsibility to comply with any other applicable federal, state or local law or regulation.

(3) The issuance of an approval does not relieve any person of the responsibility for obtaining any other necessary permits or approvals from any federal, state, regional, or local agency.

(4) The issuance of an approval does not authorize any injury to persons or property or invasion of other private rights, or any infringement of federal, state or local law or regulations.

(G) MODIFICATION, SUSPENSION OR REVOCATION OF APPROVAL

(1) The Director may modify, suspend, or revoke, in whole or in part, an approval for cause, including, but not limited to, the following:

(a) Information indicating that the project will result in an unsafe condition of the dam;

(b) The existence of a factor or factors which, if properly and timely brought to the attention of the Director, would have justified the application of more or less stringent conditions than required by these regulations, but only if such factor(s) arose after the approval was issued;

(c) Where circumstances on which the approval was based have materially and substantially changed since the approval was issued, including but not limited to pertinent amendment of these rules and regulations;

(d) The information or data submitted by the dam owner either on the form required or in any other material in support of the application is found to be false, misleading or erroneous; or

(e) The project is not undertaken in strict compliance with the conditions or provisions of any approval issued by the Department.

(2) A notice of revocation/suspension of an approval will be in the form of a certified letter notifying the dam owner of the revocation or suspension and the reasons why the approval is being revoked or suspended. Such notice shall be in conformance with the Administrative Procedures Act, R.I. Gen. Laws Sections 42-35-9(b) and 42-35-14, as amended.

(3) The dam owner issued a notice of revocation/suspension of an approval may request an adjudicatory hearing to contest the revocation as set forth in the provisions of Rule 15 of these Rules and Regulations. A notice of revocation/suspension of an approval automatically becomes a final order of the Director enforceable in Superior Court upon failure to request said adjudicatory hearing.

(4) Modification of an approval shall be in accordance with Rule 10(B) of these Rules and Regulations.

RULE 11. INSPECTIONS

(A) SCHEDULED INSPECTIONS

(1) Regulated dams shall be inspected in accordance with the following schedule. These time periods are the maximum time between inspections and more frequent inspections may be performed at the discretion of the Director.

Hazard Classification	Minimum Inspection Frequency	Type of Inspection
High	2 years	Visual
Significant	5 years	Visual
Low	5 years	Hazard Classification Assessment

(2) The Director shall periodically perform or require the owner to perform a visual inspection of all high hazard dams and significant hazard dams. The Director will notify the owner by certified letter in the event that the Department will require the owner to perform a visual inspection of the dam. The owner must then retain a qualified engineer to perform a visual inspection of the dam. Visual inspection by a qualified engineer must be completed within sixty (60) days following receipt of notification from the Director.

(3) At any time, the owner may elect to employ the services of a qualified engineer to perform a visual inspection of his or her dam.

(4) Whenever the findings of the visual inspection reveal, in the opinion of the Director, that the dam may be unsafe, the owner shall be required to retain a qualified engineer to perform a detailed investigation of the dam and to provide a schedule by which any work needed shall be accomplished. The owner shall be responsible for completing all work required by the Director and in a reasonable time frame required by the Director.

(5) Evaluations of regulated, low hazard dams shall be conducted by the Director at least every five (5) years to determine whether conditions have changed over time that warrant raising the hazard classification to significant or high. If the Director determines the classification of a low hazard dam should be raised to significant or high, the owner shall be informed of the classification change in accordance with Rule 9(A) of these Rules and Regulations.

(B) UNSCHEDULED INSPECTIONS

(1) Any person who has cause to believe that an unsafe dam exists may make a request to the Director to inspect the dam. If in the opinion of the Director, the failure of the dam will result in a probable loss of human life or cause major economic loss, disruption of lifeline facilities or impact other concerns detrimental to the public's health, safety or welfare, then the Director shall perform a visual inspection, or cause a visual inspection to be performed, of the dam to determine if the dam is unsafe.

(2) The Director shall, whenever he or she has cause to believe that an unsafe dam exists, perform a visual inspection, or cause a visual inspection to be performed, of the dam to determine if the dam is unsafe.

(C) INSPECTIONS

(1) Visual Inspections
A qualified engineer or a Department dam engineer must perform a visual inspection. The visual inspection shall include an assessment of the condition of the major components of the dam subjectively rated as *good*, *fair* or *poor*. The major components of a dam are the embankment(s), the spillway(s) and the low level control structure(s). *Good* is defined as meeting minimum guidelines, where no irregularities are observed and the component appears to be maintained properly. *Fair* is defined as a component that requires maintenance. *Poor* is defined as a component that has deteriorated beyond a maintenance issue and requires repair; the component no longer functions as it was originally intended.

(2) Detailed Investigations

A qualified engineer must perform a detailed investigation. A detailed investigation may include soil analysis, concrete or earth stability analysis, materials testing, foundation explorations, hydraulic and hydrologic analysis, including basin studies, flood potential, and an analysis of the dam's ability to pass flood waters.

(D) INSPECTION REPORTS

A report must be prepared for each visual inspection or detailed investigation. If deficiencies are found, the report must identify the specific deficiencies and, when warranted, specify further investigation or corrective measures. The report, completed by a qualified engineer retained by a dam owner, must provide a recommended schedule to complete any work identified as necessary to correct the deficiencies noted in the report. Such reports must be provided to the dam owner and the Director within thirty (30) days of the date of the visual inspection or within sixty (60) days of the date of the detailed investigation.

RULE 12. UNSAFE DAMS

(A) Whenever the Director determines that a dam is unsafe the Director shall determine whether the water in the reservoir shall be drawn off in whole or in part, and the actions necessary to make the dam safe.

(B) The Director shall notify the owner or person maintaining or having control of the dam, by certified mail, that the dam is unsafe, the actions necessary to make the dam safe and a schedule to complete the actions.

(C) The Director may notify the owner or person maintaining or having control of the dam, by certified mail, that the dam is unsafe after completing his/her own inspection or after receiving an inspection report completed by a qualified engineer.

(D) The Director may, pursuant to R.I. Gen. Laws Section 42-17.1-2(u), issue an immediate compliance order stating the existence of the unsafe condition and the action deemed necessary to correct the unsafe condition. The Director may order the water in the reservoir to be drawn off, in whole or in part. The immediate compliance order shall become effective immediately upon service or within such time as is specified by the Director in such order.

(E) Any emergency action taken by the owner or person maintaining or having control of a dam shall immediately be reported by the dam owner to the Director and the municipality(s) in which the dam and reservoir lies. The owner or person maintaining or having control of a dam shall also report, by telephone within twenty-four (24) hours and in writing within three (3) days, the emergency action taken.

(F) If water has been drawn off or the dam has been altered pursuant to an order by the Director, the reservoir shall not be refilled without approval of the Director.

(G) If the owner or person maintaining or having control of a dam fails to comply with an order of the Director, the Director may also, by summons and complaint, seek to enforce the order in a court of competent jurisdiction.

RULE 13. ACCESS

The Director shall conduct all inspections in accordance with the "Administrative Inspection Guidelines", adopted on January 23, 2003, and any amendments thereto.

RULE 14. ENFORCEMENT ACTIONS

As set forth in R.I. Gen. Laws Chapter 42-17.1, et seq. and Section 42-17.6-1 et seq., the Director shall have the power to issue enforcement notices, orders, administrative penalties or other requirements to ensure compliance with these Rules and Regulations. The Director may also provide written or verbal warning of his/her intent to undertake enforcement action, but is not required to do so. Nothing in these Rules and Regulations shall limit the authority of the attorney general to prosecute offenders as required by law. The Department shall forward a copy of the enforcement notices and/or orders to recognized watershed councils in accordance with the *Rules and Regulations of the Rhode Island Rivers Council for Watershed Council Grants and Notification of Proposed Actions to Watershed Councils* and the municipality wherein the dam is located.

RULE 15. APPEALS

(A) The procedures for appeal of Departmental decisions pursuant to the provisions of Chapter 42-35 of the R.I. Gen. Laws are contained in the "Administrative Rules of Practice and Procedure for the Department of Environmental Management Administrative Adjudication Division for Environmental Matters".

(B) Within thirty (30) days of the receipt of a decision from the Department regarding an application for repair of a dam or hazard classification of a dam, the owner may request an adjudicatory hearing to appeal the decision, or portions thereof. The request for an adjudicatory hearing must be in writing, must comply in form and content for such requests as required by the "Administrative Rules of Practice and Procedure for the Administrative Adjudication Division for Environmental Matters", and must be filed directly with the Administrative Adjudication Division (AAD) of the Department. A copy of such request must also be forwarded to the Dam Safety Program. A request for an adjudicatory hearing automatically stays any contested approval issued for repair of a dam. It shall be the dam owner's burden to demonstrate by a preponderance of the evidence that the application as proposed or hazard classification is consistent with the purposes of the law, complies with these Rules and Regulations and protects the public, real property and natural resources.

(C) Any person who has received a Notice of Violation (NOV) alleging violation of these Rules and Regulations, or whose approval has been suspended or revoked, may appeal to the Director for review of the decision on which the NOV, suspension or revocation is based by filing an appeal with AAD.

(1) Filing of Appeal - All appeals shall be in writing and shall be filed with and received by AAD within twenty (20) days after the date of receipt of the subject NOV, or within thirty (30) days after receipt of the revocation or suspension.

(2) Contents of Appeal - Every appeal shall contain a detailed basis upon which the appeal is taken.

RULE 16. SEVERABILITY

If any provision of these Rules and Regulations, or the application thereof to any person or circumstance, is held invalid by a court of competent jurisdiction, the validity of the remainder of the Rules and Regulations shall not be affected thereby.

RULE 17. EFFECTIVE DATE

The foregoing Rules and Regulations for Dam Safety, after due notice, are hereby adopted and filed with the Secretary of State this _____ day of _____, 2007 to become effective twenty (20) days thereafter, in accordance with the provisions of Chapters 46-19, 42-35, 42-17.1, and 42-17.6 of the General Laws of Rhode Island of 1956, as amended.

_____

W. Michael Sullivan, Director
Department of Environmental Management

Notice Given on: July 23, 2007

Public Hearing held: August 23, 2007

Filing Date:

Effective Date:

APPENDIX I: IMPACT AVOIDANCE AND MINIMIZATION

Rhode Island's Freshwater Wetlands Act (R.I. Gen. Laws Section 2-1-18 et seq.) and Water Pollution Act (R.I. Gen. Laws Section 46-12-1 et seq.) require the Director to protect freshwater wetland values and water quality, respectively. It is important for the dam owner to recognize the Director's responsibilities under these laws and to plan his/her repair projects to minimize any negative impacts to freshwater wetlands and water quality values. In particular, the dam owner must:

(A) Minimize the impacts from lowering the water elevation in a reservoir during a repair project, such as by installing a temporary cofferdam. This is necessary to reduce detrimental impacts to fish and wildlife associated with the wetland environment and to reduce loss of aquatic vegetation that serves as wildlife habitat. In the event that a dam owner is unable to install controls to maintain water in the reservoir to assist in protecting fish and wildlife habitat, the dam owner must specifically inform the Director of this situation and document in writing why water is not proposed to be maintained upstream of the dam during the repair activity. Efforts must be made to avoid drawdowns between April 15 to July 1, and to avoid significant drawdowns between October 15 and March 15.

(B) Use best management practices regarding the installation of sediment and erosion controls to prevent sediment from entering adjacent waters of the state.

(C) Minimize construction disturbance so as to keep disturbed soils and areas subject to erosion to a minimum.

(D) Prevent any hazardous substances injurious to aquatic life used during the repair activity from entering any adjacent water and freshwater wetlands.

(E) Stabilize all disturbed soils following construction activities to ensure erosion will not take place.

(F) Minimize clearing of vegetation to that necessary to conduct the project and remove the slash material from adjacent freshwater wetlands and water bodies.

(G) Use only the amount of fill of other material necessary to complete the project and minimize the placement of material in any flood plain.

(H) Replace, restore or mitigate alterations to freshwater wetlands as deemed necessary in the opinion of the Department.

Dams and Reservoir - Summary of Laws and Regulations

Summary of the SC Dams and Reservoirs Safety Act

The SC Dams and Reservoirs Safety Act is the basis of South Carolina's dams and reservoirs safety programs. The purpose of the act is protect citizens health, safety, and welfare by creating a regulatory program to reduce the risk of failure of dams. The law confers upon the Department the regulatory authority to accomplish the purposes of the act. This includes the power to promulgate regulations, require permits, conduct inspections and take enforcement actions among other things.

Section 49-11-190 of the act allows the Department to issue emergency orders as may be necessary from time to time to protect life and property. This section also allows the Department to enter on private property to take immediate actions necessary to protect life and property when the owner of a dam does not comply with an emergency order.

Section 49-11-200 of the act requires a permit from the Department before a new dam may be constructed or before the alteration, repair, or removal of an existing dam.

Section 49-11-230 grants authority to the Department to conduct inspections while Section 49-11-240 allows the Department entry on property to carry out the general provisions of the program.

In summary, this act empowers the Department to conduct the dams and reservoirs safety program through a wide range of activities such as permitting, inspections, compliance, monitoring, enforcement and public education. To meet the requirements of the act, the Department regulates a large number of dams.

Summary of Regulation 72-1: Dams and Reservoirs Safety Act Regulations

The regulations were initially approved in 1977 and they were most recently amended in July of 1997. The regulations for the most part mirror the requirements of the SC Dams and Reservoirs Safety Act. The regulations create a tiered permitting program based on a classification system of dams. Dams regulated by the Department are classified based on size and hazards. The size classifications are large, intermediate, small, and very small. Hazard classifications are high hazard, significant hazard, and low hazard.

These regulations specify the administrative process for obtaining a permit for either a new dam or the alteration, repair, or removal of an existing dam. The items required to be submitted to the Department as part of the permit application package are also given in the regulations as well as some general design criteria a dam must meet.

DISCLAIMER

The South Carolina Legislative Council is offering access to the unannotated South Carolina Code of Laws on the Internet as a service to the public. The unannotated South Carolina Code on the General Assembly's website is now current through the 2009 session. The unannotated South Carolina Code, consisting only of Code text and numbering, may be copied from this website at the reader's expense and effort without need for permission.

The Legislative Council is unable to assist users of this service with legal questions. Also, legislative staff cannot respond to requests for legal advice or the application of the law to specific facts. Therefore, to understand and protect your legal rights, you should consult your own private lawyer regarding all legal questions.

While every effort was made to ensure the accuracy and completeness of the unannotated South Carolina Code available on the South Carolina General Assembly's website, the unannotated South Carolina Code is not official, and the state agencies preparing this website and the General Assembly are not responsible for any errors or omissions which may occur in these files. Only the current published volumes of the South Carolina Code of Laws Annotated and any pertinent acts and joint resolutions contain the official version.

Please note that the Legislative Council is not able to respond to individual inquiries regarding research or the features, format, or use of this website. However, you may notify Legislative Printing, Information and Technology Systems at LPITS@scstatehouse.gov regarding any apparent errors or omissions in content of Code sections on this website, in which case LPITS will relay the information to appropriate staff members of the South Carolina Legislative Council for investigation.

Title 49 - Waters, Water Resources and Drainage

CHAPTER 11.

DAMS

ARTICLE 1.

GENERAL PROVISIONS

SECTION 49-11-10. Prohibition on dams or banks erected or water let off to injury of others.

No person shall be permitted or allowed to make or keep up any dam or bank to stop the course of any waters so as to overflow the lands of another person without the consent of such person first had and obtained nor shall any person be permitted or allowed to let off any reserved water to injure the crops upon the grounds of other persons.

SECTION 49-11-20. Persons may not keep water on other's lands.

Nothing contained herein shall be construed to authorize any person to keep water at any time on any lands other than his own.

ARTICLE 3.

DAMS AND RESERVOIRS SAFETY ACT

SECTION 49-11-110. Short title.

This article shall be cited as the "Dams and Reservoirs Safety Act."

SECTION 49-11-120. Definitions.

Unless the context otherwise requires, as used in this article:

(1) "Alterations" and "repairs" mean only the alterations or repairs which may affect the safety of a dam or reservoir.

(2) "Appurtenant works" include, but are not limited to, structures such as spillways, either in the dam or separate from it, low-level outlet works, and water conduits.

(3) "Department" means the South Carolina Department of Health and Environmental Control or its staff or agents.

(4) "Dam" means an artificial barrier with appurtenant works, including, but not limited to, dams, levees, dikes, or floodwalls for the impoundment or diversion of waters or other fluids where failure may cause danger to life or property. However, this does not include a dam:

(a) less than twenty-five feet in height from the natural bed of the stream or watercourse measured at the downstream toe of the dam, or less than twenty-five feet from the lowest elevation of the outside limit of the dam, if it is not across a stream channel or watercourse, to the maximum water storage elevation and has an impounding capacity at maximum water storage elevation of less than fifty-acre feet unless a situation exists where the hazard potential as determined by the department is such that dam failure or improper reservoir operation may cause loss of human life;

(b) owned or operated by a department or an agency of the federal government;

(c) owned or licensed by the Federal Energy Regulatory Commission, the South Carolina Public Service Authority, the Nuclear Regulatory Commission, the United States Corps of Engineers, or other responsible federal licensing agencies considered appropriate by the department;

(d) upon which the Department of Transportation or county or municipal governments have accepted maintenance responsibility for a road or highway where that road or highway is the only danger to life or property with respect to failure of the dam.

(5) "Districts" means the soil and water conservation districts of this State. For the purposes of this article the districts may serve as agents and advisors to the department.

(6) "Danger to life or property" means a situation exists where the hazard potential as determined by the department is such that dam failure or improper reservoir operation may cause injury to persons, loss of human life, or damage to property.

(7) "Detailed inspection" means all studies, investigations, and analyses necessary to evaluate conclusively the structural safety and hydraulic capacity of a dam or reservoir and appurtenant works. This inspection includes, but is not limited to, soil analyses, concrete or earth stability analyses, materials testing, foundation explorations, and hydrologic analyses, including basin studies and flood potential. This inspection must be performed by a qualified registered professional engineer.

(8) "Enlargement" means a change in or an addition to an existing dam or reservoir which raises or may raise the water storage elevation of the water impounded by the dam or reservoir.

(9) "Owner" means those who own, control, operate, maintain, manage, or propose to construct a dam or reservoir.

(10) "Removal" means destruction or breaching of an existing dam or drainage of water impoundment or reservoir.

(11) "Reservoir" means a reservoir which contains the impoundment of water by a dam or reservoir.

(12) "Order" means a written document prepared and issued by the department which mandates specific actions to be accomplished by a dam owner within a specified time frame. Failure to comply makes the owner subject to penalties outlined in Section 49-11-260.

(13) "Unsafe" means the condition of the dam is such that repairs or alterations are necessary to reduce the risk of dam failure.

SECTION 49-11-130. Declaration of purpose.

It is the purpose of this article to provide for the certification and inspection of certain dams in South Carolina in the interest of public health, safety, and welfare in order to reduce the risk of failure of the dams, prevent injuries to persons and damage to property, and confer upon the department the regulatory authority to accomplish the purposes.

SECTION 49-11-140. General duties of department.

The authority for the safe maintenance of the dams and reservoirs of this State and the powers of inspection and certification provided in this article are the responsibility of the department. The department may employ engineers and technicians it considers necessary to implement this article for which appropriations are available.

SECTION 49-11-150. Owner responsible for safe maintenance of dam or reservoir; notice of change of ownership; emergency action plan requirement.

The owner of a dam or reservoir constructed in this State solely is responsible for maintaining the dam or reservoir in a safe condition throughout the life of the structure. The owner of a dam or reservoir shall inform the department in writing within thirty days after title to the dam or reservoir legally has been transferred from his ownership. The notice must include the name and address of the new owner. The owner of a dam or reservoir whose failure likely would cause loss of life or substantial property damage, a dam or reservoir classified as a high or significant hazard under existing regulations, shall provide the department a current emergency action plan in the format the department by regulation requires.

SECTION 49-11-160. Order to maintain, alter, repair, or remove dam or reservoir; findings supporting order.

The department may issue an order directing the owner of a dam or reservoir to make at his expense the necessary maintenance, alteration, repair, or removal upon a finding that the dam or reservoir:

(a) is or has become unsafe and is dangerous to life or property;

(b) is not maintained in good repair or operating condition; or

(c) is not maintained or operated in accordance with the terms and conditions of the certificate of completion and operation issued by the department.

SECTION 49-11-170. Bringing unsafe dams to attention of department; preliminary inspections;

detailed inspection at owner's expense; notice to owner; hearings.

(A) The existence of a dam which is not maintained in good repair or operating condition or may be unsafe and a danger to life or property may be brought to the attention of the department by complaint, staff, or authorized investigation or by other means.

(B) Upon staff or other authorized investigations or upon receipt of a written private complaint alleging that the person or property of the complainant is endangered by the construction, maintenance, operation, or condition of a dam or reservoir, the department shall cause a preliminary inspection of the structure and downstream development to be made by field observations to determine if the complaint is meritorious. The department may require the owner of the dam or reservoir to provide data, records, and design plans of the structure specified by regulations.

(C) If upon the preliminary inspection it is determined that the dam or reservoir is unsafe and is dangerous to life or property, the department may order the owner at his expense to make a detailed inspection of the dam and reservoir and surrounding area and to provide to the department within a time frame specified by the department plans prepared by a qualified registered professional engineer for correction of all deficiencies of the dam or to provide to the department plans and specifications for removal of the dam. In either instance the plans must be approved by the department before implementation and implemented within a time frame specified by the department. If upon inspection it is determined that the dam or reservoir has not been maintained in good repair or operating condition, the department may order the owner at his expense to accomplish the necessary maintenance or to obtain a permit for removal and to remove the dam within a time frame specified by the department.

(D) The department shall give the owner notice of its action when:

(1) a complaint has been filed alleging that the owners' dam or reservoir is unsafe and a danger to life or property stating the nature of the complaint;

(2) a preliminary inspection has been made with findings.

(E) The owner of a dam or reservoir determined through a preliminary inspection not to be maintained in good repair or operating condition or to be unsafe and a danger to life or property may request a hearing before the board of the department within thirty days after notice of the findings are delivered. The owner may submit written or present oral evidence which must be considered by the board of the department in the issuance of the order.

SECTION 49-11-180. Voluntary compliance; time extensions.

(A) The department may solicit voluntary compliance by the owner of a dam or reservoir found to be unsafe and a danger to life or property to take remedial steps necessary to render the dam safe.

(B) Extension of time to complete work specified in an order may be granted by the department. No extension may be granted when there appears substantial and immediate danger of dam failure.

SECTION 49-11-190. Emergency orders; owner to notify department of emergency; action when owner is unknown or fails to comply with order.

(A) The department immediately shall order remedial measures necessary to protect life or property if the condition of a dam or reservoir is so dangerous to the safety of life or property as not to permit time for the issuance and enforcement of a repair order or passing or imminent floods threaten overtopping erosion or destruction of a dam or reservoir capable of danger to life or property.

(B) In applying emergency measures the department has the following limited powers to order the owner to:

(1) lower the water level by releasing water from the reservoir;

(2) empty the reservoir completely;

(3) take other steps essential to safeguard life and property.

(C) For an emergency where the owner finds repairs are necessary to safeguard life or property, he may start the repairs immediately but shall notify the department at once of the proposed repair and work underway.

(D) When the owner fails to comply with the emergency order or cannot be ascertained or found, the department or its authorized agents may enter and immediately take actions necessary to provide protection to life or property, including removal of the dam. The department may recover from the owner, in the name of the State, the expenses incurred in taking the action in the same manner debts are recoverable by law.

SECTION 49-11-200. Department approval required for construction or alteration; exceptions.

(A) The construction of a new dam or reservoir or enlargement, removal, or repair may not begin until the owner has applied for and obtained from the department written approval of plans and specifications.

(B) Where the location and size of the dam or reservoir renders the requirements of subsection (A) and Section 49-11-210 unnecessary, the department may grant approval and waive certain nonessential requirements in instances, including, but not limited to, small dams and reservoirs for agricultural, fish or wildlife, or recreational uses on private lands and of no danger to other life or property downstream.

SECTION 49-11-210. Separate application required for each alteration; information to accompany application.

A separate application for each dam or reservoir and all enlargements, removals, or repairs to existing dams or reservoirs must be filed with the department upon forms to be provided by it, except only one application need be filed for a dam and the reservoir which will contain the water impounded by the dam. The application must be accompanied by maps and plans and specifications of a character and size and setting forth pertinent details and dimensions required by regulation. The application for construction of a new dam or reservoir whose failure likely would cause loss of life or substantial property damage, a dam or reservoir classified as high or significant hazard under existing regulations, must include a fully-developed emergency action plan in a format the department by regulation requires. After the dam or reservoir is constructed, this emergency action plan must be updated by the owner of the dam or reservoir each time it becomes noncurrent.

SECTION 49-11-220. Filing of certification of approved design; designs by federal agencies excepted.

An applicant for approval of a dam or reservoir subject to Section 49-11-200 also shall file with the department a design approved by a registered professional engineer legally qualified in the State. Dams designed by the USDA-Soil Conservation Service or other federal agencies do not require certification by a registered professional engineer.

SECTION 49-11-230. Inspections during construction; maximum rate of discharge for water released during construction.

(A) The department may make necessary inspections during construction of new dams and reservoirs, enlargements, removal, and repairs of dams and reservoirs and during work done pursuant to repair orders to assure compliance with the approved plans and specifications or provisions of the order.

(B) If water is to be released during the construction, repair, or removal, the department shall specify the maximum discharge rate allowable to avoid endangering or causing injury to downstream owners.

SECTION 49-11-240. Authority of department to inspect and enter on lands and waterways; regulations.

(A) The department or its authorized agents may inspect the dam or reservoir and surrounding area to determine the safety of the structure.

(B) An authorized member, agency, or representative of the department may enter state or private lands and natural or artificial waterways in the State to discharge the duties set forth in this article.

(C) The department shall formulate reasonable regulations, including, but not limited to, minimum safety design standards for impoundments, safety inspection standards, water discharge, or drawdown rates and levels in unsafe impoundments and for other purposes necessary to administer this article.

(D) The department shall issue all orders, permits, or licenses set forth in this article.

SECTION 49-11-250. Liability for actions or failure to act.

Nothing in this article and no action or failure to act under this article:

(1) imposes liability on the State, the department, districts, or an agency or its officers or employees for the recovery of damages caused by the action or failure to act; or

(2) relieves the owner or operator of a dam or reservoir of the duties, obligations, responsibilities, or liabilities arising from or incident to the ownership or operation of a dam or reservoir.

SECTION 49-11-260. Penalties; injunction; appeals; disposition of fines.

(A) A person violating this article is guilty of a misdemeanor and, upon conviction, must be fined not less than one hundred nor more than five hundred dollars. Each day the violation continues after notice to take corrective action is a separate offense.

(B) The department may assess an administrative fine of not less than one hundred nor more than one thousand dollars against a person who violates this article or an order issued or regulation promulgated pursuant to it. In determining the amount of the fine the department shall consider the degree and extent of harm caused by the violation and the cost of rectifying the damage. Fines assessed under this subsection may be appealed to the department who may reduce them based on information presented at the appeal hearing.

(C) Upon a violation of this article or related regulations the department may institute legal action to obtain injunctive relief in the name of the department.

(D) A person against whom a final order or decision has been made, except for emergencies specified in Section 49-11-190, may appeal to the board under the Administrative Procedures Act. The burden of proof is on the party attacking an order or a decision of the department to show that the order is unlawful or unreasonable.

(E) Civil fines collected under this article must be deposited in a special account of the department to fund educational activities relating to dams and reservoirs safety, including, but not limited to, workshops, seminars, manuals, and brochures.

74:02:08:10 Emergency preparedness plan.
74:02:08:11 Periodic inspection program.

74:02:08:01. Definitions. Terms defined by SDCL 46-1 to 46-7, inclusive, have the same meaning when used in this chapter. In addition, terms used in this chapter mean:

(1) "Area capacity curves," graphic curves which show the relationship between reservoir surface area and the storage capacity of the reservoir at given elevations;

(2) "Breach analysis," a simulated dam failure performed to determine the outflow hydrograph and to route the resulting flood wave;

(3) "Category 1 dam," a high hazard dam whose failure may cause loss of life;

(4) "Category 2 dam," a significant hazard dam whose failure may cause damage to buildings, highways, railroads, bridges, or public utilities; loss of a water supply reservoir for a water distribution system; other extensive economic loss; or the reservoir is the only source of water for a water distribution system;

(5) "Category 3 dam," a low hazard dam whose failure may cause limited damage to agricultural lands or county and township roads or minimum economic loss;

(6) "Conservation storage capacity," the volume in acre-feet in the reservoir at the crest of the primary spillway;

(7) "Dam," for the purpose of this chapter an artificial barrier, including appurtenant works, which impounds or diverts water and which is 25 feet or more in height from the natural bed of the stream or watercourse measured at the downstream toe of the barrier or from the lowest elevation of the outside limit of the barrier, if it is not across a stream channel or watercourse, to the maximum water storage elevation or has an impounding capacity at maximum water storage elevation of 50 acre-feet or more. A barrier is not considered a dam for the purpose of this chapter if the height does not exceed 6 feet regardless of storage capacity or if the storage capacity at maximum water storage elevation does not exceed 15 acre-feet regardless of height;

(8) "Effective height," the difference in elevation in feet between the lowest point in the cross section taken along the centerline of the dam and the crest of the emergency spillway. If there is no emergency spillway, the top of the dam is the upper limit;

(9) "Emergency preparedness plan," "EPP," a predetermined plan of action to be taken to reduce the potential for property damage and loss of lives in an area that may be affected by a dam break;

(10) "Engineer," a person who is registered as a professional engineer pursuant to SDCL 36-18, or a person who is employed by a federal or state agency and who designs or inspects dams as part of the person's employment, acting under the supervision of a professional engineer registered pursuant to SDCL 36-18;

(11) "Freeboard," the vertical distance between the top of the dam and the estimated maximum water level;

(12) "Height," the difference in the elevation of either the natural bed of the stream or watercourse or the lowest point on the toe of the dam, whichever is lower, and the crest elevation of the dam;

(13) "Inspection," a visual or mechanical check by measuring, boring, or any method necessary to determine the adequacy of construction techniques and the safety and operating performance of a dam;

(14) "Intermediate storage capacity," the volume in acre-feet in the reservoir at the crest of the emergency spillway;

(15) "Maximum storage capacity," the volume in acre-feet in the reservoir at the crest of the dam;

(16) "Owner," "dam owner," a person as defined by SDCL 46-1-6(1) who owns, controls, operates, maintains, manages, or proposes to construct a dam or reservoir;

(17) "Preliminary risk assessment," as applied to dam safety, the process of identifying the downstream hazard potential for the purpose of classifying a dam;

(18) "Probable maximum flood," "PMF," the flood that may be expected from the most severe combination of critical meteorologic and hydrologic conditions that are possible in the region;

(19) "Probable maximum precipitation," "PMP," the precipitation that may be expected from the most severe combination of critical meteorologic conditions that are reasonably possible in an area as found in the National Weather Service Hydrometeorological Report No. 51, "Probable Maximum Precipitation Estimates, United States East of the 105th Meridian"; or Hydrometeorological Report No. 55, "Probable Maximum Precipitation Estimates, United States Between the Continental Divide and the 103rd Meridian";

(20) "Process water," water that may have chemicals, sewage, metals, or any other material added to it during the use of the water in an operation;

(21) "Risk assessment," as applied to dam safety, the process of identifying the likelihood and consequences of dam failure to provide the basis for informed decisions on a course of action;

(22) "Spillway," an open or closed channel, conduit, or drop structure used to convey water from a reservoir.

(23) "Spillway design flood," the flood that the spillway of a given project is designated to pass safely without overtopping the structure;

(24) "25-year, 24-hour duration flood," the flood magnitude expected to be equaled or exceeded on the average of once in 25 years, with a four percent chance of being exceeded in any given year, determined by using the 25-year, 24-hour storm unless gauging data is available and proved to be accurate;

(25) "50-year, 24-hour duration flood," the flood magnitude expected to be equaled or exceeded on the average of once in 50 years, with a two percent chance of being exceeded in any given year, determined by using the 50-year, 24-hour storm unless gauging data is available and proved to be accurate;

(26) "100-year flood," the flood magnitude expected to be equaled or exceeded on the average of once in 100 years, with a one percent chance of being exceeded in any given year, determined by using the 100-year, 24-hour storm unless gauging data is available and proved to be accurate.

General Authority: SDCL 46-2-5, 46-7-3.

Law Implemented: SDCL 46-1-6, 46-1-15, 46-5-10, 46-5-11, 46-5-47, 46-7-3, 46-7-5.

References: Hydrometeorological Report No. 51, "Probable Maximum Precipitation Estimates, United States East of the 105th Meridian," June 1978, Reprinted August 1986; Hydrometeorological Report No. 55, "Probable Maximum Precipitation Estimates, United States Between the Continental Divide and the 103rd Meridian," March 1984, prepared by the Office of Hydrology, National Weather Service, National Oceanic and Atmospheric Administration, U. S. Department of Commerce. Copies may be obtained from the Division of Water Rights, Joe Foss Building, 523 East Capitol Avenue, at no cost.

74:02:08:02. Scope. This chapter applies to all new dams and all existing Category 1 dams and Category 2 dams. Category 2 dams constructed before October 27, 1986, that have highways across the crest or that have highways, railroads, or bridges below the dams are exempt from spillway requirements unless a dam fails and is to be rebuilt and provided that an emergency plan is established by the owner to monitor the dam and procedures are established to close the crest highways or downstream highways, railroads, and bridges during flood conditions. Other category 2 dams constructed before October 27, 1986, are exempt from spillway requirements, except for dams that serve as the sole source of water for a water distribution system or whose failure may cause extensive downstream damage, unless a dam fails and is to be rebuilt and provided that the spillway capacities comply with spillway requirements for category 3 dams. Category 3 dams constructed before October 27, 1986, are exempt from spillway requirements unless a dam fails and is to be rebuilt. Reconstruction of category 2 and 3 dams that fail must comply with the requirements of § 74:02:08:07. New dams are dams constructed after October 26, 1986.

If the classification of a category 3 dam changes to a category 2 or 1 dam or if a category 2 dam changes to a category 1 dam, the spillway capacity must comply with the spillway requirements for the new category classification.

Source: 13 SDR 49, effective October 27, 1986; 13 SDR 129, 13 SDR 141, effective July 1, 1987; 13 SDR 197, effective July 2, 1987; 14 SDR 67, effective November 8, 1987.
General Authority: SDCL 46-2-5, 46-7-3.
Law Implemented: SDCL 46-5-8, 46-5-30, 46-7-3, 46-7-5.

Note: The owner of a dam may be responsible for resultant damage if a dam fails. Although § 74:02:08:02 exempts category 3 and certain category 2 dams constructed before October 27, 1986, from the spillway requirements of § 74:02:08:07, the owner should make an assessment of the risks and potential for damage in the event of dam failure.

74:02:08:03. Intent. The intent of this chapter is to provide minimum standards for design, construction, alteration, maintenance, and repair of dams and to prevent loss of life. These standards are not intended to apply to ordinary maintenance and repair of dams if the work is performed in accordance with an original design prepared by an engineer and no change in safety hazard or purpose is involved.

When conflicts develop in the interpretation of the rules in this chapter, this section will be the basis for settlement of the conflicts.

Source: 13 SDR 49, effective October 27, 1986; 13 SDR 129, 13 SDR 141, effective July 1, 1987; 13 SDR 197, effective July 2, 1987.
General Authority: SDCL 46-2-5, 46-7-3.
Law Implemented: SDCL 46-1-15, 46-5-10, 46-5-11, 46-5-30, 46-5-47, 46-7-3, 46-7-5.

74:02:08:04. Actions required to be performed by engineers. The following shall be completed by engineers:

(1) Prepare plans and specifications for the construction of new dams or alteration of existing dams;
(2) Inspect the construction or alteration of dams; and
(3) Perform periodic inspections, detailed investigations, and analyses of existing dams.

Source: 13 SDR 49, effective October 27, 1986; 13 SDR 129, 13 SDR 141, effective July 1, 1987.
General Authority: SDCL 46-2-5, 46-7-3.
Law Implemented: SDCL 46-1-15, 46-5-10, 46-5-11, 46-5-47, 46-7-3, 46-7-5.

74:02:08:05. Classification of dams -- Hazard potential. The classification of dams based on potential hazards is as follows:

CATEGORY	LOSS OF LIFE POTENTIAL	ECONOMIC LOSS POTENTIAL
3	None expected	Minimal (undeveloped to
		occasional structures)
2	None expected	Extensive (community
		or industry)
1	Potential loss	

Source: 13 SDR 49, effective October 27, 1986; 13 SDR 129, 13 SDR 141, effective July 1, 1987; 13 SDR 197, effective July 2, 1987.
General Authority: SDCL 46-2-5, 46-7-3.
Law Implemented: SDCL 46-1-15, 46-5-8, 46-5-10, 46-5-11, 46-5-30, 46-7-3, 46-7-5.

74:02:08:05.01. Preliminary risk assessment. The chief engineer may request a preliminary risk assessment. The preliminary risk assessment shall consist of an on-site inspection of the downstream area with a description of any structures and an elevation in reference to the stream channel bottom. The hazard classification is subject to approval of the preliminary risk assessment by the chief engineer. The preliminary risk assessment must be performed by an engineer as defined in this chapter.

Source: 15 SDR 158, effective April 23, 1989.
General Authority: SDCL 46-2-5, 46-7-3.

Law Implemented: SDCL 46-1-15, 46-5-8, 46-5-10, 46-5-11, 46-5-30, 46-7-3, 46-7-5.

74:02:08:06. Classification of dams -- Size. The classification of dams by size is as follows: The size classification is determined by either the maximum storage capacity or the height, whichever gives the larger size category.

SIZE	STORAGE CAPACITY	HEIGHT
	(acre-feet)	(feet)
Small	50 to 1000	25 to 40
Intermediate	1001 to 50,000	41 to 100
Large	greater than 50,000	greater than 100

Source: 13 SDR 49, effective October 27, 1986; 13 SDR 129, 13 SDR 141, effective July 1, 1987; 13 SDR 197, effective July 2, 1987.
General Authority: SDCL 46-2-5, 46-7-3.
Law Implemented: SDCL 46-5-8, 46-5-30, 46-7-3, 46-7-5.

74:02:08:07. Minimum spillway design flood requirements -- Exception. The hydraulic capacity of a dam must, by category and size, be such that the following minimum spillway design floods can be passed through the spillways without overtopping the structure:

CATEGORY	SIZE	SPILLWAY DESIGN FLOOD
3	Small	50-year frequency unless dam
		qualifies for § 74:02:08:07.01
		exception
	Intermediate	100-year frequency
	Large	0.5 PMF
2	Small	100-year frequency
	Intermediate	0.5 PMF, unless dam qualifies
		for § 74:02:08:07.02 exception
	Large	PMF
1	Small	0.5 PMF
	Intermediate	0.5 PMF
	Large	PMF

A spillway system for a dam must meet the requirements in this section unless the owner can provide information and justification to show the chief engineer that the proposed design

flow can be stored, passed through, or passed over the dam without failure of the dam or if a variance is granted pursuant to SDCL 46-7-5.3.

Source: 13 SDR 49, effective October 27, 1986; 13 SDR 129, 13 SDR 141, effective July 1, 1987; 13 SDR 197, effective July 2, 1987; 14 SDR 67, effective November 8, 1987.
General Authority: SDCL 46-2-5, 46-7-3.
Law Implemented: SDCL 46-5-8, 46-5-30, 46-7-3, 46-7-5, 46-7-5.3.

74:02:08:07.01. Category 3 spillway design flood exception. For small size category 3 dams with an emergency spillway, the minimum spillway design flood is a 25-year frequency if the product of the intermediate storage capacity times the effective height is less than 3000. For small size category 3 dams without an emergency spillway, the spillway design flood is a 25-year frequency if the product of the maximum storage capacity times the effective height is less than 3000.

Source: 13 SDR 197, effective July 2, 1987.
General Authority: SDCL 46-2-5, 46-7-3.
Law Implemented: SDCL 46-5-8, 46-5-30, 46-7-3, 46-7-5.

74:02:08:07.02. Category 2 spillway design flood exemption. Unless the reservoir of a category 2 dam serves as the sole water supply source for a water distribution system, the spillway design flood for a new or rebuilt intermediate size category 2 dam may be lowered to a design flood between the 0.5 PMF and 100-year spillway design flood based upon a risk assessment. The risk assessment must be submitted to and approved by the chief engineer.

Source: 14 SDR 67, effective November 8, 1987.
General Authority: SDCL 46-2-5, 46-7-3.
Law Implemented: SDCL 46-5-8, 46-5-30, 46-7-3, 46-7-5.

74:02:08:07.03. Design requirements for category 1 tailings dams. Dams constructed to store, without discharge, tailings as defined by 45-6B-3 (14) shall be sized to retain the PMF plus at least a 100-year flood.

Source: 14 SDR 67, effective November 8, 1987.
General Authority: SDCL 46-2-5, 46-7-3.
Law Implemented: SDCL 46-5-8, 46-5-30.

74:02:08:07.04. Design requirements for dams constructed without spillways. Dams which are designed and constructed without spillways and constructed so that there is no external drainage into the facility, and constructed for the purpose of containing process water shall be sized to contain design operating volumes from the operation plus enough freeboard to contain the PMP falling on the facility.

Source: 15 SDR 158, effective April 23, 1989.
General Authority: SDCL 46-2-5, 46-7-3.
Law Implemented: SDCL 46-5-8, 46-5-30.

74:02:08:08. Additional design requirements. In addition to the minimum spillway design flood requirements of § 74:02:08:07, all new category 1 and 2 dams must have low-level drawdown facilities. If an existing category 1 or 2 dam undergoes extensive repairs which require complete drawing down of the reservoir or is being repaired after the dam has failed, a low-level drawdown facility must be installed. A low-level drawdown facility may be either a gated pipe through the embankment that would allow the release of water below the primary spillway or sufficient available pumping capacity to draw down the reservoir. A breach analysis report must be completed by the owner for the proposed dam if a preliminary risk assessment indicates that the dam is a category 1 or 2 dam and must be submitted to the chief engineer with the plans and specifications required by § 74:02:08:09. A breach analysis, if required, must be performed with a simulated water surface at or above the top of the dam.

Source: 13 SDR 49, effective October 27, 1986; 13 SDR 129, 13 SDR 141, effective July 1, 1987; 13 SDR 197, effective July 2, 1987; 15 SDR 158, effective April 23, 1989.
General Authority: SDCL 46-2-5, 46-7-3.
Law Implemented: SDCL 46-5-8 to 46-5-11, 46-5-47, 46-7-3, 46-7-5.

74:02:08:09. Contents of plans and specifications. Minimum plans and specifications submitted to the chief engineer for review must include the following:

(1) A topographic map of the dam site specifying the legal description of the proposed dam and the location of the spillway and outlet works, and all test borings, test pits, and borrow pits. The map shall also show all property contiguous to the dam site and contiguous to the flood zone behind the dam and the owners of the contiguous property;

(2) A profile along the dam axis showing the location, elevations, and depth of borings or test pits, including logs of bore holes or test pits;

(3) A maximum cross-section of the dam showing the elevation and width of the crest; slopes of upstream and downstream faces; thickness of riprap; zoning of earth embankment; location of cutoff and bonding trenches; and elevations, size, and type of outlet conduit, valves, and operating mechanism;

(4) Area-capacity curves of the proposed reservoir;

(5) Detailed drawings showing plans, cross and longitudinal sections of the outlet conduits, valves and controls for operating the outlet, and trash racks;

(6) The discharge capacity in cubic feet per second of the spillway for each foot in water depth above the spillway crest up to the maximum high-water level and the formula used in making the calculations;

(7) Detailed plans of spillway structures, cross-section of the channel heading to and from the spillway, spillway profile, and procedures for operation of the spillway structure;

(8) Specifications including provisions during the period of construction for supervision by an engineer; and

(9) An EPP for a proposed category 1 dam.

Reconstruction, alteration, or repair that requires plans and specifications, or breaching of an existing dam may not begin until plans and specifications have been approved by the chief engineer. Construction of a new dam pursuant to this chapter may not begin until plans and specifications have been approved by the chief engineer and a water permit to construct the dam has been approved by the water management board pursuant to SDCL 46-2A-7 or 46-2A-11.

Source: 13 SDR 49, effective October 27, 1986; 13 SDR 129, 13 SDR 141, effective July 1, 1987; 13 SDR 197, effective July 2, 1987; 14 SDR 67, effective November 8, 1987.
General Authority: SDCL 46-2-5, 46-7-3.
Law Implemented: SDCL 46-1-15, 46-5-8 to 46-5-11, 46-5-47, 46-7-3, 46-7-5.

74:02:08:10. Emergency preparedness plan. An EPP shall be prepared by the owner for all existing category 1 dams and submitted to the chief engineer for approval prior to January 1, 1988.

Source: 13 SDR 49, effective October 27, 1986; 13 SDR 129, 13 SDR 141, effective July 1, 1987.
General Authority: SDCL 46-2-5, 46-7-3.
Law Implemented: SDCL 46-5-8, 46-7-3, 46-7-5.

74:02:08:11. Periodic inspection program. The chief engineer may inspect all category 1 dams at least once every five years or as often as necessary in order to ensure the continued safety of a dam.

Source: 13 SDR 49, effective October 27, 1986; 13 SDR 129, 13 SDR 141, effective July 1, 1987.
General Authority: SDCL 46-2-5, 46-7-3.
Law Implemented: SDCL 46-2-19, 46-5-8, 46-5-30, 46-7-3, 46-7-5.

SOUTH DAKOTA DAM SAFETY LAWS AND REGULATIONS

Citation

South Dakota dam safety statutes are contained in the South Dakota Codified Laws (SDCL) Chapter 46-7, enacted in 1955 and last amended in 1996. Dam safety regulations are in Administrative Rules of South Dakota (ARSD) Chapter 74:02:08, which became effective in 1986 and were last amended in 1992.

History

South Dakota participated in the U.S. Army Corps of Engineers National Dam Safety inspection program of 1978-1981. South Dakota Safety of Dams Rules, Chapter 74:02:08 were adopted in 1986 after the 1984 failure of Menno Dam, a state-owned high-hazard-potential dam.

Definitions/Dam Classifications

The term *dam* is defined in ARSD 74:02:08:01 (7) as "an artificial or manmade barrier that is 25 feet or more in height or that may store more than 50 acre-feet of water". A barrier is not considered a dam if the height does not exceed 6 feet regardless of storage capacity, or if the storage capacity at maximum storage elevation does not exceed 15 acre-feet regardless of height. The term *height* is defined in the same section as "the difference in the elevation of either the natural bed of the stream or watercourse or the lowest point on the toe of the dam, whichever is lower, and the crest elevation of the dam.

Dams are classified according to hazard potential and size:

Hazard Potential

Category	Loss of Life Potential	Economic Loss Potential
3	none expected	minimal
2	none expected	appreciable
1	potential loss	extensive

Size Classification

Size	Storage Capacity (acre-feet)	Height (feet)
Small	50 - 1000	25 - 40
Intermediate	1001 - 50,000	41 - 100
Large	greater than 50,000	greater than 100

Design Criteria

Hydrologic:

74:02:08:07. Minimum spillway design flood requirements -- Exception. The hydraulic capacity of a dam must, by category and size, be such that the

following minimum spillway design floods can be passed through the spillways without overtopping the structure:

Category	*Size*	*Spillway Design Flood*
3	Small	50-year frequency unless dam qualifies for exception
	Intermediate	100-year frequency
	Large	0.5 PMF
2	Small	100-year frequency
	Intermediate	0.5 PMF, unless dam qualifies
	Large	PMF
1	Small	0.5 PMF
	Intermediate	0.5 PMF
	Large	PMF

A spillway system for a dam must meet these requirements unless the owner can provide information and justification to show the chief engineer that the proposed design flow can be stored, passed through, or passed over the dam without failure of the dam or if a variance is granted pursuant to SDCL 46-7-5.3.

Seismic: South Dakota has no specific Seismic Criteria.

Jurisdiction/Powers of Department

The Chief Engineer of the SD Water Rights Program has the statutory authority to review and approve or disapprove plans to construct, alter, maintain or repair dams.

(See ARSD 74:02:08:03 and :09) The Chief Engineer, according to the provisions of SDCL 46-7-5, may also inspect dams, and if a dam is found to be in an unsafe condition, issue orders for remedial work to be done at the owner's expense. The statutes (Section 46-7-5.1) also grant to the Chief Engineer the authority to enter upon the property of a dam owner who has failed or refused to comply with an order to repair, for the purpose of making the necessary changes. Powers in an emergency situation are addressed in SDCL Section 46-7-5.2

Section 78:02:08:09 of the Rules states that the Chief Engineer must review and approve plans and specifications prior to the new construction, reconstruction, alteration, repair or breaching of a dam. In addition, the Water Management Board has the power to issue permits for construction and impoundment, and a permit must be obtained prior to the construction of a new dam. The Water Management Board is also responsible for the promulgation of rules to establish minimum safety standards for the design, construction, alteration, maintenance and repair of works. (See SDCL 46-7-3)

Permit/Approval Process

ARSD 74:02:08:09 requires that minimum plans and specifications for the design, construction, or alteration of dams be submitted to the Chief Engineer for review, and sets forth the types of information which must be included. Plans and specifications must be prepared, and construction or alteration inspections must be performed by a

registered professional engineer in accordance with the provisions of ARSD 74:02:08:01. Plans and specifications must be approved, and a water permit to construct must be acquired from the Water Management Board before new construction can begin.

Minimum spillway design flood requirements are listed for each hazard category and size of dam in the rules, section 74:02:08:07. Exceptions to these standards, standards for tailings dams, and additional design requirements are addressed in ARSD 74:02:08:07.01 through :07.04. Water permit application fees are addressed in SDCL Section 46-2-13.

Fees: Fees are based on storage capacity, the 1st 120 acre-feet = $150.00, the 2nd 120 acre-feet = $75.00 and then each additional 120 acre-feet = $25.00 plus a $50.00 inspection fee.

Inspection Process

ARSD 74:02:08:11 authorizes the Chief Engineer to inspect all category 1 dams at least once every 5 years or as often as necessary in order to ensure the continued safety of a dam. If the works are found to be unsafe, the Chief Engineer is authorized by law (SDCL 46-7-5) to issue an order for necessary changes within a specified time, and if the owner fails to make the repairs, the Chief Engineer may enter the property and put the works in a safe condition. Costs incurred are borne by the owner. Inspection fees are not assessed by the state.

Section 46-7-3 of the statutes charges the owner of a dam with the responsibility of keeping the works "in good repair at all times" to ensure safety of the works. Additionally, the rules (section 74:02:08:04) require that periodic inspections, detailed investigations, and analysis of existing dams be performed by registered professional engineer. No requirements regarding the scheduling or frequency of such inspections are found in the statutes or rules.

Frequency of Inspections

Hazard Classification	*Inspection Cycle*
High	Every 3 years.
Significant	Every 3 years.
Low	Every 3 years if state-owned

Owner Non-Compliance/Violations/Penalties

SDCL Sections 46-7-5 and 5.1 state that if upon inspection, the Chief Engineer finds that a dam is in an unsafe condition, he may issue an order for remedial work or repairs within a specified time limit. If the owner fails or refuses to make the required repairs, the Chief Engineer is authorized to enter the property and make them. Costs of such repairs are the responsibility of the owner, and may be recorded as a lien against the owner's property until paid. It is also noted in the statutes that the authorization of these activities does not limit any other remedy against the owner of the works, although additional penalties may include fines, and are referenced in SDCL 46-1-11.

Emergencies

Emergency procedures are addressed in SDCL 46-7-5.2. The Chief Engineer may immediately breach or repair any works if, in his judgment, it is necessary to protect human life from imminent danger. Emergency Preparedness Plans (Rules 74:02:08:09 & :10) are required to be prepared and submitted by the owners of all existing category 1 dams, and as part of the plans and specifications for proposed category 1 dams.

Liability

SDCL 46-7-5 provides that "The Chief Engineer, the state or its employees shall not incur any liability, either sovereign or personal, as a result of the duties imposed by this section or other provisions related to the inspection and repair, maintenance or alteration of works or the notification to owners of unsafe conditions".

Oversight

A hearing process by which owners may contest an order of the Chief Engineer is described in SDCL 46-7-5. Owners may file a written protest, which suspends the operation of the order until a hearing has been scheduled and action taken by the Water Management Board. In addition, Section 46-7-5.3 allows owners to petition the Chief Engineer for a variance to board rules relating to minimum spillway design requirements. The Chief Engineer then investigates the works and conducts the necessary analysis to determine the potential for damage to downstream residents or property in the case of failure due to inadequate spillway capacity. After the investigation and analysis, the Chief Engineer may recommend to the Water Management Board that the variance request be granted or denied.

SDCL 46-7-5.4 through 5.11 provides that owners of privately owned high hazard dams who refuse to correct an unsafe condition identified by order of the Chief Engineer may execute an affidavit assuming liability for the dam and holding the state harmless from all such liability and damages to the dam's failure. The affidavit must certify, among other things, that the owner's family is the only family inhabiting the floodplain.

Miscellaneous

1. SDCL 46-7-1 provides that the owners of a storage or diversion works may be required to make excess capacity of the works (over and above that needed by the owner for lawful application of water to beneficial use) available at reasonable rates, to any person entitled to use water for beneficial purposes. The Water Management Board is responsible for determining the amount of excess capacity, establishing reasonable rates, and setting the amount of compensation to be paid the owner for damage to the works.

2. The Water Management Board is authorized in SDCL 46-7-2 to require any appropriator to construct head gates and measuring devices before allowing the diversion of water.

3. Section 46-7-14 of the statutes makes it unlawful in the state for any person to interfere with, damage or destroy any dam or embankment, or to interfere with or damage any pier, boom, gate or piles used in securing a dam.

1200-5-7-.04	Certificates of Construction, Operation and Alteration	1200-5-7-.09	Fees
		1200-5-7-.10	Emergency Action by Owner
1200-5-7-.05	Classification of Dams	1200-5-7-.11	Repealed

1200-5-7-.01 GENERAL.

(1) Passed on May 1, 1973, "The Safe Dams Act of 1973", *T.C.A. §69-11-101 et seq.,* provides that on or after July 1, 1973, no person shall construct, enlarge, repair, alter, remove, maintain, or operate a non-federal dam in the State of Tennessee without first obtaining a certificate. The Act further requires every owner of a dam file with the Commissioner of Environment and Conservation an application for a certificate.

(2) Under the Act, certain provisions and conditions are established for the issuance and continuance of said certificates, and authority is granted the Commissioner for the adoption of general rules and regulations which he deems necessary to accomplish the purpose of the Act. To safeguard the public by reducing the risk of failure of such dams, the following rules and regulations are made to (1) effect the orderly inventory and inspection of existing dams in Tennessee; (2) provide for pre-construction review and approval of all future dam construction and alteration of dams; and (3) allow for a program of regular inspection of dams within the State.

Authority: *T.C.A. §§4-5-202, 69-11-101 et seq., and 69-11-104.* ***Administrative History:*** *Original rule filed August 19, 1987; effective October 3, 1987. Amendment filed August 2, 1995; effective October 15, 1995.*

1200-5-7-.02 DEFINITIONS. For the purpose of these rules and regulations, the term:

(1) Abutment means the bordering area of the dam site which functions as a support for the ends of the dam structure.

(2) Act means "The Safe Dams Act of 1973", *T.C.A. §69-11-101 et seq.*, as amended.

(3) Alterations means any repair, change to the structure, removal or change in use of a dam that may affect the safety of that dam.

(4) Applicant means any owner of an existing or new dam who applies to the Division for a "Certificate" under the provisions of the Act.

(5) Appurtenant Works means such structures as spillways, either in the dam or separate therefrom; the reservoir and its rims; water level outlet works; access bridges; and water conduits such as tunnels, pipelines or penstocks, either through the dam or its abutments.

(6) Certificate means a "Certificate" as required by the Act for the construction, alteration, or operation of a dam.

(Rule 1200-5-7-.02, continued)

(7) Commence Construction means the actual start of on-site building but does not include preliminary surveying work or engineering plans preparation.

(8) Commissioner means the Commissioner of the Department of Environment and Conservation, his duly authorized representatives and in the event of his absence or a vacancy in the office of Commissioner, the Deputy Commissioner .

(9) Conduit means any closed waterway including but not limited to, a cast-in-place cut-and-cover culvert, a precast or prefabricated pipe embedded in the dam or foundation or a tunnel bored through the dam.

(10) Dam means any artificial barrier, together with appurtenant works, which does or may impound or divert water, and which either (1) is or will be twenty (20) feet or more in height from the natural bed of the stream or watercourse at the downstream toe of the barrier, as determined by the Commissioner, or (2) has or will have an impounding capacity at maximum water storage elevation of thirty (30) acre-feet or more. Provided, however, that any such barrier which is or will be less than six (6) feet in height, regardless of storage capacity, or which has or will have a maximum storage capacity not in excess of fifteen (15) acre-feet, regardless of height, shall not be considered a dam, nor shall any barrier, regardless of size, be considered a dam, if, in the judgment of the Commissioner, such barrier creates an impoundment used only as a farm pond. Diversion weirs, roadbeds, water tanks, and wastewater impoundment barriers as defined in this section are not dams.

(11) Days means calendar days, including Sundays and holidays.

(12) Division means the Division of Water Supply of the Tennessee Department of Environment and Conservation.

(13) Director means the Director of the Division of Water Supply of the Department of Environment and Conservation of the State of Tennessee.

(14) Diversion Weir means a structure substantially within the bed of a stream, designed to impound water only during low flow conditions, that would not cause substantial overflow of water onto the downstream floodplain in the event of failure, and meets the definition of a Category 3 dam in Rule 1200-5-7-.05(2)(b)(3).

(15) Easily Erodible means any soil with a plasticity index of less than ten (10) or greater than forty (40).

(16) Emergency Spillway means the spillway which conveys out of the reservoir any runoff in excess of that conveyed by the principal spillway.

(17) Engineer means a professional engineer registered by the State of Tennessee.

(18) Erosion Resistant means any soil not easily erodible.

(19) Existing Dam means any dam complete and capable of impounding water prior to October 3, 1987.

(20) Enlargement means any change in, or addition to, an existing dam or reservoir, which does or may raise the water storage elevation of the dam.

(Rule 1200-5-7-.02, continued)

(21) Factor of Safety means the ratio of the forces or moments resisting mass movement to the forces or moments tending to produce mass movement.

(22) Farm Pond means any impoundment used only for providing water for agricultural and domestic purposes such as livestock and poultry watering, irrigation of crops, recreation, and conservation, for the owner or occupant of the farm, his family, and invited guests, but does not include any impoundment for which the water, or privileges or products of the water, are available to the general public.

General Public as used above means patrons, members, and customers of institutions and/or clubs such as but not limited to summer camps, schools, retirement facilities, churches, private clubs, communes, hunting clubs, and health care facilities.

The following are some examples of impoundments which are not farm ponds:

Lakes owned or operated by a city, county, or the state, lakes that lie on three or more property parcels, residential subdivision lakes, industrial waste impoundments, industrial water supply impoundments, impoundments owned or used by hunting clubs, public water supply impoundments, commercial land development impoundments, and watershed district impoundments.

The following are some examples of impoundments which are farm ponds:

1. Impoundments directly used in support of farming operations.

2. Impoundments used for agriculture, livestock watering, recreation or conservation solely by the owner and not available to the general public.

(23) Foundation means the earth or rock on which the dam rests.

(24) Freeboard means the difference in elevation between the top of the dam and the maximum reservoir water surface that would result should the inflow design flood occur and should the outlet works function as planned.

(25) Impoundment means the water or liquid substance that is or will be stored by a dam.

(26) Maximum Water Storage Elevation means the elevation of the lowest point on the top of the dam, excluding any spillway structures.

(27) Maximum Storage Capacity means the volume of water stored at the maximum water storage elevation.

(28) New Dam means any dam that is not an existing dam.

(29) Normal Water Storage Elevation means the normal elevation of water surface which is obtained by the reservoir when the intake and outlet works are operating as planned during periods of normal precipitation and runoff and not during periods of drought or flood.

(30) Owner means any person who owns an interest in, controls, or operates a dam.

(31) Person means any individual, firm, association, organization, partnership, business trust, corporation, company, county, municipal or quasi-municipal corporation, public utility, utility or other district, the State of Tennessee and its departments, divisions, institutions, and agencies, and the duly authorized officers, agents, and representatives thereof, or any

(Rule 1200-5-7-.02, continued)

combination of any of the above. Person does not include the United States government nor any agency owned by the United States or any agency thereof, nor those who own a dam or reservoir leased to or operated by the United States or any agency thereof, nor those dams licensed by the Federal Energy Regulatory Commission (previously the Federal Power Commission).

(32) Principal Spillway means the spillway which conveys normal runoff out of the reservoir.

(33) Probable Maximum Precipitation (PMP) means the greatest amount of rainfall of a six-hour duration which would be expected for a given drainage basin as determined by National Weather Service meteorological estimates. The PMP for 10 square miles shall be used for watersheds smaller than 10 square miles.

(34) Probable Maximum Flood (PMF) means the flood that may be expected from the most severe combination of critical meteorologic and hydrologic conditions that are reasonably possible in the region. The PMF is derived from the probable maximum precipitation (PMP).

(35) Removal means altering a dam such that it is no longer a dam as defined in these rules.

(36) Reservoir means any basin which contains or will contain the water impounded by a dam.

(37) Roadbed means the earth support work of a road prepared for surfacing which is not intended to impound water and which does not impound water continuously.

(38) Spillway means the feature of a storage or detention dam which is designed to release surplus water, and at diversion dams is a means to bypass flows exceeding those which are turned into the diversion system.

(39) Structural Height means the height of the dam measured from the natural bed of the stream or watercourse at the downstream toe of the barrier to the low point in the top of the dam.

(40) Wastewater Impoundment Barrier means an artificial barrier impounding a body of wastewater for the purpose of treatment and designed so that no surface runoff from areas adjacent to the barrier is introduced into the impoundment.

(41) Water Tank means a vessel designed and used to hold water.

Authority: *T.C.A. §§4-5-202, 69-11-101 et seq., and 69-11-104.* ***Administrative History:*** *Original rule filed August 19, 1987; effective October 3, 1987. Amendment filed August 2, 1995; effective October 15, 1995. Amendment filed December 6, 2000; effective February 19, 2001. Amendment filed April 18, 2008; effective July 2, 2008.*

1200-5-7-.03 DUTIES AND AUTHORITY. The general responsibility to administer and enforce the provisions of this Act and all rules and regulations thereunder shall be carried out by the Division of Water Supply of the Department of Environment and Conservation.

Authority: *T.C.A. §§4-5-202, 69-11-101 et seq., and 69-11-104.* ***Administrative History:*** *Original rule filed August 19, 1987; effective October 3, 1987. Amendment filed August 2, 1995; effective October 15, 1995.*

1200-5-7-.04 CERTIFICATES OF CONSTRUCTION, OPERATION, AND ALTERATION.

(1) General Provisions for Certificates.

(Rule 1200-5-7-.04, continued)

(a) Certificate applications shall be made on forms available from the Commissioner. Where there are multiple owners of a dam, each owner shall not be required to file an application if all owners are listed in the application filed by any one of them.

(b) Application for a Certificate shall be made on forms available from the Commissioner and shall include the following information:

1. The name of the dam.

2. The name of the owner.

3. The legal address of the owner and/or lessee.

4. The location of the dam.

5. The type, size and height of the dam.

6. The storage capacity and reservoir surface area for normal and maximum water surface elevation.

7. The purpose or purposes for which the dam or reservoir is to be used.

8. In the case of an application by an owner or lessee of a dam, the names and addresses of all persons having a real property interest in the dam.

9. Such other plans and detailed information as the Commissioner may deem reasonable and necessary to fulfill his responsibilities hereunder.

(c) An owner making application for an Alteration or Construction Certificate shall engage a qualified professional engineer, practicing in accordance with the registration laws of Tennessee, to plan, to prepare designs and specifications, and to supervise construction. This engineer must be qualified and experienced in the design and construction of dams of the type proposed and may be required to present evidence of his qualifications to undertake the project.

(d) The Commissioner shall examine the application for a certificate of approval and cause an on-the-ground inspection to be made of the existing or proposed dam or reservoir and downstream floodplain. He shall then, within sixty (60) days of the receipt of the completed application for a certificate of approval, either grant the certificate or disapprove it in writing, stating the reasons for disapproval. In the case of applications for construction certificates, applicants who fail to submit, within 18 months from the date of the original application submittal, plans or other detailed information required by the Commissioner must refile an application and plans review fee to obtain a construction certificate.

(e) Certificates are not transferable from one person to another or from one dam to another.

(f) The Commissioner shall be notified of any proposed change in the operation of a dam.

(g) Certificates shall not be granted until all fees required by the provisions of the Act and these rules have been paid.

(Rule 1200-5-7-.04, continued)

(h) It shall be a violation of the Safe Dams Act for any person to knowingly submit a false or inaccurate report, data, or information.

(2) Operating Certificate.

(a) No person shall operate a dam without an Operating Certificate.

(b) Application for an Operating Certificate for a new dam already having a Construction Certificate shall be made on forms available from the Commissioner within thirty (30) days of the completion of the dam. The application shall be accompanied by a history of the construction of the dam as maintained by the responsible engineer and by a statement signed by the responsible engineer certifying that the project was constructed in conformity with approved plans and specifications. The history of construction shall include but not be limited to:

1. A record of all geological and foundation data.

2. Date, location, and results of all material tests made.

3. Narrative of problems encountered during construction and changes in design. (Necessity for such changes shall be reported to the Division for approval before proceeding with construction.)

4. Photographs of completed foundations, critical features (such as construction and backfilling around conduits and low level outlet structures) and periodic stages of construction are desirable. These may be required for selected projects.

5. A record of permanent location points, benchmarks, and any instruments embedded in the structure.

6. Plans which show the actual construction of the dam after changes in the original design.

(c) Application for an Operating Certificate for a dam already having an Alteration Certificate shall be made within thirty (30) days from the completion of the alteration on forms available from the Commissioner. The application shall be accompanied by a statement signed by the responsible engineer certifying that the project was constructed in conformity with the approved plans and specifications. Additional information about the construction, such as that listed in 1200-5-7-.04(2)(b), must be included if the Commissioner determines that such information is needed to insure that the alteration is constructed properly.

(d) Any new dam or dam alteration must be constructed in accordance with the approved plans and specifications in order to receive an Operating Certificate.

(e) A new dam must not be allowed to impound water other than transient storage due to storm runoff until an Operating Certificate has been issued.

(f) Application for an Operating Certificate shall be made on forms available from the Commissioner. Any dam owner who is notified by the Commissioner of the need to apply for an Operating Certificate shall submit such application within thirty (30) days.

(Rule 1200-5-7-.04, continued)

(g) Whenever legal title to a dam, for which a certificate of approval has been issued, is modified to create real property interests, including leasehold interests, in persons not listed on the application for such certificate, the owner of such dam shall make application for a new certificate within ninety (90) days of the date such interests are created, other provisions of this chapter notwithstanding.

(h) An Operating Certificate shall be issued only on evidence satisfactory to the Commissioner that the requirements of Rule 1200-5-7-.06 are being met for an existing dam and the requirements of Rule 1200-5-7-.07 are being met for a new dam.

(3) Construction Certificate.

(a) No person shall commence construction on a new dam without first obtaining a Construction Certificate from the Commissioner.

(b) Application for a Construction Certificate shall be made at least 60 days prior to the commencement of construction on forms available from the Commissioner.

(c) The Commissioner shall issue a Construction Certificate for construction of a new dam only if the requirements of Rule 1200-5-7-.07 Design Standards for New Dams, Rule 1200-5-7-.08 Engineering Requirements, and Rule 1200-5-7-.09 Fees, are met.

(d) The owner or his agent shall provide written notice to the Commissioner within five days of the date that construction commences and shall include the name of the engineer's inspector. For dams which are to be greater than 30 feet high or which will impound more than 100 acre-feet at the maximum storage capacity, the engineer in charge of construction or his inspector shall be on site whenever construction is occurring. The Commissioner may require such full time inspectors on smaller dams as he deems necessary. During construction the Commissioner may make such inspections as are needed to ensure conformity with approved plans and specifications. The inspection by the Commissioner does not relieve the owner or the responsible engineer from providing adequate inspection of the construction in progress.

(e) If at any time during the progress of the work the Commissioner finds that the work is not being done in accordance with the approved plans and specifications or approved revisions, he shall serve written notice to that effect to the owner. Such notice shall state the particulars in which the approved plans and specifications have not been complied with and may request the suspension of work until such compliance has been effected. If, after due notice, the owner, or his duly authorized agents, fails to comply with the requirements of the above notice, the Certificate by which construction is authorized shall be subject to revocation by the Commissioner.

(f) The owner or his agent shall give written notice of the completion of the dam to the Commissioner within five (5) days of the completion or in time for the Commissioner's representative to be present at the final inspection with the engineer and the contractor, whichever occurs sooner.

(4) Alteration Certificate.

(a) No person shall make an alteration to a dam without first obtaining an Alteration Certificate.

(Rule 1200-5-7-.04, continued)

(b) Application for an Alteration Certificate shall be made on forms available from the Commissioner at least 60 days prior to a planned alteration. The application shall identify the dam, state reasons why alteration, repair, or removal is necessary, give details of the proposed work, and provide an evaluation of the effects of the contemplated action. Plans and specifications will accompany the application along with a schedule for accomplishing the proposed project. The plans and specifications shall be submitted in conformance with Rule 1200-5-7-.08. The Commissioner may require full time inspection of any alteration construction by the responsible engineer or his inspector as he determines is necessary to ensure that the construction is performed properly.

(c) The owner or his agent shall provide written notice to the Commissioner within five days of the date that construction commences and shall include the name of the engineer's inspector if an inspector is required. The owner or his agent shall give written notice of the completion of the alteration to the Commissioner within five (5) days of the completion or in time for the Commissioner's representative to be present at the final inspection with the engineer and the contractor, whichever occurs sooner.

(d) In the event of an emergency where immediate repairs are necessary to safeguard life and property, such repairs shall be made immediately by the owner, or his duly authorized agents, and in accordance with Rule 1200-5-7-.10. In such events, the Commissioner shall be notified of the necessary emergency repairs and of work under way. The owner shall give written notice to the Commissioner within two days of learning of the emergency.

(5) Duration of Certificates.

(a) Construction and Alteration Certificates shall be for a single construction event. Construction Certificates shall be valid only for construction that begins within one year of issuance of the certificate.

(b) Alteration and Operating Certificates shall be valid for a definite period of time, not to exceed five (5) years, as determined by the Commissioner and stated on the certificate. In determining the period of approval, the Commissioner may take account of any circumstances pertinent to the situation, including, but not limited to, the size and type of dam, topography, geology, soil conditions, hydrology, climate, use of reservoir and the lands lying in the floodplain downstream from the dam, and the hazard category of the dam.

(6) Imposition of Additional Conditions - Hazard Categories.

(a) In granting a Certificate, the Commissioner may impose such conditions relating to the inspection, operation, maintenance, alteration, repair, use, or control of a dam or reservoir as he determines are necessary for the protection of public health, safety, or welfare.

(b) The Commissioner shall establish hazard categories for dams in accordance with Rule 1200-5-7-.05(2).

(7) Modification of certificates. The Commissioner may modify a Certificate or the conditions attached to it. Such modifications shall become effective ninety (90) days following issuance by the Commissioner of a revised Certificate, except when the Commissioner finds that a state of emergency exists, and that life or property would be endangered by delay. In case of

an emergency declared by the Commissioner, the new conditions shall be effective immediately.

(8) Suspension, Revocation, or Modification. The Commissioner may revoke, suspend, or modify any Certificate issued pursuant to the Act or deny the issuance of a Certificate for cause including, but not limited to the following:

(a) Violation of any condition of said Certificate.

(b) Obtaining a Certificate by misrepresentation, or failure to disclose fully all relevant facts.

(c) Violation of any provision of the Act or any rule promulgated thereunder.

(9) Rights of Appeal. Any applicant aggrieved by the denial of a Certificate or any term or condition in a Certificate may appeal to the Commissioner for a hearing within sixty (60) days of the date of issuance of the Certificate or the denial of a Certificate. After sixty (60) days no such appeal may be filed. All appeals shall be conducted in accordance with *T.C.A. §69-11-118* of the Act and Uniform Administrative Procedures Act, *T.C.A. §§4-5-301 et seq.*

Authority: *T.C.A. §§4-5-202, 69-11-101 et seq., and 69-11-104.* ***Administrative History:*** *Original rule filed August 19, 1987; effective October 3, 1987. Amendment filed August 2, 1995; effective October 15, 1995. Amendment filed December 6, 2000; effective February 19, 2001. Amendment filed April 18, 2008; effective July 2, 2008.*

1200-5-7-.05 CLASSIFICATION OF DAMS. Dams will be classified in accordance to size, hazard potential, and design characteristics in order to formulate a priority basis for selecting dams to be scheduled in the inspection program and also to provide compatibility between guideline requirements and involved risks. When conditions at the dam or the hazard potential changes, the dam may be reclassified, and, if necessary, the dam must be upgraded to meet the standards of the new classification. The downstream conditions will be evaluated for hazard potential reclassification at least every 5 years.

(1) Size. The classification for size is based on the height of the dam and storage capacity in accordance with the table below. The height of the dam is established with respect to the maximum water storage elevation measured from the natural bed of the stream or watercourse at the downstream toe of the barrier, or if it is not across a stream or watercourse, the height from the lowest elevation of the outside limit of the barrier, to the maximum water storage elevation. For the purpose of determining project size, the maximum storage elevation will be considered equal to the top of dam elevation as defined in Rule 1200-5-7-.02(26). Size classification will be determined by either storage or height, whichever gives the larger size category. For size classification purposes, fractions of heights and storages shall be rounded down to the nearest whole number, e.g., 49.9 feet would be classified in the 20 to 49 feet category.

Size Classification

Category	Storage (Ac-Ft)	Height (Ft)
Small	30 to 999	20 to 49
Intermediate	1,000 to 49,999	50 to 99
Large	50,000 or greater	100 or greater

(2) Hazard Potential Category.

(Rule 1200-5-7-.05, continued)

(a) Every dam will be assigned a hazard potential category to reflect the damage which might occur in the event of a dam failure, either structurally or operationally. The hazard potential will take into account a number of factors which will include, but not be limited to: the physical characteristics and degree of development of the site and valley downstream; the relationship of the site to industrial and residential areas; use of downstream properties throughout the danger reach; geological considerations; public and private uses of the impoundment or reservoir; and probable future downstream development.

(b) The hazard potential category of a dam may impose different standards at different sites for design and conditions for issuance of a Certificate and will have a bearing upon the frequency of inspections by the Commissioner. The following categories are established to permit the association of criteria with the damage that might result from such a failure.

1. Category 1 dams are located where failure would probably result in any of the following: loss of human life; excessive economic loss due to damage of downstream properties; excessive economic loss, public hazard, or public inconvenience due to loss of impoundment and/or damage to roads or any public or private utilities.

2. Category 2 dams are located where failure may damage downstream private or public property, but such damage would be relatively minor and within the general financial capabilities of the dam owner. Public hazard or inconvenience due to loss of roads or any public or private utilities would be minor and of short duration. Chances of loss of human life would be possible but remote.

3. Category 3 dams are located where failure may damage uninhabitable structures or land but such damage would probably be confined to the dam owner's property. No loss of human life would be expected.

(3) Removal of Dams. A dam shall be considered removed if it meets one of the following criteria.

(a) A portion of the dam is removed such that at the invert of the removed portion the dam is less than six feet high or has less than 15 acre-feet of storage capacity.

(b) A portion of the dam is removed or an open-channel spillway is built such that the invert of the removed portion is at the approximate elevation of the top of the tailings or sediment in the impoundment and the dam can no longer permanently impound water. In the case of embankment dams that receive surface runoff from areas adjacent to the impoundment, the open channel must be sufficiently large to preclude overtopping during the Freeboard Design Storm specified in Rule 1200-5-7-.06(3)(b) or Rule 1200-5-7-.07(4)(d), respectively.

Authority: *T.C.A. §§4-5-202, 69-11-101 et seq., and 69-11-104.* ***Administrative History:*** *Original rule filed August 19, 1987; effective October 3, 1987. Amendment filed August 2, 1995; effective October 15, 1995. Amendment filed December 6, 2000; effective February 19, 2001. Amendment filed April 18, 2008; effective July 2, 2008.*

1200-5-7-.06 STANDARDS FOR EXISTING DAMS.

(1) Stability. All dams shall be stable. There shall not be excessive cracks, sloughing, seepage or other signs of instability or deterioration. In cases where the stability of the dam is questionable, it shall be the responsibility of the owner to either demonstrate to the

(Rule 1200-5-7-.06, continued)

Commissioner that the dam is stable or drain the reservoir and remedy the unstable condition prior to refilling the reservoir.

(2) Slope Protection

(a) Earth embankments shall be protected from surface erosion by appropriate vegetation or some other type protective surface such as riprap or paving and shall be maintained. Examples of appropriate vegetation include, but are not limited to, Bermuda grass and fescue. All inappropriate vegetation such as honeysuckle, briers, bushes, and trees shall be removed from the dam. Some trees may be allowed to remain on a dam if the Commissioner concurs with a justification from a qualified engineer for doing so. Such justification must satisfy the Commissioner that the number, size, location, root characteristics, etc., of such trees will not adversely affect the dam's structural integrity and safety nor impede inspection.

(b) The root mass of all trees larger than four (4) inches in diameter as measured at two feet above ground level shall be grubbed out and the hole backfilled with suitable fill material properly compacted. Smaller trees may either be cut at ground level or be removed as specified above. The Commissioner may require an engineer to oversee the tree removal.

(3) Emergency Spillway.

(a) All dams shall have an emergency spillway system with capacity to pass a flow resulting from a 6 hour design storm indicated in (b) below for a hazard classification appropriate for the dam. However, if the applicant's engineer provides calculations, designs, and plans to show that the design flow can be stored, passed through, or passed over the dam without failure occurring, or if he can successfully demonstrate to the Commissioner by engineering analysis that the dam is a safe structure and can certify that the dam is sufficient to protect against probable loss of human life downstream, said dam design may be approved by the Commissioner.

(b) Minimum Freeboard Design Storms.

Hazard Potential Category	Size	Freeboard Design Storm (6 Hours)
Category 3 (Low)	Small	100 year
	Intermediate	1/3 PMP
	Large	1/2 PMP
Category 2 (Significant)	Small	1/3 PMP
	Intermediate	1/2 PMP
	Large	PMP
Category 1 (High)	Small	1/2 PMP
	Intermediate	PMP
	Large	PMP

(c) No dam which is modified after original construction to increase its design storm to a 1/2 PMP or greater shall be required to pass a larger design storm unless the dam itself is enlarged or its normal or maximum storage volume is increased.

(4) Concrete and Masonry Dams. Concrete and/or masonry dams shall be structurally sound and shall have joints free of trees and other vegetation and shall show no signs of significant

(Rule 1200-5-7-.06, continued)

structural deterioration such as excessive cracks, spallation, efflorescence and exposed reinforcing steel.

Authority: *T.C.A. §§4-5-202, 69-11-101 et seq., and 69-11-104.* ***Administrative History:*** *Original rule filed August 19, 1987; effective October 3, 1987. Amendment filed August 2, 1995; effective October 15, 1995. Amendment filed December 6, 2000; effective February 19, 2001.*

1200-5-7-.07 DESIGN STANDARDS FOR NEW DAMS.

(1) Design of Dams. Designs of dams shall conform to accepted practices and procedures of the engineering profession. Design references developed by the U.S. Army Corps of Engineers, Soil Conservation Service, and the Bureau of Reclamation may be used although the limiting criteria must be in accordance with these rules.

(a) All dams will be considered on an individual basis and reviewed in accordance with prevailing practices that are currently accepted by the engineering profession.

(b) All structures other than Category 3 dams constructed before 2008 shall be designed to withstand seismic accelerations of the following intensities: Zone 1 = 0.025g, Zone 2 = 0.05g, Zone 3 = 0.15g. Zones refer to "Geologic Hazards Map of Tennessee" by Robert A. Miller, 1978. All dams constructed during or after 2008 shall be designed to withstand the peak ground acceleration for an earthquake with a 10% probability of exceedance in 50 years as determined by the United States Geological Survey at the time the construction permit is issued. A different peak ground acceleration may be used if site specific studies using accepted engineering practices determine that a different value is appropriate.

(c) A complete engineering report, plans, and specifications shall be submitted for each dam.

(d) A complete geotechnical report shall be submitted as an integral part of the engineering report for all Hazard Potential Category (HPC) 1 and 2 dams (defined in Rule 1200-5-7-.05). For HPC 3 dams, sufficient investigation will have to be made to determine if the site and the fill material to be used are suitable, and this information will have to be included in the engineering report.

(e) A hydrologic/hydraulic analysis shall be submitted as an integral part of the engineering report for all dams. A breach analysis shall be submitted for all HPC 1 and HPC 2 dams and, for the former, shall be included in the Emergency Action Plan. The breach analysis must use surveyed cross sections at all stations where homes or other structures may be flooded. A sunny-day breach shall be modeled with the impoundment at the elevation of the emergency spillway invert when the failure begins, or, if there is no emergency spillway, at the elevation of the inlet of the principal spillway. Breach modeling under sunny-day, overtopping, or any other conditions, is site specific.

(f) All Category 1 dams shall submit to the Commissioner an Emergency Action Plan. This plan shall include, but not be limited to, the following:

1. Inundation information and an inundation map based on the breach analysis.

2. Procedures for notification of people downstream and law enforcement and other government agencies.

(Rule 1200-5-7-.07, continued)

3. Resources for emergency actions such as contractors, equipment supply businesses, etc.

(g) Design calculations for all major components of the structure, i.e., spillways, pipes, etc., shall be included in the engineering report.

(2) Principal Spillways.

(a) All component parts of the principal spillway except attached gates and trash racks will be of equal durability. The structural design criteria and detailing of such spillways will conform to recognized standards and codes of practice.

(b) In requiring the capacity of the principal spillway, the Commissioner may consider: (1) the benefits that accrue to the reduction of the discharge rate, (2) damages that may result from prolonged storage in the reservoir, (3) damages that may result from prolonged outflow, (4) the possibility of occurrence of significant runoff from two or more consecutive storm events within the time required to empty the reservoir, and (5) limitations in water rights or other legal requirements.

1. All conduits under a dam shall support the external loads imposed with an adequate factor of safety. They must withstand the internal hydraulic pressures without leakage under full external load and settlement. They must convey water at the design velocity without damage to the interior surface of the conduit.

2. Principal spillway conduits under earth dams shall be designed to support fill heights greater than the original constructed height where there is a reasonable possibility that it may become desirable to raise the embankment height at a later date to incorporate additional storage.

3. Principal spillway conduits shall be of reinforced concrete pipe, cast-in-place reinforced concrete, ductile iron pipe, or plastic pipe. Fill height and foundation conditions require special considerations for ductile iron pipe and plastic pipe so that each use will be checked on an individual basis; cradling or encasement in concrete may be required. Welded steel pipe is not acceptable for Category 1 and Category 2 dams, and corrugated metal pipe is not acceptable for any class of dam.

4. Principal spillway conduits shall be field tested for watertightness before backfilling. This requirement as well as the method of testing shall appear on the plans or in the specifications.

5. Rigid principal spillway conduits shall be designed as positive projecting conduits.

6. All reinforced concrete water pipe - steel cylinder type - prestressed, all reinforced concrete water pipe - steel cylinder type - not prestressed, and all reinforced concrete water pipe - noncylinder type - not prestressed, shall meet the AWWA specifications effective at the time of application.

7. Elliptical or other systems of reinforcement requiring special orientation of pipe sections are not permitted in pipe drop inlet barrels.

8. Reinforced concrete pipe, with or without cradles, shall be designed to support at least 12 feet of earth fill above the pipe at all points along the conduit.

(c) The minimum inside diameters of pipes shall be as follows:

1. Category 3 dams: The minimum diameter of the principal spillway barrel will be 18 inches for fill heights up to 50 feet and 24 inches for greater heights; or

   Where the drop inlet is designed hydraulically in such a way that the flow in the barrel under all possible conditions of discharge and foundation consolidation is positively known to be open channel flow with the water surface in the conduit subject to atmospheric pressure only, the minimum diameter shall be 18 inches; or

   Where welded steel pipe is used, the principal spillway shall be designed in accordance with conditions presented in Rule 1200-5-7-.07(2)(e).

2. Category 2 dams: The minimum diameter of the principal spillway barrel shall be 24 inches.

3. Category 1 dams: The minimum diameter of the principal spillway barrel shall be 30 inches.

4. Smaller conduits may be used if detailed calculations show them to be hydraulically and structurally adequate and all other requirements of Rule 1200-5-7-.07 are met.

(d) Where the barrel and cradle or bedding are to rest directly on firm bedrock thick enough so that there is essentially no foundation consolidation under the barrel, the cradle under the pipe need not be articulated.

(e) Principal spillways of welded steel pipe may be used for Category 3 dams under the following conditions, all of which must be met:

1. The minimum diameter of the barrel will be 18 inches.

2. The height of fill over the pipe will be less than 35 feet.

3. Welded steel pipe conduits are to conform to American Society of Testing Materials (ASTM) specifications A53, A120, A135, A139, or A134 and are to be structurally designed as rigid pipe. A joint extension safety margin of 1.5 inches is to be provided for conduits on yielding foundations. Welded pipe is to be protected by an approved exterior coating.

(f) Conduit joints will be designed and constructed to remain water tight under maximum anticipated hydrostatic head and maximum probable conditions of joint opening, including the effects of joint rotation, and must have a margin of safety where required.

(g) Trash racks will be designed and built to provide positive protection against clogging of the spillway at any point. The average velocity of flow through a clean trash rack will not exceed 2.5 feet per second with the water elevation in the reservoir five feet above the top of the trash rack or at the crest of the emergency spillway, whichever is lower. Velocity will be computed on the basis of the net area of opening through the rack.
For dry dams, a trash rack may be used in lieu of a ported concrete riser. The principal spillway trash rack will extend sufficiently above the anticipated sediment elevation at the inlet to provide full design flow through the spillway with velocities through the net

area of the trash rack above the sediment elevation not in excess of two feet per second when the water surface in the reservoir is five feet above the top of the trash rack.

(h) All closed conduit principal spillways designed for pressure flow will have an anti-vortex device.

(3) Drawdown Facilities.

(a) All new dams shall have a drawdown facility. This facility shall be capable of draining the reservoir in ten (10) days or less. It may be assumed that this requirement has been met if seventy-five (75) percent of the liquid volume from the normal water storage elevation has been evacuated in the ten (10) day period. The use of a longer period must be justified.

(b) The necessary drawdown facility for any dam shall be made an integral part of the principal spillway structure if the principal spillway configuration warrants it, but in no case will the drawdown facility be valved on the downstream side of the embankment. Siphon facilities will be accepted after proper engineering justification.

(c) The above stated requirement does not apply in the case of a water supply line through the dam, but in such cases provision must be made for a positive shutoff on the upstream side of the structure.

(d) Drawdown systems shall be maintained in an operable condition. Drawdown valves shall be opened and closed at least annually to ensure operability.

(4) Emergency Spillways.

(a) An emergency spillway shall be provided for each structure, unless the principal spillway is large enough to pass the routed freeboard hydrograph discharge and the debris that comes to it. A conduit type principal spillway having a barrel with a cross-sectional area of 20 square feet or more, an inlet which will not clog, and an elbow designed to facilitate the passage of debris, is the minimum size and design that may be utilized without an emergency spillway. If a principal spillway of this type and size is not provided, danger from clogging requires the use of an emergency spillway regardless of the volume of storage provided.

(b) A single uncontrolled open channel spillway may be used for all purposes provided it is designed to accommodate all discharges, including the freeboard storm, without damage to the structure. However, a positive means to drain the reservoir must also be provided.

(c) Emergency spillways shall be proportioned so that they will pass the freeboard hydrograph at the safe velocity determined for the site. They shall have sufficient capacity to pass the freeboard hydrograph with the water surface in the reservoir at or below the maximum storage elevation.

(d) Minimum Freeboard Design Storms

Size	Freeboard Design Storm (6 Hour)
Small	½ PMP
Intermediate	PMP

Large PMP

(e) All dams shall have an emergency spillway system with capacity to pass a flow resulting from a 6 hour design storm indicated in (d) above for the size corresponding to the dam. Any new dam constructed between October 3, 1987, and February 19, 2001, shall be required to pass the Freeboard Design Storm specified in subparagraph 1200-5-7-.06(3)(b). However, if the applicant's engineer provides calculations, designs, and plans to show that the design flow can be stored, passed through, or passed over the dam without failure occurring, or if he can successfully demonstrate to the Commissioner that the dam is a safe structure and can certify that the dam is sufficient to protect against probable loss of human life downstream, said dam design may be approved by the Commissioner. The establishment of the criteria in (d) above does not eliminate the need for sound engineering judgment but only establishes the lowest limit of design considered acceptable.

(f) The relationship between the water surface elevation in the reservoir and the discharge through the emergency spillway shall be evaluated by computing the head losses in the inlet channel upstream of the control section, or if a control section is not used, by computing the water surface profile through the full length of the spillway. Manning's formula will be used to evaluate friction losses and determine velocities.

(g) The freeboard hydrograph shall be routed through the reservoir starting with the water surface at the elevation of the principal spillway inlet.

(h) A vegetated earth or unlined emergency spillway shall be approved when computations indicate that it will pass the design storm without jeopardizing the safety of the structure. The risk of recurring storms, excessive erosion, and inadequate vegetative cover will be considered acceptable in such a spillway when its average frequency of use is predicted to be not more frequent than once in 25 years for Category 3 dams, once in 50 years for Category 2 dams, and once in 100 years for Category 1 dams.

1. Vegetated and earth emergency spillways may be open channels and may consist of an inlet channel, a control section and an exit channel. Subcritical flow exists in the inlet channel and the flow may be supercritical in the exit channel.

2. Vegetated emergency spillways may be trapezoidal in cross-section and shall be protected from damaging erosion by a grass cover. They shall be used at sites where a vigorous grass growth can be sustained by normal maintenance without irrigation.

3. Earth spillways may be used in those areas where vegetative growth cannot be maintained. They are similar to vegetated spillways but are designed for lower permissible velocities and less frequent use. The needed maintenance after a flow occurs is the responsibility of the certificate holder.

4. Earth and vegetated emergency spillways are designed on the basis that some erosion or scour is permissible if its occurrence is infrequent, if maintenance facilities are provided, and if damage from a severe storm, as represented by the freeboard inflow hydrograph, will not endanger the structure.

5. A Manning's "n" of 0.040 may be used for determining the velocity and capacity in vegetated spillways. Permissible velocities in earth spillways may be based on an "n" value of 0.020 but the capacity of earth spillways will be based on an appraisal of the roughness condition at the site.

6. When the anticipated average use of a vegetated emergency spillway is more frequent than once in 50 years, the maximum permissible velocity will be in accordance with the values given below. The values may be increased 10 percent when the anticipated average use is not more frequent than once in 50 years or 25 percent when the anticipated average use is not more than once in 100 years. The maximum velocity limitations given below for vegetated or earth emergency spillways apply to the exit channel.

7. The values given will be the upper limit for all grasses. Values for grasses or grass mixtures will be determined by comparison with the values shown, with due consideration given to the growth characteristics and density attained in the local area by the species under consideration.

8. Where bona fide studies or investigations have been made to determine the permissible velocity for a specific soil and site, these values may be used in lieu of those shown below.

9. Maximum Permissible Velocities for Vegetated Earth Spillways.

Grasses or Grass Mixtures

Soil Type	Slope	Maximum Permissible Velocity
Erosion Resistant	0-5 %	8.0 fps
	5-10%	7.0 fps
Easily Erodible	0-5 %	6.0 fps
	5-10%	5.0 fps

(5) Earth Embankments.

(a) Sufficient freeboard shall be provided to prevent overtopping with the passage of the freeboard hydrograph plus the additional freeboard required by the site for wave action.

(b) The top width of earth embankments will not be less than the value given by the following equation:

$$W = \frac{H + 35}{5}$$

where H = height of embankment in feet.

W = minimum top width of embankment in feet.

(c) The earth embankment will be riprapped or have other wave erosion protection provided over the full range in stage between three feet above and below the normal pool elevation.

(d) All dams shall be designed and constructed to prevent the development of instability due to excessive seepage forces, uplift forces, or loss of materials in the embankment, abutments, spillway areas, or foundation. Seepage analysis for design and inspection during construction shall be in sufficient detail to prevent the occurrence of critical

(Rule 1200-5-7-.07, continued)

seepage gradients. All dams permanently impounding water shall be constructed with an embankment toe drain with drain pipes installed to discharge the seepage.

(e) All dams shall have a permanent bench mark monument located near the embankment in undisturbed soil or in bedrock. This bench mark shall be detailed in the plans and specifications.

(f) All dams shall be protected from surface erosion by appropriate vegetation or some other type of protective surface such as rip-rap or paving and shall be maintained. Examples of appropriate vegetation include, but are not limited to, Bermuda grass and fescue. All inappropriate vegetation such as honeysuckle, briers, bushes and trees shall be kept off the dam by routine mowing.

Authority: *T.C.A. §§4-5-202, 69-11-101 et seq., and 69-11-104.* ***Administrative History:*** *Original rule filed August 19, 1987; effective October 3, 1987. Amendment filed August 2, 1995; effective October 15, 1995. Amendment filed December 6, 2000; effective February 19, 2001. Amendments filed April 18, 2008; effective July 2, 2008.*

1200-5-7-.08 ENGINEERING REQUIREMENTS.

(1) Engineering Standards. The design engineer shall take into consideration the standards and recommendations made in accepted publications concerning dams, and also the current practices of the various agencies that may be concerned with the design and construction of dams.

(2) Engineering Drawings. All drawings shall be submitted in the form of permanent type drawings of a standard and uniform size. Drawings that do not conform to standard practices and drawings that are not easily legible will not be reviewed.

(3) Engineering Plans. At least four (4) complete sets of construction plans and specifications shall be submitted to the Commissioner. Upon approval, each submitted copy shall be stamped accordingly, two copies retained for the Division's file, and the remaining copies returned to the applicant. An approved copy bearing the stamp of approval must be kept at the construction site during all times of construction.

(4) Engineering Report. The engineering report shall be submitted for review prior to or along with the submittal of the plans and specifications. The engineering report is the basis of the design and shall include, but not be limited to, the data and analyses required by Rule 1200-5-7-.07 for new dam construction or by Rule 1200-5-7-.06 for alterations to existing dams.

(5) Plans and Specifications. The plans and specifications shall provide the details of the structure designed in the engineering report, the construction materials, the construction methods, and shall include, but not be limited to, the following:

(a) Standard and uniform paper. Preferably 24" x 36".

(b) Cover sheet.

(c) Site plan.

(d) Embankment plan and profile views.

(e) Spillways plan and profile views.

(Rule 1200-5-7-.08, continued)

(f) Seepage control detail including collection system.

(g) Wave protection detail.

(h) Service spillway outfall structure and energy dissipator details.

(i) Location of permanent bench mark.

(j) Location sketch.

(k) Actual mean sea level (MSL) elevations of the dam and its appurtenant works.

Authority: *T.C.A. §§4-5-202, 69-11-101 et seq., and 69-11-104.* ***Administrative History:*** *Original rule filed August 19, 1987; effective October 3, 1987. Amendment filed August 2, 1995; effective October 15, 1995. Amendment filed December 6, 2000; effective February 19, 2001.*

1200-5-7-.09 FEES.

(1) Project Review Fee. A project review fee will be charged by the Commissioner for all new dam and reservoir construction. The fee is to accompany the application for a Construction Certificate. New dams will not be charged for the inspection fee for the initial Operating Certificate. The fee will be based upon the size categories shown below, but in no case shall the total project review fee exceed one percent (1%) of the total estimated cost of the dam.

Schedule of Charges

Height of Dam	Charge for Project Review
6 - 40 feet	$1000
41 - 60 feet	$1500
greater than 60 feet	$2000

If a construction certificate expires without construction having begun, the certificate holder may re-apply for a new construction certificate within one year of the expiration date of the original certificate and pay a project review fee of only $500, provided that no substantial changes have been made to the plans and specifications.

(2) Safety Inspection Fee. Fees will be charged for Safety Inspections by the Division. The fee is to accompany the application for an Operating Certificate. The fee will be $500 per inspection. All fees and charges shall be payable only by check or money order to the State of Tennessee.

(3) No fees shall be imposed for inspections of dams which are constructed, operated, or maintained by a watershed district pursuant to *T.C.A. §69-7-101 et seq.*

Authority: *T.C.A. §§4-5-202, 69-11-101 et seq., and 69-11-104.* ***Administrative History:*** *Original rule filed August 19, 1987; effective October 3, 1987. Amendment filed August 2, 1995; effective October 15, 1995. Amendment filed December 6, 2000; effective February 19, 2001. Amendment filed April 18, 2008; effective July 2, 2008.*

1200-5-7-.10 EMERGENCY ACTION BY OWNER. Nothing in *T.C.A. §69-11-117* of the Act, whereby the Commissioner has the authority to act under a state of emergency requested of and declared by the Governor, nor any provisions or requirements for Certificates, shall be construed to relieve or prevent an owner or operator of a dam of the legal duties, obligations, or liabilities incident to the ownership or

operation of the dam. In the event of an emergency where immediate repairs are necessary to safeguard life and property, such repairs shall be made immediately by the owner or his duly authorized agents. In such events, the Commissioner shall be promptly notified of the necessary emergency repairs and of work under way, if any, and such work shall conform to such requirements as specified by the Commissioner.

Authority: *T.C.A. §§4-5-202, 69-11-101 et seq., and 69-11-104.* ***Administrative History:*** *Original rule filed August 19, 1987; effective October 3, 1987. Amendment filed August 2, 1995; effective October 15, 1995.*

1200-5-7-.11 REPEALED.

Authority: *T.C.A. §§4-5-202, 69-11-101 et seq. and 69-11-104.* ***Administrative History:*** *Original rule filed August 19, 1987; effective October 3, 1987. Repeal filed August 2, 1995; effective October 15, 1995.*

CHAPTER 1

Introduction to Guidelines

1.0 Introduction

These guidelines present instructions, standards, and accepted procedures for the hydrologic and hydraulic analysis of existing and proposed dams in Texas. They also clarify the expectations of the TCEQ with respect to submitted analyses, and simplify review by standardizing processes and elements so they will be acceptable to the reviewer. Though the guidelines are relatively specific, the engineer may always submit alternate procedures that either are more conservative or are sufficiently explained and justified.

Dams and spillways designed to comply with TCEQ rules, using hydrologic and hydraulic procedures of the Natural Resources Conservation Service, are acceptable, provided that they are shown to be equally conservative as, or more conservative than, designs developed using the criteria contained in this set of guidelines. The breach-analysis procedures described in Chapter 8 do not depend on which design method is used, and more exact full breach-analysis procedures can always be used in lieu of the conservative simplified procedures.

1.1 Regulatory Authority

These guidelines supplement the Texas Administrative Code, Title 30, Part 1, Chapter 299.

1.2 Professional Responsibility and Duty

These guidelines assume that anyone using or referencing them is a licensed professional engineer or is working under the guidance of a professional engineer. Users should also have appropriate knowledge of the processes and methodologies referenced, and be able to use standard software common in the engineering profession that is appropriate to the analysis.

The hydrologic and hydraulic analyses associated with the design or evaluation of dams, or their rehabilitation, in Texas is considered the practice of Engineering and, as such, subject to the Texas Engineering Practice Act, as amended.

1.3 Copies

Copies of the guidelines may be viewed online at <www.tceq.state.tx.us/goto/damhhguidelines>.

1.4 Feedback

Direct any questions or comments on the content of these guidelines to the coordinator of the Dam Safety Program, Texas Commission on Environmental Quality.

1.5 Applicability

The guidelines described in this document apply to all dams and all design floods determined for dams under the jurisdiction of the TCEQ Dam Safety Program. Some dams may also need to meet the requirements of other agencies such as the NRCS or the U.S. Army Corps of Engineers. Design floods developed to meet requirements of these agencies will be accepted by TCEQ as long as their results are shown to be at least as conservative as would be required by this document.

1.6 Definitions

Many of the words and terms used throughout these guidelines are defined in the Glossary.

1.7 Acknowledgments

These guidelines were prepared by Freese and Nichols, Inc., Austin, under the direction of Warren D. Samuelson, P.E., coordinator of the Dam Safety Program, Texas Commission on Environmental Quality, and Jack Kayser, Ph.D., P.E., senior water resources engineer, Dam Safety Program, TCEQ.

These guidelines have drawn liberally upon the work of many agencies and individuals who have greatly contributed to the state of the art in hydrologic and hydraulic designs of dams in the United States. Acknowledgments of the contributions of these agencies and individuals appear throughout the text of these guidelines.

Appreciation is expressed to the following organizations and firms that supplied data and gave input or reviewed these guidelines:

Federal Agencies

U.S. Army Corps of Engineers
Natural Resources Conservation Service
U.S. Bureau of Reclamation
Interagency Committee on Dam Safety
Federal Energy Regulatory Commission
National Weather Service
U.S. Geologic Survey

State Agencies

Texas Department of Transportation
North Central Texas Council of Governments

Professional Associations

Association of State Dam Safety Officials
American Society of Civil Engineers

Project Consultants

Freese and Nichols, Inc., Austin
Raymond Chan and Associates, Austin

CHAPTER 2

Submitting Reports

2.0 Introduction

All hydrologic and hydraulic analysis reports investigating one or more dams in Texas are to be prepared by, or under the direct supervision of, a professional engineer with direct responsibility for the analysis of the dam. Reports submitted to the TCEQ must document the technical basis for the analysis sufficiently for a thorough review by TCEQ personnel, including methods used, key assumptions, the results and conclusions of the analysis, and any recommendations. Such reports must also include all pertinent and significant data utilized in the analysis and necessary for the TCEQ to perform their desired review of the analysis. The engineer should supply the required information regardless of whether the analysis is a standalone review of an existing dam or supports the design of a new dam or the rehabilitation of an existing one.

The TCEQ's requirements as to detailed preparation of plans, specifications, and designs are not part of these guidelines.

2.1 Minimum Requirements for Submission

For hydrologic and hydraulic studies that are either individual or part of a design project, include their bases and results in a report. Fill in all appropriate Dam Information Forms (Appendix B) and submit them with the report. Tabulate the following data in the report, if applicable:

Rainfall and Runoff Information

- characteristics for the entire watershed and all subbasins, as applicable to calculation methods
- data used to develop parameters describing the watershed characteristics, including any available calibration data
- design-flood inflow and discharge hydrographs
- reservoir routing data and parameters
- discharge-frequency relationships
- determinations of hydraulic roughness
- water-surface profiles

Dam and Spillway Information

- spillway stage–discharge relationships
- maximum height and reservoir storage values
- elevation-area-storage relationship
- key operational elevations for the dam and spillway
- pertinent spillway dimensions
- energy-dissipating facility features
- results of hydraulic model tests when the hydraulic design is based on a model study
- details of low-flow release structures

Breach-Analysis information

- breach parameters
- profile of peak flood levels
- profile of warning time versus distance downstream
- delineation on the best available mapping base of the extent of inundation for the normal pool and design-flood breach events for the project
- identification of any potential loss of public services and of critical facilities
- assessment of hazard-potential classification

CHAPTER 3

Dam Classification

3.0 Introduction

Dams more than 6 ft high fall under TCEQ jurisdiction and are to comply with TCEQ regulations on dam safety regardless of whether the TCEQ requires a water right for the impoundment.

The TCEQ regulations and these guidelines do not apply to:

- dams designed by, constructed under the supervision of, and owned and maintained by federal agencies such as the Corps of Engineers and the Bureau of Reclamation;
- embankments used for roads, highways, and railroads, including low-water crossings, that may temporarily impound floodwater;
- dikes or levees designed to prevent inundation by floodwater; and
- off-channel impoundments authorized by the TCEQ under Texas Water Code Chapter 26.

3.1 Dam Size Classification

The classification for size based on the maximum height of the dam or maximum reservoir storage capacity shall be in accordance with Chapter 299 of the Texas Administrative Code (TAC).

3.2 Design-Flood Criteria

Existing and proposed dams must safely pass the design-flood hydrograph, expressed as a percentage of the probable maximum flood. The design flood is determined based upon the size (previous section) and hazard-potential classification (Chapter 9) of the dam. TAC Chapter 299 describes the required design flood for the various combinations of size and hazard classification. Safely passing a flood for an existing dam means discharging the flood without a failure of the dam or one of its critical elements. A failure would be considered an unintended release of impounded water due to the loss of all or a portion of the dam or affiliated structure. For dams without a structural design that allows for safe overtopping, any overtopping of an earthen embankment would be considered not safely passing the flood.

Design-flood criteria established by other public agencies, if shown to be more conservative, will generally be acceptable. Those that may produce a less conservative result, such as the FEMA Inflow design-flood methodology, if based on a properly prepared incremental risk analysis, may be acceptable, but will require a thorough review of the risk analysis as well as the hydrologic and hydraulic analyses.

3.3 Minimum Freeboard

No freeboard for wave action is required for existing dams above the peak design-flood level, either for determination of existing conditions or for the design of an upgrade or modification.

New dams should have appropriate freeboard. As part of the freeboard calculations for a proposed new dam, consider an appropriate wave run-up. Overtopping from wave action due to design wind loads, as described below, is generally not allowable. It may, however, be acceptable if the design engineer can show reasonable cause—as in the case of a new concrete dam or a dam with other appropriate slope protection on the downstream side. Freeboard between the effective crest of the dam and the various water surface elevations that may be associated with the reservoir is to be based on suitable assumed wind speeds and related wave heights.

The longer that a reservoir is shown to be at or above a certain level, the higher the potential wind speeds that should be considered. In addition, the timing of the peak lake level with respect to the storm event that generated it is also a factor. For example, the freeboard above the maximum normal operating level should be greater than or equal to the maximum wave height, including run-up, caused by the maximum wind potential along the maximum fetch of the reservoir.

Freeboard above higher flood levels in the reservoir, such as the top of any dedicated flood pool, should consider wave height and run-up for lesser winds consistent with the potential risks associated with wind-driven waves overtopping or eroding the embankment and potential flood durations at those levels. Freeboard above the maximum reservoir level resulting from the design flood does not need to reflect significant wave height from unusual wind conditions, if it can be shown that the peak

reservoir level occurs after the intense portions of the storm that generated the design flood. Multiple storm events do not need to be considered.

The freeboard should include the expected wind effects that could occur during the design-flood event if the peak reservoir level occurs within the critical portion of the storm event itself. This critical portion would generally be considered the portion of the critical duration prior to the break point, if the temporal distribution described in Chapter 4 is employed. An acceptable rule of thumb would be to use 50 percent of the maximum wind speed if the peak occurs before the break point, 33 percent of the maximum if the peak is after the break point but before the onset of the critical storm, and 20 percent of the maximum wind speed if the peak occurs after the end of the assumed rainfall event.

These are general guidelines and the engineer should provide reasonable explanation of assumed winds for freeboard determination. Appropriate determinations will be needed if a different temporal distribution is used.

All freeboard calculations should include the expected future settlement and consolidation of the embankment after construction in addition to wave run-up.

Determining the Design Flood—Precipitation

CHAPTER 4

4.0 Introduction

The design flood hydrograph for existing and proposed dams shall be derived from the appropriate percentage of the probable maximum flood (PMF), which is, in turn, derived from the estimated runoff resulting from the probable maximum precipitation (PMP). The PMP varies depending on the size and shape of the dam's contributing drainage area. The intent of the precipitation analysis is to find the critical storm size, location, orientation, and duration that would produce the most critical loading on the dam. PMP values in Texas are generally derived from HMR-51 (Schreiner and Riedel 1978) and HMR-52 (Hansen, Schreiner, and Miller 1982) for most of the state and HMR-55A (Hansen et al.1988) for parts of extreme west Texas. (*HMR* = 'hydrometeorological report.') These would apply unless an approved site-specific PMP study is performed. All references to "PMP" are to one of these sources of derivation.

4.1 Watershed Delineation

Many of the dams in Texas can be modeled appropriately with a single basin. However, many will need to be divided into multiple subbasins. The size and delineation of the subbasins is dependent on the rainfall-runoff method used and various hydrologic factors. Subdivision should also be considered if there are portions of the drainage basin that:

- possess hydrologic characteristics obviously different from the average characteristics of the total basin,
- may contribute to delays in flood passage, such as upstream lakes,
- are controlled by large constrictions that can act as hydraulic control structure by restricting, cross-sectional areas and attenuating water flow, as may occur at some bridges,
- have a total drainage area that is too large for averaging a single storm distribution, or
- have stream gauges or observed data that may be used for calibration.

Watersheds should be delineated and their characteristics determined in accordance with the standards of the following references:

- *National Engineering Handbook,* Part 630 (Hydrology) (NRCS 1997)
- EM 1110-2-1417 (U.S. Army Corps of Engineers, 1994)
- Federal Energy Regulatory Commission (2001)

4.2 Minimum PMP Duration

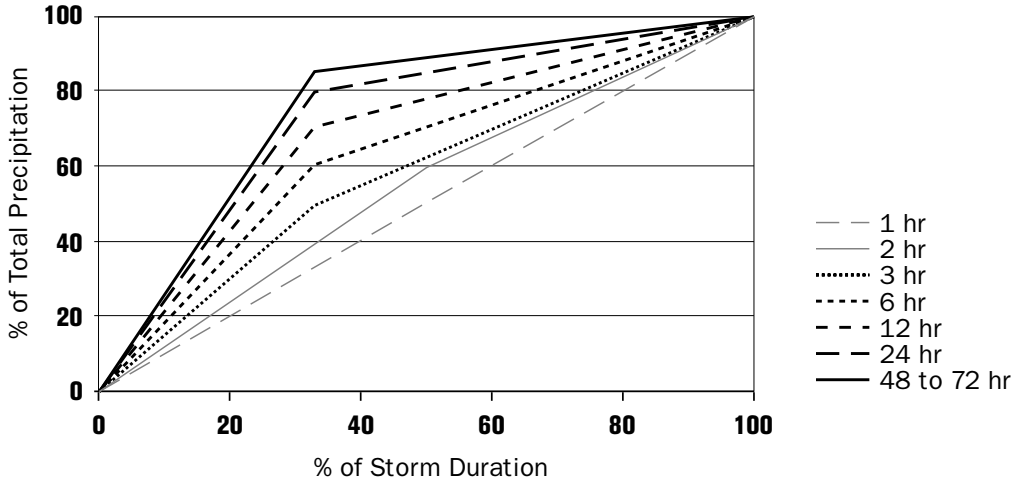
The PMP depths for a particular storm size and range of storm durations are used to determine the critical storm duration for a dam. The intent is to review multiple potential durations of storm events in order to determine a critical event, namely, that which produces the maximum reservoir level. Possible durations would include 1, 2, 3, 6, 12, 24, 48, and 72 hours. The minimum design-storm duration is based on the total contributing drainage area for the dam, as shown in Table 4.1.

Table 4.1. Minimum PMP Duration

Contributing Drainage Area (DA) (sq mi)	Minimum Storm Duration (hr)
DA < 25	1
25 ≤ DA < 100	3
100 ≤ DA < 1,000	6
1,000 ≤ DA < 10,000	24
DA ≥ 10,000	72

The PMP depths should first be determined for the minimum storm duration listed in Table 4.1. Then each possible duration up to 72 hours should be reviewed in order to determine the critical duration. For example, for a reservoir with a drainage area of 80 sq mi, the minimum duration is 3 hr. First, the peak reservoir level from a 3-hour PMP is determined, then that of a 6-hour and a 12-hour PMP event. This continues until the peak reservoir level from a longer duration event is lower than the previous one, thus bounding

the critical duration. The duration that produces the maximum reservoir level then becomes the critical duration and that duration event is used for the PMF. If the 72-hour PMP produces the maximum reservoir level, then a 72-hour PMF is utilized. No durations longer than 72 hours need to be reviewed.



4.3 Temporal Distribution of Design-Storm Precipitation

Distribute the total depth of the PMP, for both the entire basin as well as for each subbasin, as appropriate, temporally in accordance with the dimensionless parameters of Figure 4.1 and Equation 4.1. **Since the new temporal distributions are different for each duration, a dam needs to be evaluated for all of the durations required by Section 4.2 and the peak elevation for each duration must be estimated in order to determine the critical duration for that structure.** This critical peak lake level may then be compared, if desired, to the peak lake level determined by other methods in order to determine which method is more conservative.

The new temporal distributions will tend to reduce the conservatism of the PMP on the flood routings by reducing the intensity of the peak portion of the rainfall event. The result will be tend to include flatter inflow hydrographs, significantly lower peak inflow rates, and slightly lower peak lake levels.

The development of the guideline's temporal distributions is based on observed evidence that near-PMP values for significantly different durations have not occurred in the same event. In other words, though previous methods assumed the PMP value for the peak one-hour event occurred within the same event as the peak PMP value for 24 hours and also for 72 hours, such storms have never actually been observed. Historical data has also shown that the most extreme near-PMP events tend to be front loaded, with most of the rainfall occurring early in the event. The guidelines attempt to provide a reasonably conservative temporal distribution for the given set of durations. It is important to note that only the distribution of the rainfall has changed; the total rainfall amounts for any given duration are unchanged from previous methods. More

Figure 4.1. Temporal Distribution of Total Depth of PMP for All Durations of PMPs

This distribution can be estimated within calculations and spreadsheets as:

Eq. 4.1 For $T \le x$: $P = (T / x) \cdot y$

For $T > x$: $P = y + ((100–y) / (100–x)) \cdot (T–x)$

Where:
P = percentage of total precipitation
T = percentage of storm duration
x, y = coordinates of breakpoint

The breakpoint will vary depending on the duration storm being analyzed (Table 4.2). For a one-hour event, a breakpoint with coordinates at 50 percent, 50 percent is listed for consistency, though that represents a linear distribution of rainfall over the hour.

conservative distributions can be used, such as the HMR-51 or the NRCS distributions.

Table 4.2. Breakpoints for PMP Temporal Distributions

Duration (hr)	x (%)	y (%)
1	50	50
2	50	60
3	33	50
6	33	60
12	33	70
24	33	80
48 to 72	33	85

4.4 Storm Location and Spatial Distribution of PMP

Drainage Areas ≤ 10 Square Miles: Apply the total depth of the PMP, estimated as the point values delineated in HMR-51 and HMR-52, over the entire drainage area for all storm durations.

Drainage Areas > 10 Square Miles: Distribute the total depth of the PMP for all storm durations spatially over the drainage area using the single-centered concentric ellipse pattern and methodology specified in HMR-52. For single basins, the center of the storm should generally be at the centroid of the basin and a basin-average total depth of design storm precipitation calculated for the specified duration. For larger basins, when the watershed is divided into multiple subbasins, the center of the PMP storm isohyets must be moved to multiple locations away from the geometric centroid of the overall drainage area to verify the critical design storm location and orientation that produces the maximum corresponding PMF level in the reservoir. This will generally be the same storm center that produces the maximum basin-average total PMP depth. However, in very large basins (greater than 10,000 sq mi), the location of the storm center producing the maximum rainfall depth and the storm center producing the maximum basin discharge may not be the same, depending on the size and orientation of the various tributaries, so the full flood routing through the reservoir should include iterative trials to determine the critical storm location.

CHAPTER 5

Determining the Design Flood—Runoff Calculations

5.0 Introduction

Precipitation hyetographs, developed as described in Chapter 4, that are calculated for the watershed above a reservoir are used to develop estimates of runoff hydrographs in two basic steps. First, the excess precipitation is generated by deducting estimated losses from the total precipitation. This excess precipitation will generate the full volume of runoff from the storm event. In the second step, the excess rainfall is applied to a suitable unit hydrograph for the basin or subbasins to produce a runoff hydrograph.

5.1 Antecedent Moisture Conditions

Superimpose the PMP upon watershed soils assumed to be saturated. This will equate to losses at the beginning of the design storm equal to zero or Natural Resources Conservation Service Antecedent Runoff Conditions III (ARC III), or some other equivalent and approved assumptions. In Texas, there is no need to analyze snowmelt contributions to runoff or frozen ground conditions for infiltration for design-flood calculations.

5.2 Infiltration Losses—Excess Precipitation

Determination of excess rates of precipitation and infiltration losses can be determined by one of several precipitation loss methods. The two most common are:

- Initial and Constant-Rate Loss Method
- NRCS Curve Number Loss Method

Other usable methods include:

- Green and Ampt Loss Method
- Holton Loss Rate
- Exponential Loss Rate

These methods are described in most hydrology textbooks and in user manuals for modeling software.

For certain areas—paved areas, buildings, and open water—it may be appropriate to assume a certain percentage of the basin or subbasin has no infiltration at all. Such areas are typically designated by an impervious-area percentage in the description of the basin characteristics. A large area—such as the reservoir area itself, if it is a significant portion of the drainage area—can be modeled as a unique subbasin with zero infiltration losses.

The methodologies for the first two methods and their associated input parameters are described below.

Initial and Uniform

This simple method is widely used and consists of establishing an initial loss amount and a uniform loss rate. The initial assumption is that all rainfall is lost to infiltration up to the initial loss amount. After that, the uniform rate is adjusted to the calculation time step and then subtracted from each rainfall amount for that time step. The remaining precipitation is the excess rainfall.

For all design-flood calculations, the initial loss amount should be zero, equivalent to saturated conditions. The uniform rate is estimated based on soil types. The values will typically range from 0.05 in/hr for clays to as high as 0.4 in/hr for sandy soils.

NRCS Curve Number Loss Method

The NRCS has standardized detailed procedures for developing estimates of infiltration rates based on soil types and land use characteristics. The process is summed up in the derivation of the curve number (CN), from which estimates for soil moisture deficit, initial abstraction, and the resulting excess rainfall are derived. Multiple NRCS publications are available that provide guidelines for estimating the CN based on soil classifications and land use parameters. Soil classifications are most readily obtained from NRCS County soil maps. Many of these were published when the agency was known as the Soil Conservation Service (SCS). All of the soil classifications listed in the County Survey reports are classified in one of the four hydrologic soil groups, A, B, C, and D. These four groups range from the most pervious, A, to the most impervious, D. Generally, multiple groups will

be represented within a basin or subbasin and the representative values can be averaged over the basin, weighted by representative area. Either calculate the average to develop a basin average hydrologic group and then assign the entire basin a CN, or assign each of the various soil types within the basin a hydrologic group and then a CN, and average all the CNs, weighted by area.

Most of the available tables indicating CN assume an ARC (formerly referred to as *antecedent moisture condition*, or *AMC*) II antecedent condition. This needs to be adjusted to reflect ARC III conditions.

Infiltration Loss Methods

For comparison, Table 5.1 shows a general relationship between the NRCS soil classification (described in the next section) and uniform loss rates.

5.3 Land-Use Assummptions

For developing the design storm runoff hydrograph for design and risk assessment of proposed dams or modifications to existing dams, assume land uses expected to exist at the completion of the modification or construction project. Dam owners will be held responsible for the safety of the dam throughout its entire life; therefore, they should attend to the build-out conditions that are reasonably expected to occur within the entire drainage area during the operational life of the dam.

5.4 Unit Hydrograph Method

The PMP needs to be transformed into the PMF runoff hydrograph for each basin or subbasin using an acceptable unit hydrograph method. The two most commonly used methods for hydrologic and hydraulic studies associated with dams are:

- Snyder Unit Hydrograph Method
- NRCS Dimensionless Unit Hydrograph Method

Other possible methods that are used include:

- Clark Unit Hydrograph Method
- Kinematic Wave Method

Table 5.1. NRCS Hydrologic Soil Groups and Uniform Infiltration (Loss) Rates

Soil Group	Description	Range of Uniform Loss Rates (in/hr)
A	Deep sand, deep loess, aggregated silts	0.30–0.40
B	Shallow loess, sandy loam	0.15–0.30
C	Clay loams, shallow sandy loam, soils low in organic content, soils usually high in clay	0.05–0.15
D	Soils that swell significantly when wet, heavy plastic clays, certain saline solutions	0.00–0.05

References: NRCS 1997, Skaggs and Khaleel 1982

These two most widely used methods, the Initial and Constant Rate method and the NRCS Curve Number method, are contrasted in Table 5.2.

Table 5.2. Infiltration-Loss Methods Compared

Method	Pros	Cons	References
Initial and Constant Rate	■ Simple and easy to use. ■ Easy to calibrate. ■ Apply to all storm durations.	Since it does not reflect varying loss rates, it can misestimate losses within the event, particularly those of very short duration.	■ EM 1110-2-1417 (U.S. Army Corps of Engineers 1994) ■ *Hydrology Handbook* (ASCE 1996)
NRCS Curve Number	■ Simple and easy to use. ■ Easy to calibrate. ■ Good availability of material to estimate parameters for ungauged areas.	Infiltration rate will be asymptotic to zero and losses tend to be understated for storms longer than 24 hours in duration.	■ EM 1110-2-1417 ■ *Hydrology Handbook* (ASCE 1996) ■ Win TR-55 (NRCS 1998) ■ *National Engineering Handbook* (NRCS 1997)

These methods are described in most hydrology textbooks and in user manuals for modeling software.

Procedures for the first two methods and their associated input parameters are described below.

Snyder Unit Hydrograph

The Snyder method estimates a peak discharge and a time to the peak of the unit hydrograph. It also estimates shape parameters. Rainfall runoff models, such as HEC-1, will typically complete the unit hydrograph based on assumed parameters and relationships. Typically, two parameters are needed to develop a Snyder Unit Hydrograph:

- T_L, lag time
- C_p, shape factor, also commonly expressed as C_p640.

The lag time has historically been calculated in multiple ways. The following equation is best suited to regional parameters:

$$T_L = C_T(L \cdot L_{CA}/S^{0.5})^{0.38}$$

T_L = Lag Time (hr)
C_T = coefficient
L = hydraulic length of watershed along the longest flow path (mi)
L_{CA} = hydraulic length along the longest water course from the point under consideration to a point opposite the centroid of the drainage basin (mi)
S = weighted slope of the basin (ft/mi), measured from the 85% to the 10% points along the longest stream path in the basin (EM 1110-2-1405)

The value C_T is a dimensionless parameter that is typically assumed to be consistent for various areas of the state. For instance, it could be estimated from neighboring areas or calibrated for the whole or portions of the basin, and then applied to multiple subbasins within the watershed.

Note that there are multiple forms of the Snyder equation for T_L. Some use ft/ft for the slope and some do not include the slope at all. If a regional value for C_T is used, verify that the same equation was used in the study within which it was developed. Values generally range from about 0.7 up to about 3.0, though values outside that range have been calibrated.

The shape factor, C_p640, reflects the sharpness of the hydrograph. High values, up to about 500, reflect a rapidly responding basin with a sharp peaked hydrograph. Low values, such as 250, generally reflect a flatter, slow responding basin with a longer, flatter hydrograph. These values are generally divided by 640 and entered into HEC-1, if that model is used, as the C_p value, ranging from about 0.4 to 0.8. Generally, smaller C_T times are associated with higher C_p640 values, though many exceptions exist.

NRCS Dimensionless Unit Hydrograph

Only one parameter is used in the models that use the NRCS Unit Hydrograph method—the lag time, T_L, typically estimated as 0.6 times the time of concentration, T_C, which is estimated through a procedure of several steps based on parameters reflecting the basin. The factor 0.6 for conversion from T_C to T_L has been shown to vary with certain urban characteristics, but, without detailed information, 0.6 is generally considered acceptable for most situations. The time of concentration, T_C, is the time it takes for water to flow from the most hydraulically remote point of the drainage area to the outlet of the drainage basin. There are multiple methods to determine the time of concentration, each generally associated with a particular unit hydrograph estimation procedure.

One of the more common methods for estimating T_C is to sum three runoff time components: overland sheet flow, shallow concentrated flow, and open channel. *Sheet flow* reflects the uppermost end of the basin and consists of flow traveling over the open planar surfaces and not in formed channels. Its length is generally estimated from maps, but should be no greater than 100 ft. The primary factors for estimating the time for sheet flow are length, slope, and roughness. *Shallow concentrated flow* reflects the flow as more concentrated, but still not in a fully formed channel. It may be in minor ditches and swales and is also affected primarily by the length, slope, and roughness. *Open channel flow* is the flow in distinct, well formed channels, within which flow can be readily depicted using Manning's equation. More than one channel type, with separate time calculations for each, may be added to obtain the overall time of concentration. However, there cannot be more than one component for sheet flow or shallow concentrated flow.

The intention of these estimates is to sum the estimated travel time of flow across each component. The factors listed above are estimated in order to determine a flow velocity which is assumed constant over the defined length. Times for each of the three components are estimated, totaled, and the sum used as the time of concentration for the basin, which is then adjusted to estimate the lag time, T_L. These two widely used unit hydrograph methods, Snyder's and the NRCS method, are contrasted in Table 5.3.

5.5 Calibration

The calibration of hydraulic and hydrologic runoff parameters is strongly preferable in most cases. For breach analyses, a recently prepared PMF analysis usually suffices. If the previously prepared

Table 5.3. Unit Hydrograph Methods Compared

Method	Pros	Cons	References
Snyder's Unit Hydrograph	■ Simple and easy to use. ■ Easy to calibrate. ■ Applies to wide range of area.	Parameters cannot be estimated from field observations. Values must be calibrated or estimated from similar areas.	■ EM 1110-2-1417 (U.S. Army Corps of Engineers 1994) ■ *Hydrology Handbook* (ASCE 1996)
NRCS Dimensionless Unit Hydrograph	■ Simple and easy to use. ■ Easy to calibrate. ■ Good availability of material to estimate parameters for ungauged areas.	Not well-suited to large drainage areas. Should not be used for subbasins larger than about 20 sq mi.	■ EM 1110-2-1417 ■ *Hydrology Handbook* ■ TR-55 (NRCS 1998) ■ *National Engineering Handbook* (NRCS 1997)

PMF was not based on calibrated runoff values, a new calibration is not needed, except for large, high-hazard dams. For PMF determinations associated with new dams or the upgrade of existing dams, use calibrated values for all intermediate and large high-hazard dams and large significant-hazard dams. Exceptions may be allowed if the values chosen can be demonstrated to be conservative or if insufficient data are available.

The following suggestions should be considered during calibration:

- The process compares calculated runoff hydrographs to observed hydrographs from gauges or calculated from lake levels. Inflow rates estimated from reservoir levels will generally need some smoothing, as small errors in lake-level measurements typically represent a large error in inflow. However, these will tend to be self-correcting in subsequent time steps.
- There is error in all observed data, so multiple storms should be used for calibration. Three or four events are preferable. If an event suggests values that are inconsistent with others, consider not using that event.
- Most rain gauges use daily values and their temporal distribution will need to be estimated based on adjacent hourly gauges. Some lag time between the gauges is often appropriate.
- The Theissen Polygon method is a simple and suitable way to distribute rainfall values across basins. However, multiple tools that make use of GIS technology are also available and well-suited to the task.
- Distributing observed rainfall values across large areas will tend to exacerbate the errors inherent in the rainfall. Inevitably, the calibration of infiltration rates tends to be more of a correction of rainfall errors than a determination of true infiltration. Unless a strong, repetitive pattern is noted, determine loss rates from analysis of the soil types with little emphasis on the calibrated infiltration rates.
- When calibrating a model, first adjust infiltration losses to obtain a matching runoff volume. Then, adjust the parameters that reflect the timing to match the time of the peak flow. Finally, adjust the hydrograph shape, including the magnitude of the peak flow. Some iterations will typically be necessary.
- Minimize the number of variables to be calculated. For example, rather than attempting to adjust the lag time for each subbasin within the Snyder methodology, assume one C_T and one C_p640 value for the entire group of subbasins above the observed hydrograph, with each basin's lag time calculated based on the dimensions of its own basin. If variations in the C_p640 values are deemed appropriate, then it helps to keep the ratios between them constant so that all are effectively calibrated together.

CHAPTER 6

Determining the Design Flood—Routing Methodologies

6.0 Introduction

The last of the three primary steps in determining the design flood is the routing of hydrographs through the reservoir. Watersheds modeled as a single basin need no streamflow routing, and the design-flood runoff hydrograph is the reservoir-inflow hydrograph. Watersheds modeled with multiple subbasins need streamflow routing unless all subbasins drain directly into the reservoir.

6.1 Methods for Hydrologic and Hydraulic Streamflow Routing

In models that require routing of the design-storm runoff hydrographs through a stream channel, either a hydrologic or hydraulic routing method may be used. The hydrologic methods are either empirical or semi-empirical. Approved hydrologic routing methods include:

- Muskingum
- Muskingum-Cunge
- Average-Lag
- Successive Average-Lag (Tatum)
- Modified Puls
- Working R and D

Hydraulic routing methods are more complicated and difficult to use as they are based on theoretical hydraulic equations, but they more accurately reflect flood-routing conditions. Hydraulic methods are typically used under the following conditions:

- Very flat channel slopes, less than 5 ft/mi
- Wide floodplains with significant storage effects on the hydrograph
- High flows from a tributary
- Unusual backwater effects from structures

Acceptable hydraulic modeling methods include:

- Kinematic Wave
- Dynamic Wave
- Diffusion Wave

6.2 Base Flow

Estimates of base flow conditions to which calculated runoff hydrographs are added are sometimes appropriate on larger rivers, particularly for frequency flood–level events, such as 10-year or 100-year floods. However, in Texas, they are rarely a significant component of the design-storm peak flows, generally much less than 1 percent. For any river with a dependable flow that could be counted as a base flow, the drainage area is usually quite large and the resulting design-flood runoff will still dwarf the base flow. For these reasons, base flow is not required within design-flood calculations but may be employed if the analyst deems appropriate; it will typically be of the same order of magnitude as median flows or estimated as the receding limb of an antecedent event.

6.3 Hydraulic Input Parameters

All of the streamflow routing methods use various input parameters, generally measured or estimated from the physical characteristics of the channel. All will include a parameter that measures the length of the channel directly or reflects it in an estimate of travel time. For these, use the full length of the channel without assuming shortening due to overbank flooding. Even in very high flows, the predominant conveyance is usually within the channel itself. If the overbank flows are thought to be a dominant factor in the flood conveyance, then employ a routing method that takes differing floodplain flow characteristics into account, possibly including hydraulic models.

The Muskingum routing method, instead of physically measured values, incorporates an estimate of storage effects though the storage coefficient, x. This value ranges from 0.0 to 0.5, where 0.0 reflects a straight translation of a hydrograph and 0.5 reflects a storage-controlled routing process. The former would indicate of a steep narrow channel with little attenuation of the peak expected. The latter would reflect a broader, flatter channel with significant attenuation of the peak from overbank storage effects. This parameter cannot be measured from physical characteristics of the channel, but can be calibrated or estimated with experience.

Most methods will also typically use some description of a typical cross-section or multiple cross-sections. These should simply be measured from available mapping and should represent average conditions. For hydraulic models, where the entire length of the channel is modeled with cross-sections, reasonable mapping will be necessary, though rarely are surveyed cross-sections justified. For unsteady-flow hydraulic models, such as the NWS models and HEC-RAS, it is important that the cross-sections reflect with reasonable accuracy the existing floodplain storage. In steady-state models, there is a tendency to place cross-sections at constrictions and other features that control the flow rate. However, in unsteady models, the full flood storage of the floodplain tends to control the downstream movement of the hydrograph. Therefore, cross-sections should reflect both the constricted sections and the wider sections, as well as the storage that occurs in tributaries and adjacent draws. Off-channel storage, or ineffective flow area—often ignored in steady-state models—can be significant in unsteady models.

Manning's Roughness Coefficients

Except for the purely empirical hydrologic equations, each of the streamflow routing models will use the most widely recognized flow relationship, Manning's equation. Input parameters to Manning's equation consist simply of descriptions of the topography through the use of cross-sections, either in detail or simplified, and the roughness coefficient.

Numerous sources exist that describe the use of the equation and provide means to estimate Manning's coefficient (*n*), both for channel flow and overbank flow. The primary criterion is the size of the roughness particle, usually vegetation or the exposed channel surface, relative to the overall flow area. For example, the same grass-lined channel will have a smaller value for *n* if the channel area is large than if it is small. For that reason, roughness values will decrease with increasing flow for a consistent channel. However, this trend is often countered by the fact that roughness in the form of vegetation tends to increase quickly when significant portions of the flow are in the overbank areas. Single *n* values for a channel regardless of flow apply only in simplified estimates or in a narrow range of flows.

For design-flood calculations, where there is likely to be a large component of flow area in the floodplain, some variation in the value of *n* will need to taken into account. The simplest way to do this is to use three *n* values, one for the channel and one for each overbank. This is a very common technique, used in some routing methods in HEC-1 and often in the hydraulic model, HEC-RAS. The NWS models require input roughness values that are related to each top-width elevation or to flow, so weighted values need to be determined. These are typically best weighted by conveyance rather than by area as that will proportion the effective roughness relative to the portion of the flow it affects.

Table 6.1 compares some of the more common hydrologic and hydraulic streamflow routing methods and gives some of the pros and cons of each.

6.4 Calibration

The calibration of hydraulic and hydrologic streamflow routing parameters, similar to runoff parameters, is strongly preferable in most cases when sufficient data is available. For breach analyses, a recently prepared PMF analysis can usually be employed. If the previously prepared PMF was not based on calibrated runoff values, a new calibration is not needed, except for large high-hazard dams when sufficient data are available. For PMF determinations associated with new dams or the upgrade of existing dams, use calibrated values for all intermediate and large high-hazard dams and large significant-hazard dams. Exceptions may be allowable if the values used can be demonstrated to be conservative or insufficient data are available. During calibration, consider the following:

- The process compares calculated routed hydrographs to observed hydrographs from gauges or calculated from lake levels. Inflow rates estimated from reservoir levels will generally need some smoothing, as small errors in lake-level measurements typically represent a large error in inflow. However, these will tend to be self-correcting in subsequent time steps.
- There is error in all observed data, so multiple storms should be used for calibration. Three or four events are preferable. If an event suggests values that are inconsistent with others, consider not using that event.
- When calibrating a model, first calibrate runoff components, if they can be isolated, in order to match the flow volume. Then, adjust the streamflow parameters to match the translation time of the peak flow. Finally, adjust the hydrograph shape, including the magnitude of the peak flow. Some iterations will typically be necessary.
- Isolate the variables to be calculated and minimize their number as much as possible. For example, if two stream gauges exist, use the observed upstream hydrograph with lateral inflows estimated and calibrated separately, if possible, and estimate the resulting downstream hydrograph. This will isolate the routing parameters of that reach. As another example, rather than attempting to calibrate a wide range of roughness coefficients, relating all the appropriate values of *n* to standard channel and overbank values will allow the calibration of only two or three values. This can be carried out with overbank roughness values representing clear and

wooded areas, for instance, that are averaged for different reaches based on field conditions.

6.5 Modeling Through Reservoirs

Hydrologic Routing

For hydrologic routing, the peak design-flood reservoir elevation is determined by routing the estimated inflow hydrograph through the reservoir using one of the various hydrologic models. The methods most typically used for routing a hydrograph through a reservoir in hydrologic models are:

- Level Pool Routing
- Modified Puls

Take the following into consideration:

- Assume that reservoir losses equal zero.
- For gated dams, route the design-flood inflow hydrograph through the reservoir and through the dam's hydraulic control structures using the planned flood operational rules for the spillway or in a manner that takes into consideration downstream flood risks.
- The antecedent reservoir elevation in the reservoir should be the maximum normal operating pool (MNOP) level, which is the highest water surface elevation within the range of planned operating levels for the reservoir, above which floodwaters would be released. No antecedent storm is required. This applies to all upstream reservoirs in the drainage area.
  - ▼ For detention ponds that are dry or do not have significant permanent storage, consider the MNOP to be at the level of the primary outlet, above which water is always released.

Table 6.1. Streamflow Routing Methods Compared

Method	Pros	Cons	References
Muskingum	■ Simple and easy to use. ■ Easy to calibrate. ■ Applies to wide range of channel types.	■ Parameters cannot be estimated from field observations. Values must be calibrated or estimated from similar areas. ■ Does not account for backwater effects of structures or tributaries.	■ EM 1110-2-1417 (U.S. Army Corps of Engineers 1994) ■ HEC-1 user's manual ■ *Hydrology Handbook* (ASCE 1996)
Muskingum-Cunge	■ Simple and easy to use. ■ Parameters can be estimated from field observations.	■ Does not account for overbank or other storage effects well in broad, flat channels.	■ EM 1110-2-1417 ■ HEC-1 user's manual ■ *Hydrology Handbook* (ASCE 1996)
Kinematic Wave	■ Simple and easy to use. ■ Parameters can be estimated from field observations.	■ Does not account for overbank or other storage effects well in broad, flat channels.	■ EM 1110-2-1417 ■ HEC-1 user's manual ■ *Hydrology Handbook* (ASCE, 1996)
Modified Puls Storage	■ Simple and easy to use. ■ Applies to storage routing for reservoirs.Well suited to flat, broad channels with significant overbank storage.	■ Can be difficult to apply to streams if no relationship between flow and storage is available.	■ EM 1110-2-1417 ■ HEC-1 user's manual ■ *Hydrology Handbook* (ASCE 1996)
Dynamic Wave	■ Most accurate, particularly in broad, flat channels, with slopes less than about 5 ft/mi. ■ Best method for translating values calibrated from actual events up to design flood–level event. ■ Good availability of material to estimate parameters for ungauged streams. ■ Only method that can accurately describe the impact of major tributary flow that creates backwater or even reverse flow on the main stem.	■ Difficult to use, requires a large quantity of data.	■ HEC-RAS user's manual ■ NWS user's manuals (DWOPER, NETWORK, DAMBRK)

- For recharge reservoirs that are normally dry but have no release capabilities, the MNOP would be an empty reservoir provided that it can be shown that the lake has historically been, or will typically be, dry within a week of a major storm event. If not, the design engineer should show a statistically based justification for an appropriate starting water level.
- For existing storage reservoirs that have not filled up to their MNOP within the last 10 years, use starting levels at both the MNOP and the maximum level of the lake within the last decade. If the dam can safely pass its appropriate design flood at the lower historical level, but not at the MNOP, then modifications to enable the dam to pass the design flood will still be required. However, these modifications do not need to be initiated until such time as the reservoir reaches a water level starting at which it cannot safely pass the design flood. Determine this "trigger starting elevation"—at which the dam is overtopped by the design flood—and report it along with the rest of the analysis.

- Do not assume the reservoir to be drawn down below the maximum normal operating level in advance of the design storm.
- For new structures, no long-term effects of sedimentation on flood storage capacity need to be assessed for flood routing. For modification or rehabilitation of existing structures, a revised state-storage curve, accounting for sedimentation, should be developed from a field survey.

Hydraulic Routing

For hydraulic routing of hydrographs through reservoirs, there is no distinction between streamflow and reservoir routing. The reservoir is simply modeled with cross-sections as part of the stream with the spillway modeled either directly in the computer model or as an internal boundary based on the spillway rating curve. Though the modeling methodology is the same, certain issues should be considered.

- Through all but the shallowest portions of the reservoir, water levels are not sensitive to roughness coefficients.
- Adjust cross-sections and the intervening lengths to match the overall reservoir elevation-storage relationship.
- For gated dams, route the design-storm inflow hydrograph through the reservoir and through the dam's hydraulic control structures using the planned flood-operation rules for the spillway or in a manner that takes into consideration downstream flood risks.
- Do not assume the reservoir to be drawn down below the maximum normal operating level in advance of the design storm.

Each method will require hydraulic data about the reservoir and spillway, as described in Chapter 7.

6.6 Design-Flood Hydrographs

After estimating the full PMF hydrograph, determine the design-flood level, based on the size and hazard classification as described in Section 3.2. For hydrologic models that produce a full reservoir-inflow hydrograph, determine the design flood by multiplying each ordinate of the PMF inflow hydrograph by the required percentage. For example, if the design flood is 75 percent of the PMF, then multiply the 100 percent PMF-inflow hydrograph ordinates by 0.75. Make no adjustments to the precipitation data. This design flood–inflow hydrograph is then routed through the reservoir appropriately to determine the peak design-flood level.

For models using hydraulic flood routing methods for the streamflow components and the reservoir, similarly adjust each runoff hydrograph that represents a boundary or lateral inflow hydrograph, multiplying each ordinate of the hydrograph by the specified percentage. Then route these adjusted hydrographs would through the hydraulic model to determine the design-flood level.

6.7 Computer Models

Acceptable computer models for hydrologic and some hydraulic modeling methods include:

- HEC-HMS (U.S. Army Corps of Engineers)
- HEC-1 (U.S. Army Corps of Engineers)
- SITES (National Resource Conservation Service)
- WIN TR20 (National Resource Conservation Service)
- WIN TR55 (National Resource Conservation Service)

Acceptable computer models for hydraulic modeling include:

- HEC-RAS, unsteady flow (U.S. Army Corps of Engineers)
- NWS Dynamic Wave Models (DAMBRK, DWOPER, FLDWAV) (National Weather Service)

Other models may be acceptable upon written approval of the coordinator of the Dam Safety Program.

CHAPTER 7

Hydraulic Design Criteria

7.0 Introduction

Important components of any design flood determination are the accurate representation of the elevation-area-capacity (EAC) relationship for the reservoir and the dam's spillway rating curve. Each is an essential component of the process of routing hydrographs through the reservoir.

7.1 Elevation-Area-Capacity

Determine the EAC from the best mapping available, commonly by simply measuring the area within the reservoir at all available contours. GIS techniques often suffice, giving due importance to properly accounting for islands within the overall area. In many areas of Texas, U.S. Geological Survey 1:24,000 mapping is the best available with 10-foot contour intervals. If no other updated information is available, these are generally sufficiently accurate for flood routing. In such situations, measure and plot the areas at each contour interval from the bottom of the reservoir to the first contour above the top of the dam. Then use the curve generated through these points to pull off areas at individual one-foot increments and tabulate a summation of the average area for each one-foot increment. This process will generate appropriate volumes of storage at each elevation needed for flood routing.

For existing reservoirs for which no mapping below the water surface is available, this process can be performed starting with an assumed storage at the maximum normal operating level, which will be used as the starting water surface elevation for the flood routing. Incremental storage amounts below the starting water surface do not impact hydrologic flood routing procedures.

For hydraulic routing procedures, do not use an EAC directly, as the reservoir is to be modeled using cross-sections. As described in the previous chapter, adjust the cross-sections or the distances between them so that the volumes calculated within the model are reasonably close to the actual EAC.

7.2 Spillway Rating Curves

The spillway rating curve needs to be determined for both existing and proposed reservoirs and for each component of the dam that will be used to pass flood flows during the design flood event. For many dams, this will be a combination of a principal spillway that is used for all flood events and an emergency spillway that is only used in larger, rarer events. Numerous sources describe appropriate methodologies for determining rating curves. Widely used references—for both existing and proposed spillways—include *Design of Small Dams* (U.S. Department of the Interior, Bureau of Reclamation, 1987) and NRCS methodologies.

Principal Spillways

Rating-curve development needs to reflect the unique characteristics of the individual spillway. Ungated spillways will generally be shaped as a weir—either ogee, sharp crested, or broad crested—or as a drop-inlet, or morning-glory, spillway. The weirs would utilize the simple weir equation, $Q = CLH^{3/2}$, with C set by the shape and dimensions of the structure. In planning stages, C can be assumed to be constant, but in design-level analyses C will also vary with the height of water over the crest. Gated spillways will typically require the same procedure for determining total capacity, assuming the gates are opened sufficiently so as to not affect the flow. For discharges through partial gate openings, use orifice-flow assumptions. Standard drawdown profiles are necessary, assuming unimpeded flows, in order to determine the size of the gate opening needed to switch back to weir control for the rating curve.

Rating curves for drop-inlet, or morning-glory, spillways are generally calculated assuming two different types of hydraulic control. For low flows, the circumference of the inlet operates as a weir, with discharge estimated using the weir equation. For higher flows, the inlet will work as an orifice at the narrowest portion, or throat, of the vertical column. If the spillway conduit through the dam is designed for pressure flow, then the hydraulic control may rest with the sum of energy losses acting through the closed system as a whole. In these cases, sum entrance, bend, friction, and exit loss coefficients, along with other losses that may apply, and determine the rating curve

determined for a closed, pressure-flow system. For these spillways of these types, make calculations assuming each type of flow patterns and use the lowest discharge as the controlling situation.

Points on the final rating curve developed for reservoir routing reflect the total discharge, typically more points at the lower end of the curve where the rates change more rapidly, with points plotted for key break points such as the crest of the emergency spillway or where changes in the gate operating procedures occur.

For proposed dams and new spillways, keep in mind the following concepts in order to determine the most appropriate principal spillway type:

- Generally use drop-inlet, or morning-glory, spillways when there is plenty of available flood-storage volume. The flow capacity of the spillway does not significantly increase once the reservoir reaches a level at which the spillway "plugs" or operates under pressure or orifice control. Morning-glory spillways are well suited to flood control.
- In morning-glory spillways, it is preferable that the conduit through the dam be designed to have open channel flow with depths no more than 75 percent of the height of the conduit. This will generally require a hydraulically steep slope carrying supercritical flow and a diameter greater than that of the throat of the spillway riser. If that is not practical, then a conduit significantly smaller than the riser that forces pressure flow through the conduit quickly will be preferable. Both of these concepts attempt to minimize the large pressure fluctuations that typically occur with flow transitioning from open channel to pressure flow.
- Larger morning-glory inlets will need anti-vortex devices to break up naturally occurring vortices in the entering flow.
- Gated spillways require considerable additional cost for the operating system, operating personnel, and maintenance. In addition, it is generally perceived that an owner takes on significant additional potential liability with a gated spillway.

Emergency Spillways

Emergency spillways are generally cut into an abutment and have little or no erosion protection from flows discharging through them. For this reason, only for the largest and rarest of floods are they an economical way to pass large quantities of flow. It is often accepted that erosion damage will occur should the emergency spillway operate, but that the effective cost of the very infrequent repairs is much lower than the upfront capital costs of the means to prevent the erosion. Most emergency spillways are built to prevent passage of flows for less than about the 50- or 100-year flood.

Generally, determine rating curves for emergency spillways using a backwater analysis with a steady-state water- surface profile model, such as HEC-RAS. Perform several runs with varying discharges, relating each to a reservoir water-surface elevation. Enough sections are needed such that the most upstream section has minimal approach velocity; ignore any energy losses upstream from that point. Then find the rating curve by assuming that the energy level, not the water surface elevation, at the most upstream section equates to the reservoir level for the specified discharge. Then plot these values and determine the discharges for set elevations from the curve. A standard equation for broad-crested weirs should be used only for rough planning. For such an equation to be accurate, the slope downstream from the crest would need to be steep enough to create supercritical flow down the slope, which has the consequence of causing much more damage than would occur under critical flow.

For proposed dams and new emergency spillways, consider the following in order to determine the most appropriate configuration and location:

- Locate emergency spillways such that any flows that discharge through them will not strike or flow against the dam embankment.
- Configure the channel such that critical flow will occur as far downstream as reasonably possible so as to maximize the length of any erosion path back to the reservoir. The crest can be centered, but the slope downstream from the crest should be set to effect subcritical flow—generally be a slope of about 0.25 percent or less, depending on the vegetation. An alternative would be to address the potential erosion from supercritical flow, either with the provision of an erosion-resistant surface or a determination that the final configuration will not erode sufficiently to cause a significant release of water from the reservoir.
- The crest of the spillway should be set above the 50- or 100-year flood level to minimize its frequency of operation. In general, the less frequently an emergency spillway operates, the more erosion will be acceptable.
- The roughness coefficients used in the analysis should reflect ultimate vegetative conditions of the emergency spillway, not newly constructed conditions.

CHAPTER 8

Dam-Breach Analyses

8.0 Introduction

Breach analyses for existing dams can be performed in one of two manners, *simplified* and *full*.

The simplified method is for proposed and existing small dams, and existing intermediate dams. The method is empirical and conservatively approximates the assumptions for downstream flow and extent of flooding. It will significantly reduce the preparation time and cost of inundation mapping. A full breach analysis may be used for a dam of any size if the owner wishes either to demonstrate a lower hazard classification than that determined using the simplified method or simply to estimate inundation more accurately.

For large dams, use the full breach analysis, whether evaluating a proposed or an existing dam. Also use a full breach analysis for proposed intermediate-sized dams.

8.1 Hydrologic Conditions

Perform full breach analyses for the following hydrologic conditions at a minimum:

- *Sunny-day breach:* Reservoir at its maximum normal operating pool level.
- *Barely overtopping breach:* Inflow design flood set to the percentage of the PMF or design flood that equals the top of the dam. If the dam passes 100 percent of the design flood without overtopping, this scenario does not need to be run.
- *Design-flood breach:* Inflow hydrograph equal to the full design flood.

Compare barely overtopping and design-flood breach runs to runs for the same event assuming that the dam does not fail. The simplified breach method for existing dams only reviews the impacts from a breach occurring with the reservoir at the effective crest of the dam.

If the design-flood breach overtops the dam, the analysis will need to either assume flow over the top of the dam or not. The former adds complexity to the model as the length of the dam that is overtopped is reduced by the breach width, but it also provides a more exact and less conservative determination of breach discharge for existing conditions. For dams for which upgrades to the dam are being considered, assume no flow over the crest, as if the dam were raised to contain the design flood. This is simpler and more conservative.

Initiate the breach at the peak reservoir level under each scenario.

8.2 Downstream Conditions

Under the barely overtopping and design-flood conditions, estimate inflows from downstream tributaries by extending the design-flood ellipses under the HMR-52 methodology over the associated areas. Use the size, location, and orientation of the ellipses used for determining the critical design flood without adjustment. Adjust downstream-runoff hydrographs to the same degree that the barely overtopping flood is upstream of the reservoir. Assume that runoff parameters from the dam's watershed apply, or extrapolate them appropriately to the adjacent basins. No additional calibration downstream is warranted. If the stream on which the breach hydrograph is being routed opens into a much larger river, then multiple considerations are necessary:

- DAMBRK cannot model a dendritic system and can only be used iteratively, with the initial and receiving stream each modeled separately. The stage hydrograph on the receiving stream will serve as a downstream boundary of the initial stream and the discharge hydrograph of the upstream river will serve as a lateral inflow hydrograph to the downstream river. Iterations continue until agreement is reached. HEC-RAS and FLDWAV can model a dendritic system and are usually more appropriate.
- A large volume of water discharging into the receiving stream will tend to distribute flows in both the upstream and downstream directions. Depending on the initial flow on the receiving stream, this can be seen as a reduction in flow rate or even in negative

flows traveling upstream. Therefore, sufficient cross-sections on the receiving stream need to be included upstream of the junction to allow for this phenomenon, if appropriate.

- If the drainage area of the receiving stream is too large for it to be effectively covered by the ellipses representing the design flood, an assumption on initial flows is needed. It can be assumed that significant flows will occur coincidental to the design flood on the tributary; however, their timing and magnitude will be virtually unrelated and indeterminate. Therefore a constant flow hydrograph can be assumed. As an example, this could be equal to the 10-, 50-, or 100-year flood, depending on the relative sizes of the two streams. The larger the ratio of the drainage areas (the receiving stream drainage area divided by the dam watershed area), the smaller the assumed flow level should be in the receiving stream. A reasonable level that puts the receiving stream at or slightly above flood stage before the breach flows arrive will usually produce the critical incremental impact due to the breach. This should be considered in the decision.

8.3 Breach Parameters

Breach Location

Perform the breach analysis on the component of the dam for which failure would create the worst impact downstream, regardless of the relative likelihood of failure. Analyze this component of the structure for the hydrologic conditions listed above. Review each major component of the dam to determine the maximum discharge. This review will not take into account the likelihood of failure of any component, but should look at the most likely configuration of a breach, should one occur. For each structure component, the breach section should be at the maximum portion of the structure that can contain the full bottom width of the breach. For example, if the breach width for an embankment is 200 feet wide, the location should be planned for the lowest 200 ft section of the dam above natural ground at the toe. If the channel downstream is only 50 feet wide, then it would not be in the original channel or at the maximum height of the dam. However, the 200-foot-wide breach at a higher level should be compared to a 50-foot-wide breach at the maximum section over the river channel. Use whichever has the higher peak discharge.

Breach Configuration (Embankments)

Assume breach configurations in an embankment, regardless of the failure mechanism to have, at a minimum, a width of three times the depth of water impounded under each hydrologic condition described above, with vertical side slopes. Any configuration that will produce a larger peak breach discharge will be acceptable. This configuration represents a minimum; larger values may be more appropriate in certain situations, based on the engineer's judgment.

Breach Configuration (Structural Components)

Determine breach configurations in a structural component of the dam, such as the spillway or gravity section, case by case. The minimum breach width will generally match individual elements of the structure, such as one buttress in a slab and buttress dam or one monolith in a gravity non-overflow section. Review multiple adjacent components with varying failure times in order to determine the critical configuration.

Time of Failure (Embankments)

Assume that breach configurations in an embankment—regardless of the failure mechanism—form at a minimum rate of three feet of depth of water impounded per minute under each hydrologic condition described above. Any time of failure that will produce a larger peak breach discharge is acceptable. This failure time represents a maximum. Smaller values may be more appropriate in certain situations, based on the engineer's judgment. Longer times to failure may be used in the modeling process if needed for computational stability and if it can be shown that the peak breach discharge is not sensitive to the time to failure. This is often the case for dams with large storage volumes for which the lake level does not change significantly during the elapsed time of the breach formation.

Time of Failure (Structural Components)

Determine time of failure for a breach configuration in a structural component of the dam case by case. When assuming an individual element of the structure, such as one buttress in a slab and buttress dam or one monolith in a gravity non-overflow section, the time should be instantaneous. Also review more than one adjacent component with varying failure times in order to determine the critical configuration. Base the incremental failure time of adjacent structures on the estimated time for the component to fail due to erosion of the foundation. Present justification in all cases. However, the amount of failure time per adjacent component needs not exceed 30 minutes per component in an alluvial foundation and one hour in a rock foundation. The analyst should also consider the likelihood that this failure mechanism of adjacent structural components will occur in both directions outward from the original component.

8.4 Dam-Breach Models

When using a full breach analysis method, choose appropriate models that can properly determine and route full breach flood waves. For large high-hazard dams, choose an unsteady, dynamic wave model—such as HEC-RAS, DAMBRK, or FLDWAV—to determine the downstream impacts and inundation limits of a breach. For existing small or intermediate-size dams, regardless of hazard rating, a simpler (but less accurate) hydrologic model, such as HEC 1 (HMS), is acceptable for modeling the breach flood wave and to determine inundation limits. However, a dam owner who is performing the breach analysis in order to justify a reduction from a high hazard classification should use one of the dynamic wave models.

8.5 Breach Inundation Lengths

Extend models of breach flood waves far enough downstream to allow analysis of the area that is likely to be significantly affected by a breach of the dam and to provide sufficient information for proper development and execution of an EAP. Though judgment is needed on the part of the engineer performing the analysis, the following guidelines will generally be suitable:

- *Sunny-day breach*—The floodwave should be modeled for a length downstream, beyond which approximately 75% of the flow is within the channel and no structures are threatened.
- Barely overtopping and design-flood breaches—These floodwaves should be modeled for a length downstream, beyond which the increase, due to the breach, in the peak flood level over the non-breach condition is insignificant and with no adverse effects—generally 1 ft in developed areas. In undeveloped areas, a higher differential may be acceptable.

8.6 Dams in Sequence

For design-flood PMF analyses, generally assume that upstream reservoirs remain intact, unless the design flood for the dam under consideration would overtop the upstream dam. If so, further analysis of the upstream dam may be warranted. For an upstream dam assumed to breach, assume it to breach in both the breach and non-breach runs for the downstream dam under consideration. Multiple combinations of breach and non-breach conditions for multiple dams are not necessary.

Assume that downstream dams breach if overtopped by either the breach or non-breach condition and that they do not breach if not overtopped. Assumptions possibly could differ if specific information indicates otherwise. However, as with upstream dams, multiple combinations of breach and non-breach conditions for multiple dams are not necessary. It is possible that the design flood for the upstream dam does not overtop the downstream dam, but does so with a failure of the upstream dam. In that case, assume that the downstream dam fails in the breach scenario and does not in the non-breach scenario. The failure of the upstream dams will contribute to the inflow hydrograph, and have an impact on whether the downstream dam overtops and breaches.

8.7 Inundation Mapping

As described above, perform full breach analyses for a sunny-day breach, a barely overtopping breach (if needed), and a design-flood breach. In a breach study, the barely overtopping breach flood is compared to a barely overtopping flood which does not have a breach. A similar comparison would be done using the design-flood breach, and the design flood with no breach. However, inundation mapping, which is to be used in an Emergency Action Plan, should only include the outline of the water levels reached in the sunny-day and the design-flood breach runs. Do not show non-breach runs in EAP inundation maps. The report should compare breach and non-breach runs in tabular form. As described in the following section, for studies using the simplified breach method, only one inundation condition, equivalent to a flood level at the top of the dam, is to be shown.

Base inundation maps on the best available mapping and present them as sequenced 11" × 17" maps for ease in inclusion in EAPs. Choose scales that allow for clear depiction of structures and major infrastructure, yet that do not generate a large number of sequenced maps that would be difficult to interpret during an emergency by non-technical personnel. USGS 1:24,000 maps are generally suitable, though often outdated with respect to showing structures and major infrastructure. Aerial photos, if available with reasonable clarity and scale, can also be used as a background for inundation maps.

Inundation maps should also indicate times to flood, or the time from the breach to the time that critical structures are flooded. Label these times directly on the map at occasional intervals or at critical structures.

8.8 Simplified Breach Method

For small and intermediate-size dams, the following approximation of peak discharge and inundation limits can be applied. The peak discharge from a breach, using the assumed breach criteria for the dam as described above, can be estimated by the following equation:

Eq. 8.1 $Q_B = 3.1 \cdot B \cdot H^{3/2}$, where

Q_B = peak total discharge from the breach, in cfs
B = bottom width of breach, assumed to be $3 \cdot H$ for embankments or $^1/_2$ the width of a structural spillway or concrete structure, in ft
H = maximum height of the dam, in ft

The total release discharge (Q_T) would then be:

Eq. 8.2 $Q_T = Q_B + Qs$, where

Q_S = peak discharge capacity from the spillway(s) with the reservoir at the top of the dam, in cfs

Estimate the inundation at selected locations downstream using normal flow calculations and an appropriate representation of the cross-section from available mapping. Manning's equation should be used for the normal flow calculations. Within this equation, roughness coefficients estimates should be increased by 25% to account for increased turbulence and energy losses typically associated with breach floodwaves. The peak discharge should be assumed to attenuate at a linear rate from its peak at the downstream toe of the dam, Q_T, down to Q_S over the "inundation length" of the stream downstream. This inundation length, L_U, is to be determined by the following equation:

Eq. 8.3 $L_U = 0.012 \cdot K_S \cdot \sqrt{2 \cdot C \cdot H}$, where

L_U = inundation length in miles.
K_S = Correction factor for spillway size
$K_S = Q_B/Qs$; Maximum value = 2.0
Minimum value = 0.5
C = Total capacity of the reservoir at the top of the dam, in acre-feet
H = Maximum height of the dam, in ft

If the inundation length extends past the point where the stream on which the dam is located flows into a larger stream, continue the length on the larger stream either for the full inundation length or to a point where the normal flow estimates show approximately 75 percent of the flow within the channel and no structures threatened.

For each location of interest, estimate the inundation limits by normal flow calculations, as described above, for sufficient points within the inundation length to map an approximate inundation boundary. Also estimate the limits at all identified structures—residences and infrastructure elements alike. At locations where the stream on which the dam is located flows into a larger stream, the first elevation determined on the larger receiving stream shall be used as the elevation of all backwater inundation on that larger stream upstream of where the tributary joined. The downstream surface calculations can also be performed, if desired, using a standard water-surface-profile model, such as HEC-RAS in steady-state mode, using the interpolated discharges along the inundation length.

Then use this entire approximate inundation limit for impact evaluation, hazard classification, and EAP development. Since time is not considered in this simplified method, consider all structures that may be affected as having no warning time for evaluations of hazard classifications. No times to flood need be estimated or shown on inundation maps developed using the simplified method.

CHAPTER 9

Risk Assessment and Classification of Hazard Potential

9.0 Introduction

Based upon its hazard potential, a dam is classified into one of three risk categories: low, significant, and high. Determine each hazard-potential classification, as described in the following sections, based on the consequences and losses caused by a dam breach under the most critical assumptions for the three hydrologic scenarios described in Chapter 8: sunny-day, barely overtopping (if applicable), and design-flood breaches. In hazard-potential classification, give consideration to potential adverse consequences including deaths and the loss of major infrastructure elements—infrastructure whose loss may indirectly place such a burden on a community that lives would be at risk as a result. Examples include major roads and highways, hospitals, water supply reservoirs, cooling reservoirs, and the like. Hazard assessment is also based on the potential economic risk associated with the flooding of industry, businesses, and infrastructure. This risk and the related regulatory issues are also handled within the confines of local flood protection regulations, such as those enforcing FEMA's 100-year-floodplain regulations. A hazard-potential classification does not reflect any estimate of the likelihood that a dam may fail, but only reviews the consequences of the assumed failure.

In many cases, the hazard potential classification of a dam is visually apparent from field reconnaissance and, with TCEQ approval, a description of the observations will be sufficient to support a determination. These will typically be for dams that are clearly either low or high hazard. In other cases, classifications must be based on the recommendations—in which conservatism is expected—of a licensed professional engineer knowledgeable in the field. To determine the potential of lowering the hazard classification from a conservative field evaluation, detailed studies including dam-breach analyses are to be performed for various hydrologic conditions to evaluate the effects of a failure of a dam, as described below. For this study, use either the full breach analysis or the conservative, simplified breach-inundation estimation method, as described in Chapter 8, to identify the areas at risk.

9.1 Multiple Dams

If failure of an upstream dam will not cause failure of another dam downstream, then the hazard-potential classification of the upstream dam must be determined independently from that of the downstream dam. If the failure of an upstream dam will likely cause the failure of a downstream dam, then the hazard-potential classification of the upstream dam needs to take into account the potential failure of the downstream dam.

9.2 Individual Components of a Dam

Separate components of a dam may not be assigned separate hazard classifications. Determine a single hazard classification for the entire dam. If the harmless failure of an isolated dike or levee reduces the likely failure of the dam, then the failure of the isolated component should be properly incorporated into the design and operation of the dam, as in the example of a fuse-plug spillway. However, a breach analysis to demonstrate the different incremental impacts of various components may be a useful means of allocating limited resources for repair and maintenance.

9.3 Hazard-Potential Classification

Upon completing the mapping of a breach inundation area and the identification of the population and infrastructure at risk, determine the hazard-potential classification. These guidelines do not provide any set numerical markers or definitive equations for defining the hazard classification. The evaluation is to be a conservative judgment based on the available information. General guidelines and descriptions appear in the Texas Administrative Code, Title 30, Part 1, Chapter 299.

9.4 Alternative Means of Assessing Risk and Hazard

Hazard classifications are subjective, but conservative, evaluations reflecting the quantity of structures that exist within the

breach inundation area, based on the assumption that structures reflect lives at risk. Though purposefully simple and adaptable to many situations, the procedure may not prove capable of discerning clear distinctions in marginal cases. More precise assessments of risk can be made through a variety of procedures. These alternative methods can be used to determine the population at risk within the inundation zone or the incremental value at risk from a breach relative to the costs of implementing modifications to reduce that risk. Such alternative methods are typically based on evaluating the probability of people being home when the flood passes by, or on a more exact analysis of the flood depth and velocity effects on the population exposed to the flood. Statistical economic methods can also be applied. Submission of alternative analyses such as these must include documentation of a theoretical explanation for the method, verifiable calculations, and adequate references for justifying the assumptions and parameters used. The TCEQ must approve all alternative methods.

Glossary

breach—An excavation through a dam or spillway that is capable of draining the entire reservoir so the structure—no longer considered a dam—will no longer impound water.

breach analysis—The determination of the most likely uncontrolled release of water from a dam (magnitude, duration, and location), using accepted engineering practice, to evaluate the inundation downstream.

breach area—An area that would be flooded as a result of a dam failure.

dam—Any barrier or barriers, with any appurtenant structures, constructed for the purpose of impounding water.

design flood—The flood used in the design and evaluation of a dam and appurtenant structures, particularly for determining the size of spillways, outlet works, and the effective crest of the dam.

effective crest—The elevation of the lowest point on the crest (top) of the dam, excluding spillways.

emergency action plan (EAP)—A written document prepared by the owner or the owner's professional engineer describing a detailed plan to prevent or lessen the effects of a potential failure of the dam or appurtenant structures.

emergency spillway—A secondary spillway designed to pass a large, but infrequent, volume of flood flows.

fetch—The straight-line distance across a reservoir subject to wind forces.

fuse-plug spillway—An auxiliary spillway that is intentionally blocked by an erodible berm. A higher discharge elevation is maintained during normal floods, while during extreme flooding the discharge elevation is lowered by erosion.

hazard classification—A categorization of the potential for loss of life or property damage in the area downstream of the dam in the event of a failure or malfunction of the dam or appurtenant structures. Does not represent the condition of the dam.

height of dam—The difference in elevation between the natural bed of the watercourse or the lowest point on the toe of the dam, whichever is lower, and the effective crest of the dam.

isohyet—An elliptical area representing the size, shape, and rainfall intensity of a PMP event.

inundation map—Map delineating the area that would be newly covered by water in a particular flood event.

maximum normal operating level—The highest water-surface elevation within the range of planned operating levels for the reservoir, above which floodwaters would be released.

maximum storage capacity—The volume, in acre-feet, of the impoundment created by the dam at its effective crest. Only water that can be stored above natural ground level or that could be released by a failure of the dam is considered in assessing the storage volume.

minimum freeboard—The difference in elevation between the effective crest of the dam and the maximum water surface elevation resulting from routing the design flood appropriate for the dam.

normal storage capacity—The volume, in acre-feet, of the impoundment created by the dam at the lowest uncontrolled spillway crest elevation, or at the maximum elevation of the reservoir under normal operating conditions.

population at risk—The number of people present in an area that would be flooded by a particular flood event.

principal spillway—The primary or initial spillway, designed to pass normal flows, that is engaged during a rainfall-runoff event.

probable maximum flood (PMF)—The flood magnitude that may be expected from the most critical combination of meteorological and hydrologic conditions that are reasonably possible for a given watershed.

probable maximum precipitation (PMP)—The theoretically greatest depth of precipitation for a given duration that is physically possible over a given storm area at a particular geographic location at a certain time of the year.

professional engineer—An individual licensed by the Texas Board of Professional Engineers to practice engineering in Texas, with expertise in the investigation, design, construction, repair, and maintenance of dams.

proposed dam—Any dam not yet under construction.

spillway—An appurtenant structure that conducts overflow from a reservoir.

top width elevation—The elevation of the water surface of a flood, associated with the top width of the flood cross-section.

R655-10-1. Authority.

The following rule is established under the authority of Title 73, Chapter 5a. The procedures constitute minimum requirements for dams. Additional procedures may

be required to comply with any other governing statute, federal law, federal regulation, or local ordinance.

R655-10-2. Purpose.

The purpose of this rule is to outline the procedures necessary to obtain approval to design, construct, operate, and remove a dam. This rule in no way waives the right of the State Engineer to evaluate the merits of different procedures or to require additional information before approval of any project.

R655-10-3. Applicability.

These rules apply to any dam constructed in the state with the exception of those specifically exempted by Section 73-5a-102. Some dams may have an abbreviated approval process as outlined in Section 73-5a-202.

R655-10-4. Definitions.

ABUTMENT is the part of the valley side against which the dam is constructed. Right and left abutments are those on respective sides of an observer when viewed looking downstream.

ACRE-FOOT (AC-FT) of water is the volume of water required to cover one acre, one foot deep. This is the term commonly associated with reservoir storage. It is equal to 43,560 cubic feet.

ACTIVE FAULT is a fault that has exhibited one or more of the following characteristics:

(a) movement at or near the ground surface at least once in the last 35,000 years;

(b) instrumentally determined seismicity that demonstrates a causal relationship with the fault;

(c) structural relationship to an active fault such that movement on one fault could be expected to cause movement on the other.

ACTIVE STORAGE CAPACITY is the amount of storage that can be released and utilized.

ANISOTROPY means having physical characteristics which vary in different directions.

APPURTENANT STRUCTURE means the outlet works, spillways, access structures, bridges, and other related structure to a dam.

AXIS OF DAM is the plane or curved surface, arbitrarily chosen by a designer, appearing as a line, in plan or in cross section, to which the horizontal dimensions of the dam can be referred.

BENCHMARK is a permanent physical mark of known horizontal coordinates and elevation.

BREACH is an opening or a breakthrough in a dam.

CALIBRATED WATERSHEDS are watersheds with sufficient precipitation and streamflow measuring devices and records to allow for computations of the relationships between precipitation and streamflow.

CAMBER is additional material placed on the dam crest to protect design freeboard from anticipated settlement.

CAPACITY is the maximum volume that can be stored in a reservoir below the

primary spillway level.

CAVITATION is wear on a hydraulic structure where a high hydraulic gradient is present.

CHANGE ORDER is a document used to modify approved plans or make adjustments in pay quantities.

COLLECTION PIPE is a conduit used to collect seepage waters from drainage blankets and drains and convey the water to a point downstream of the dam.

CONDUIT is a closed channel to convey water through, under, or around a dam.

CONDUIT FILTER DRAIN is a pervious filter drain around a conduit for the purpose of seepage control.

CONTROL SECTION is the section where flow passes through critical depth.

CONTOUR LINE is a line of constant elevation on a map or drawing.

CREST LENGTH is the developed length of the top of a dam.

CREST WIDTH is the developed width of the top of a dam.

CUBIC FEET PER SECOND (CFS) is a unit expressing rates of discharge. One cubic foot per second is equal to the discharge through a rectangular cross-section, one foot wide and one foot deep, flowing at an average velocity of one foot per second.

CUTOFF COLLAR is a projecting collar, usually of concrete, built around the outside of a pipe, tunnel, or conduit, to lengthen the seepage path along the outer surface of the conduit.

DAM is any artificial barrier or obstruction, together with appurtenant works, if any, which impounds or diverts water.

DEAD STORAGE is the storage that lies below the invert of the lowest outlet and that cannot be withdrawn from the reservoir without pumping.

DEFORMATION ANALYSIS is a study of how a dam will permanently deform as a result of strains caused by seismic loads.

DENTAL CONCRETE is concrete used to level discontinuities in dam foundations and abutments.

DESICCATION is the process of cracking of soils due to shrinkage during drying.

DIFFERENTIAL SETTLEMENT is unequal settlement of a structure or soil mass, often leading to excessive stresses or unacceptable strains.

DISPERSIVE CLAYS are clays whose particles detach in the presence of water and may be transported by the water, leading to a piping failure.

DRAINAGE AREA or watershed is the area that drains naturally to a particular point on a river, stream or creek.

DRAINAGE BLANKET is a drainage layer placed directly over the foundation material.

DRAINAGE WELLS or pressure relief wells are wells or boreholes usually downstream of impervious cores, grout curtains, or cutoffs, designed to collect and control seepage through or under a dam, so as to reduce uplift pressures under or within a dam. A line of wells forms a drainage curtain.

DRAWDOWN is the lowering of a reservoir's water surface level due to releases.

DRAWINGS are graphical details of proposed construction.

DROP STRUCTURES are permanent structures used to facilitate the vertical downward movement of water without causing erosion.

DYNAMIC ANALYSIS is an analysis which predicts the stability and/or deformation of a dam due to seismic loads.

EARLY WARNING SYSTEM is an automatic device used to alert downstream interests of existing or impending high flows caused by storms or dam failures.

EMERGENCY ACTION PLAN is a predetermined plan of action to be taken to reduce the potential for loss of life and property damage in an area affected by a dam break.

EMERGENCY SPILLWAY, or secondary spillway, is the spillway designed to convey excess water generated by unusual hydrological events through, over or around a dam.

ENLARGEMENT is any change or addition to an existing dam or its appurtenant works which increases, or may increase, the maximum quantity of water which can be stored therein.

EPICENTER is the point on the earth's surface directly above the site of initial movement on the fault.

EXIT CHANNEL is an open channel, located downstream from any conduit or spillway, which conducts the flow to a point where it may be released without jeopardizing the dam.

FACE, in reference to a structure, is the external surface that limits the structure.

FILTER or filter zone is a band or zone that is incorporated in a dam and is graded, either naturally or by selection, so as to allow seepage to flow across or down the filter without allowing the migration of material from zones adjacent to the filter.

FLASHBOARDS are lengths of timber, concrete, or steel placed on the crest of a spillway to raise the water level but that may be quickly removed in the event of a flood, either by a tripping device or by a deliberately designed failure of the flashboards or their supports.

FLOOD ROUTING is a computation of the changes in the rise and fall in stream flow or reservoir levels as a flood moves downstream. The results provide hydrographs of flow or elevation versus time at given points on the stream or in a reservoir.

FLOOD STAGE is the stage or elevation in which overflow of the natural banks of a stream or body of water begins.

FLOWLINE or invert is the lowest point in a water conveyance structure where water can flow.

FOUNDATION OF DAM is the natural material on which the dam structure is placed.

GALLERY is a permanent accessible structure within the interior of a dam used for seepage collection, monitoring, and remedial work.

GEOLOGIST is a person with a degree in geology or a related field from an accredited college or university with at least three years of experience in engineering geology.

GEOMEMBRANE is a term for a geosynthetic which is designed to be an

impermeable barrier.

GEOSYNTHETICS is a broad term used to describe manmade fabrics used in geotechnical applications.

GEOTEXTILE is a term for a geosynthetic which is designed to be a filter, a drain, act as reinforcement, or for separation.

GROIN is that area along the contact or intersection of the face of a dam with the abutments.

GROUT CURTAIN is a barrier to reduce seepage under a dam, produced by injecting grout into a vertical zone in the foundation.

HYDRAULIC FRACTURING is the fracturing of soil materials due to excessive fluid pressures.

HYDRAULIC HEIGHT is the vertical dimension of a dam as measured from the natural streambed at the downstream toe to the elevation of the water surface at the crest of the primary spillway.

HYDRAULICS is the science of the static and dynamic behavior of fluids.

HYDROGRAPH is a graphical representation of discharge, stage, volume, or other hydraulic property, with respect to time, for a particular point.

HYDROLOGY is the study of the properties, distribution and movement of water on the earth's surface, in the soil and underlying rocks.

INCREMENTAL DAMAGE ASSESSMENT (IDA) is an analysis showing the influence of a dam failure when superimposed upon an extreme hydrologic event.

INDEPENDENT CONSULTANT is a consultant used, in addition to the owner's engineer, to assess the design, construction, investigation or operation of a dam.

INFILTRATION RATE is the rate at which a given soil can accept surface water.

INFLOW DESIGN FLOOD (IDF) means the flood hydrograph which is used to size a dam's spillway.

INITIAL FILLING PLAN is a written procedure used during the first filling of a reservoir.

INLET CHANNEL is an open channel upstream from a spillway or conduit.

INTERNAL EROSION is piping.

INUNDATION MAPS show areas that would be subject to flooding due to storm conditions or failure of a dam.

LIQUEFACTION is the sudden loss of strength or stiffness of a soil resulting from dynamic loading as from earthquakes.

LOG BOOM is a floating device intended to prevent large floating debris from being carried into a spillway.

LOW-LEVEL OUTLET is a conduit from a reservoir, generally used for lowering the reservoir or for providing downstream releases.

MAGNITUDE of an earthquake is a quantity characteristic of the total energy released by an earthquake.

MAXIMUM CAPACITY is the maximum volume of water that can be stored in a reservoir when filled to the crest of the dam.

MAXIMUM CREDIBLE EARTHQUAKE (MCE) -- All active sources of seismicity with the potential to impact the stability of a dam should be assigned a maximum credible seismic event. The event which has the greatest potential to cause damage at the site will be defined as the Maximum Credible Earthquake.

NAPPE is the free-falling stream from a weir.

NORMAL FREEBOARD is the vertical distance between the primary spillway overflow crest and the top of the dam.

ONE HUNDRED YEAR FLOOD means the flood having a one percent probability of being equalled or exceeded in any given year.

ONE HUNDRED YEAR PRECIPITATION means the precipitation having a one percent probability of being equalled or exceeded in any given year.

OPERATING BASIS EARTHQUAKE (OBE) -- All active sources of seismicity with the potential to impact the stability of a dam should be assigned an operating basis seismic event. This event is considered to have a return interval of at least 200 years. The event which has the greatest potential to cause damage at the site will be defined as the Operating Basis Earthquake.

OWNER includes all who own, control, operate, maintain, manage, or propose to construct a dam; also, their agents, lessees, trustees, and receivers.

OWNER'S ENGINEER is a professional engineer, licensed in Utah, retained to design, construct, monitor, operate, or evaluate a dam.

PEAK FLOW is the maximum instantaneous discharge that occurs during a flood. It is coincident with the peak of a flood hydrograph.

PERVIOUS ZONE is a part of the cross section of an embankment dam comprising material of high permeability.

PHREATIC SURFACE is the free surface of ground water at atmospheric pressure.

PIEZOMETER is an instrument for measuring pore water pressure within soil, rock, or concrete.

PIPING is the progressive development of internal erosion by seepage, appearing downstream as a hole or seam, discharging water that contains soil particles.

PLANS are engineering drawings, specifications, and design reports supporting the design of a dam and detailing the construction of the dam.

POROUS INTERVAL is the portion of a piezometer where infiltrating water is allowed to act on the device.

PRINCIPAL SPILLWAY is the main spillway for normal operating conditions.

PROBABLE MAXIMUM FLOOD (PMF) is the flood that may be reasonably expected from the most severe combination of critical meteorologic and hydrologic conditions that are possible in the region.

PROBABLE MAXIMUM PRECIPITATION (PMP) is the maximum amount of precipitation that could be expected to fall on a drainage under the most severe meteorologic condition.

PSEUDO STATIC ANALYSIS is an approximate method for predicting the dynamic stability of a structure using static loads.

RESERVOIR AREA is the surface area of a reservoir when filled to a given water

elevation.

RESERVOIR RIM is a term used to describe the land forms around the perimeter of a reservoir which could have an adverse impact on the dam or reservoir due to movement.

RESERVOIR STAGE is the measure of the depth or elevation of water in a reservoir relative to an established datum.

RESIDUAL FREEBOARD means the vertical distance between the maximum water surface during a given hydrologic event and the top of the dam.

RESPONSE SPECTRUM is a graphical representation of actual motions, including displacement, velocity, and acceleration, caused by seismic events.

RIPRAP is a layer of large stones, broken rock, or precast blocks placed on the upstream slope of an embankment dam, on a reservoir shore, or on the sides of a channel, as a protection against waves, ice, and scour.

SEDIMENT POOL is the portion of the reservoir allotted to the accumulation of submerged sediment during the design life of the dam.

SEISMIC means pertaining to an earthquake or earth vibration.

SLOPE PROTECTION is the protection of an embankment slope against wave action or erosion.

SPECIFICATIONS are written descriptions of the proposed construction.

SPILLWAY is an open or closed channel, conduit or drop structure used to convey excess water through a reservoir. It may contain gates, either manually or automatically controlled, to regulate the discharge of the water.

SPILLWAY EVALUATION FLOOD (SEF) is the flood that may be expected at the dam from applying the SEP to a given watershed.

SPILLWAY EVALUATION PRECIPITATION (SEP) is the lowest, site specific, precipitation estimate allowed by the State Engineer, used in the analysis of new, existing, high or moderate hazard dams.

STAFF GAGE is a permanent instrument or device used to read reservoir stage.

STANDARD OPERATING PLAN is a written procedure outlining the operation and maintenance of a dam and its appurtenant structures and equipment.

STATE ENGINEER is the Director of the Utah Division of Water Rights.

STILLING BASIN is a basin constructed to dissipate excess energy of waters emerging from a spillway or outlet.

STOPLOGS are beams placed on top of each other with their ends held in guides on each side of a channel or conduit.

STORAGE CAPACITY is the volume of water which can be stored at the elevation of the primary spillway, including both active and dead storage.

STRUCTURAL HEIGHT means the vertical dimension of a dam as measured from the natural streambed at the downstream toe of a dam to the top of a dam.

SURVEY MARKER is a permanent physical mark on a dam or appurtenant structure used to measure changes in horizontal and vertical movement.

TECTONICS is a study of the broader features of the earth's crust and the causes of its deformation.

TEST BORINGS are holes drilled to determine the type and physical properties of subsurface materials.

TEST PIT is an excavation used to evaluate and observe subsurface materials.

TOE OF DAM is the junction of a dam face with the foundation. For an embankment dam, the junction of the upstream face with ground surface is called the upstream toe, and the junction of the downstream face with the ground surface is referred to as the downstream toe.

TRANSITION ZONE is a zone of material used to provide filter requirements between two zones of material which do not meet filter requirements.

TRASH RACK is a screen located at an intake to prevent the entry of floating or submerged debris.

UNGATED OUTLET is an outlet that allows uncontrolled flow through or around a dam.

UNIT HYDROGRAPH is a hydrograph which shows the rates at which runoff occurs for one inch of storm runoff from a drainage area.

UPLIFT is the upward water pressure in the pores of a material or on the base of a structure.

WATER STOPS are strips of material used to prevent leakage through joints between adjacent sections of concrete.

WEIR is a device used to measure or control water.

R655-10-5. Hazard Classification.

Hazard classification of a dam places the dam into a category based upon the consequences of failure of the dam. The State Engineer is the ultimate authority on the hazard classification designation for a given dam.

R655-10-5A. Hazard Classification--Criteria.

The hazard classification analysis should include a determination of the threat to human life and property damage in the event of the failure of a dam. In some cases the classification can be assigned by observance of the downstream development in relationship to the location of the dam. In other cases it will be necessary to prepare inundation maps to determine the downstream consequences of failure. In preparing the inundation maps, the following criteria relative to the dam should be used.

1. No concurrent flooding conditions exist.

2. The reservoir level is at the emergency spillway crest.

3. The low level outlet is discharging at capacity.

4. The breach times and geometric parameters used to simulate the dam failure should be acceptable to the State Engineer and consistent with accepted practices.

5. The inundation study should be carried downstream to a point that the breach flows are contained within the banks of the natural channel or a downstream reservoir.

R655-10-5B. Hazard Classification--Exceptions.

It should be noted that the hazard classification as outlined in R655-10-5A may not be an absolute indicator of the hazard of the dam, since a dam failure superimposed on natural flooding conditions may cause incremental risk to life and

property. Although this scenario is not normally used in the hazard classification process, it is a factor the owner should consider in determining their overall liability. Under special circumstances, as determined by the State Engineer, a hazard classification may be determined giving consideration to concurrent flooding events.

R655-10-6. Approval Processes.

There are two procedures for obtaining approval from the State Engineer to construct or modify a dam. The first procedure requires the filing of an application, while the second procedure requires the submission of plans. No approval will be given for any dam unless the water rights are in order.

R655-10-6A. Application Procedure.

For dams not requiring submission of plans as outlined in Section 73-5a-202, an application must be submitted and approved by the State Engineer. Blank applications are available upon request. Upon reviewing the application the State Engineer may approve it, reject it, return it for correction, or approve it with conditions.

R655-10-6B. Submission of Plans.

A. All projects requiring submission of plans should include a package including the drawings, specifications, design reports, and any other information which will assist in reviewing the project. The amount of information generated becomes more involved as the size and hazard rating of the structure increases. The following guidelines are included to alert the designer to the basic information required.

B. All drawings submitted should comply with the following:

1. The size of all drawings submitted for review, shall be 24 inches by 36 inches. Following approval of the project by the State Engineer, two sets of 11 inch by 17 inch drawings shall be submitted.

2. All drawings should include a bar scale to allow for accurate scaling of reductions.

3. All drawings shall have a title block in the lower right corner showing the project name, the owner's name, the sheet number, and the date of preparation of the plans.

4. All drawings shall have provisions for noting the dates of any modifications.

5. Each drawing shall include the signature and seal of the responsible engineer. Geological drawings should also be signed by the responsible geologist.

C. Drawings to be included in plans are:

1. Title sheet, including:

a. General location map including access roads.

b. Signature block for owner's acceptance.

c. Index of drawings.

d. Reference to the water rights for the reservoir.

e. Reservoir stage/storage curve.

f. Rating curves for outlets and spillways.

2. Plan view of reservoir, including:

a. Existing topography.

b. Borrow areas.

c. Supply canals and pipelines.

d. Suitable contour lines.

e. Clearing limits.

f. Waste areas.

3. Plan view of dam, including:

a. Location of all pertinent features.

b. A survey tie, to an outside section corner, where the longitudinal axis of the dam intersects the axis of the original stream channel or the low level outlet.

c. Clearing limits.

4. Longitudinal profile, showing:

a. Original ground line.

b. Location of core trench or other cutoff features.

c. Location of outlets and spillways.

d. Camber and anticipated settlement.

5. Typical cross-sections of dam, showing:

a. Embankment geometrics including internal zones.

b. Slope protection.

c. Cutoff.

d. Delineation of embankment on natural ground surface.

e. Freeboard.

f. Internal drainage.

g. Limits of foundation excavation.

6. Plan, profile, cross sections and details of all outlets, spillways, and other structures.

7. Structural details for reinforcing steel, metal fabrication, or waterstops.

8. Site geology map of the damsite and reservoir basin including locations of all borings and test pits.

9. Longitudinal geologic profile of both the dam and reservoir, showing:

a. Original ground line.

b. Location and orientation of borings.

c. Geological profile showing pertinent lithologic, hydrologic, and structural information.

10. Logs of borings with classifications of soil and rock, results of water pressure tests and other downhole material property tests, soil classification, standard penetration tests, core recovery, rock quality designations, and strength tests.

11. Any additional drawings such as instrumentation details necessary to construct the project.

D. Specification Requirements.

The State Engineer must review and approve all technical specifications for a proposed project. A partial list of specifications directly related to dam safety follows:

1. Site Preparation.

a. Clearing and Grubbing.

b. Soil Stripping.

c. Structure Removal.

d. Diversion and Care of Stream.

2. Foundation Preparation.

a. Foundation Dewatering.

b. Relief Wells.

c. Grouting.

d. Cutoffs.

e. Abutment Contacts.

f. Exploration.

g. Dental Concrete.

3. Earthwork.

a. Excavation.

b. Earth Fill.

c. Drain Fill.

d. Rock Fill.

e. Material Handling.

f. Testing Procedures.

4. Concrete and Reinforcement.

a. Concrete Mixing and Placement.

b. Steel Reinforcement.

c. Admixtures.

d. Curing and Curing Compounds.

e. Joint Fillers and Waterstops.

5. Outlets.

a. Water Control Gates and Valves.

b. Air Vent.

c. Operating Equipment.

d. Bedding Requirements.

6. Aggregates and Rock.

a. Drain Fill and Filters.

b. Concrete Aggregates.

c. Riprap.

7. Erosion Control.

8. Miscellaneous Structural Work.

a. Metal Fabrication and Installation.

b. Instrumentation.

9. All technical specifications should also include testing intervals to assure compliance with the specifications.

E. Design Report Requirements. The design report should include all information used to design the dam, including assumptions made and methodology used with sufficient documentation. Any building codes or design manuals used in the design should be referenced, including the year of publication of the source. If the design report is a product of a team effort, the names of all persons producing the report should be included along with the sections they prepared. Examples of items to be included in the design report are as follows:

1. Hydrology calculations for determining the spillway requirements.

2. Hydraulic characteristics of the outlets and spillways.

3. Subsurface investigation including logs of test borings and geologic cross-sections.

4. Material testing results and the location and logs of test pits.

5. Foundation treatment and abutment contact design.

6. Calculations for the reinforced concrete design and the loading conditions utilized.

7. Stability analysis of the dam, abutments, and reservoir rim, including appropriate seismic loading, safety factors and embankment zone characteristics.

8. Geological investigations including:

a. Regional perspective of the site's geologic and seismic setting at a scale appropriate to the geologic complexity of the area.

b. Seismic evaluation establishing the relationship of the site to all seismic features of concern and the potential for reservoir induced seismicity.

c. Site geology of areas affected by construction activities and appropriate adjacent areas.

d. Plans to compensate for any geological weakness in the dam foundation, abutment areas, and reservoir rim.

9. Seepage considerations including the cutoff trench design and internal drainage design.

10. Post-construction monitoring or alarm systems.

R655-10-7. Independent Consultant Review.

The State Engineer may require an independent consultant review to assess the adequacy of the design, construction, or operation of a dam. For purposes of these rules, an independent consultant review is a review of the owner's engineers' work in addition to the review provided by the State Engineer.

R655-10-7A. Review of Design.

The following situations will require an independent consultant review of the design of a new dam or significant enlargement of an existing dam.

1. All high hazard dams, which have a structural height over 50 feet and an active storage over 1,000 acre-feet, will require an independent review unless exempted in writing by the State Engineer.

2. Any high or moderate hazard dam which, in the opinion of the State Engineer, has a unique problem requiring additional review.

3. Any high or moderate hazard dam whose design is not typical of dams normally built in the state and is thus beyond the technical abilities of the State Engineer's dam safety staff.

4. If the owner's engineer and the State Engineer cannot reach an agreement on the design of a dam.

5. If the owner specifically requests an independent consultant review.

R655-10-7B. Review of Construction.

The State Engineer may require an independent consultant review when peculiar problems are noted during construction of a dam or the dam is not being constructed as per approved plans and specifications.

R655-10-7C. Operation.

The State Engineer may require an independent consultant review of the operation of a dam including initial filling plans, standard operating plans, emergency action plans, and performance of the dam if, in his opinion, conditions require a review.

R655-10-7D. Selection of Independent Consultants.

Upon notification to the owner, the owner will select independent consultants to conduct the required review. Prior to contracting with the proposed consultants, they must be approved by the State Engineer.

R655-10-7E. Qualifications of Independent Consultants.

All independent consultants must have a minimum of ten years' experience related to dams. In the case of engineers, they need to be licensed in the state where they reside, unless exempted by the State Engineer. All proposed consultants must demonstrate that they have the expertise to investigate problems identified and that they have insignificant past association with the dam in question.

R655-10-7F. Scope of Work.

In requiring the owner to obtain the services of an independent consultant, the State Engineer will include specific items needing investigation, the format for the reports submitted by the independent consultant, and a timetable for completion of the investigations.

R655-10-7G. Purpose of Independent Consultants Investigations.

The purpose of an independent consultant is to provide additional technical expertise and to insure safety issues are addressed. Conclusions generated by the independent consultants are not binding on the State Engineer.

R655-11-1. Authority and Applicability.

The following rule is established under the authority of Title 73, Chapter 5a. The procedures constitute minimum design requirements for dams. Additional procedures may be required to comply with any other governing statute, federal law, federal regulation, or local ordinance. These rules apply to any dam constructed in the state with the exception of those specifically exempted by Section 73-5a-102 and those dams not requiring plans as outlined in Section 73-5a-202.

R655-11-2. Purpose and Scope.

A. The following minimum design requirements will serve as a guide to the owner's engineer. It should be noted that these are minimum requirements for general conditions and may be changed when dealing with a specific structure. Designs below the minimum requirements must be approved in writing by the State Engineer prior to final design submittal of the project. The design requirements are quite rigid, allowing little latitude in the utilization of new materials and unproven construction methods. The burden to show adequate protection of public interests with the use of new materials or unproven methods rests with the owner's engineer.

B. The following minimum design requirements apply to all proposed dams where applicable. Since the vast majority of dams in the state are earthfill or rockfill dams, the focus of the design criteria is on these dams. Specific structural design

criteria for concrete dams is not given. The State Engineer, upon approval in writing, will accept structural design criteria for concrete dams developed by other dam regulatory or dam design agencies, providing it reflects state-of-the-art criteria for the design of concrete dams and does not conflict with the following rules.

R655-11-3. Definitions.

Definitions are as outlined in R655-10-4.

R655-11-4. Hydrologic Design.

In order to arrive at an Inflow Design Hydrograph or Inflow Design Flood (IDF) more representative of actual conditions in Utah, the State Engineer has commissioned, or has been involved in, numerous studies to supplement the National Oceanic and Atmospheric Administration's (NOAA) Report entitled "Hydrometeorological Report No. 49 (HMR49) - "Probable Maximum Precipitation Estimates, Colorado River and Great Basin Drainages". The results of most of these studies are used to better identify soil conditions, discharge coefficients, and unit hydrograph parameters. The results of two of the studies are used directly to refine the calculation of the design rainfall values. Both studies were completed by Donald Jensen of the Utah Climate Center and are entitled, "2002 Update for Probable Maximum Precipitation, Utah 72 Hour Estimates to 5,000 sq. mi. - March 2003" (USUL) and "Probable Maximum Precipitation Estimates for Short Duration, Small Area Storms in Utah - October 1995 "(USUS). All of HMR49, Table 1, page 4 of USUL, and Table 15, pages 74-75 of USUS are hereby incorporated by reference. All High Hazard and Moderate Hazard dams in Utah must use the precipitation values obtained from the use of all three publications. To avoid confusion, precipitation values obtained from HMR49 exclusively will be referred to as the Probable Maximum Precipitation (PMP), while those obtained from using HMR49 in conjunction with USUL or USUS, will be referred to as the Spillway Evaluation Precipitation (SEP). The resulting hydrographs generated will be referred to as the Probable Maximum Flood (PMF) and the Spillway Evaluation Flood (SEF) respectively.

R655-11-4A. Inflow Design Hydrograph Determination.

A) In Utah, the IDF for all High and Moderate Hazard Dams will be the SEF. It will be necessary to calculate both the 72 hour SEF using HMR49/ USUL as well as the 6 hour SEF using HMR49/ USUS. Both of these hydrographs must be routed through the reservoir to determine which one represents the most extreme event.

B) Once the critical SEF has been determined, it must be compared to a flood generated by the 100 year, 6 hour (for local storms), or 100 yr, 24 hour (for general storms) precipitation applied on a saturated watershed. If the routed 100 year event, including appropriate allowances for freeboard, is more critical than the SEF it must be used as the minimum IDF. This 100 year flood should also be used as the IDF for all Low Hazard Dams.

R655-11-4B. Freeboard Requirements.

All dams must have a normal freeboard above the crest of the principal spillway capable of containing the maximum wave action considering site wind-duration and fetch control characteristics. Wave action includes wave height and maximum runup, as well as reservoir setup against the embankment slope. Unless otherwise justified by specific data acceptable to the State Engineer, an extreme wind velocity (fastest mile) over land of 100 miles per hour should be considered. In addition, while routing the 100 year precipitation event through the spillway, sufficient residual freeboard must be available to control wave action from a fetch controlled 50 miles per hour wind. In no case will the normal freeboard be less than three feet for high

and moderate hazard dams. The State Engineer may reduce the three feet minimum freeboard requirement for low hazard dams based upon a review of the relative increase in risk associated with this reduction.

R655-11-4C. Spillways.

In designing the spillway for a dam to pass the IDF, the State Engineer will consider the use of a principal spillway in conjunction with emergency spillways. The principal spillway must be designed so that no structural damage will occur during passage of the IDF. Emergency spillways, including Fuse Plug Spillways, may be designed so that some damage may be expected during use provided the anticipated damage does not represent a threat to the dam. Sunny day failure modeling of Fuse Plug Spillways may be required to determine if they are creating an additional unacceptable risk. Overtopping of the dam will not be considered as an emergency spillway on earthfill dams, unless it can be demonstrated that the dam is protected from erosion, and the duration of overtopping will not saturate the dam and reduce its stability.

R655-11-4D. Infiltration Rates.

The State Engineer will accept an IDF using SEP values in conjunction with soil moisture conditions representative of historical maximums. If the design engineer is using infiltration rates which represent something less than saturated conditions, information should be submitted to justify the lower soil moisture selection.

R655-11-4E. Flood Routing.

A. In routing the IDF through the reservoir, the initial water surface should reflect conservative estimates which would exist at the time of the flood event. Unless documentation can be provided to the contrary, it should be assumed that all low level outlets are closed during routing of the IDF. For dams receiving inflow from pipelines and supply canals, it should be assumed these additional sources are operating at capacity during the flood event. In the event the spillway is gated or has "stop logs", which are only allowed on existing dams, documentation must be provided to show the gates are automated or operational procedures are in place to insure that the gates can be opened or the stop logs removed in a timely manner.

B. The SEF can be routed so the maximum water surface is at an elevation equal to the lowest point on the crest of the dam with no residual freeboard.

C. In generating the IDF, the basin characteristics used and the parameters used to generate the unit hydrograph should be based on the best information available. Unit hydrographs generated from historical records or calibrated watersheds should be used, where data is available, rather than using synthetic procedures.

R655-11-4F. Incremental Damage Assessment for High and Moderate Hazard Dams.

The State Engineer may, at his discretion, accept an IDF less than the SEF based on the results of an Incremental Damage Assessment (IDA) which shows that failure of the dam would cause insignificant incremental damage to property and no additional threat to human life. The State Engineer may consider the use of early warning systems in evaluating the threat to human life. In requesting the acceptance of an IDF determined from an IDA, documentation must be furnished that the owner of the dam is aware that the design reflects something less than the SEF and they are willing to accept the additional liability. In no case will the State Engineer approve an IDF generated by something less than the applicable 100 year flood event. The resulting selected IDF, based on the IDA, should be reported as a percent of the SEF.

R655-11-4G. Historical Records.

In some cases it may be appropriate to use historical streamflow records to generate a 100 year flood. If these records are used as a basis for the IDF, they should be accompanied by the Synthetic IDF established by using the 100 year precipitation. Following a review of the data, the State Engineer will make a determination of which flood will be used as the IDF.

R655-11-5. Seismic Design.

A. Because each dam site has a unique seismic and geological setting, detailed direction cannot be provided for seismic design which is applicable to all dams. Rather, an order of evaluation is presented beginning with more simplified methods and progressing, as required, to more rigorous procedures. In determining the sophistication of analysis required, the State Engineer may consider factors including consequences of failure, available freeboard, duration of reservoir pool, and site geometry. Regardless of the method of analysis, the final determination of seismic adequacy of a dam will be based on all pertinent factors involved and not strictly on the numerical analysis. The order of progression of the seismic analysis follows:

1. Undertake geological and seismological investigations to determine the potential for earthquakes and associated ground motions at the site, including the source and magnitude of the earthquakes to be considered and the selected motions, including potential fault rupture.

2. Undertake field and laboratory investigations of the dam and foundation materials to determine their properties and liquefaction potential.

3. Undertake an appropriate analysis for seismic events to predict factors of safety against slope failures, structural deformations, and liquefaction resulting from earthquake shaking or fault rupture.

4. Incorporate defensive design measures based on the analysis and proven practices.

B. In many instances, an adequate seismic analysis can be determined from the geological study and determination of the general properties of the dam and foundation. Other projects may require more detailed investigations and analyses. Decisions as to seismic safety and risk should be made as the analysis progresses and the extent of further investigations required after each step should be determined following consultation with the State Engineer as necessary.

R655-11-5A. Geological and Seismic Study.

A review of the seismic or earthquake history of the region will be performed to establish the relationship of the site to known faults and epicenters. This will be based primarily on review of existing maps and technical literature and should include major earthquakes during historic time, epicenter locations and magnitudes, and the location of any major or regional fault traces. Geologic conditions at or near the dam site that might indicate recent fault or seismic activity should be included. Resulting design earthquakes and associated site ground motion parameters will be selected considering all available evidence including tectonic and seismological history. The ground motion parameters to be selected for the site will consist of those that are needed by the analyses that are appropriately selected for design and may include peak accelerations, velocities, displacements, response spectra, and acceleration time histories. Both the Maximum Credible Earthquake (MCE) and the Operating Basis Earthquake (OBE) will need to be investigated for all projects. The MCE should be evaluated from the following analyses:

1. A deterministic analysis from active faults in the region surrounding the dam.

2. Unless otherwise required by the State Engineer, the random or background event will consist of a minimum magnitude 6.5 event having a peak horizontal site acceleration obtained from a map, herein incorporated by reference, produced by the USGS and entitled "Peak Accelerations (%g) with 5,000 Year Return Time; no fault-specific sources." Alternatively, site specific evaluations may be performed to define ground motions for this event if the methods used and assumptions made are acceptable to the State Engineer. At the discretion of the State Engineer, the OBE requirement may be waived.

3. The OBE will be determined by probabilistic methods acceptable to the State Engineer.

R655-11-5B. Determination of Dam and Foundation Material Properties.

Results of the geological and seismological studies may be sufficient to evaluate seismic safety. However, if it appears the dam cannot safely withstand the earthquake motions or if sufficient information is not available to make an adequate determination, the next step of a phased evaluation program would be a field investigation and laboratory testing program. Field investigation should include a sufficient number of borings and test pits to accurately define the embankment, foundation, and abutment materials types, properties, and extent. Particular care and sufficient field data should be obtained where potentially liquefiable soils are present. In place and laboratory testing should be performed to adequately assess the material properties under the anticipated dynamic conditions.

R655-11-5C. Method of Analysis.

A. Procedures are available for selecting design earthquakes and associated site-specific motions and for assessing the resistance of dams to these earthquake motions. Procedures and techniques for evaluating the effects on dams from estimated earthquake ground motions range from simplified concepts to comprehensive dynamic analyses. When the degree of sophistication of analytical procedures is far advanced, however, uncertainty is produced in the results by imperfect knowledge of input parameters obtained through field exploration and laboratory testing programs.

B. The extent or scope of studies, investigations, tests and analyses which may be required to adequately determine the seismic safety of a dam will vary from site to site. In general, the following physical factors will indicate a high priority and a greater degree of investigations and analysis:

1. Proximity to known active faults.

2. Indications of low-density materials in the dam or foundation.

3. Zones of high pore pressures or potential liquefaction.

4. Indications of marginal static stability.

5. Lack of adequate construction records for existing dams.

C. Regardless of these factors, however, one of the major considerations will be the "consequences of a failure". High and moderate hazard structures with permanent pools which could result in loss of life or extensive property damage from a failure will, in general, require a greater scope of investigation and analyses.

D. Following are the general analysis requirements for MCE design earthquakes:

1. Embankments, foundations, and abutments not subject to liquefaction:

a. For a maximum acceleration of 0.2g or less, or a maximum acceleration of .35g

or less if the embankment consists of clay on a clay or bedrock foundation, a pseudo-static coefficient which is at least 50 percent of the maximum peak bedrock acceleration at the site should be used in the stability analysis. The minimum factor of safety in an analysis should be 1.0.

b. For a maximum peak acceleration greater than indicated above, a deformation and settlement analysis should be performed to estimate anticipated total crest movement. The evaluation should be performed for both the upstream and downstream slopes of the dam. Total crest movement should consider potential accumulation of movement from both sides. The minimum factor of safety against overtopping should be 2.5.

2. Embankment, foundation, or abutment soils subject to liquefaction:

a. A liquefaction analysis should be completed with enough detail to establish the boundaries of the liquefiable soils and the physical characteristics of the soil following liquefaction.

b. A post earthquake stability analysis should be performed to show that the embankment is stable after liquefaction occurs with a minimum factor of safety of 1.2.

c. Calculated deformation and settlement of the embankment total crest movement should result in a minimum factor of safety, against overtopping, of 3.0.

3. Other more sophisticated analytical procedures may be required at the discretion of the State Engineer, where conditions warrant greater detailed studies.

E. In addition to analysis of deformation and liquefaction, it will be necessary to assess the potential for internal erosion and cracking. Judgment must be used to decide whether or not erosion would tend to be self- healing as a result of filtering.

F. Construction of dams on active faults will not be allowed unless evidence is presented to, and approved by, the State Engineer that the dam can safely withstand the anticipated offset.

G. Evaluation of a dam under OBE conditions should be completed by similar methods to those described for the MCE. Under the OBE loading conditions the dam should experience no significant damage.

R655-11-5D. Design Measures.

Design of new dams should include measures, which provide multiple lines of defense, that enhance their performance under seismic loading. Measures may include:

1. Significantly wide transition and drainage zones in the embankment of material not vulnerable to cracking.

2. Controlled compaction of embankment zones to enhance dynamic performance.

3. Removal or treatment of foundation materials of low strength or density.

4. Enhanced ability to drain reservoir.

5. Flare the embankment core at abutment contacts.

6. Locate the core to minimize saturation of materials.

7. Stabilize slopes around the reservoir rim.

R655-11-5E. Appurtenant Structures.

The effects of seismic loading should also be considered during the design of all appurtenant structures.

R655-11-6. Embankment Requirements.

All embankment designs should meet the following criteria.

R655-11-6A. Factors of Safety.

A. All dams should meet the following criteria for factors of safety under normal loading conditions.

TABLE

Condition	Minimum Factor of Safety
End of Construction Case--upstream and downstream slopes	1.3
Steady State Seepage--upstream and downstream slopes (full pool)	1.5
Instantaneous Drawdown--upstream slope	1.2
OR	
Actual Drawdown--upstream slope	1.5

B. All factors of safety should be generated by methodology acceptable to the State Engineer. In undertaking the analysis, the effects of anisotropy should be considered and a ratio of horizontal to vertical permeability of at least nine should be used in the seepage analysis. Ratios of up to 100 should be considered if the material types and construction techniques will cause excessive stratification.

C. The strengths used in the stability analysis should be obtained from tests which best model the situation being analyzed.

D. The analysis of the upstream slope stability for actual drawdown should consider drawdown rates which the low level outlets are capable of generating. Actual residual pore pressures should be used.

E. For low hazard dams the State Engineer may waive the requirements of a stability analysis, including a seismic analysis, if it can be demonstrated that conservative slopes and competent materials are used in the dam, and seismic problems (i.e., liquefiable materials, active faults close to the dam) are not present.

F. Stability evaluations where residual strengths are used must have a minimum factor of safety of 1.3.

R655-11-6B. Dam Crest Requirements.

A. The crest width of all dams should be, at a minimum, equal to the structural height of the dam divided by five plus five feet. The absolute minimum required shall be 12 feet and the absolute maximum required shall be 25 feet. Wider crest widths may be used at the designer's discretion.

B. All dams shall have a cross slope on the crest of 2% to 3% towards the reservoir.

C. All crests shall be protected with a wearing surface of granular material to prevent vehicular rutting.

D. Dam crests should be cambered to allow for anticipated settlement. The side slopes of the dam may be steepened to accommodate the camber.

E. For dams over 500 feet long which have a crest that dead ends, a turn-around should be provided at the abutment.

F. The impervious portion of the dam under the crest may need to be terminated at the anticipated frost line to prevent desiccation cracking and damage from frost; however, it needs to be carried high enough to prevent seepage over the core by capillary rise.

R655-11-6C. External Erosion Control.

A. All downstream slopes of dams should be protected from erosion by placing armor or seeding with grasses. No planting of any shrubs, trees, or other woody vegetation will be allowed unless it is approved in writing by the State Engineer.

B. All downstream groins of dams receiving runoff from adjacent abutments shall be protected from erosion.

C. All upstream slopes on dams which impound water for significant lengths of time shall be armored. If rock riprap is used it shall be well graded, durable, and sized to withstand wave action. If the material underlying the riprap is fine grained and subject to erosion, a properly designed filter blanket must be installed. Geotextiles may be used in lieu of the filter blanket at the discretion of the State Engineer.

R655-11-6D. Internal Erosion Control.

A. All dams should have design provisions for controlling internal erosion. In zoned dams all adjacent zones must meet filter criteria with the abutting zones and foundation soils. If filter criteria cannot be met, a transition zone must be provided.

B. All filter zones in a dam must meet criteria acceptable to the State Engineer.

C. In designing filter zones where dispersive clays or broadly-graded materials exist, special considerations may be imposed by the State Engineer.

D. All internal filter zones will have a minimum width of three feet to facilitate construction. Wider zones are encouraged especially in active seismic areas.

E. Proper filtering is essential in all dams where cracking from differential settlement, hydraulic fracturing, or earthquake shaking is possible.

R655-11-6E. Internal Drainage.

A. All underdrains and collection pipes shall be constructed using non-corrodible materials capable of withstanding the anticipated loads.

B. Underdrains and collection pipes should be designed to conduct flows several times larger than anticipated. All pipes within the dam which are not easily accessible shall have a minimum diameter of six inches.

C. All internal drain pipes should be enveloped with free draining material, meeting filter requirements with adjacent zones.

D. Where multiple pipes are used to conduct drainage from internal portions of the dam, they should be carried to the downstream toe or gallery separately without intervening connections or manifold systems. If the drain pipes are connected at their termination points, manholes should be provided to facilitate observation and measurement of the separate drain lines.

E. All underdrains and collection pipes should have provisions for measuring discharges in manholes or at their discharge points. If the anticipated discharge is in excess of 10 gallons per minute (gpm), a weir or other suitable measuring device

should be provided. If the anticipated flows are less than 10 gpm, provisions should be made so the water can be discharged freely into a vessel 1.5 feet high and one foot in diameter.

F. All exposed underdrain and collection pipes shall have an appropriate rodent screen attached.

G. All underdrains and collection pipes should be cleaned out prior to the first filling of the reservoir.

H. All seepage collection systems must include a collection pipe to discharge flows.

I. All internal drains must have a minimum cover of 3 feet of impermeable material to eliminate the collection of surface waters.

R655-11-7. Outlet Requirements.

All outlet designs should meet the following criteria.

R655-11-7A. Outlet Sizing.

A. All dams shall have a low level outlet capable of draining the reservoir to the sediment pool. The outlet should be sized to meet the project demands as well as the following criteria.

1. All outlets shall be 24 inches in diameter or larger unless exempted in writing by the State Engineer. Outlets should have valves or capped flanges which can facilitate entry into the pipe by personnel or video equipment.

2. All outlets shall have the capacity to evacuate 90% of the active storage capacity of the reservoir within 30 days neglecting reservoir inflows. The State Engineer may adjust this requirement on large reservoirs if it can be demonstrated that compliance would result in an unreasonably sized outlet or potential releases would exceed the downstream channel carrying capacity.

3. All outlets shall have the capacity to satisfy prior downstream water rights and the owners' release requirements.

R655-11-7B. Outlet Materials.

All outlets will be made of appropriate materials with due regard for loading condition, seismic forces, thermal expansion, resistance to corrosion, and potential abrasion. The use of corrugated metal pipes and other thin-walled steel pipes will not be accepted unless they serve only to provide a form for a poured-in-place concrete conduit or they are specifically accepted in writing by the State Engineer.

R655-11-7C. Outlet Details.

A. All outlets shall have a trash rack to prevent clogging.

B. All outlets connected directly to a downstream pipeline shall have an emergency bypass valve.

C. All outlets shall have a suitable energy dissipator at the discharge end to prevent erosion of the downstream channel.

D. All outlets will be placed on a concrete cradle or encased in concrete unless specifically exempted by the State Engineer in writing.

E. All outlets, with the exception of ungated outlets, shall have an operating gate or a guard gate on the upstream end.

F. All outlets shall have seepage control measures to reduce the potential for piping along the conduit. Common methods may include locating the outlet conduit in bedrock and installing a conduit filter drain to intercept seepage.

G. Outlets encased in concrete should have battered sides to facilitate compaction against the encasement.

H. Every attempt should be made to locate the outlet on bedrock or consolidated materials. In the event this is not possible, consideration should be given to articulating the outlet to allow for settlement.

I. Outlet gates and valves can be either mechanically or hydraulically operated. In either case the hydraulic lines or mechanical stems must be adequately protected from debris, wave action, settlement, and ice damage. Buried stems should be encased in an oil-filled pipe supported on pedestals. No catwalks or similar access structures will be allowed on reservoirs where freezing occurs or significant floating debris is present. All outlets which are operated with electrical equipment must have back-up generating capability or a manual bypass system capable of being operated in a reasonable amount of time.

J. All outlets shall be properly vented to avoid cavitation, surging, and reservoir vortexes. On low head dams adequate ventilation may naturally occur through the conduit if a free water surface is maintained. In most cases a vent pipe and air manifold around the perimeter of the conduit immediately downstream of the gate will be required. The air supply lines should be conservatively sized for the anticipated flows and protected in the same manner as the outlet control lines or stems.

K. All operators and supporting equipment for outlet controls should be properly protected and secured. Particular attention needs to be given to protection from vandals and unauthorized operation. All outlet controls should be clearly marked as to which way the gates and valves operate so that overloading of a closed gate or valve should not occur.

L. Outlet controls should be accessible when the spillways are in use.

R655-11-8. Spillway Requirements.

A. On all spillway control structures, provisions should be made for aeration of the nappe.

B. All spillways excavated in soils or soft rock should include a check structure to avoid headcutting and lowering of the spillway flowline.

C. All spillway channels should have suitable armor to prevent erosion.

D. If the spillway has concrete sidewalls, adequate weepholes should be provided or the walls should be designed with full hydrostatic loads in conjunction with the soil loads.

E. For spillways in remote areas where significant snowfall occurs, efforts should be made to maximize the southern exposure of the spillway to prevent ice blockage. In many cases elimination of tall trees will be required.

F. All construction joints should be provided with adequate water stops.

G. Design provisions should be made so that downstream spillway channel flows cannot encroach on the dam.

H. All spillways draining reservoirs with large amounts of floating debris should include a log boom to avoid plugging the spillway.

I. Spillway designs should provide for energy dissipation so that waters returned to the natural channel will not cause erosion.

J. For spillways with concrete floors, provisions should be made to control uplift pressures.

K. Stop logs or flashboards which restrict the design spillway capacity will not be allowed.

R655-11-9. Other Design Requirements.

A. To facilitate inspection, all dams shall have a zone 25 feet beyond all contacts at the downstream groins and toe of the dam in which all woody vegetation is to be removed.

B. If the dam is located in an area where grazing occurs, then livestock must be restricted from the dam by suitable fencing.

C. Unless the dam crest serves as a public road, a suitable gate or other barrier should be installed to prohibit traffic.

D. Geosynthetics may not be used in a dam as the primary design feature unless specifically approved, in writing, by the State Engineer.

E. The foundation downstream of a dam should be graded to convey seepage waters and runoff away from the dam.

F. All control houses and other structures housing instrumentation and operating devices should be designed to discourage unauthorized entry and damage from vandalism.

G. If burrowing animal activity is anticipated to be excessive, design consideration should be made to prohibit their entry, or place materials as a shell which are not capable of sustaining a rodent hole.

R655-11-10. Instrumentation.

Instrumentation on a dam serves the purposes of comparing actual performance with predicted performance and to observe the long term performance for unexpected changes, indicating a safety problem. Since each dam site and design varies, considerable judgment is needed in developing an instrumentation plan. The State Engineer may require any instrumentation necessary to adequately monitor a dam to insure its safety. Where instrumentation is required threshold values should be established for field personnel. Readings which exceed threshold values will indicate that the design criteria has been exceeded and the stability analysis should be reevaluated. Some minimal instrumentation will be required on dams as outlined in the following paragraphs.

R655-11-10A. Reservoir Staff Gages.

All dams shall have a suitable staff gage to monitor reservoir levels. Staff gages should be designed to be durable and capable of resisting movement, water forces and ice. All gages shall have permanent markings at a minimum of one foot intervals with actual elevations recorded at five foot intervals. The State Engineer may allow the use of other measuring devices if it can be demonstrated that they are reliable and accurate.

R655-11-10B. Survey Markers and Bench Marks.

All moderate and high hazard dams shall have permanent survey markers on the crest of the dam to monitor vertical and horizontal movement. The survey markers should be located to prevent damage from traffic. In conjunction with the survey

markers a permanent bench mark shall be installed on each abutment, sufficiently removed from the dam so any effects of the dam movement will not be felt at the bench mark. Reference markers should be established so the bench mark can be reset in the event of damage. Spacing of survey markers should not exceed 200 feet and spacing should be decreased as the height of the dam increases.

R655-11-10C. Piezometers.

A. All high hazard dams as well as moderate hazard dams, at the State Engineer's discretion, shall include piezometers. As a minimum, piezometers should be installed along two cross sections of the dam, one of which should be at or near the maximum section. Each cross section should include piezometers at critical locations in the embankment and foundation. It is preferable to have only one piezometer in each hole; however, more than one piezometer may be installed in each hole if the intervening zone between the piezometer tips can be adequately sealed.

B. All piezometers should have a surface casing projecting beyond the ground with the surface casing adequately sealed. The surface casing should include a locking cap to prevent unauthorized access.

C. All piezometer holes should be logged during drilling and any pertinent information included on the as-constructed plans. As-built locations, designations and elevations of the top, bottom, and porous interval of the piezometers should be shown on the as-constructed plans.

R655-11-10D. Seepage Measurements.

Seepage measurements for all drains and collection pipes should be provided, as outlined in R655-11- 6E, for all high and moderate hazard dams. Any significant seepage areas which develop following the initial filling should also be provided with measuring devices.

R655-11-10E. Strong Motion Instruments.

The State Engineer may require strong-motion instrumentation in seismic zones 2 and 3.

R655-11-11. Abandonment of Dams.

Abandonment of all dams requires approval by the State Engineer.

R655-11-11A. Removal of Dam.

If it is proposed to totally remove a dam, the main concern is to return the stream and reservoir basin to their pre-dam condition. Plans should be submitted showing how the original channel is to be reclaimed, how deposited silts are to be controlled, and what methods will be used to revegetate the reservoir basin and riparian areas.

R655-11-11B. Breaching of Dam.

If a dam is to be breached the following minimum criteria should be met:

1. The flowline of the breach should be excavated down to natural ground or stabilized at the top of the silt level. In most cases grade control and drop structures will be required to avoid mobilization of reservoir silts and debris.

2. The breach should be designed to pass a flood with a return interval of 100 years without backing water up in the historic reservoir more than five feet.

3. Regardless of hydraulic requirements the bottom width of the breach will be one half the structural height of the dam with an absolute minimum of 10 feet. Additional width may be required by the State Engineer in areas where beaver

activity occurs.

4. Breach side slopes must be flat enough to hold the slope when saturated, with an absolute minimum of one vertical on one horizontal. In areas where there is significant human travel, the minimum side slopes should be one vertical on two horizontal.

5. The exposed banks and bottom of the breach should be protected with riprap, vegetation, or other suitable means to prevent downcutting and lateral slope erosion.

6. Barriers should be placed on the original dam crest to warn any possible traffic on the crest of the breach.

R655-11-12. Construction.

The State Engineer will monitor construction of approved projects as outlined in the following paragraphs.

R655-11-12A. Informal Construction Inspections.

During the course of constructing, enlarging, repairing, or removing a dam, the State Engineer may make periodic inspections to determine compliance with plans and specifications, as well as to observe field conditions to see if actual conditions are consistent with those used during design. Any problems observed will be pointed out to the resident inspector or engineer for correction or change. All significant problems noted will be outlined in a letter to the owner and the owner's engineer. The engineer must respond in writing to the State Engineer as to what steps were undertaken to correct the problems.

R655-11-12B. Formal Construction Inspections.

In approving plans the State Engineer may require his approval of certain construction operations before the next phase of construction can commence. The owner's engineer or inspector must notify the State Engineer and determine a mutually acceptable time to observe and approve the work prior to continuation of the construction. Written acceptance of work inspected during formal inspections will be sent to the owner and his engineer.

R655-11-12C. Construction Reporting Requirements.

Written documentation of all construction activities should be maintained by the owner's engineer. The documentation must be submitted weekly to the State Engineer by the owner's engineer when any work is underway. At a minimum the documentation should include:

1. All materials certifications submitted by suppliers to insure compliance with specifications.

2. Results of all material tests or any other testing undertaken during construction. Any tests not meeting the requirements of the plans must include notations indicating what was done to correct the sub-standard work.

3. All engineers' and inspectors' diaries, field notes, or other written documentation.

4. Photographs to clarify work completed or problems noted.

5. All geological logs of foundation excavations.

R655-11-12D. Change Order Approvals.

All change orders revising the plans that involve technical changes must be

approved by the State Engineer. Since the State Engineer is not a party to the construction contract, change orders involving strictly payment to the contractor do not need to be approved by the State Engineer.

R655-11-12E. Final Inspection.

Before any dam can be placed in operation a final inspection of the project must be undertaken by the State Engineer and his written acceptance of the project received. The Emergency Action Plan, Standard Operating Plan, and Initial Filling Plan, if required, must be completed and approved before final acceptance and authorization for filling can be given. As-constructed plans of the project must be submitted within 60 days of the date of the final inspection. All as-constructed plans submitted must be on a high quality reproducible medium. As-constructed plans should reflect design changes made during construction, geological logs of the foundation excavation, and piezometer borings.

R655. Natural Resources, Water Rights.
R655-11. Requirements for the Design, Construction and Abandonment of Dams.
R655-11-4. Hydrologic Design.

In order to arrive at an Inflow Design Hydrograph or Inflow Design Flood (IDF) more representative of actual conditions in Utah, the State Engineer has commissioned, or has been involved in, numerous studies to supplement the National Oceanic and Atmospheric Administration's (NOAA) Report entitled "Hydrometeorological Report No. 49 (HMR49) - " Probable Maximum Precipitation Estimates, Colorado River & Great Basin Drainages". The results of most of these studies are used to better identify soil conditions, discharge coefficients, and unit hydrograph parameters. The results of two of the studies are used directly to refine the calculation of the design rainfall values. Both studies were completed by Donald Jensen of the Utah Climate Center and are entitled, "2002 Update for Probable Maximum Precipitation, Utah 72 Hour Estimates to 5,000 sq. mi. - March 2003" (USUL) and " Probable Maximum Precipitation Estimates for Short Duration, Small Area Storms in Utah - October 1995 "(USUS). All of HMR49, Table 1, page 4 of USUL, and Table 15, pages 74-75 of USUS are hereby incorporated by reference. All High Hazard and Moderate Hazard dams in Utah must use the precipitation values obtained from the use of all three publications. To avoid confusion, precipitation values obtained from HMR49 exclusively will be referred to as the Probable Maximum Precipitation (PMP), while those obtained from using HMR49 in conjunction with USUL or USUS, will be referred to as the Spillway Evaluation Precipitation (SEP). The resulting hydrographs generated will be referred to as the Probable Maximum Flood (PMF) and the Spillway Evaluation Flood (SEF) respectively.

R655-11-4A. Inflow Design Hydrograph Determination.

A) In Utah, the IDF for all High and Moderate Hazard Dams will be the SEF. It will be necessary to calculate both the 72 hour SEF using HMR49/ USUL as well as the 6 hour SEF using HMR49/ USUS. Both of these hydrographs must be routed through the reservoir to determine which one represents the most extreme event.

B) Once the critical SEF has been determined, it must be compared to a flood generated by the 100 year, 6 hour (for local storms), or 100 yr, 24 hour (for general storms) precipitation applied on a saturated watershed. If the routed 100 year event, including appropriate allowances for freeboard, is more critical than the SEF it must be used as the minimum IDF. This 100 year flood should also be used as the IDF for all Low Hazard Dams.

R655-11-4B. Freeboard Requirements.

All dams must have a normal freeboard above the crest of the principal spillway capable of containing the maximum wave action considering site wind-duration and fetch control characteristics. Wave action includes wave height and maximum runup, as well as reservoir setup against the embankment slope. Unless otherwise

justified by specific data acceptable to the State Engineer, an extreme wind velocity (fastest mile) over land of 100 miles per hour should be considered. In addition, while routing the 100 year precipitation event through the spillway, sufficient residual freeboard must be available to control wave action from a fetch controlled 50 miles per hour wind. In no case will the normal freeboard be less than three feet for high and moderate hazard dams. The State Engineer may reduce the three feet minimum freeboard requirement for low hazard dams based upon a review of the relative increase in risk associated with this reduction.

R655-11-4C. Spillways.

In designing the spillway for a dam to pass the IDF, the State Engineer will consider the use of a principal spillway in conjunction with emergency spillways. The principal spillway must be designed so that no structural damage will occur during passage of the IDF. Emergency spillways, including Fuse Plug Spillways, may be designed so that some damage may be expected during use provided the anticipated damage does not represent a threat to the dam. Sunny day failure modeling of Fuse Plug Spillways may be required to determine if they are creating an additional unacceptable risk. Overtopping of the dam will not be considered as an emergency spillway on earthfill dams, unless it can be demonstrated that the dam is protected from erosion, and the duration of overtopping will not saturate the dam and reduce its stability.

R655-11-4D. Infiltration Rates.

The State Engineer will accept an IDF using SEP values in conjunction with soil moisture conditions representative of historical maximums. If the design engineer is using infiltration rates which represent something less than saturated conditions, information should be submitted to justify the lower soil moisture selection.

R655-11-4E. Flood Routing.

A. In routing the IDF through the reservoir, the initial water surface should reflect conservative estimates which would exist at the time of the flood event. Unless documentation can be provided to the contrary, it should be assumed that all low level outlets are closed during routing of the IDF. For dams receiving inflow from pipelines and supply canals, it should be assumed these additional sources are operating at capacity during the flood event. In the event the spillway is gated or has "stop logs", which are only allowed on existing dams, documentation must be provided to show the gates are automated or operational procedures are in place to insure that the gates can be opened or the stop logs removed in a timely manner.

B. The SEF can be routed so the maximum water surface is at an elevation equal to the lowest point on the crest of the dam with no residual freeboard.

C. In generating the IDF, the basin characteristics used and the parameters used to generate the unit hydrograph should be based on the best information available. Unit hydrographs generated from historical records or calibrated watersheds should be used, where data is available, rather than using synthetic procedures.

R655-11-4F. Incremental Damage Assessment for High and Moderate Hazard Dams.

The State Engineer may, at his discretion, accept an IDF less than the SEF based on the results of an Incremental Damage Assessment (IDA) which shows that failure of the dam would cause insignificant incremental damage to property and no additional threat to human life. The State Engineer may consider the use of early warning systems in evaluating the threat to human life. In requesting the acceptance of an IDF determined from an IDA, documentation must be furnished that the owner of the dam is aware that the design reflects something less than the SEF and they are willing to accept the additional liability. In no case will the State Engineer approve an IDF generated by something less than the applicable 100 year flood event. The resulting selected IDF, based on the IDA, should be reported as a percent of the SEF.

R655-11-4G. Historical Records.

In some cases it may be appropriate to use historical streamflow records to generate a 100 year flood. If these records are used as a basis for the IDF, they should be accompanied by the Synthetic IDF established by using the 100 year precipitation. Following a review of the data, the State Engineer will make a determination of which flood will be used as the IDF.

Notice of Continuation July 12, 2001
73-5a
Effective Date: 12/10/2003

Utah Code
Title 73 Water and Irrigation
Chapter 5a Dam Safety
Section 101 Power of state engineer to regulate dams.

73-5a-101. Power of state engineer to regulate dams.

(1) The state engineer has the authority to regulate dams for the purpose of protecting public safety.

(2) To protect life and property, the state engineer may make rules controlling the construction and operation of dams, including rules controlling:

(a) design;

(b) maintenance;

(c) repair;

(d) removal; and

(e) abandonment.

(3) The state engineer may by rule exempt from this chapter any dam that:

(a) impounds less than 20 acre-feet of water and does not constitute a threat to human life if it fails; or

(b) does not constitute a threat to human life and would result in only minor damage to property of the owner if it fails.

73-5a-102. Chapter does not apply to certain federal dams and reservoirs.

This chapter does not apply to works owned by the United States Bureau of Reclamation. However, the Bureau of Reclamation shall file plans, drawings, and specifications of its works with the state engineer.

73-5a-103. Liability of owner or operator.

(1) Nothing in this chapter shall be construed to relieve an owner or operator of a dam or reservoir of the legal duties, obligations, or liabilities incident to the ownership or operation of the dam or reservoir.

(2) The owner or operator of a dam or reservoir may not be held to be strictly liable for any act or omission incident to the construction, ownership, or operation of the dam or reservoir.

73-5a-104. Qualifications of persons designing dams.

Each plan for the construction, enlargement, repair, alteration, or removal of any dam in this state shall be prepared by a qualified engineer who is:

(1) licensed in Utah; and

(2) experienced in dam design and construction.

73-5a-105. Independent consultants -- Owner to pay costs.

(1) The state engineer may require the owner of a dam or proposed dam to obtain the services of an independent consultant or team of consultants approved by the state engineer to consult regarding the adequacy of the design, construction, or operation of the dam if safety considerations pertaining to the

design, construction, or operation of the dam warrant an independent review.

(2) The state engineer shall make rules specifying:

(a) the safety considerations that will be considered in determining if an independent review is required;

(b) the requisite qualifications and experience of the independent consultants; and

(c) the timing of the consultants' review so that their recommendations are made in a timely manner.

(3) (a) The independent consultants shall be considered to be the agents of the owner of the dam.

(b) The costs of the independent consultants' services shall be paid by the owner of the dam.

(c) The owner of the dam may require the independent consultants to consider other issues, in addition to safety considerations, such as:

(i) design selections or alternatives;

(ii) site selection;

(iii) cost effectiveness; or

(iv) other tasks as defined by the contract.

73-5a-106. Dams classified according to hazard and use.

(1) Dams shall be classified according to hazard and use.

(2) Hazard classifications are as follows:

(a) high hazard - those dams which, if they fail, have a high probability of causing loss of human life or extensive economic loss, including damage to critical public utilities;

(b) moderate hazard - those dams which, if they fail, have a low probability of causing loss of human life, but would cause appreciable property damage, including damage to public utilities; and

(c) low hazard - those dams which, if they fail, would cause minimal threat to human life, and economic losses would be minor or limited to damage sustained by the owner of the structure.

(3) Use classifications are as follows:

(a) water storage - dams which impound water for prolonged periods, including those built for irrigation, power generation, water supply, aquatic culture, and recreation;

(b) flood control - dams constructed to operate only during significant runoff events and which impound water for a small percentage of time, including those built for flood control or sediment control and debris basins;

(c) tailings - dams in which a large component of the material impounded consists of saturated solids; and

(d) other - dams which impound a minimal amount of water or where the head behind the dam is minimal, including stock ponds, wash water ponds, recirculated process water ponds, regulating reservoirs, and diversion dams.

E.45. Vermont

State of Vermont
Department of Environmental Conservation

Instructions for Completing
Application for Authorization to Construct or Alter a Dam

10 V.S.A. Chapter 43

Item 1: **Applicant.** Ordinarily, the applicant(s) should be the owner(s) of the dam and land upon which the dam is or will be located. If there is more than one owner, all owners must be listed and become joint applicants. If the dam is on leased land, both the lessor and lessee become co-applicants.

Item 2: **Legal Entity.** Complete only if applicant is not applying as an individual, e.g., corporation, partnership, municipality, etc.

Item 3: **Contact.** Person to contact regarding this application if other than applicant.

Item 4: **Land Ownership and Flowage Rights.** Complete *Schedule A* and provide any required documentation.

Item 5: **Project Description**

a. Check appropriate box.

b. Name of existing dam, if any, or name of applicant or pond as appropriate.

c. Name of town(s) in which the **dam** is located.

d. Name of water course (river, stream, lake or pond) on which the dam is or will be located. If the dam is an offstream structure or on an unnamed watercourse, indicate that it is on an unnamed tributary of the nearest named watercourse.

e. Drainage area in acres at the dam.

f. Indicate type of dam, e.g., earthfill, concrete gravity, earthfill-stonewall, stone masonry, timber A-frame, etc.

g. Surface area of impoundment in acres (A), at Normal Water Level (NWL) and with water level at Top of Dam.

h. Storage in acre-fee (AF). NOTE: One acre-foot is equal to 43,560 cubic feet; 500,000 cubic feet is approximately 11.48 AF. Provide storage values for both NWL and **top of dam**, i.e., top of non-overflow part of dam or top of freeboard, conditions. Storage will be based on one of the following cases.

Case I. Totally artificial (man-made) lakes, ponds, reservoirs, lagoons or other impoundments. Includes man-made dams constructed on beaver ponds. Storage, including accumulated sediments, controlled by the dam **and** any storage created by excavating below the lowest elevation of the dam foundation. If there is no dam above original ground elevation, e.g., a “dug pond,” lagoon,

etc., it is the total storage created by excavation below the lowest ground elevation along the periphery of the pond.

Case II. Dams at the outlets of natural lakes or ponds. Storage is total storage, including any accumulated sediments, controlled by the dam but does not include existing **natural** storage below the lowest foundation elevation of the dam. However, it does include any additional **man-made** storage created by dredging or enlarging a natural pond with a dam on it.

i. The maximum height is the vertical distance from the lowest point along the downstream toe of the dam (usually the original bed of the stream or watercourse) to the top of the non-overflow part of the structure. For impoundments without dams indicate N/A (not applicable).

j. Indicate, for existing lakes, ponds or dams if the existing normal water level will be raised or lowered and by how much. If there is no existing lake or pond or dam, indicate N/A.

k. Provide a brief narrative description of the project and its purpose.

l. Describe the method of operation. Include such things as any proposed manipulation of water levels and any diversions of water into or out of the pond.

Item 6: **Engineer.** List name, address, telephone, and Vermont P.E. license number for engineer providing design and construction supervision services. Sections 1080(4), 1083(b) and 1090 of the statute require that the dam owner retain the services of a professional engineer, registered in Vermont, who has experience in the design and investigation of dams to design and supervise construction or alteration of any dam requiring approval from the department under 1082.

It is desirable, but not necessary, that the design engineer also provide the required construction supervision. **Full time construction supervision and submittal of daily construction status reports is ordinarily required.**

Item 7: **Estimated Construction Cost.** Estimated construction cost – exclusive of cost of land.

Item 8: **Estimated Start and Completion Dates.** Indicate when you would like to begin the project and when it would be completed.

NOTE: For most projects the work should be scheduled to be completed during one construction season (generally April 15 – November 15). For projects that require more than one construction season, a longer construction period may be approved provided there are adequate provisions to safely “winter over” the uncompleted project. If project is to be phased, provide detailed schedule.

Item 9: **Financial Information.** Complete *Schedule B.*

Item 10: **Right of Entry.** Complete *Schedule C.*

Item 11: **Public Good.** Complete *Schedule D.*

Item 12: Documents and Schedules Attached.

A. The following items are required for all applications:

1. Location map. Show location of dam on section from U.S. Geological Survey topographic map.

2. Schedules A, B, C, and D.

3. Plans and Specifications. Complete and detailed engineering plans and specifications must accompany the application. Submit two (2) complete sets of 24 inch by 36 inch engineering plans and one (1) complete set of 11 inch by 17 inch engineering plans.

   NOTE: Prior to submitting the application, the department encourages the applicant's engineer to discuss preliminary design concepts and parameters before completing the detailed plans and specifications. Contact with state fish and wildlife, water quality and wetlands personnel is strongly recommended prior to preliminary design.

B. The following items are generally required for all new construction and most reconstruction and alterations.

1. Soils Information. Provide boring and test pit logs, laboratory analyses of soils for foundation, embankment, filters, spillways, etc. Provide filter design and stability analyses as appropriate. Filter gradation requirements should be designed in accordance with NRCS (formerly SCS), *Part 633, National Engineering Handbook, Chapter 26, Gradation Design of Sand and Gravel Filters* (May 1994 or later revisions), or other appropriate standard nationally recognized by the engineering profession as suitable for dams.

2. Hydrology and Hydraulics. Provide detailed H&H study of site and basin hydrology and project hydraulics showing adequate freeboard, spillway capacity and drain capacity to support downstream hazard classification using appropriate and generally accepted methodologies.

3. Storage and Surface Area Data. Provide area-capacity curves or tables for full range of storage controlled by the dam.

4. Breach Analysis. Provide breach analysis and inundation mapping for determination of downstream hazard classification, for sizing spillways and outlet works, and, where appropriate, for use in preparation of Engineering Action Plans (EAP).

   The downstream hazard classification used by the department is the same as that used by the U.S. Army Corps of Engineers in *Recommended Guidelines for Safety Inspections of Dams* (ER 1110-2-106: 24 Mar 80, Chg. 1, page D-8). The classification used by the Soil Conservation Service (SCS) as given on page 1-1 of *Technical Release 60* (Revised October 1985) is acceptable, but the classifications should be corrected with the Corps designations.

The breach analysis may be done by generally accepted method such as the National Weather Service (NWS) DAMBRK and FLDWAV models or Corps of Engineers HEC-1 Dam Break computer models. For further guidance, see the Federal Energy Regulatory Commission (FERC), *Engineering Guidelines for the Evaluation of Hydropower Projects, Appendix II-A, Dambreak Studies* October 1993. The NWS models are the preferred methodologies.

5. Spillway Design Flood (SDF)

   SDF and outlet works capacities should be consistent with guidelines or service criteria established by Federal agencies such as the Corps of Engineers, Soil Conservation Service and the Bureau of Reclamation for a given size and hazard classification, with the following additional requirements:

   - SDF, **as appropriate**, but in no case less than a routed Q100 (one hundred-year frequency) inflow (Ref: FERC *Engineering Guidelines . . .* , October 1993, Paragraph 2-3.3.).

   - Freeboard, as appropriate, but not less than 1.5 feet with a routed Q100 inflows, and not less than 3.0 feet from principal spillway crest (usually NWL). Applies to all embankment dams and other dams where appropriate.

6. **Operation and Maintenance (O&M) Manual.** Prepare O&M manual for dam owner/operator. Include, as appropriate, project description, records, photos; operating practices for gates, spillways, etc.; maintenance practices; inspections, frequency for owner/operator and owner's engineer; inspection check lists; recordkeeping, etc.

7. **First Filling Plan.** Provide a plan to be followed by the dam owner and his engineer to monitor dam during first filling following construction or modification.

8. **Emergency Action Plan (EAP).** An EAP is recommended for all dams, particularly Class I (high hazard) structures. An EAP is required for all new Class I and Class II dams. The EAP should be developed in coordination with the affected municipalities and be acceptable to them. Coordination with Vermont Emergency Management is also recommended.

Item 13: **Application Fee Enclosed.** Compute from fee Schedule and submit a check payable to *State of Vermont*.

Item 14: **Certification.** Sign, date and provide typed name and title. If more than one applicant, **all** must sign.

Dam Design

The department expects all dams will be designed in accordance with generally accepted, modern engineering practices by qualified and experienced professional engineers **registered in the State of Vermont**. Although, the department has not formally adopted specific design criteria, the following general standards are used by the department:

1. **Low level outlets.** All new and reconstructed dams must have an adequate low level (bottom) outlet that is operable from the surface and is of sufficient size to drain the reservoir. Slide gates or gate valves are preferred. ”Flap valves” are unacceptable.

2. **Corrugated Galvanized Metal Pipe (CGMP).** CGMP is not acceptable for spillways, low level outlets or drains in new or reconstructed dams.

3. **Seepage Control.** The department places strong emphasis on adequate seepage control to prevent piping (internal erosion) and instability of embankments, structures, foundations and abutments of dams.

   All conduits and structures passing through earth dams must be protected by properly designed mineral filters. In accordance with modern practice, rigid anti-seep collars or diaphragms are no longer to be used on conduits.

   Mineral filter design should be in accordance with NRCS (SCS) Chapter 26, NEH (See Item 12, B-1) or other appropriate standard nationally recognized by the engineering profession as sustainable for dams.

   Filter fabrics should not be used to wrap piezometer screws or as filter material within or on the upstream face of dams, or within any portion of the embankment. (Ref: Corps of Engineers, EM 1110-2-1901, 9/30/86, *Seepage Analysis and Control for Dams*.

Mail completed application to:

Department of Environmental Conservation
Facilities Engineering Division
Dam Safety Section
103 South Main Street
Waterbury, VT 05671-0511

Notes:

(1) The department may request other information from the applicant it considers necessary to properly review the application.

(2) The department will have a notice of the completed application published in an area newspaper, request posting in the town clerk's Office and will seek comments from state, municipal or regional agencies and other individuals or organizations who have requested a notice.

(3) The applicant is requested to provide the department with the names and addresses of any persons the applicant knows to have an interest in the application and would like to receive a notice.

(4) Under 10 V.S.A. Section 1083(a) notice of the application must be given **by the applicant** to governing body of the municipality or municipalities in which the dam or any part of the dam is to be located.

July 2009

STATE OF VERMONT
DEPARTMENT OF ENVIRONMENTAL CONSERVATION

INSPECTION OF DAMS

The Department of Environmental Conservation has for many years made routine safety inspections of non-federal, non-hydroelectric dams. Since 1982, the Department has been required to carry out periodic inspections of dams subject to its jurisdiction under provisions of 10 V.S.A. § 1105. This section reads as follows:

§ 1105. Inspection of dams

> The state agency having jurisdiction shall employ an engineer to make periodic inspections of non-federal dams in the state to determine their condition and the extent, if any, to which they pose a potential or actual threat to life and property, or shall promulgate rules pursuant to chapter 25 of Title 3 to require an adequate level of inspection by an independent registered engineer experienced in the design and investigation of dams. The agency shall provide the owner with the findings of the inspection and any recommendations. - Added 1981, No. 242 (Adj. Sess.), § 13, amended 1985, No. 60

The Department classifies dams according to a dam's potential for causing loss of life and property damage in the area downstream of the dam if it were to fail. The following Downstream Hazard Classification system is used by the Department. It is same as the U.S. Army Corps of Engineers system given in *Recommended Guidelines for Safety Inspection of Dams* (ER 1110-2-106, 25 Sept. 79, 24 Mar 80 Chg 1).

DOWNSTREAM HAZARD CLASSIFICATION OF DAMS

Class	Hazard Category	Potential Loss of Life	Potential Economic Loss
3	Low	None expected (No permanent structures for human habitation)	Minimal (Undeveloped to occasional structures or agriculture)
2	Significant	Few (No urban developments and no more than a small number of inhabitable structures)	Appreciable (Notable agriculture, industry or structures)
1	High	More than few	Excessive (Extensive community, industry or agriculture)

Under the Corps system, the classifications are further described as follows:

(a) *LOW Hazard (Class 3)*

Dams conforming to criteria for the low hazard potential category generally will be located in rural or agricultural areas where failure may damage farm buildings, limited agricultural land, or township and country roads.

(b) *SIGNIFICANT Hazard (Class 2)*

Significant hazard potential category structures will be those located in predominantly rural or agricultural areas where failure may damage isolated homes, secondary highways or minor railroads or cause interruption of use or service of relatively important public utilities.

(c) *HIGH Hazard (Class 1)*

Dams in the high hazard potential category will be those located where failure may cause serious damage to homes, extensive agricultural, industrial and commercial facilities, important public utilities, main highways or railroads.

Additional information:

1. The terminology HIGH, SIGNIFICANT, AND LOW hazard refers to the potential for damage or loss of life and does **not** refer to the condition of the dam. For example, a HIGH hazard (Class 1) dam may be in excellent condition and a LOW hazard (Class 3) dam may be in poor condition.

2. A dam's classification may change from what it was when it was built or at the last inspection because of changes in downstream conditions. For example, a Class 3 (low hazard) dam may become a Class 2 (significant hazard) or Class 1 (high hazard) dam if some houses are built downstream that could be impacted by a failure. The classification could also change (either up or down) if a more detailed breach analysis is carried out that more accurately determines downstream damage potential.

3. It should not be assumed that the failure of a Class 3 (low hazard) dam would never be a threat to lives. Although direct loss of life (such as by flooding a house) is not expected, the failure could, for example, wash out a road and result in a fatal accident.

The Department bases its minimum periodic inspection frequency on the downstream hazard classification. The Department's goal is to inspect dams as follows:

Class	Downstream Hazard Classification Category	Inspection Frequency
1	High	1
2	Significant	1-5
3	Low	7-10

The Department may increase the inspection frequency when in its opinion more frequent or non-routine inspections are warranted. Reasons to increase the frequency or undertake non-routine inspections may include: (1) problems or concerns with the condition or safety of the dam; (2) following significant flood events, and (3) during and subsequent to impounding water following construction or reconstruction of the dam.

The inspections by the Department do not and are not intended to relieve the owner of the dam of the owner's legal duties, obligations or liabilities incidental to the ownership, operation, maintenance, emergency preparedness or inspection of the dam. The owner should inspect or have the dam inspected on a frequent basis so that routine maintenance may be undertaken as needed and to monitor and/or identify any changes or conditions that could indicate problems with the dam. Should any such conditions or changes occur the owner should contact an engineer experienced with the design and investigation of dams. The engineer should evaluate the significance of the change or condition so that the engineer can advise the owner accordingly. Even if no changes are observed, the owner should have an experienced and qualified engineer inspect and evaluate the dam on an appropriate periodic basis, e.g., annually, biannually, etc. The inspections by the owner or owner's engineer are independent of any inspections that may be carried out by the Department.

The Department's current policy is to inspect only those dams that are capable of impounding more than 500,000 cubic feet. Although the statute does not limit size when considering "unsafe" dams (10 V.S.A. § 1095), only those dams impounding more than 500,000 cubic feet require prior authorization to construct, alter or remove (10 V.S.A. § 1082).

The inspection program relies on the voluntary assistance of dam owners. Before an inspection is made, a diligent effort will be made to contact the landowner for access permission. The landowner may deny permission for inspection. Consult your attorney.

The purpose of the inspection is to investigate and determine the condition of the dam and the extent, if any, to which it may pose a potential or actual threat to life and property. A report on the findings of the inspection and any recommendations are provided the dam owner. The report provides an assessment of the general condition of the dam which is based upon available data and a visual inspection. Detailed investigations and analyses involving topographic mapping, subsurface investigations, testing and detailed computational evaluations or detailed hydrologic and hydraulic analyses are beyond the scope of the inspection, however, the inspection may identify a need for further studies.

The reported condition of the dam is based on observations of field conditions at the time of inspection along with data available to the Department. In cases where the reservoir was lowered or drained prior to inspection, such action, while usually improving the stability and safety of the dam, removes the normal load on the structure and may obscure certain conditions which might otherwise be detectable if inspected under the normal operating environment of the structure.

The safety of a dam depends on numerous and constantly changing internal and external conditions, and is evolutionary in nature. It would be incorrect to assume that the present condition of the dam will continue to represent the condition of the dam at some point in the future. Only through continued care and inspection can there be any chance that unsafe conditions are detected.

No dam can ever be considered to be completely "safe" (i.e., it can't fail) even if it has been well designed, constructed, operated and maintained. Even if it is considered that the chance of a failure is remote, it is still a possibility and should not be ignored. All dams to some degree, but old dams in particular, are unpredictable and can fail under conditions as or less severe than they have survived in the past.

The scope of an inspection report does not include an assessment of the need for fences, gates, no-trespassing signs, repairs to existing fences and railings and other items which may be needed to minimize trespass and provide greater security for the facility and safety to the public. An evaluation of the project for compliance with OSHA rules and regulations is beyond the scope of the inspection program.

Revised August 2007

The Vermont Statutes Online

Title 10: Conservation and Development

Chapter 43: DAMS

§ 1080. Definitions

As used in this chapter:

(1) "Department" means the department of environmental conservation.

(2) "Person" means any individual; partnership; company; corporation; association; joint venture; trust; municipality; the state of Vermont or any agency, department, or subdivision of the state, any federal agency, or any other legal or commercial entity.

(3) "Person in interest" means, in relation to any dam, a person who has riparian rights affected by that dam, a substantial interest in economic or recreational activity affected by the dam, or whose safety would be endangered by a failure of the dam.

(4) "Engineer" means a professional engineer registered under Title 26 who has experience in the design and investigation of dams.

(5) "Time" shall be reckoned in the manner prescribed by 1 V.S.A. § 138. (Added 1981, No. 242 (Adj. Sess.), § 1; amended 1987, No. 76, § 18; 2003, No. 115 (Adj. Sess.), § 22.)

§ 1081. Jurisdiction of department and public service board

(a) Unless otherwise provided, the powers and duties authorized by this chapter shall be exercised by the department, except that the public service board shall exercise those powers and duties over dams and projects that relate to or are incident to the generation of electric energy for public use or as a part of a public utility system.

(b) Transfer of jurisdiction. Jurisdiction over a dam is transferred from the department to the public service board whenever the Federal Energy Regulatory Commission grants a license to generate electricity at the dam or whenever the public service board receives an application for a certificate of public good for electricity generation at that dam. Jurisdiction is transferred from the public service board to the department whenever such a federal license expires or is otherwise lost, whenever such a certificate of public good is revoked or otherwise lost, or whenever the public service board denies an application for a certificate of public good.

(c) Upon transfer of jurisdiction as set forth above and upon written request, the state agency having former jurisdiction shall transfer copies of all records pertaining to the dam to the agency acquiring jurisdiction. (Amended 1959, No. 203; 1959, No. 329 (Adj. Sess.), § 39, eff. March 1, 1961; 1961, No. 100, § 2; 1981, No. 242 (Adj. Sess.), § 2.)

§ 1082. Authorization

(a) No person shall construct, enlarge, raise, lower, remodel, reconstruct, or otherwise alter any dam, pond or impoundment or other structure which is or will be capable of impounding more than 500,000 cubic feet of water or other liquid after construction or alteration, or remove, breach or otherwise lessen the capacity of an existing dam that is or was capable of impounding more than 500,000 cubic feet within or along the borders of this state where land in this state is proposed to be overflowed, or at the outlet of any body of water within this state, unless authorized by the state agency having jurisdiction so to do. However, in the matter of flood control projects where cooperation with the federal government is provided for by the provisions of section 1100 of this title that section shall control.

(b) For the purposes of this chapter, the volume a dam or other structure is capable of impounding is the volume of water or other liquid, including any accumulated sediments, controlled by the structure with the water or liquid level at the top of the nonoverflow part of the structure. (Amended 1975, No. 179 (Adj. Sess.), § 1; 1981, No. 242 (Adj. Sess.), § 3.)

§ 1083. Application

(a) Any person who proposes to undertake an action subject to regulation pursuant to section 1082 of this title shall apply in writing to the state agency having jurisdiction, and shall give notice thereof to the governing body of the municipality or municipalities in which the dam or any part of the dam is to be located. The application shall set forth:

(1) the location, the height, length and other dimensions and any proposed changes to any existing dam;

(2) the approximate area to be overflowed and the approximate number of, or any change in the number of cubic feet of water to be impounded;

(3) the plans and specifications to be followed in the construction, remodeling, reconstruction, altering, lowering, raising, removal, breaching, or adding to;

(4) any change in operation and maintenance procedures; and

(5) other information that the state agency having jurisdiction considers necessary to properly review the application.

(b) The plans and specifications shall be prepared under the supervision of an engineer. (Amended 1959, No. 329 (Adj. Sess.), § 23(d), eff. March 1, 1961; 1975, No. 179 (Adj. Sess.), § 2; 1981, No. 242 (Adj. Sess.), § 4.)

§ 1083a. Agricultural dams

(a) Notwithstanding the provisions of sections 1082, 1083, 1084 and 1086 of this title, the owners of an agricultural enterprise who propose, as an integral and exclusive part of the enterprise, to construct or alter any dam, pond or impoundment or other structure requiring a permit under section 1083 shall apply to the natural resources conservation district in which his land is located. The natural resources conservation districts created under the

provisions of chapter 31 of this title shall be the state agency having jurisdiction and shall review and approve the applications in the same manner as would the department. The districts may request the assistance of the department for any investigatory work necessary for a determination of public good and for any review of plans and specifications as provided in section 1086.

(b) As used in this section, "agricultural enterprise" means any farm, including stock, dairy, poultry, forage crop and truck farms, plantations, ranches and orchards, which does not fall within the definition of "activities not engaged in for a profit" as defined in section 183 of the Internal Revenue Code and regulations relating thereto. The growing of timber does not in itself constitute farming.

(c) Notwithstanding the provisions of this section, jurisdiction shall revert to the department when there is a change in use or when there is a change in ownership which affects use. In those cases the department may, on its own motion, hold meetings in order to determine the effect on the public good and public safety. The department may issue an order modifying the terms and conditions of approval.

(d) The natural resources conservation districts may adopt any rules necessary to administer this chapter. The districts shall adhere to the requirements of chapter 25 of Title 3 in the adoption of those rules.

(e) Notwithstanding the provisions of chapter 7 of Title 3, the attorney general shall counsel the districts in any case where a suit has been instituted against the districts for any decision made under the provisions of this chapter. (Added 1975, No. 179 (Adj. Sess.), § 5; amended 1981, No. 242 (Adj. Sess.), § 5.)

§ 1084. Department of fish and wildlife; investigation

The commissioner of fish and wildlife shall investigate the potential effects on fish and wildlife habitats of any proposal subject to section 1082 of this title and shall certify the results to the state agency having jurisdiction prior to any hearing or meeting relating to the determination of public good and public safety. (Amended 1975, No. 179 (Adj. Sess.), § 3; 1981, No. 242 (Adj. Sess.), § 6; 1983, No. 158 (Adj. Sess.), eff. April 13, 1984.)

§ 1085. Notice of application

Upon receipt of the application required by section 1082 of this title, the state agency having jurisdiction shall give notice to all persons interested.

(1) For any project subject to its jurisdiction under this chapter, on the petition of 25 or more persons the department shall, or on its own motion it may, hold a public information meeting in a municipality in the vicinity of the proposed project to hear comments on whether the proposed project serves the public good and provides adequately for the public safety. Public notice shall be given by posting in the municipal offices of the towns in which the project will be completed and by publishing in a local newspaper at least 10 days before the meeting.

(2) For any project subject to its jurisdiction under this chapter, the public service board shall hold a hearing on the application. The purpose of the hearing shall be to determine

whether the project serves the public good as defined in section 1086 of this title and provides adequately for the public safety. The hearing shall be held in a municipality in the vicinity of the proposed project and may be consolidated with other hearings, including hearings under 30 V.S.A. § 248 concerning the same project. Notice shall be given at least 10 days before the hearing to interested persons by posting in the municipal offices of the towns in which the project will be completed and by publishing in a local newspaper. (Amended 1981, No. 242 (Adj. Sess.), § 7.)

§ 1086. Determination of public good; certificates

(a) "Public good" means the greatest benefit of the people of the state. In determining whether the public good is served, the state agency having jurisdiction shall give due consideration, among other things, to the effect the proposed project will have on:

(1) the quantity, kind, and extent of cultivated agricultural land that may be rendered unfit for use by or enhanced by the project, including both the immediate and long range agricultural land use impacts;

(2) scenic and recreational values;

(3) fish and wildlife;

(4) forests and forest programs;

(5) the need for a minimum water discharge flow rate schedule to protect the natural rate of flow and the water quality of the affected waters;

(6) the existing uses of the waters by the public for boating, fishing, swimming, and other recreational uses;

(7) the creation of any hazard to navigation, fishing, swimming, or other public uses;

(8) the need for cutting clean and removal of all timber or tree growth from all or part of the flowage area;

(9) the creation of any public benefits;

(10) the classification, if any, of the affected waters under chapter 47 of this title;

(11) any applicable state, regional or municipal plans;

(12) municipal grand lists and revenues;

(13) public safety; and

(14) in the case of proposed removal of a dam that formerly related to or was incident to the generation of electric energy, but which was not subject to a memorandum of understanding dated prior to January 1, 2006 relating to its removal, the potential for and value of future power production.

(b) If the state agency having jurisdiction finds that the proposed project will serve the public good, and, in case of any waters designated by the board as outstanding resource waters, will preserve or enhance the values and activities sought to be protected by designation, the agency shall issue its order approving the application. The order shall include conditions for minimum stream flow to protect fish and instream aquatic life, as determined by the agency of natural resources, and such other conditions as the agency having jurisdiction considers necessary to protect any element of the public good listed above. Otherwise it shall issue its order disapproving the application.

(c) The agency shall provide the applicant and interested parties with copies of its order.

(d) In the case of a proposed removal of a dam that is under the jurisdiction of the department and that formerly related to or was incident to the generation of electric energy but that was not subject to a memorandum of understanding dated before January 1, 2006 relating to its removal, the department shall consult with the department of public service regarding the potential for and value of future power production at the site. (Amended 1969, No. 281 (Adj. Sess.), § 10; 1975, No. 179 (Adj. Sess.), § 4; 1981, No. 242 (Adj. Sess.), § 8; 1987, No. 67, § 13; No. 76, § 18; 2005, No. 208 (Adj. Sess.), § 4.)

§ 1087. Review of plans and specifications

Upon receipt of an application, the state agency having jurisdiction shall employ a registered engineer experienced in the design and investigation of dams to investigate the property, review the plans and specifications, and make additional investigations as it considers necessary to ensure that the project adequately provides for the public safety. The engineer shall report his findings to the agency. (Amended 1981, No. 242 (Adj. Sess.), § 9.)

1088. Repealed. 1975, No. 179 (Adj. Sess.), § 6.

§ 1089. Employment of hydraulic engineer

With the approval of the governor, the state agency having jurisdiction may employ a competent hydraulic engineer to investigate the property, review the plans and specifications, and make such additional investigation as such agency shall deem necessary, and such engineer shall report to the agency his findings in respect thereto.

§ 1090. Construction supervision

The construction, alteration or other action authorized in section 1086 of this title shall be supervised by a registered engineer employed by the applicant. Upon completion of the authorized project, the engineer shall certify to the agency having jurisdiction that the project has been completed in conformance with the approved plans and specifications. (Amended 1981, No. 242 (Adj. Sess.), § 10.)

§ 1091-1094. Repealed. 1981, No. 242 (Adj. Sess.), § 18.

§ 1095. Unsafe dam; petition; hearing; emergency

(a) On receipt of a petition signed by not less than ten persons in interest or the legislative body of a municipality, the agency having jurisdiction shall, or upon its own motion it may,

institute investigations by an engineer as described in section 1087 of this title regarding the safety of any existing dam or portion of a dam, of any size. The agency may fix a time and place for hearing and shall give notice in the manner it directs to all parties interested. The engineer shall present his findings and recommendations at the hearing. After the hearing, if the agency finds that the dam or portion of the dam as maintained or operated is unsafe or is a menace to people or property above or below the dam, it shall issue an order directing reconstruction, repair, removal, breaching, draining or other action it considers necessary to make the dam safe.

(b) If, upon the expiration of such date as may be ordered, the owner of such dam has not complied with the order directing the reconstruction, repair, breaching, removal, draining or other action of such unsafe dam, the state agency having jurisdiction may petition the superior court in the county in which the dam is located to enforce its order or exercise the right of eminent domain to acquire such rights as may be necessary to effectuate a remedy as the public safety or public good may require. If the order has been appealed, the court may prohibit the exercise pending disposition of the appeal.

(c) If, upon completion of the investigation described in subsection (a), the state agency having jurisdiction considers the dam to present an imminent threat to human life or property it shall take whatever action it considers necessary to protect life and property and subsequently conduct the hearing described in subsection (a). (Amended 1959, No. 329 (Adj. Sess.), § 39, eff. March 1, 1961; 1961, No. 100, § 2; 1969, No. 281 (Adj. Sess.), § 12; 1981, No. 242 (Adj. Sess.), § 11.)

1096. Repealed. 1981, No. 242 (Adj. Sess.), § 18.

§ 1097. Survey of existing dams; orders for protection of salmon

The fish and wildlife board shall forthwith make a survey of all dams within the state which impound more than three hundred thousand cubic feet of water and determine if the operation of such dams adversely affects the propagation and preservation of salmon, or materially diminishes the amount of flow in portions of a stream likely to be used for such preservation and propagation of salmon. If the board determines that the operation of an existing dam does adversely affect the propagation and preservation of salmon or materially diminishes the flow of water over portions of stream likely to be used therefor, it shall order such changes in operation for such length of time or times as are reasonably necessary in its judgment to fully protect such preservation and propagation of salmon. Any order of the board made under this section shall be based upon facts found and stated. Appeal from an order of the board may be taken in the manner prescribed for appeals from the public service b

oard as provided in chapter 1 of Title 30. (Amended 1959, No. 329 (Adj. Sess.), §§ 23(d), 39, eff. March 1, 1961; 1983, No. 158 (Adj. Sess.), eff. April 13, 1984.)

§ 1098. Removal of obstructions; appropriation

The department may contract for the removal of sandbars, debris or other obstructions from streams which the department finds that while so obstructed may be a menace in time of flood, or endanger property or life below, or the property of riparian owners. The expense of investigation and removal of the obstruction shall be paid by the state from funds provided

for that purpose. (Amended 1981, No. 242 (Adj. Sess.), § 14.)

§ 1099. Appeals

(a) Appeals of any act or decision of the department under this chapter shall be made in accordance with chapter 220 of this title.

(b) Appeals from actions or orders of the public service board may be taken in the supreme court in accord with 30 V.S.A. § 12. (Amended 1981, No. 242 (Adj. Sess.), § 15; 2001, No. 94 (Adj. Sess.), § 3; 2003, No. 115 (Adj. Sess.), § 23, eff. Jan. 31, 2005.)

§ 1100. Federal cooperation

As a basis for cooperation with the federal government and its duly established agencies in the matter of flood control, the state defines its policy with reference to flood control developments as follows:

(1) A flood control project, which shall contemplate as an incident thereof, the generation of electric energy, shall not be built on any waters within the state without the certificate of the public service board provided for in this chapter having first been obtained in the manner herein provided by the proper federal agency or authority, having in charge the building of such flood control project. Any modifications of flood control dams erected by authority of the federal government in this state shall not be made with a view to their utilization for the generation of electric energy, except by like authority first being obtained;

(2) Where such flood control project is strictly for flood control purposes, no village or city in this state shall be inundated, flooded, or destroyed thereby;

(3) Adequate compensation shall be made to any town whose grand list shall be substantially adversely affected by such strictly flood control project for the loss of its tax revenue;

(4) Where cultivated agricultural lands in excess of one hundred acres are to be taken for the purposes of a flood control project, or the recreational development of the state or the economy of the river basin involved may be affected thereby, the department, of its own motion, may, and upon petition to it by interested parties, shall, appoint a time and place for hearing in the vicinity of the flood control project, hold a public information meeting after giving notice to interested parties as it directs. Upon hearing, the department shall determine the effect the flood control project will have upon agricultural land uses or recreational values in this state, or upon the economy of the river basin involved, and report its findings and recommendations to the proper federal agency or authority having the flood control project in charge for its consideration and recognition. (Amended 1959, No. 329 (Adj. Sess.), § 39, eff. March 1, 1961; 1961, No. 100, § 2; 1981, No. 242 (Adj.

Sess.), § 16.)

1101. Repealed. 1959, No. 35, § 2, eff. March 12, 1959.

§ 1102. Federal receipts, distribution

All sums of money which the state receives from the United States under the provisions of section 701c-3 of Title 33 of the United States Code, as the same may be amended, being a portion of the rentals of property acquired and owned by the United States for purposes of flood control dams and reservoirs, shall be distributed to the municipality or political subdivision in which the dams and reservoirs are located. The department shall administer payment of money so received and the commissioner of finance and management shall issue his warrants on orders of the department. (1959, No. 35, § 1, eff. March 12, 1959; amended 1959, No. 328 (Adj. Sess.), § 8; 1961, No. 100, § 2; 1981, No. 242 (Adj. Sess.), § 17; 1983, No. 195 (Adj. Sess.), § 5(b).)

§ 1103. Approval for flood control dams

(a) No department or agency of the federal government shall construct any flood control dam which is within the state of Vermont, either in whole or in part, or cause any land within the state of Vermont to be overflowed through the operation of a flood control dam located outside the state, except with the approval of the governor and the general assembly.

(b) For purposes of this section "flood control dam" means any dam which has among its principal purposes the prevention or control of floods either within or without the state, or which is financed in whole or in part with funds appropriated, allocated or made available under a federal flood control program, excepting programs under Public Law 83-566, known as the Watershed Protection and Flood Prevention Act. (Added 1971, No. 167 (Adj. Sess.), § 3.)

1104. Repealed. 1989, No. 98, § 4(b)

§ 1105. Inspection of dams

The state agency having jurisdiction shall employ an engineer to make periodic inspections of nonfederal dams in the state to determine their condition and the extent, if any, to which they pose a potential or actual threat to life and property, or shall promulgate rules pursuant to chapter 25 of Title 3 to require an adequate level of inspection by an independent registered engineer experienced in the design and investigation of dams. The agency shall provide the owner with the findings of the inspection and any recommendations. (Added 1981, No. 242 (Adj. Sess.), § 13; amended 1985, No. 60.)

§ 1106. Unsafe dam revolving loan fund

(a) There is hereby established a special fund to be known as the Vermont unsafe dam revolving loan fund which shall be used to provide grants and loans to municipalities, nonprofit entities, and private individuals, pursuant to rules proposed by the agency of natural resources and enacted by the general assembly, for the reconstruction, repair, removal, breaching, draining, or other action necessary to reduce the threat of a dam or portion of a dam determined to be unsafe pursuant to section 1095 of this chapter.

(b) The fund created by this section shall be established and held separate and apart from any other funds or moneys of state and shall be used and administered exclusively for the purposes set forth in this section. The funds shall be invested in the same manner as permitted for investment of funds belonging to the state or held in the treasury. The fund shall consist of the following:

(1) Such sums as may be appropriated or transferred thereto from time to time by the general assembly, the emergency board, or the joint fiscal committee during such times as the general assembly is not in session.

(2) Principal and interest received from the repayment of loans made from the fund.

(3) Capitalization grants and awards made to the state by the United States of America for the purposes for which the fund has been established.

(4) Interest earned from the investment of fund balances.

(5) Private gifts, bequests, and donations made to the state for the purposes for which the fund has been established.

(6) Other funds from any public or private source intended for use for any of the purposes for which the fund has been established.

(c) The secretary may bring an action under this subsection or other available state and federal laws against the owner of the dam to seek reimbursement to the fund for all loans made from the fund pursuant to this section. (Added 2003, No. 121 (Adj. Sess.), § 66, eff. June 8, 2004.)

E.46. Virginia

VIRGINIA SOIL AND WATER CONSERVATION BOARD GUIDANCE DOCUMENT ON DAM BREAK INUNDATION ZONE AND INCREMENTAL DAMAGE ANALYSIS AND MAPPING PROCEDURES

(Approved XXXXX, 2010)
Working Draft Version January 14, 2010

Summary:
This guidance document specifies the procedures to be utilized by the Virginia Soil and Water Conservation Board in determining the adequacy of a dam break inundation zone analysis and map prepared in accordance with 4VAC50-20-54 and the adequacy of an incremental damage analysis conducted in accordance with 4VAC50-20-52.

Electronic Copy:
An electronic copy of this guidance in PDF format is available on the Regulatory TownHall under the Virginia Soil and Water Conservation Board at http://townhall.virginia.gov/L/GDocs.cfm.

Contact Information:
Please contact the Department of Conservation and Recreation's Division of Dam Safety and Floodplain Management at dam@dcr.virgina.gov or by calling 804-371-6095 with any questions regarding the application of this guidance.

Disclaimer:
This document is provided as guidance and, as such, sets forth standard operating procedures for the Virginia Soil and Water Conservation Board and the Department of Conservation and Recreation that administers the program on behalf of the Board. This guidance provides a general interpretation of the applicable Code and Regulations but is not meant to be exhaustive in nature. Each situation may differ and may require additional interpretation of the Dam Safety Act and attendant regulations.

Dam Break Inundation Zone and Incremental Damage Analysis and Mapping Procedures

I. Background:
The Impounding Structure Regulations require an owner of a regulated dam to conduct a dam break analysis to support the appropriate hazard classification of the impounding structure in accordance with 4VAC50-20-40 (Hazard Potential Classification of Impounding Structures). Additionally, in accordance with Section 4VAC50-20-54 of the Impounding Structure Regulations, a dam break inundation zone map shall be developed that meets the requirements of the Dam Safety Act and the Impounding Structure Regulations for regulated dams with a High, Significant or Low Hazard Potential. The spillway design flood requirement of dams may also be reduced if it can be demonstrated through an incremental damage analysis in accordance with

4VAC50-20-52 that such a determination will not reduce the protection of public safety that would be afforded by using the spillway design flood that would otherwise by specified by Table 1. This guidance outlines the procedures that dam owners and their engineers should utilize to conduct dam break and incremental damage assessment analyses as well as to produce the associated maps.

II. Definitions (pursuant to § 10.1-604 and 4VAC50-20-30):
"Dam break inundation zone" means the area downstream of a dam that would be inundated or otherwise directly affected by the failure of a dam.

III. Authority:
The Dam Safety Act in the Code of Virginia contains the following authorities applicable to this guidance:

> **§ 10.1-605. Promulgation of regulations by the Board.**
> The Board shall promulgate regulations to ensure that impounding structures in the Commonwealth are properly and safely constructed, maintained and operated.

The Impounding Structure Regulations contain the following authorities applicable to this guidance:

> **4VAC50-20-54. Dam break inundation zone mapping.**
> A. Dam break inundation zone maps shall be provided to the department to meet the requirements set out in Hazard Potential Classifications of Impounding Structures (4VAC50-20-40), Emergency Action Plan for High and Significant Potential Hazard Impounding Structures (4VAC50-20-175), and Emergency Preparedness for Low Hazard Potential Impounding Structures (4VAC50-20-177), as applicable.
> B. The location of the end of the inundation mapping should be indicated where the water surface elevation of the dam break inundation zone and the water surface elevation of the spillway design flood during an impounding structure nonfailure event converge to within one foot of each other. The inundation maps shall be supplemented with water surface profiles showing the peak water surface elevation prior to failure and the peak water surface elevation after failure.
> C. All inundation zone map(s), except those utilized in meeting the requirements of Emergency Preparedness for Low Hazard Potential Impounding Structures (4VAC50-20-177), shall be signed and sealed by a licensed professional engineer.
> D. For determining the hazard potential classification, a minimum of the following shall be provided to the department:
> 1. A sunny day dam break analysis utilizing the volume retained at the normal or typical water surface elevation of the impounding structure;
> 2. A dam break analysis utilizing the spillway design flood with a dam failure;
> 3. An analysis utilizing the spillway design flood without a dam failure; and
> 4. For the purposes of future growth planning, a dam break analysis utilizing the probable maximum flood with a dam failure.
> E. To meet the requirements of Emergency Preparedness set out in 4VAC50-20-177, all Low Hazard Potential impounding structures shall provide a simple map, acceptable to the department, demonstrating the general inundation that would result

from a dam failure. Such maps do not require preparation by a professional licensed engineer, however, it is preferred that the maps be prepared by a licensed professional engineer.

F. To meet the Emergency Action Plan requirements set out in 4VAC50-20-175, all owners of High and Significant Hazard Potential impounding structures shall provide dam break inundation map(s) representing the impacts that would occur with both a sunny day dam failure and a spillway design flood dam failure.

1. The map(s) shall be developed at a scale sufficient to graphically display downstream inhabited areas and structures, roads, public utilities that may be affected, and other pertinent structures within the identified inundation area. In coordination with the local organization for emergency management, a list of downstream inundation zone property owners and occupants, including telephone numbers may be plotted on the map or may be provided with the map for reference during an emergency.

2. Each map shall include the following statement: "The information contained in this map is prepared for use in notification of downstream property owners by emergency management personnel."

4VAC50-20-40. Hazard potential classifications of impounding structures.

A. Impounding structures shall be classified in one of three hazard classifications as defined in subsection B of this section and Table 1.

B. For the purpose of this chapter, hazards pertain to potential loss of human life or damage to the property of others downstream from the impounding structure in event of failure or faulty operation of the impounding structure or appurtenant facilities. Hazard potential classifications of impounding structures are as follows:

1. High Hazard Potential is defined where an impounding structure failure will cause probable loss of life or serious economic damage. "Probable loss of life" means that impacts will occur that are likely to cause a loss of human life, including but not limited to impacts to residences, businesses, other occupied structures, or major roadways. Economic damage may occur to, but not be limited to, building(s), industrial or commercial facilities, public utilities, major roadways, railroads, personal property, and agricultural interests. "Major roadways" include, but are not limited to, interstates, primary highways, high-volume urban streets, or other high-volume roadways.

2. Significant Hazard Potential is defined where an impounding structure failure may cause the loss of life or appreciable economic damage. "May cause loss of life" means that impacts will occur that could cause a loss of human life, including but not limited to impacts to facilities that are frequently utilized by humans other than residences, businesses, or other occupied structures, or to secondary roadways. Economic damage may occur to, but not be limited to, building(s), industrial or commercial facilities, public utilities, secondary roadways, railroads, personal property, and agricultural interests. "Secondary roadways" include, but are not limited to, secondary highways, low-volume urban streets, service roads, or other low-volume roadways.

3. Low Hazard Potential is defined where an impounding structure failure would result in no expected loss of life and would cause no more than minimal economic damage. "No expected loss of life" means no loss of human life is anticipated.

C. The hazard potential classification shall be proposed by the owner and shall be subject to approval by the board. To support the appropriate hazard classification, dam break analysis shall be conducted by the owner's engineer. Present and planned land-use for which a development plan has been officially approved by the locality in the dam break inundation zones downstream from the impounding structure shall be considered in determining the classification.

D. Impounding structures shall be subject to reclassification by the board as necessary.

4VAC50-20-52. Incremental damage analysis.

A. When appropriate, the spillway design flood requirement may be reduced by the board in accordance with this section.

B. The owner's engineer may proceed with an incremental damage an alysis. Once the owner's engineer has determined the required spillway design flood through application of Table 1, further analysis may be performed to evaluate the limiting flood condition for incremental damages Site-specific conditions should be recognized and considered. This analysis may be used to lower the spillway design flood. In no situation shall the allowable reduced level be less than the level at which the incremental increase in water surface elevation downstream due to failure of an impounding structure is no longer considered to present an additional downstream threat. This engineering analysis will need to present water surface elevations at each structure that may be impacted downstream of the dam. An additional downstream threat to persons or property is presumed to exist when water depths exceed two feet or when the product of water depth (in feet) and flow velocity (in feet per second) is greater than seven.

C. The spillway design flood shall not be reduced below the minimum threshold values as determined by Table 1.

D. The required spillway design flood shall be subject to reclassification by the board as necessary to reflect changed conditions at the impounding structure and in the dam break inundation zone.

IV. Discussion and Interpretation:

Dam Break Analysis and Inundation Zone Mapping

The Impounding Structure Regulations require an owner of a regulated dam to conduct a dam break analysis to support the appropriate hazard classification of the impounding structure in accordance with 4VAC50-20-40 (Hazard Potential Classification of Impounding Structures). Additionally, in accordance with Section 4VAC50-20-54 of the Impounding Structure Regulations, a dam break inundation zone map shall be developed that meets the requirements of the Dam Safety Act and the Impounding Structure Regulations for regulated dams with a High, Significant or Low Hazard Potential. This section requires that dam break inundation zone maps shall be provided to the department to meet the requirements set out in Hazard Potential Classifications of Impounding Structures (4VAC50-20-40), Emergency Action Plan for High and Significant Potential Hazard Impounding Structures (4VAC50-20-175), and Emergency Preparedness for Low Hazard Potential Impounding Structures (4VAC50-20-177), as applicable. All dam break inundation zone maps shall be signed and sealed by a professional engineer licensed in the Commonwealth of Virginia (unless solely developed to satisfy the requirements

of 4VAC50-20-177 which allows the owner to develop a simple dam break inundation map acceptable to the director, demonstrating the general inundation that would result from an impounding structure failure. Such maps required pursuant to this section do not require preparation by a professional licensed engineer; however, maps prepared by a licensed professional engineer are preferred and are additionally required to satisfy §§ 4VAC50-20-40 and 4VAC50-20-54.)

A dam break analysis using an approved hydrologic/hydraulic computer model shall be conducted by the dam owner's professional engineer. The modeling effort must conform to the intended use of the chosen computer model. Mixing the criteria of one procedure, listed in 4VAC50-20-320 (Acceptable design procedures and references) with criteria from another procedure, unless otherwise mentioned, is prohibited. Compute modeling must generate appropriate inflow hydrographs which are routed through the dam and downstream of the dam. Some computer models that are acceptable include HEC-1, HEC-HMS, HEC-RAS and the NRCS computer models TR-60 with TR-66. Other computer models may be used if approved by the DCR Regional Engineer prior to submitting the results to the Division of Dam Safety and Floodplain Management. Present and planned land-use for which a development plan has been officially approved by the locality in the dam break inundation zones downstream from the impounding structure shall be considered when conducting the dam break analysis.

For the validation of the hazard potential of a dam and the development of an Emergency Action Plan, at a minimum, the following shall be reflected on each map using an approved hydrologic/hydraulic computer model and shown on one map (numerous sheets are allowed to accommodate scale):

1. Sunny day dam break with the starting water surface elevation at the normal or typical water surface elevation of the impounding structure. If the impounding structure was designed and built for flood control, the starting water surface elevation shall be at the crest of the auxiliary or emergency spillway.
2. Dam failure during the required spillway design flood. An overtopping failure shall be modeled if the emergency spillway is unable to pass the spillway design flood without overtopping the crest of the dam. A piping failure shall be modeled if the emergency spillway has enough capacity to pass the required spillway design flood without overtopping the crest of the dam.
3. Routing the spillway design flood through the dam without any failure.
4. Dam failure during the Probable Maximum Flood.

Topographic information, including TINS, that show at a minimum ten-foot contour elevations shall be used to develop the hydrologic/hydraulic computer model downstream of the dam, including cross sections at potential damage locations (homes, businesses, roads, utilities, etc.) downstream of the dam. The dam owner's engineer must develop reliable cross sections to input into the computer model. If adequate topographic information is not available, the dam owner must provide an alternative method for identifying potential damage locations that must be approved by the DCR Regional Engineer, prior to initiating the evaluation. Topography may be a component of the submitted inundation map; however, map clutter must be avoided. If the topography is not submitted on the inundation map, a copy of the topographical information or

TINS used shall be submitted with the engineering analysis. Paper copies of all hydrologic and hydraulic computer model runs shall be provided to the Regional Engineer.

The owner's engineer shall use sanctioned engineering criteria and sound professional judgment for the worst case storm conditions in the selection of:

a. Dam failure parameters
b. Rainfall distributions
c. Flood routing procedures and coefficients
d. Use of available topography and supporting field surveys
e. Development of SCS Curve Numbers
f. Development of spillway rating curves and area-capacity curves
g. Determination of the Time of Concentration and/or lag time
h. Other steps used during the modeling and analysis of flood conditions in the watershed and downstream of the impounding structure.

The judgments and the engineering criteria used by the dam owner's engineer shall be reviewed and approved by the DCR Regional Engineer for appropriateness. The DCR Regional Engineer will provide specific guidance via written correspondence to the dam owner should the judgments or the use of the engineering criteria be determined to be inappropriate. If the map is acceptable, a statement of confirmation that the map appears to be in conformance with the regulations will also be provided to the owner.

The computer model shall be extended to a point downstream of the impounding structure where the water surface elevations of the spillway design flood with and without dam failure converge to within one foot of each other or to the last impacted structure caused by a sunny-day dam failure, whichever is farthest downstream.

The following shall be clearly marked at each potential damage location on each map:

a. Cross Section number and distance downstream from the dam to the nearest tenth of a mile
b. Relative time of travel, in minutes, of the first flood waters associated with a dam failure to reach the impact location
c. Relative time of travel, in minutes, of the peak flood level associated with a dam failure to reach the impact location
d. Maximum depth of water with a dam failure at each impact location in feet (depth of water on the structure)

The map lines delineating the inundation areas shall be drawn in such thickness (solid, dashed or dotted lines in black) to identify the inundation limits as the main feature of the map. The lines shall not obliterate the location of structures, or features which are shown as being inundated. The map shall also identify the scale and show the north arrow on each map sheet.

Inundation maps may have color in the background and shall be at a scale where impacted structures downstream may be clearly seen. The maps should not utilize color-coding of the inundation lines since the maps will often be copied on black and white reproduction equipment. If the inundation area is too large to be shown on one map, an index map shall be included which

shows the full extent of the inundation area and the outline of the detailed maps with an identifier for each map sheet. Impacted structures (homes, businesses, roads, utilities, etc) shall be clearly shown and if cross-hatching is used it must not obscure the structures. The physical addresses and contact persons may be located on a separate attachment to avoid clutter. This information will be used to aid emergency responders in quickly locating impacted structures and conducting evacuations. Inundation maps shall not be produced in a size larger than 11'' by 17" and the final size must be folded to a size of 8 1/2" by 11". The inundation maps shall be submitted to the DCR Regional Engineer electronically in a Windows compatible image format and as a set of paper maps. Acceptable digital image formats consist of JPEG, TIF, BMP, GIF, PNG, or EMF files. Adobe software constructed PDFs are also acceptable. Image resolution should be sufficient to view and read the necessary information noted above.

A narrative describing the accuracy and limitation of the information supplied on the inundation maps, including reference to the datum used, shall be provided to the DCR Regional Engineer. Since local officials are likely to use the maps for evacuation purposes, the following note shall be attached to each map: "Mapping of flooded areas and flood wave travel times are approximate. Timing and extent of actual inundation may differ from the information presented on this map."

The hazard potential classification shall be proposed by the dam owner and shall be subject to reclassification by the Virginia Soil and Water Conservation Board, upon review of the information submitted by the dam owner and the owner's engineer and any pertinent information regarding potential impacts downstream of the dam caused by a failure of the dam.

Incremental Damage Assessment

Once a dam owner has had the consulting engineer complete the Dam Break Inundation Zone Analysis and Map (Map) and concluded a determination of the hazard classification and, once the hazard classification has been reviewed and accepted by the appropriate Regional Engineer; the Spillway Design Flood (SDF) would then be identified in Table 1 of the Impounding Structure Regulations (4VAC50-20-50). Should the dam owner wish to consider lowering the SDF through an Incremental Damage Analysis (IDA), the consulting engineer must then perform the following procedures. However, as noted in Table 1 of the Impounding Structure Regulations an SDF less than the Minimum Threshold will not be accepted.

1. Identify the Required SDF
Once the hazard classification is determined, Table 1 will identify the required SDF. If the dam owner decides to have the consulting engineer perform an incremental damage analysis, the computer models previously used to determine the inundation and subsequent hazard classification must be used to identify the flood event at which no significant increase in damage will occur due to a dam failure. This process may start with the required SDF or with the Minimum Threshold for IDA (Minimum Threshold), see Table 1.

2. Have Models Showing all Requirements with Backup Calculations
The consulting engineer must have at a minimum, hydrologic computer models for the Sunny-Day Dam Failure, Spillway Design Flood With a Dam Failure, Spillway Design Flood Without a

Dam Failure and the Probable Maximum Flood With a Dam Failure. These models must be routed downstream of the dam to a point in which the maximum water surface elevations during the SDF with a Dam Failure and the SDF without a Dam Failure converge to within one foot of each other or to the last impacted structure cause by a sunny-day dam failure, whichever is farthest downstream.

3. Prepare the Map
The results of the models are plotted onto the Map to demonstrate inundation expected by each event. All homes, buildings, roads and other impacted facilities shall be shown on the map.

4. Use IDA to Determine if the SDF can be Reduced
If it can be shown that the aforementioned list of potentially impacted facilities would, at some lesser flood compared to the SDF, be severely damaged due to floods associated storm flows without a dam failure then the owner can have the consulting engineer adjust the input storm in the computer models in an attempt to identify at what storm event that a dam failure would not significantly add to damaged facilities or threats to life downstream.

When structures, such as homes, businesses, and utilities buildings are identified in the inundation zone, the consulting engineer can determine significant impact to that structure if, during a dam failure, the water depth will equal or exceed two feet above the ground/building connection. If the product of the depth of water on a structure in feet and the velocity of water flowing at that location in feet per second equals seven (7) or more, then the structure is considered significantly impacted and projects the probable loss of life. If the depth of water is less than two feet on the structure and the product of the total water depth and the velocity of water at the structure is less than seven (7) during any dam failure, the structure would not be considered threatened nor would result in probable loss of life.

5. Determination of the Adjusted SDF
An IDA should always result in the same answer no matter whether you start at the SDF or at the Minimum Threshold working toward the Adjusted SDF. The Adjusted SDF should represent the maximum flood at which the dam will provide maximum flood protection downstream and no further damages would be expected with larger flood events with a dam failure.

The dam owner may choose to have the engineer design the emergency spillway to the Adjusted SDF or some flood event larger than the adjusted SDF that would consider potential increases in hazard classification due to future development downstream of the dam.

The dam owner's consulting engineer will need to provide one set of paper copies of the computer model results and an electronic copy on diskette. Profiles, calculations and other supporting information used to determine an adjusted SDF shall be submitted to the Dam Safety Regional Engineer for review and acceptance.

Dam Safety's acceptance of an adjusted SDF does not guarantee that any future development will not place new increased spillway capacity requirements on the dam owner.

For a Secondary roadway (secondary highway, low-volume urban street, service road and other low-volume roadway) located below a dam the hazard classification may be significant requiring a SDF of ½ PMF (see roadways guidance for additional information on how roadways may impact hazard classification). If the dam owner desires, an IDA may be performed that would identify at what flood event (between the ½ PMF and the 100-Year Flood) the computed water surface elevation for the flood event without a dam failure would result in a water level at or just below the roadway surface edge without a dam failure. With this storm event, if a dam failure would overtop the roadway by four (4) inches or more, it could lead to possible loss of life of persons in vehicles on the roadway or loss of the roadway itself. If the dam failure does not overtop the roadway for the Sunny-Day Failure and storm events up to the PMF with a dam failure, then the dam should be classified as Low Hazard, if there are no other impacted structures or facilities, should the dam fail. If the roadway is a major roadway (interstate, primary highway, high-volume urban street or other high-volume roadway) then the incremental damage analysis would start at PMF and could result in a SDF no less than the ½ PMF.

If there are several roadways below a dam, then the roadway that results in the largest spillway design flood applies.

If a secondary or low volume roadway crosses the dam then the SDF would usually be at a minimum the ½ PMF (see roadways guidance for additional information on how roadways may impact hazard classification) and no IDA would be permitted for a dam with a significant hazard classification. If a major roadway crosses the dam then the SDF would be the PMF and no IDA would be permitted.

In cases where there are other facilities below the dam along with roadways, the impact that creates the highest hazard classification shall dictate. If permitted, the owner may choose to have the consulting engineer perform an IDA in the hopes of lowering the SDF.

V Adoption, Amendments, and Repeal:

This document was adopted by the Board on XXXX, 2010 and may be amended or repealed as necessary by the Board.

VIRGINIA ACTS OF ASSEMBLY -- 2010 SESSION

CHAPTER 249

An Act to amend and reenact § 10.1-605 of the Code of Virginia, relating to dam safety.

[S 276]

Approved April 8, 2010

Be it enacted by the General Assembly of Virginia:

1. That § 10.1-605 of the Code of Virginia is amended and reenacted as follows:

§ 10.1-605. Promulgation of regulations by the Board.

A. The Board shall promulgate regulations to ensure that impounding structures in the Commonwealth are properly and safely constructed, maintained and operated. Dam safety regulations promulgated by the State Water Control Board shall remain in full force until amended in accordance with applicable procedures.

B. The Board's Impounding Structure Regulations shall not require any impounding structure in existence or under a construction permit prior to July 1, 2010, that is currently classified as high hazard, or is subsequently found to be high hazard through reclassification, to upgrade its spillway to pass a rainfall event greater than the maximum recorded within the Commonwealth, which shall be deemed to be 90 percent of the probable maximum precipitation.

Additionally, such an impounding structure shall be determined to be in compliance with the spillway requirements of the regulations provided that (i) the impounding structure will pass two-thirds of the reduced probable maximum precipitation requirement described in this subsection and (ii) the dam owner certifies annually that such impounding structure meets each of the following conditions:

1. The owner has a current emergency action plan that is approved by the Board and that is developed and updated in accordance with the regulations;

2. The owner has exercised the emergency action plan in accordance with the regulations and conducts a table-top exercise at least once every two years;

3. The Department has verification that both the local organization for emergency management and the Virginia Department of Emergency Management have on file current emergency action plans and updates for the impounding structure;

4. That conditions at the impounding structure are monitored on a daily basis and as dictated by the emergency action plan;

5. The impounding structure is inspected at least annually by a professional engineer and all observed deficiencies are addressed within 120 days of such inspection;

6. The owner has a dam break inundation zone map developed in accordance with the regulations that is acceptable to the Department;

7. The owner is insured in an amount that will substantially cover the costs of downstream property losses to others that may result from a dam failure; and

8. The owner shall post the dam's emergency action plan on his website, or upon the request of the owner, the Department or another state agency responsible for providing emergency management services to citizens agrees to post the plan on its website. If the Department or another state agency agrees to post the plan on its website, the owner shall provide the plan in a format suitable for posting.

A dam owner who meets the conditions of subdivisions 1 through 8, but has not provided record drawings to the Department for his impounding structure, shall submit a complete record report developed in accordance with the construction permit requirements of the Impounding Structure Regulations, excluding the required submittal of the record drawings.

2. That the Virginia Soil and Water Conservation Board may amend its Impounding Structure Regulations to conform with the provisions of this act through a regulatory process that is exempt from the requirements of the Administrative Process Act (§ 2.2-4000 et seq.) of the Code of Virginia.

3. That an emergency exists and this act is in force from its passage.

VIRGINIA ACTS OF ASSEMBLY -- 2010 SESSION

CHAPTER 270

An Act to amend and reenact §§ 10.1-605, 10.1-607.1, and 10.1-609 of the Code of Virginia, relating to dam safety.

[H 438]

Approved April 8, 2010

Be it enacted by the General Assembly of Virginia:

1. That §§ 10.1-605, 10.1-607.1, and 10.1-609 of the Code of Virginia are amended and reenacted as follows:

§ 10.1-605. Promulgation of regulations by the Board; guidance document.

A. The Board shall ~~promulgate~~ *adopt* regulations to ensure that impounding structures in the Commonwealth are properly and safely constructed, maintained and operated. Dam safety regulations promulgated by the State Water Control Board shall remain in full force until amended in accordance with applicable procedures.

B. The Board's regulations shall establish an incremental damage analysis procedure that permits the spillway design flood requirement for an impounding structure to be reduced to the level at which dam failure shall not significantly increase downstream hazard to life or property, provided that the spillway design flood requirement shall not be reduced to below the 100-year flood event for high or significant hazard impounding structures, or to below the 50-year flood event for low hazard potential impounding structures.

C. The Board shall consider the impact of limited-use or private roadways with low traffic volume and low public safety risk that are downstream from or across an impounding structure in the determination of the hazard potential classification of an impounding structure.

§ 10.1-607.1. Criteria for designating a dam as unsafe.

A. Designation of a dam as unsafe shall be based on one or more of the following findings:

1. The dam has serious deficiencies in its design or construction or has a physical condition that if left unaddressed could result in a failure that may result in loss of life or *significant* damage to downstream property.

2. The design, construction, operation, or maintenance of the dam is such that its expected performance during flooding conditions threatens the structural integrity of the dam.

B. After completion of the safety inspections pursuant to § 10.1-607, or as otherwise informed of an unsafe condition, the Department shall take actions in accordance with § 10.1-608 or 10.1-609 depending on the degree of hazard and imminence of failure caused by the unsafe condition.

§ 10.1-609. Unsafe dams presenting nonimminent danger.

A. Within a reasonable time after completion of a safety inspection of an impounding structure authorized by § 10.1-607, the Board shall issue a report to the owner of the impounding structure containing its findings and recommendations for correction of any deficiencies which could threaten life or property if not corrected. Owners who have been issued a report containing recommendations for correction of deficiencies shall undertake to implement the recommendations contained in the report according to the schedule of implementation contained in the report. If an owner fails or refuses to commence or diligently implement the recommendations for correction of deficiencies according to the schedule contained in an issued report, the Director shall have the authority to issue an administrative order directing the owner to commence implementation and completion of such recommendations according to the schedule contained in the report with modifications as appropriate. Within thirty days after being served by personal service or by mail with a copy of an order issued pursuant to this section, any owner shall have the right to petition the Board for a hearing. *As part of his petition, a dam owner may submit to the Board his own plan, consistent with regulations adopted pursuant to § 10.1-605, to address the recommendations for correction of deficiencies and the schedule of implementation contained in the report. The Board shall determine if the submitted plan and schedule are sufficient to address deficiencies.* A timely filed petition shall stay the effect of the administrative order.

The hearing shall be conducted before the Board or a designated member thereof pursuant to § 2.2-4019. The Board shall have the authority to affirm, modify, amend or cancel the administrative order. Any owner aggrieved by a decision of the Board after a hearing shall have the right to judicial review of the final Board decision pursuant to the provisions of the Administrative Process Act (§ 2.2-4000 et seq.).

B. The provisions of subsection A of this section notwithstanding, if the Director determines, after the report is issued, that changed circumstances justify reclassifying the deficiencies of an impounding structure as an imminent danger to life or property, the Director may proceed directly under § 10.1-613 for enforcement of his order, and the owner shall have the opportunity to contest the fact based upon

which the administrative order was issued.

C. The Director, upon a determination that there is an unsafe condition at an impounding structure, is authorized to cause the lowering or complete draining of such impoundment until the unsafe condition has been corrected at the owner's expense and prior to any authorization to refill.

An owner who fails to comply with the provisions contained in an administrative order of the Department shall be subject to procedures set out in § 10.1-613 and the penalties authorized under §§ 10.1-613.1 and 10.1-613.2.

D. No persons, other than those authorized to maintain an impounding structure, shall interfere with the operation of an impounding structure.

Virginia Administrative Code

Database updated through November 15, 2010

Part I

General

4VAC50-20-10. Authority.

This chapter is promulgated by the Virginia Soil and Water Conservation Board in accordance with the provisions of the Dam Safety Act, Article 2, Chapter 6, Title 10.1 (§ 10.1-604 et seq.), of the Code of Virginia.

Statutory Authority

§ 10.1-605 of the Code of Virginia.

Historical Notes

Derived from VR625-01-00 § 1.1, eff. February 1, 1989.

4VAC50-20-20. General provisions.

A. This chapter provides for the proper and safe design, construction, operation and maintenance of impounding structures to protect public safety. This chapter shall not be construed or interpreted to relieve the owner or operator of any impoundment or impounding structure of any legal duties, obligations or liabilities incident to ownership, design, construction, operation or maintenance.

B. Approval by the board of proposals for an impounding structure shall in no manner be construed or interpreted as approval to capture or store waters. For information concerning approval to capture or store waters, see Chapter 8 (§ 62.1-107) of Title 62.1 of the Code of Virginia, and other provisions of law as may be applicable.

C. In promulgating this chapter, the board recognizes that no impounding structure can ever be completely "fail-safe," because of incomplete understanding of or uncertainties associated with natural (earthquakes and floods) and manmade (sabotage) destructive forces; with material behavior and response to those forces; and with quality control during construction.

D. All engineering analyses required by this chapter, including but not limited to, plans, specifications, hydrology, hydraulics and inspections shall be conducted or overseen by and bear the seal of a professional engineer licensed to practice in Virginia.

E. Design, inspection and maintenance of impounding structures shall be conducted utilizing

competent, experienced, engineering judgment that takes into consideration factors including but not limited to local topography and meteorological conditions.

F. The forms noted in this chapter are available from the department at the department's website.

Statutory Authority

§ 10.1-605 of the Code of Virginia.

Historical Notes

Derived from VR625-01-00 § 1.2, eff. February 1, 1989; amended, Virginia Register Volume 24, Issue 25, eff. September 26, 2008.

4VAC50-20-30. Definitions.

The following words and terms when used in this chapter shall have the following meanings unless the context clearly indicates otherwise:

"Acre-foot" means a unit of volume equal to 43,560 cubic feet or 325,853 gallons (equivalent to one foot of depth over one acre of area).

"Agricultural purpose" means the production of an agricultural commodity as defined in § 3.1-249.27 of the Code of Virginia that requires the use of impounded waters.

"Agricultural purpose dams" means impounding structures which are less than 25 feet in height or which create a maximum impoundment smaller than 100 acre-feet, and operated primarily for agricultural purposes.

"Alteration" means changes to an impounding structure that could alter or affect its structural integrity. Alterations include, but are not limited to, changing the height or otherwise enlarging the dam, increasing normal pool or principal spillway elevation or physical dimensions, changing the elevation or physical dimensions of the emergency spillway, conducting necessary structural repairs or structural maintenance, or removing the impounding structure. Structural maintenance does not include routine maintenance.

"Alteration permit" means a permit required for any alteration to an impounding structure.

"Board" means the Virginia Soil and Water Conservation Board.

"Conditional Operation and Maintenance Certificate" means a certificate required for impounding structures with deficiencies.

"Construction" means the construction of a new impounding structure.

"Construction permit" means a permit required for the construction of a new impounding structure.

"Dam break inundation zone" means the area downstream of a dam that would be inundated or otherwise directly affected by the failure of a dam.

"Department" means the Virginia Department of Conservation and Recreation.

"Design flood" means the calculated volume of runoff and the resulting peak discharge utilized in the evaluation, design, construction, operation and maintenance of the impounding structure.

"Director" means the Director of the Department of Conservation and Recreation or his designee.

"Drill" means a type of emergency action plan exercise that tests, develops, or maintains skills in an emergency response procedure. During a drill, participants perform an in-house exercise to verify telephone numbers and other means of communication along with the owner's response. A drill is considered a necessary part of ongoing training.

"Emergency Action Plan or EAP" means a formal document that recognizes potential impounding structure emergency conditions and specifies preplanned actions to be followed to minimize loss of life and property damage. The EAP specifies actions the owner must take to minimize or alleviate emergency conditions at the impounding structure. It contains procedures and information to assist the owner in issuing early warning and notification messages to responsible emergency management authorities. It shall also contain dam break inundation zone maps as required to show emergency management authorities the critical areas for action in case of emergency.

"Emergency Action Plan Exercise" means an activity designed to promote emergency preparedness; test or evaluate EAPs, procedures, or facilities; train personnel in emergency management duties; and demonstrate operational capability. In response to a simulated event, exercises should consist of the performance of duties, tasks, or operations very similar to the way they would be performed in a real emergency. An exercise may include but not be limited to drills and tabletop exercises.

"Emergency Preparedness Plan" means a formal document prepared for Low Hazard impounding structures that provides maps and procedures for notifying owners of downstream property that may be impacted by an emergency situation at an impounding structure.

"Freeboard" means the vertical distance between the maximum water surface elevation associated with the spillway design flood and the top of the impounding structure.

"Height" means the hydraulic height of an impounding structure. If the impounding structure spans a stream or watercourse, height means the vertical distance from the natural bed of the stream or watercourse measured at the downstream toe of the impounding structure to the top of the impounding

structure. If the impounding structure does not span a stream or watercourse, height means the vertical distance from the lowest elevation of the downstream limit of the barrier to the top of the impounding structure.

"Impounding structure" or "dam" means a man-made structure, whether a dam across a watercourse or structure outside a watercourse, used or to be used to retain or store waters or other materials. The term includes: (i) all dams that are 25 feet or greater in height and that create an impoundment capacity of 15 acre-feet or greater, and (ii) all dams that are six feet or greater in height and that create an impoundment capacity of 50 acre-feet or greater. The term "impounding structure" shall not include: (a) dams licensed by the State Corporation Commission that are subject to a safety inspection program; (b) dams owned or licensed by the United States government; (c) dams operated primarily for agricultural purposes which are less than 25 feet in height or which create a maximum impoundment capacity smaller than 100 acre-feet; (d) water or silt retaining dams approved pursuant to § 45.1-222 or § 45.1-225.1 of the Code of Virginia; or (e) obstructions in a canal used to raise or lower water.

"Impoundment" means a body of water or other materials the storage of which is caused by any impounding structure.

"Life of the impounding structure" and "life of the project" mean that period of time for which the impounding structure is designed and planned to perform effectively, including the time required to remove the structure when it is no longer capable of functioning as planned and designed.

"Maximum impounding capacity" means the volume of water or other materials in acre-feet that is capable of being impounded at the top of the impounding structure.

"Normal or typical water surface elevation" means the water surface elevation at the crest of the lowest ungated outlet from the impoundment or the elevation of the normal pool of the impoundment if different than the water surface elevation at the crest of the lowest ungated outlet. For calculating sunny day failures for flood control impounding structures, stormwater detention impounding structures, and related facilities designed to hold back volumes of water for slow release, the normal or typical water surface elevation shall be measured at the crest of the auxiliary or emergency spillway.

"Operation and Maintenance Certificate" means a certificate required for the operation and maintenance of all impounding structures.

"Owner" means the owner of the land on which an impounding structure is situated, the holder of an easement permitting the construction of an impounding structure and any person or entity agreeing to

maintain an impounding structure. The term "owner" may include the Commonwealth or any of its political subdivisions, including but not limited to sanitation district commissions and authorities, any public or private institutions, corporations, associations, firms or companies organized or existing under the laws of this Commonwealth or any other state or country, as well as any person or group of persons acting individually or as a group.

"Planned land use" means land use that has been approved by a locality or included in a master land use plan by a locality, such as in a locality's comprehensive land use plan.

"Spillway" means a structure to provide for the controlled release of flows from the impounding structure into a downstream area.

"Stage I Condition" means a flood watch or heavy continuous rain or excessive flow of water from ice or snow melt.

"Stage II Condition" means a flood watch or emergency spillway activation or impounding structure overtopping where a failure may be possible.

"Stage III Condition" means an emergency spillway activation or impounding structure overtopping where imminent failure is probable.

"Sunny day dam failure" means the failure of an impounding structure with the initial water level at the normal reservoir level, usually at the lowest ungated principal spillway elevation or the typical operating water level.

"Tabletop Exercise" means a type of emergency action plan exercise that involves a meeting of the impounding structure owner and the state and local emergency management officials in a conference room environment. The format is usually informal with minimum stress involved. The exercise begins with the description of a simulated event and proceeds with discussions by the participants to evaluate the EAP and response procedures and to resolve concerns regarding coordination and responsibilities.

"Top of the impounding structure" means the lowest point of the nonoverflow section of the impounding structure.

"Watercourse" means a natural channel having a well-defined bed and banks and in which water normally flows.

Statutory Authority

§ 10.1-605 of the Code of Virginia.

Historical Notes

Derived from VR625-01-00 § 1.3, eff. February 1, 1989; amended, Virginia Register Volume 18, Issue 14, eff. July 1, 2002; Volume 24, Issue 25, eff. September 26, 2008.

4VAC50-20-40. Hazard potential classifications of impounding structures.

A. Impounding structures shall be classified in one of three hazard classifications as defined in subsection B of this section and Table 1.

B. For the purpose of this chapter, hazards pertain to potential loss of human life or damage to the property of others downstream from the impounding structure in event of failure or faulty operation of the impounding structure or appurtenant facilities. Hazard potential classifications of impounding structures are as follows:

1. High Hazard Potential is defined where an impounding structure failure will cause probable loss of life or serious economic damage. "Probable loss of life" means that impacts will occur that are likely to cause a loss of human life, including but not limited to impacts to residences, businesses, other occupied structures, or major roadways. Economic damage may occur to, but not be limited to, building(s), industrial or commercial facilities, public utilities, major roadways, railroads, personal property, and agricultural interests. "Major roadways" include, but are not limited to, interstates, primary highways, high-volume urban streets, or other high-volume roadways.

2. Significant Hazard Potential is defined where an impounding structure failure may cause the loss of life or appreciable economic damage. "May cause loss of life" means that impacts will occur that could cause a loss of human life, including but not limited to impacts to facilities that are frequently utilized by humans other than residences, businesses, or other occupied structures, or to secondary roadways. Economic damage may occur to, but not be limited to, building(s), industrial or commercial facilities, public utilities, secondary roadways, railroads, personal property, and agricultural interests. "Secondary roadways" include, but are not limited to, secondary highways, low-volume urban streets, service roads, or other low-volume roadways.

3. Low Hazard Potential is defined where an impounding structure failure would result in no expected loss of life and would cause no more than minimal economic damage. "No expected loss of life" means no loss of human life is anticipated.

C. The hazard potential classification shall be proposed by the owner and shall be subject to approval by the board. To support the appropriate hazard classification, dam break analysis shall be conducted by the owner's engineer. Present and planned land-use for which a development plan has been officially

approved by the locality in the dam break inundation zones downstream from the impounding structure shall be considered in determining the classification.

D. Impounding structures shall be subject to reclassification by the board as necessary.

Statutory Authority

§ 10.1-605 of the Code of Virginia.

Historical Notes

Derived from VR625-01-00 § 1.4, eff. February 1, 1989; amended, Virginia Register Volume 24, Issue 25, eff. September 26, 2008.

4VAC50-20-50. Performance standards required for impounding structures.

A. In accordance with the definitions provided by § 10.1-604 of the Code of Virginia and 4VAC50-20-30, an impounding structure shall be regulated if the impounding structure is 25 feet or greater in height and creates a maximum impounding capacity of 15 acre-feet or greater, or the impounding structure is six feet or greater in height and creates a maximum impounding capacity of 50 acre-feet or greater and is not otherwise exempt from regulation by the Code of Virginia. Impounding structures exempted from this chapter are those that are:

1. Licensed by the State Corporation Commission that are subject to a safety inspection program;

2. Owned or licensed by the United States government;

3. Operated primarily for agricultural purposes that are less than 25 feet in height or that create a maximum impoundment capacity smaller than 100 acre-feet;

4. Water or silt-retaining dams approved pursuant to § 45.1-222 or 45.1-225.1 of the Code of Virginia; or

5. Obstructions in a canal used to raise or lower water.

Impounding structures of regulated size and not exempted shall be constructed, operated and maintained such that they perform in accordance with their design and purpose throughout the life of the project. For impounding structures, the spillway(s) capacity shall perform at a minimum to safely pass the appropriate spillway design flood as determined in Table 1. For the purposes of utilizing Table 1, Hazard Potential Classification shall be determined in accordance with 4VAC50-20-40.

TABLE 1

Impounding Structure Regulations

Applicable to all impounding structures that are 25 feet or greater in height and that create a maximum impounding capacity of 15 acre-feet or greater, and to all impounding structures that are six feet or greater in height and that create a maximum impounding capacity of 50 acre-feet or greater and is not otherwise exempt from regulation by the Code of Virginia.

Hazard Potential Class of Dam	Spillway Design Flood (SDF)[B]	Minimum Threshold for Incremental Damage Analysis
High	PMF[C]	.50 PMF
Significant	.50 PMF	100-YR[D]
Low	100-YR[D]	50-YR[E]

B. The spillway design flood (SDF) represents the largest flood that need be considered in the evaluation of the performance for a given project. The impounding structure shall perform so as to safely pass the appropriate SDF. Reductions in the established SDF may be evaluated through the use of incremental damage analysis pursuant to 4VAC50-20-52. The SDF established for an impounding structure shall not be less than those standards established elsewhere by state law or regulations, including but not limited to the Virginia Stormwater Management Program (VSMP) Permit Regulations (4VAC50-60). Due to potential for future development in the dam break inundation zone that would necessitate higher spillway design flood standards or other considerations, owners may find it advisable to consider a higher spillway design flood standard than is required.

C. PMF: Probable Maximum Flood is the flood that might be expected from the most severe combination of critical meteorologic and hydrologic conditions that are reasonably possible in the region. The PMF is derived from the current probable maximum precipitation (PMP) available from the National Weather Service, NOAA. In some cases, a modified PMF may be calculated utilizing local topography, meteorological conditions, hydrological conditions, or PMP values supplied by NOAA. Any deviation in the application of established developmental procedures must be explained and justified by the owner's engineer. The owner's engineer must develop PMF hydrographs for 6-, 12-, and 24-hour durations. The hydrograph that creates the largest peak outflow is to be used to determine capacity for nonfailure and failure analysis. Present and planned land-use conditions shall be considered in determining the runoff characteristics of the drainage area.

D. 100-Yr: 100-year flood represents the flood magnitude expected to be equaled or exceeded on the average of once in 100 years. It may also be expressed as an exceedence probability with a 1.0% chance of being equaled or exceeded in any given year. Present and planned land-use conditions shall be

considered in determining the runoff characteristics of the drainage area.

E. 50-Yr: 50-year flood represents the flood magnitude expected to be equaled or exceeded on the average of once in 50 years. It may also be expressed as an exceedence probability with a 2.0% chance of being equaled or exceeded in any given year. Present and planned land-use conditions shall be considered in determining the runoff characteristics of the drainage area.

Statutory Authority

§ 10.1-605 of the Code of Virginia.

Historical Notes

Derived from VR625-01-00 § 1.5, eff. February 1, 1989; amended, Virginia Register Volume 18, Issue 14, eff. July 1, 2002; Volume 24, Issue 25, eff. September 26, 2008; Errata, 25:3 VA.R. 542 October 13, 2008.

4VAC50-20-51. Special criteria for certain low hazard impounding structures.

A. Notwithstanding the requirements of this chapter, should the failure of a low hazard potential impounding structure cause no expected loss of human life and no economic damage to any property except property owned by the impounding structure owner, then the owner may follow the below requirements instead of the requirements specified in this chapter:

1. No map required pursuant to 4VAC50-20-54 shall be required to be developed for the impounding structure should a licensed professional engineer certify that the impounding structure is a low hazard potential impounding structure and eligible to utilize the provisions of this section;

2. The spillway design flood for the impounding structure is recommended as a minimum 50-year flood; however, no specific spillway design flood shall be mandatory for an impounding structure found to qualify under the requirements of this section;

3. No emergency preparedness plan prepared pursuant to 4VAC50-20-177 shall be required. However, the impounding structure owner shall notify the local emergency services coordinator in the event of a failure or emergency condition at the impounding structure;

4. An owner shall perform inspections of the impounding structure annually in accordance with the requirements of 4VAC50-20-105. No inspection of the impounding structure by a licensed professional engineer shall be required, however, so long as the owner certifies at the time of operation and maintenance certificate renewal that conditions at the impounding structure and downstream are unchanged since the last inspection conducted by a licensed professional

engineer; and

5. No certificate or permit fee established in this chapter shall be applicable to the impounding structure.

B. Any owner of an impounding structure electing to utilize the requirements of subsection A of this section shall otherwise comply with all other requirements of this chapter applicable to low hazard impounding structures.

C. The owner shall notify the department immediately of any change in circumstances that would cause the impounding structure to no longer qualify to utilize the provisions of this section.

Statutory Authority

§ 10.1-605 of the Code of Virginia.

Historical Notes

Derived from Virginia Register Volume 24, Issue 25, eff. September 26, 2008.

4VAC50-20-52. Incremental damage analysis.

A. When appropriate, the spillway design flood requirement may be reduced by the board in accordance with this section.

B. The owner's engineer may proceed with an incremental damage analysis. Once the owner's engineer has determined the required spillway design flood through application of Table 1, further analysis may be performed to evaluate the limiting flood condition for incremental damages Site-specific conditions should be recognized and considered. This analysis may be used to lower the spillway design flood. In no situation shall the allowable reduced level be less than the level at which the incremental increase in water surface elevation downstream due to failure of an impounding structure is no longer considered to present an additional downstream threat. This engineering analysis will need to present water surface elevations at each structure that may be impacted downstream of the dam. An additional downstream threat to persons or property is presumed to exist when water depths exceed two feet or when the product of water depth (in feet) and flow velocity (in feet per second) is greater than seven.

C. The spillway design flood shall not be reduced below the minimum threshold values as determined by Table 1.

D. The required spillway design flood shall be subject to reclassification by the board as necessary to reflect changed conditions at the impounding structure and in the dam break inundation zone.

Statutory Authority

§ 10.1-605 of the Code of Virginia.

Historical Notes

Derived from Virginia Register Volume 24, Issue 25, eff. September 26, 2008.

4VAC50-20-54. Dam break inundation zone mapping.

A. Dam break inundation zone maps shall be provided to the department to meet the requirements set out in Hazard Potential Classifications of Impounding Structures (4VAC50-20-40), Emergency Action Plan for High and Significant Potential Hazard Impounding Structures (4VAC50-20-175), and Emergency Preparedness for Low Hazard Potential Impounding Structures (4VAC50-20-177), as applicable.

B. The location of the end of the inundation mapping should be indicated where the water surface elevation of the dam break inundation zone and the water surface elevation of the spillway design flood during an impounding structure nonfailure event converge to within one foot of each other. The inundation maps shall be supplemented with water surface profiles showing the peak water surface elevation prior to failure and the peak water surface elevation after failure.

C. All inundation zone map(s), except those utilized in meeting the requirements of Emergency Preparedness for Low Hazard Potential Impounding Structures (4VAC50-20-177), shall be signed and sealed by a licensed professional engineer.

D. For determining the hazard potential classification, a minimum of the following shall be provided to the department:

1. A sunny day dam break analysis utilizing the volume retained at the normal or typical water surface elevation of the impounding structure;

2. A dam break analysis utilizing the spillway design flood with a dam failure;

3. An analysis utilizing the spillway design flood without a dam failure; and

4. For the purposes of future growth planning, a dam break analysis utilizing the probable maximum flood with a dam failure.

E. To meet the requirements of Emergency Preparedness set out in 4VAC50-20-177, all Low Hazard Potential impounding structures shall provide a simple map, acceptable to the department, demonstrating the general inundation that would result from a dam failure. Such maps do not require preparation by a professional licensed engineer, however, it is preferred that the maps be prepared by a licensed professional engineer.

F. To meet the Emergency Action Plan requirements set out in 4VAC50-20-175, all owners of High

and Significant Hazard Potential impounding structures shall provide dam break inundation map(s) representing the impacts that would occur with both a sunny day dam failure and a spillway design flood dam failure.

1. The map(s) shall be developed at a scale sufficient to graphically display downstream inhabited areas and structures, roads, public utilities that may be affected, and other pertinent structures within the identified inundation area. In coordination with the local organization for emergency management, a list of downstream inundation zone property owners and occupants, including telephone numbers may be plotted on the map or may be provided with the map for reference during an emergency.

2. Each map shall include the following statement: "The information contained in this map is prepared for use in notification of downstream property owners by emergency management personnel."

Statutory Authority

§ 10.1-605 of the Code of Virginia.

Historical Notes

Derived from Virginia Register Volume 24, Issue 25, eff. September 26, 2008.

4VAC50-20-58. Local government notifications.

For each certificate issued, the impounding structure owner shall send a copy of the certificate to the appropriate local government(s) with planning and zoning responsibilities. A project description and the map(s) required under 4VAC50-20-54 showing the area that could be affected by the impounding structure failure shall be submitted with the certificate. The department will provide a standard form cover letter for forwarding the certificate copy and accompanying materials.

Statutory Authority

§ 10.1-605 of the Code of Virginia.

Historical Notes

Derived from Virginia Register Volume 24, Issue 25, eff. September 26, 2008.

4VAC50-20-59. Reporting.

For the purposes of categorizing and reporting information to national and other dam safety databases, impounding structure size shall be classified as noted in Table 2.

Table 2

Impounding Structure Regulations

Maximum Impounding Capacity (Ac-Ft)	Height (Ft)
Large ≥ 50,000	≥ 100
Medium ≥ 1,000 & < 50,000	≥ 40 & < 100
Small ≥ 15 & < 1,000	≥ 6 & < 40

Statutory Authority

§ 10.1-605 of the Code of Virginia.

Historical Notes

Derived from Virginia Register Volume 24, Issue 25, eff. September 26, 2008.

Part II

Permit Requirements

4VAC50-20-60. Required permits.

A. No person or entity shall construct or begin to construct a new impounding structure until the board has issued a construction permit.

B. No person or entity shall alter or begin to alter an existing impounding structure until the board has issued an alteration permit. If an owner or the owner's engineer has determined that circumstances are impacting the integrity of the impounding structure that could result in the imminent failure of the impounding structure, temporary repairs may be initiated prior to approval from the board. The owner shall notify the department within 24 hours of identifying the circumstances impacting the integrity of the impounding structure. Such emergency notification shall not relieve the owner of the need to obtain an alteration permit as soon as may be practicable, nor shall the owner take action beyond that necessary to address the emergency situation.

C. When the owner submits an application to the board for any permit to construct or alter an impounding structure, the owner shall also inform the local government jurisdiction or jurisdictions that might be affected by the permit application.

D. In evaluating construction and alteration permit applications the director shall use the design criteria and standards referenced in 4VAC50-20-320.

Statutory Authority

§ 10.1-605 of the Code of Virginia.

Historical Notes

4VAC50-20-70. Construction permits.

A. Prior to preparing the complete design report for a Construction Permit, applicants may submit a preliminary design report to the department to determine if the project concept is acceptable to the department. The preliminary design report should contain, at a minimum, a general description of subdivisions 1 through 12 of subsection B of this section and subdivisions 1 and 2 of this subsection:

1. Proposed design criteria and a description of the size of the impounding structure, ground cover conditions, extent of current upstream development within the watershed and the hydraulic, hydrological and structural features, geologic conditions and the geotechnical engineering assumptions used to determine the foundation, impoundment rim stability and materials to be used.

2. Preliminary drawings of a general nature, including cross sections, plans and profiles of the impounding structure, proposed pool levels and types of spillway(s).

B. An applicant for a Construction Permit shall submit a design report. A form for the design report is available from the department (Design Report for the Construction or Alteration of Virginia Regulated Impounding Structures). The design report shall be prepared in accordance with 4VAC50-20-240. The design report is a required element of a complete application for a Construction Permit and shall include the following information:

1. Project information including a description of the proposed construction, name of the impounding structure, inventory number if available, name of the reservoir, and the purpose of the reservoir.

2. The proposed hazard potential classification in conformance with Table 1 of 4VAC50-20-50.

3. Location of the impounding structure including the city or county, number of feet or miles upstream or downstream of a highway and the highway number, name of the river or the stream, and the latitude and longitude.

4. Owner's name or representative if corporation, mailing address, residential and business telephone numbers, and other means of communication.

5. Owner's engineer's name, firm, professional engineer Virginia number, mailing address, and business telephone number.

6. Impounding structure data including type of material (earth, concrete, masonry or other) and the

following design configurations:

a. Top of impounding structure (elevation);

b. Downstream toe – lowest (elevation);

c. Height of impounding structure (feet);

d. Crest length – exclusive of spillway (feet);

e. Crest width (feet);

f. Upstream slope (horizontal to vertical); and

g. Downstream slope (horizontal to vertical).

7. Reservoir data including the following:

a. Maximum capacity (acre-feet);

b. Maximum pool (elevation);

c. Maximum pool surface area (acres);

d. Normal capacity (acre-feet);

e. Normal pool (elevation);

f. Normal pool surface area (acres); and

g. Freeboard (feet).

8. Spillway data including the type, construction material, design configuration, and invert elevation for the low level drain, the principal spillway, and the emergency spillway.

9. Watershed data including drainage area (square miles); type and extent of watershed development; time of concentration (hours); routing procedure; spillway design flood used and state source; design inflow hydrograph volume (acre-feet), peak inflow (cfs), and rainfall duration (hours); and freeboard during passage of the spillway design flood (feet).

10. A description of properties located in the dam break inundation zone downstream from the site of the proposed impounding structure, including the location and number of structures, buildings, roads, utilities and other property that would be endangered should the impounding structure fail.

11. Evidence that the local government or governments have been notified of the proposal by the owner to build an impounding structure.

12. Maps showing the location of the proposed impounding structure that include: the county or city in which the proposed impounding structure would be located, the location of roads and

access to the site, and the outline of the impoundment. Existing aerial photographs or existing topographic maps may be used for this purpose.

13. A report of the geotechnical investigations of the foundation soils, bedrock, or both and of the materials to be used to construct the impounding structure.

14. Design assumptions and analyses sufficient to indicate that the impounding structure will be stable during its construction and during the life of the impounding structure under all conditions of impoundment operations, including rapid filling, flood surcharge, seismic loadings, and rapid drawdown of the impoundment.

15. Evaluation of the stability of the impoundment rim area to safeguard against impoundment rim slides of such magnitude as to create waves capable of overtopping the impounding structure and evaluation of rim stability during seismic activity.

16. Design assumptions and analyses sufficient to indicate that seepage in, around, through or under the impounding structure, foundation and abutments will be reasonably and practically controlled so that internal or external forces or results thereof will not endanger the stability and integrity of the impounding structure. The design report shall also include information on graded filter design.

17. Calculations and assumptions relative to hydraulic and structural design of the spillway or spillways and energy dissipater or dissipaters. Spillway capacity shall conform to the criteria of Table 1 and 4VAC50-20-52.

18. Provisions to ensure that the impounding structure and appurtenances will be protected against unacceptable deterioration or erosion due to freezing and thawing, wind, wave action, and rain or any combination thereof.

19. Other pertinent design data, assumptions and analyses commensurate with the nature of the particular impounding structure and specific site conditions, including when required by this chapter, a plan and water surface profile of the dam break inundation zone.

20. A description of the techniques to be used to divert stream flow during construction so as to prevent hazard to life, health and property, including a detailed plan and procedures to maintain a stable impounding structure during storm events, a drawing showing temporary diversion devices, and a description of the potential impoundment during construction. Such diversion plans shall also be in accordance with applicable environmental laws.

21. A plan for project construction monitoring and quality control testing to confirm that construction materials and performance standards meet the design requirements set forth in the specifications.

22. Plans and specifications as required by 4VAC50-20-310.

23. Certification by the owner's engineer that the information provided pursuant to this subsection is true and correct in their professional judgment. Such certification shall include the engineer's signature, printed name, Virginia number, date, and the engineer's Virginia seal.

24. Owner's signature certifying receipt of the information provided pursuant to this subsection.

C. A plan of construction is a required element of a complete permit application for a Construction Permit and shall include:

1. A construction sequence with milestones.

2. Elements of the work plan that should be considered include, but are not limited to, foundation and abutment treatment, stream or river diversion, excavation and material fill processes, phased fill and compaction, testing and control procedures, construction of permanent spillway and drainage devices.

3. The erosion and sediment control plan, as approved by the local government, which minimizes soil erosion and sedimentation during all phases of construction.

4. The stormwater management plan or stormwater management facility plan, as approved by the local government, if the impounding structure is a stormwater management best management practice.

D. A Temporary Emergency Action Plan is a required element of a complete application for a Construction Permit and shall include:

1. A notification list of state and local emergency response agencies;

2. Provisions for notification of potentially affected residences and structures;

3. Construction site evacuation routes; and

4. Any other special notes particular to the project.

E. Within 120 days of receipt of a complete Construction Permit Application the board shall act on the application. If the application is not acceptable, the director shall inform the applicant within 60 days of receipt and shall explain what changes are required for an acceptable application. A complete Construction Permit Application consists of the following:

1. A final design report, submitted on the department form (Design Report for the Construction or Alteration of Virginia Regulated Impounding Structures), with attachments as needed, and certified by the owner and the owner's engineer;

2. A plan of construction that meets the requirements of subsection C of this section; and

3. A Temporary Emergency Action Plan that meets the requirements of subsection D of this section.

F. Prior to and during construction the owner shall provide the director with any proposed changes from the approved design, plans, specifications, or plan of construction. Approval shall be obtained from the director prior to the construction or installation of any changes that will affect the integrity or impounding capacity of the impounding structure.

G. The Construction Permit shall be valid for the plan of construction specified in the Construction Permit Application.

H. Construction must commence within two years after the permit is issued. If construction does not commence within two years after the permit is issued, the permit shall expire, except that the applicant may petition the board for extension of the two-year period and the board may extend such period for good cause with an appropriately updated plan of construction and Temporary Emergency Action Plan.

I. The board, the director, or both may take any necessary action consistent with the Dam Safety Act (§ 10.1-604 et seq. of the Code of Virginia) if any terms of this section or of the permit are violated, if the activities of the owner are not in accordance with the approved plans and specifications, if construction is conducted in a manner hazardous to downstream life or property, or for other cause as described in the Act.

J. Within 90 days after completion of the construction of an impounding structure, the owner shall submit:

1. A complete set of record drawings signed and sealed by a licensed professional engineer and signed by the owner:

2. A complete Record Report (Record Report for Virginia Regulated Impounding Structures) signed and sealed by a licensed professional engineer and signed by the owner that includes:

a. Project information including the name and inventory number of the structure, name of the reservoir, and whether the report is associated with a new or old structure;

b. Location of the impounding structure including the city or county, number of feet or miles

upstream or downstream of a highway and the highway number, name of the river or the stream, and the latitude and longitude;

c. Owner's name or representative if corporation, mailing address, residential and business telephone numbers, and other means of communication;

d. Information on the design report, including who it was prepared by, the date of design report preparation, whether it was for new construction or for an alteration, and the permit issuance date;

e. Owner's engineer's name, firm, professional engineer Virginia number, mailing address, and business telephone number;

f. Impounding structure data including type of material (earth, concrete, masonry or other) and the following configurations:

(1) Top of impounding structure (elevation);

(2) Downstream toe – lowest (elevation);

(3) Height of impounding structure (feet);

(4) Crest length – exclusive of spillway (feet);

(5) Crest width (feet);

(6) Upstream slope (horizontal to vertical); and

(7) Downstream slope (horizontal to vertical).

g. Reservoir data including the following:

(1) Maximum capacity (acre-feet);

(2) Maximum pool (elevation);

(3) Maximum pool surface area (acres);

(4) Normal capacity (acre-feet);

(5) Normal pool (elevation);

(6) Normal pool surface area (acres); and

(7) Freeboard (feet).

h. Spillway data including the type, construction material, design configuration, and invert elevation for the low level drain, the principal spillway, and the emergency spillway; a description of the low level drain and principal spillway including dimensions, trash guard

information, and orientation of intake and discharge to impounding structure if looking downstream; and a description of the emergency spillway including dimensions and orientation to impounding structure if looking downstream;

i. Watershed data including drainage area (square miles); type and extent of watershed development; time of concentration (hours); routing procedure; spillway design flood used and state source; design inflow hydrograph volume (acre-feet), peak inflow (cfs), and rainfall duration (hours); and freeboard during passage of the spillway design flood (feet);

j. Impounding structure history including the date construction was completed, who it was designed by and the date, who it was built by and the date, who performed inspections and dates, description of repairs, and confirmation as to whether the impounding structure has ever been overtopped;

k. A narrative describing the impounding structure procedures for operation, maintenance, filling, emergency action plan implementation, and structure evaluation;

l. A narrative describing the hydraulic and hydrologic data on the spillway design flood, hydrologic records, flood experience, flood potential, reservoir regulation, and comments or recommendations regarding these attributes;

m. A narrative describing stability of the foundation and abutments, embankment materials, and a written evaluation of each;

n. A complete set of record drawings signed and sealed by a licensed professional engineer and signed by the owner;

o. Certification by the owner's engineer that the information provided pursuant to subdivision J 2 of this section is true and correct in their professional judgment. Such certification shall include the engineer's signature, printed name, Virginia number, date, and the engineer's Virginia seal; and

p. Owner's signature certifying receipt of the information provided pursuant to subdivision J 2 of this section.

3. Certification from the licensed professional engineer who has monitored construction of the impounding structure during construction that, to the best of the engineer's judgment, knowledge and belief, the impounding structure and its appurtenances were constructed in conformance with the plans, specifications, drawings and other requirements approved by the board;

4. Operation and Maintenance Certificate Application (Operation and Maintenance Certificate Application for Virginia Regulated Impounding Structures) in accordance with 4VAC50-20-105; and

5. Emergency Action Plan or Emergency Preparedness Plan in accordance with 4VAC50-20-175 or 4VAC50-20-177.

K. Upon completion of construction, the impoundment may be filled upon board issuance of an Operation and Maintenance Certificate.

Statutory Authority

§ 10.1-605 of the Code of Virginia.

Historical Notes

Derived from VR625-01-00 § 2.2, eff. February 1, 1989; amended, Virginia Register Volume 18, Issue 14, eff. July 1, 2002; Volume 24, Issue 25, eff. September 26, 2008.

4VAC50-20-80. Alterations permits.

A. Alterations which would potentially affect the structural integrity of an impounding structure include, but are not limited to, changing the height or otherwise enlarging the dam, increasing normal pool or principal spillway elevation or physical dimensions, changing the elevation or physical dimensions of the emergency spillway, conducting necessary repairs or structural maintenance, or removing the impounding structure. Structural maintenance does not include routine maintenance.

B. An applicant for an Alteration Permit shall submit a design report. A form for the design report is available from the department (Design Report for the Construction or Alteration of Virginia Regulated Impounding Structures). The design report shall be prepared in accordance with 4VAC50-20-240. The design report shall include, but not be limited to, the following information:

1. Project information including a description and benefits of the proposed alteration, name of the impounding structure, inventory number if available, name of the reservoir, and the purpose of the reservoir.

2. The hazard potential classification in conformance with Table 1 in 4VAC50-20-50.

3. Location of the impounding structure including the city or county, number of feet or miles upstream or downstream of a highway and the highway number, name of the river or the stream, and the latitude and longitude.

4. Owner's name or representative if corporation, mailing address, residential and business telephone numbers, and other means of communication.

5. Owner's engineer's name, firm, professional engineer Virginia number, mailing address, and business telephone number.

6. Impounding structure data including type of material (earth, concrete, masonry or other) and the following configurations (note both existing and design configurations for each):

a. Top of impounding structure (elevation);

b. Downstream toe – lowest (elevation);

c. Height of impounding structure (feet);

d. Crest length – exclusive of spillway (feet);

e. Crest width (feet);

f. Upstream slope (horizontal to vertical); and

g. Downstream slope (horizontal to vertical).

7. Reservoir data including the following (note both existing and design configurations for each):

a. Maximum capacity (acre-feet);

b. Maximum pool (elevation);

c. Maximum pool surface area (acres);

d. Normal capacity (acre-feet);

e. Normal pool (elevation);

f. Normal pool surface area (acres); and

g. Freeboard (feet).

8. Spillway data including the type, construction material, design configuration, and invert elevation for the low level drain, the principal spillway, and the emergency spillway.

9. Watershed data including drainage area (square miles); type and extent of watershed development; time of concentration (hours); routing procedure; spillway design flood used and state source; design inflow hydrograph volume (acre-feet), peak inflow (cfs), and rainfall duration (hours); and freeboard during passage of the spillway design flood (feet).

10. Evidence that the local government has been notified of the alteration and repair plan.

11. Plans and specifications as required by 4VAC50-20-310. The plan view of the impounding structure site should represent all significant structures and improvements that illustrate the location of all proposed work.

12. A report of the geotechnical investigations of the foundation soils, bedrock, or both in the areas affected by the proposed alterations and of the materials to be used to alter the impounding structure.

13. Design assumptions and analyses sufficient to indicate that the impounding structure will be stable during the alteration of the impounding structure under all conditions of reservoir operations.

14. Calculations and assumptions relative to design of the improved spillway or spillways, if applicable.

15. Provisions to ensure that the impounding structure and appurtenances during the alteration will be protected against unacceptable deterioration or erosion due to freezing and thawing, wind, wave action and rain or any combination thereof.

16. Other pertinent design data, assumptions and analyses commensurate with the nature of the particular impounding structure and specific site conditions, including when required by this chapter, a plan and water surface profile of the dam break inundation zone.

17. If applicable, a description of the techniques to be used to divert stream flow during alteration work so as to prevent hazard to life, health and property, including a detailed plan and procedures to maintain a stable impounding structure during storm events, a drawing showing temporary diversion devices, and a description of the potential impoundment during the alteration. Such diversion plans shall be in accordance with the applicable environmental laws.

18. A plan for project construction monitoring and quality control testing to confirm that materials used in the alteration work and that performance standards meet the design requirements set forth in the specifications.

19. Certification by the owner's engineer that the information provided pursuant to this subsection is true and correct in their professional judgment. Such certification shall include the engineer's signature, printed name, Virginia number, date, and the engineer's Virginia seal.

20. Owner's signature certifying receipt of the information provided pursuant to this subsection.

C. A plan of construction is a required element of complete permit application and shall include:

1. A construction sequence with milestones.

2. Elements of the work plan that should be considered include, but are not limited to, foundation and abutment treatment, excavation and material fill processes, phased fill and compaction, testing and control procedures, construction of permanent spillway and drainage devices, if applicable.

3. The erosion and sediment control plan, as approved by the local government, which minimizes soil erosion and sedimentation during all phases of construction.

D. Within 120 days of receipt of a complete Alteration Permit Application, the board shall act on the application. If the application is not acceptable, the director shall inform the applicant within 60 days of receipt and shall explain what changes are required for an acceptable application. A complete Alteration Permit Application consists of the following:

1. A final design report with attachments as needed, and certified by the owner;

2. A plan of construction that meets the requirements of subsection C of this section;

3. Any necessary interim provisions to the current Emergency Action Plan or Emergency Preparedness Plan. Interim provisions shall be submitted to the local organization for emergency management, the Virginia Department of Emergency Management, and the department; and

4. If the owner is requesting the deregulation of an impounding structure, the application shall specify whether the impounding structure is to be removed so that the impounding structure is incapable of storing water, either temporarily or permanently; or whether the impounding structure is to be altered in such a manner that either the height or storage capacity of the impounding structure causes the impounding structure to be of less than regulated size.

E. During the alteration work, the owner shall provide the director with any proposed changes from the approved design, plans, specifications, or a plan of construction. Approval shall be obtained from the director prior to the alteration or installation of any changes that will affect the integrity or impounding capacity of the impounding structure.

F. The Alteration Permit shall be valid for the construction sequence with milestones specified in the approved Alteration Permit Application.

G. Work identified in the Alteration Permit must commence within the time frame identified in the Alteration Permit. If work does not commence within the prescribed time frame, the permit shall expire, except that the applicant may petition the board for extension of the prescribed time frame and the board may extend such period for good cause with an updated construction sequence with milestones.

H. The board, the director, or both may take any necessary action consistent with the Dam Safety Act (§ 10.1-604 et seq. of the Code of Virginia) if any terms of this section or of the permit are violated, if the activities of the owner are not in accordance with the approved plans and specifications, if the alteration is conducted in a manner hazardous to downstream life or property, or for other cause as described in the

Act.

I. Within 90 days after completion of the alteration of an impounding structure, the owner shall submit a complete Record Report. A form for the Record Report is available from the department (Record Report for Virginia Regulated Impounding Structures). The Record Report shall be signed and sealed by a licensed professional engineer and signed by the owner and shall be sent to the department indicating that the modifications made to the structural features of the impounding structure have been completed. This report is not required when the Alteration Permit has been issued for the removal of an impounding structure. The Record Report shall include the following:

1. Project information including the name and inventory number of the structure, name of the reservoir, and whether the report is associated with a new or old structure;

2. Location of the impounding structure including the city or county, number of feet or miles upstream or downstream of a highway and the highway number, name of the river or the stream, and the latitude and longitude;

3. Owner's name or representative if corporation, mailing address, residential and business telephone numbers, and other means of communication;

4. Information on the design report, including who it was prepared by, the date of design report preparation, whether it was for new construction or for an alteration, and the permit issuance date;

5. Owner's engineer's name, firm, professional engineer Virginia number, mailing address, and business telephone number;

6. Impounding structure data including type of material (earth, concrete, masonry or other) and the following configurations:

a. Top of impounding structure (elevation);

b. Downstream toe – lowest (elevation);

c. Height of impounding structure (feet);

d. Crest length – exclusive of spillway (feet);

e. Crest width (feet);

f. Upstream slope (horizontal to vertical); and

g. Downstream slope (horizontal to vertical).

7. Reservoir data including the following:

a. Maximum capacity (acre-feet);

b. Maximum pool (elevation);

c. Maximum pool surface area (acres);

d. Normal capacity (acre-feet);

e. Normal pool (elevation);

f. Normal pool surface area (acres); and

g. Freeboard (feet).

8. Spillway data including the type, construction material, design configuration, and invert elevation for the low level drain, the principal spillway, and the emergency spillway; a description of the low level drain and principal spillway including dimensions, trash guard information, and orientation of intake and discharge to impounding structure if looking downstream; and a description of the emergency spillway including dimensions and orientation to impounding structure if looking downstream;

9. Watershed data including drainage area (square miles); type and extent of watershed development; time of concentration (hours); routing procedure; spillway design flood used and state source; design inflow hydrograph volume (acre-feet), peak inflow (cfs), and rainfall duration (hours); and freeboard during passage of the spillway design flood (feet);

10. Impounding structure history including the date construction was completed, who it was designed by and the date, who it was built by and the date, who performed inspections and dates, description of repairs, and confirmation as to whether the impounding structure has ever been overtopped;

11. A narrative describing the impounding structure procedures for operation, maintenance, emergency action plan implementation, and structure evaluation;

12. A narrative describing the hydraulic and hydrologic data on the spillway design flood, hydrologic records, flood experience, flood potential, reservoir regulation, and comments or recommendations regarding these attributes;

13. A narrative describing stability of the foundation and abutments, embankment materials, and a written evaluation of each;

14. A complete set of record drawings signed and sealed by a licensed professional engineer and signed by the owner;

15. Certification by the owner's engineer that the information provided pursuant to this subsection is true and correct in their professional judgment. Such certification shall include the engineer's signature, printed name, Virginia number, date, and the engineer's Virginia seal; and

16. Owner's signature certifying receipt of the information provided pursuant to this subsection.

J. For altered impounding structures, a certification from a licensed professional engineer who has monitored the alteration of the impounding structure that, to the best of the engineer's judgment, knowledge, and belief, the impounding structure and its appurtenances were altered in conformance with the plans, specifications, drawings and other requirements approved by the board.

Statutory Authority

§ 10.1-605 of the Code of Virginia.

Historical Notes

Derived from VR625-01-00 § 2.3, eff. February 1, 1989; amended, Virginia Register Volume 24, Issue 25, eff. September 26, 2008.

4VAC50-20-90. Transfer of permits.

A. Prior to the transfer of ownership of a permitted impounding structure the permittee shall notify the director in writing and the new owner shall file a transfer notification with the department. A form for the transfer notification is available from the department (Transfer of Impounding Structure Notification form Past Owner to New Owner). The new owner shall amend the existing permit application as necessary and shall certify to the director that he is aware of and will comply with all of the requirements and conditions of the permit.

B. The transfer notification shall include the following required information:

1. Project information including the name and inventory number of the structure, name of the reservoir, and impoundment hazard classification;

2. Location of the impounding structure including the city or county, number of feet or miles upstream or downstream of a highway and the highway number, name of the river or the stream, and the latitude and longitude;

3. Type of certificates and permits to be transferred including effective date and expiration date of all certificates and permits;

4. Past owner's name, mailing address, and residential and business telephone numbers;

5. New owner's name, mailing address, and residential and business telephone numbers;

6. Request to transfer certification statement signed and dated by the past owner;

7. Certification of compliance with permit or certificate with all said terms and conditions signed and dated by the new owner; and

8. Contact information updates for Emergency Action Plan or Emergency Preparedness Plan provided by the new owner. Such updates shall include the name, mailing address, and residential and business telephone numbers for the impounding structure owner, impounding structure operator, rainfall and staff gage observer, and alternate observer.

Part III

Certificate Requirements

4VAC50-20-105. Regular Operation and Maintenance Certificates.

A. A Regular Operation and Maintenance Certificate is required for an impounding structure. Such six-year certificates shall include the following based on hazard classification:

1. High Hazard Potential Regular Operation and Maintenance Certificate;

2. Significant Hazard Potential Regular Operation and Maintenance Certificate; or

3. Low Hazard Potential Regular Operation and Maintenance Certificate.

B. The owner of an impounding structure shall apply for the renewal of the six-year Regular Operation and Maintenance Certificate 90 days prior to its expiration. If a Regular Operation and Maintenance Certificate is not renewed as required, the board shall take appropriate enforcement action.

C. Any owner of an impounding structure that does not have a Regular Operation and Maintenance

Certificate or any owner renewing a Regular Operation and Maintenance Certificate shall file an Operation and Maintenance Certificate Application. A form for the application is available from the department (Operation and Maintenance Certificate Application for Virginia Regulated Impounding Structures). Such application shall be signed by the owner and signed and sealed by a licensed professional engineer. The following information shall be submitted on or with the application:

1. The application shall include the following required information:

a. The name of structure and inventory number;

b. The proposed hazard potential classification;

c. Owner's name or representative if corporation, mailing address, residential and business telephone numbers, and other means of communication;

d. An operating plan and schedule including a narrative on the operation of control gates and spillways and the impoundment drain;

e. For earthen embankment impounding structures, a maintenance plan and schedule for the embankment, principal spillway, emergency spillway, low-level outlet, impoundment area, downstream channel, and staff gages;

f. For concrete impounding structures, a maintenance plan and schedule for the upstream face, downstream face, crest of dam, galleries, tunnels, abutments, spillways, gates and outlets, and staff gages;

g. An inspection schedule for operator inspection, maintenance inspection, technical safety inspection, and overtopping situations;

h. A schedule including the rainfall amounts, emergency spillway flow levels or storm event that initiates the Emergency Action or Preparedness Plan and the frequency of observations;

i. A statement as to whether or not the current hazard potential classification for the impounding structure is appropriate and whether or not additional work is needed to make an appropriate hazard potential designation;

j. For newly constructed or recently altered impounding structures, a certification from a licensed professional engineer who has monitored the construction or alteration of the impounding structure that, to the best of the engineer's judgment, knowledge, and belief, the impounding structure and its appurtenances were constructed or altered in conformance with the plans, specifications, drawings and other requirements approved by the board;

k. Certification by the owner's engineer that the Operation and Maintenance Certificate Application information provided pursuant to subdivision 1 of this subsection is true and correct in their professional judgment. Such certification shall include the engineer's signature, printed name, Virginia number, date, and the engineer's Virginia seal; and

l. Owner's signature certifying the Operation and Maintenance Certificate Application information provided pursuant to subdivision 1 of this subsection and that the operation and maintenance plan and schedule shall be conducted in accordance with this chapter.

2. An Inspection Report (Annual Inspection Report for Virginia Regulated Impounding Structures) in accordance with subsection E of this section;

3. An Emergency Action Plan in accordance with 4VAC50-20-175 or an Emergency Preparedness Plan in accordance with 4VAC50-20-177 and evidence that the required copies of such plan have been submitted to the local organization for emergency management and the Virginia Department of Emergency Management; and

4. Any additional analysis determined necessary by the director, the board or the owner's engineer to address public safety concerns. Such additional analysis may include, but not be limited to, seismic stability, earthen spillway integrity, adequate freeboard allowance, stability assessment of the impoundment's foundation, potential liquefaction of the embankment, overturning or sliding of a concrete structure and other structural stress issues.

D. If the Operation and Maintenance Certificate Application submittal is found to be not complete, the director shall inform the applicant within 30 days and shall explain what changes are required for an acceptable submission. Within 60 days of receipt of a complete application the board shall act upon the application. Upon finding that the impounding structure as currently operating is in compliance with this chapter, the board shall issue a Regular Operation and Maintenance Certificate. Should the board find that the impounding structure as currently operating is not in compliance with this chapter, the board may deny the permit application or issue a Conditional Operation and Maintenance Certificate in accordance with 4VAC50-20-150.

E. Inspections shall be performed on an impounding structure annually.

1. Inspection Reports (Annual Inspection Report for Virginia Regulated Impounding Structures) signed and sealed by a licensed professional engineer shall be submitted to the department in accordance with the following schedule:

a. For a High Hazard Potential impounding structure, every two years,

b. For a Significant Hazard Potential impounding structure, every three years,

c. For a Low Hazard Potential impounding structure, every six years.

In years when an Inspection Report signed and sealed by a licensed professional engineer is not required, an owner shall submit the Annual Inspection Report for Virginia Regulated Impounding Structures.

2. The Inspection Report shall include the following required information:

a. Project information including the name and inventory number of structure, name of the reservoir, and purpose of the reservoir;

b. City or county where the impounding structure is located;

c. Owner's name or representative if corporation, mailing address, residential and business telephone numbers, and other means of communication;

d. Owner's engineer's name, firm, professional engineer Virginia number, mailing address, and business telephone number;

e. Inspection observation of the impounding structure including the following:

(1) Earthen embankment information including any embankment alterations; erosion; settlement, misalignments or cracks; seepage and seepage flow rate and location;

(2) Upstream slope information including notes on woody vegetation removed, rodent burrows discovered, and remedial work performed;

(3) Intake structure information including notes on deterioration of concrete structures, exposure of rebar reinforcement, need to repair or replace trash rack, any problems with debris in the reservoir, and whether the drawdown valve operated;

(4) Abutment contacts including notes on seepage and seepage flow rate and location;

(5) Earthen emergency spillway including notes on obstructions to flow and plans to correct, rodent burrows discovered, and deterioration in the approach or discharge channel;

(6) Concrete emergency spillway including notes on the deterioration of the concrete, exposure of rebar reinforcement, any leakage below concrete spillway, and obstructions to flow and plans to correct;

(7) Downstream slope information including notes on woody vegetation removed, rodent

burrows discovered, whether seepage drains are working, and any seepage or wet areas;

(8) Outlet pipe information including notes on any water flowing outside of discharge pipe through the impounding structure and a description of any reflection or damage to the pipe;

(9) Stilling basin information including notes on the deterioration of the concrete, exposure of rebar reinforcement, deterioration of the earthen basin slopes, repairs made, and any obstruction to flow;

(10) Gates information including notes on gate malfunctions or repairs, corrosion or damage, and whether any gates were operated and if so how often and to what extreme;

(11) Reservoir information including notes on new developments upstream of the dam, slides or erosion of lake banks, and general comments to include silt, algae, or other influence factors;

(12) Instruments information including any reading of instruments and any installation of new instruments; and

(13) General information including notes on new development in the downstream dam break inundation zone that would impact hazard classification or spillway design flood requirements, the maximum stormwater discharge or peak elevation during the previous year, whether general maintenance was performed and when, and actions that need to be completed before the next inspection.

f. Evaluation rating of the impounding structure and appurtenances (excellent, good, or poor), general comments, and recommendations;

g. Certification by the owner and date of inspection; and

h. Certification and seal by the owner's engineer and date of inspection, as applicable.

F. The owner of an impounding structure shall notify the department immediately of any change in the use of the area downstream that would impose hazard to life or property in the event of failure.

Statutory Authority

§ 10.1-605 of the Code of Virginia.

Historical Notes

Derived from Virginia Register Volume 24, Issue 25, eff. September 26, 2008.

4VAC50-20-110. (Repealed.)

Historical Notes

4VAC50-20-125. Delayed effective date for Spillway Design Flood requirements for impounding structures.

A. If an impounding structure has been determined to have an adequate spillway capacity prior to September 26, 2008, and is currently operating under a Regular Operation and Maintenance Certificate, but will now require spillway modifications due to changes in these regulations, the owner shall submit to the board an Alteration Permit Application in accordance with 4VAC50-20-80 to address spillway capacity at the time of the expiration of their Regular Operation and Maintenance Certificate or by September 26, 2011, whichever is later. The Alteration Permit Application shall contain a construction sequence with milestones for completing the necessary improvements within five years of Alteration Permit issuance. The board may approve an extension of the prescribed time frame for good cause. Should the owner be able to demonstrate that no spillway capacity change is necessary, the impounding structure may be found to be in compliance with this chapter.

B. In accordance with 4VAC50-20-105, the owner shall submit the Operation and Maintenance Certificate Application (Operation and Maintenance Certificate Application for Virginia Regulated Impounding Structures), the Emergency Action Plan or Emergency Preparedness Plan, and the Inspection Report (Annual Inspection Report for Virginia Regulated Impounding Structures) 90 days prior to the expiration of the Regular Operation and Maintenance Certificate.

C. If circumstances warrant more immediate repairs to the impounding structure, the board may direct alterations to the spillway to be completed sooner.

D. During this delay period, owners are required to address other deficiencies that may exist that are not related to the spillway design flood.

Statutory Authority

§ 10.1-605 of the Code of Virginia.

Historical Notes

4VAC50-20-140. (Repealed.)

Historical Notes

Derived from VR625-01-00 § 3.5, eff. February 1, 1989; repealed, Virginia Register Volume 24, Issue 25, eff. September 26, 2008.

4VAC50-20-150. Conditional operation and maintenance certificate.

A. During the review of any Operation and Maintenance Certificate Application (Operation and Maintenance Certificate Application for Virginia Regulated Impounding Structures) completed in accordance with 4VAC50-20-105 should the director determine that the impounding structure has nonimminent deficiencies, the director may recommend that the board issue a Conditional Operation and Maintenance Certificate.

B. The Conditional Operation and Maintenance Certificate for High, Significant, and Low Hazard Potential impounding structures shall be for a maximum term of two years. This certificate will allow the owner to continue normal operation and maintenance of the impounding structure, and shall require that the owner correct the deficiencies on a schedule approved by the board.

C. A Conditional Certificate may be extended in accordance with the procedures of 4VAC50-20-155 provided that Inspection Reports (Annual Inspection Report for Virginia Regulated Impounding Structures) are on file, and the board determines that the owner is proceeding with the necessary corrective actions.

D. Once the deficiencies are corrected, the board shall issue a Regular Operation and Maintenance Certificate based upon the impounding structure's meeting the requirements of 4VAC50-20-105.

Statutory Authority

§ 10.1-605 of the Code of Virginia.

Historical Notes

Derived from VR625-01-00 § 3.6, eff. February 1, 1989; amended, Virginia Register Volume 24, Issue 25,

eff. September 26, 2008.

4VAC50-20-155. Extension of Operation and Maintenance Certificates.

The board may extend an Operation and Maintenance Certificate for impounding structures provided that the owner submits a written request justifying an extension, the amount of time needed to comply with the requirements set out in the current Operation and Maintenance Certificate, and any required fees. The owner must have demonstrated substantial and continual progress towards meeting the requirements of the certificate in order to receive an extension.

Statutory Authority

§ 10.1-605 of the Code of Virginia.

Historical Notes

Derived from Virginia Register Volume 24, Issue 25, eff. September 26, 2008.

4VAC50-20-160. Additional operation and maintenance requirements.

A. The owner of an impounding structure shall not, through action or inaction, cause or allow such structure to impound water following receipt of a written report from the owner's engineer that the impounding structure will not safely impound water.

B. In accordance with § 10.1-609.2 of the Code of Virginia, impounding structure owners shall not permit the growth of trees and other woody vegetation and shall remove any such vegetation from the slopes and crest of embankments and the emergency spillway area, and within a distance of 25 feet from the toe of the embankment and abutments of the dam.

Statutory Authority

§ 10.1-605 of the Code of Virginia.

Historical Notes

Derived from VR625-01-00 § 3.7, eff. February 1, 1989; amended, Virginia Register Volume 24, Issue 25, eff. September 26, 2008.

4VAC50-20-165. Agricultural exemption.

A. Impounding structures operated primarily for agricultural purposes that are less than 25 feet in height or that create a maximum impoundment capacity smaller than 100 acre-feet are exempt from the Impounding Structure Regulations.

B. An owner covered by an agricultural exemption pursuant to § 10.1-604 of the Code of Virginia and

4VAC50-20-30 may validate such exemption by submitting an Agricultural Exemption Report (Agricultural Exemption Report for Impounding Structures). The Agricultural Exemption Report shall include the following information:

1. Project information including the name and inventory number of the structure and name of the reservoir;

2. Location of the impounding structure including the city or county, number of feet or miles upstream or downstream of a highway and the highway number, name of the river or the stream, and the latitude and longitude;

3. Owner's name or representative if corporation, mailing address, residential and business telephone numbers, and other means of communication;

4. The impounding structure height in feet and the maximum impounding capacity in acre-feet;

5. A list of the agricultural functions for which the impoundment supplies water;

6. The date of validation; and

7. The owner's signature validating that the impoundment is operated primarily for agricultural purposes and is exempt from the regulations.

C. The Agricultural Exemption Report may be verified by the department through a site visit.

Statutory Authority

§ 10.1-605 of the Code of Virginia.

Historical Notes

Derived from Virginia Register Volume 24, Issue 25, eff. September 26, 2008.

4VAC50-20-170. Transfer of certificates.

A. Prior to the transfer of ownership of an impounding structure the certificate holder shall notify the director in writing and the new owner shall file a transfer notification with the department. A form for the transfer notification is available from the department (Transfer of Impounding Structure Notification from Past Owner to New Owner). The new owner may elect to continue the existing operation and maintenance certificate for the remaining term or he may apply for a new certificate in accordance with 4VAC50-20-105. If the owner elects to continue the existing certificate, he shall certify to the director that he is aware of and will comply with all of the requirements and conditions of the certificate.

B. The transfer notification shall include the following required information:

1. Project information including the name and inventory number of the structure, name of the reservoir, and impoundment hazard classification;

2. Location of the impounding structure including the city or county, number of feet or miles upstream or downstream of a highway and the highway number, name of the river or the stream, and the latitude and longitude;

3. Type of certificates and permits to be transferred including effective date and expiration date of all certificates and permits;

4. Past owner's name, mailing address, and residential and business telephone numbers;

5. New owner's name, mailing address, and residential and business telephone numbers;

6. Request to transfer certification statement signed and dated by the past owner;

7. Certification of compliance with permit or certificate with all said terms and conditions signed and dated by the new owner; and

8. Contact information updates for Emergency Action Plan or Emergency Preparedness Plan provided by the new owner. Such updates shall include the name, mailing address, and residential and business telephone numbers for the impounding structure owner, impounding structure operator, rainfall and staff gage observer, and alternate observer.

Statutory Authority

§ 10.1-605 of the Code of Virginia.

Historical Notes

Derived from VR625-01-00 § 3.8, eff. February 1, 1989; amended, Virginia Register Volume 24, Issue 25, eff. September 26, 2008.

4VAC50-20-175. Emergency Action Plan (EAP) for High and Significant Hazard Potential impounding structures.

A. In order to protect life during potential emergency conditions at an impounding structure, and to ensure effective, timely action is taken should an impounding structure emergency occur, an EAP shall be required for each High and Significant Hazard Potential impounding structure. The EAP shall be coordinated with the Department of Emergency Management in accordance with § 44-146.18 of the Code of Virginia. The EAP required by these regulations shall be incorporated into local and interjurisdictional emergency plans pursuant to § 44-146.19 of the Code of Virginia.

B. It is the impounding structure owner's responsibility to develop, maintain, exercise, and implement a site-specific EAP.

C. An EAP shall be submitted every six years. The EAP shall be submitted with the owner's submittal of their Regular Operation and Maintenance Certificate application (Operation and Maintenance Certificate Application for Virginia Regulated Impounding Structures).

D. The owner shall update and resubmit the EAP immediately upon becoming aware of necessary changes to keep the EAP workable. Should an impounding structure be reclassified, an EAP in accordance with this section shall be submitted.

E. A drill shall be conducted annually for each high or significant hazard impounding structure. To the extent practicable, the drill should include a face-to-face meeting with the local emergency management agencies responsible for any necessary evacuations to review the EAP and ensure the local emergency management agencies understand the actions required during an emergency. A table-top exercise shall be conducted once every six years,although more frequent table-top exercises are encouraged. Drills and table-top exercises for multiple impounding structures may be performed in combination if the involved parties are the same. Owners shall certify to the department annually that a drill, a table-top exercise, or both has been completed and provide any revisions or updates to the EAP or a statement that no revisions or updates are needed.

F. Impounding structure owners shall test existing monitoring, sensing, and warning equipment at remote or unattended impounding structures at least twice per year or as performed by the Virginia Department of Emergency Management pursuant to § 10.1-609.1 of the Code of Virginia and maintain a record of such tests.

G. An EAP shall contain the following seven basic elements unless otherwise specified in this subsection.

1. Notification chart. A notification chart shall be included for all classes of impounding structures that shows who is to be notified, by whom, and in what priority. The notification chart shall include contact information providing 24-hour telephone coverage for all responsible parties including, but not limited to, the impounding structure operator or manager, state and local emergency management officials, local police or sheriffs' departments, and the owner's engineer. The notification chart shall also identify the process by which downstream property owners will be notified, and what party or parties will be responsible for making such notifications.

2. Emergency Detection, Evaluation, and Classification. The EAP shall include a discussion of the procedures for timely and reliable detection, evaluation, and classification of emergency situations considered to be relevant to the project setting and impounding features. Each relevant emergency situation is to be documented to provide an appropriate course of action based on the urgency of the situation. Where appropriate, situations should address impounding structure failures that are imminent or in progress, a situation where the potential for impounding structure failure is rapidly developing, and a situation where the threat is slowly developing.

3. Responsibilities. The EAP shall specify responsibilities for EAP-related tasks. The EAP shall also clearly designate the responsible party for making the decision that an emergency condition no longer exists at the impounding structure. The EAP shall include procedures and the responsible parties for notifying to the extent possible any known local occupants, owners, or lessees of downstream properties potentially impacted by the impounding structure's failure.

4. Preparedness. The EAP shall include a section that describes preparedness actions to be taken both before and following development of emergency conditions.

5. Dam Break Inundation Maps. The EAP shall include dam break inundation maps developed in accordance with 4VAC50-20-54.

6. Appendices. The appendices shall contain information that supports and supplements the material used in the development and maintenance of the EAP such as analyses of impounding structure failure floods; plans for training, exercising, updating, and posting the EAP; and other site-specific concerns.

7. Certification. The EAP shall include a section that identifies all parties with assigned responsibilities in the EAP pursuant to subdivision 3 of this subsection. This will include certification that the EAP has been received by these parties. The preparer's name, title, and contact information shall be printed in this section. The preparer's signature shall also be included in the certification section. The local organization for emergency management shall provide the owner and the department with any deficiencies they may note.

H. The development of the EAP shall be coordinated with all entities, jurisdictions, and agencies that would be affected by an impounding structure failure or that have statutory responsibilities for warning, evacuation, and postflood actions. Consultation with state and local emergency management officials at appropriate levels of management responsible for warning and evacuation of the public shall occur to

ensure that there is awareness of their individual and group responsibilities. The owner shall also coordinate with the local organization for emergency management to identify properties that upon failure of the impounding structure would result in economic impacts.

I. The EAP, or any updates to an existing EAP, shall be submitted to the department, the local organization for emergency management, and the Virginia Department of Emergency Management. Two copies shall be provided to the department.

J. The following format shall be used as necessary to address the requirements of this section.

4VAC50-20-177. Emergency Preparedness Plan for Low Hazard impounding structures.

Low Hazard impounding structures shall provide information for emergency preparedness to the department, the local organization for emergency management and the Virginia Department of Emergency Management. A form for the submission is available from the department (Emergency Preparedness Plan for Low Hazard Virginia Regulated Impounding Structures). The information shall include, but not be limited, to the following:

1. Name of the impounding structure, inventory number, city or county, latitude, and longitude;

2. Owner's name, mailing address, residential and business telephone numbers, and other means of communication. Contact information shall provide for 24-hour telephone contact capability;

3. Impounding structure operator's name, mailing address, residential and business telephone numbers, and other means of communication. Contact information shall provide for 24-hour telephone contact capability;

4. Rainfall and staff gage observer's name, mailing address, residential and business telephone numbers, and other means of communication. Contact information shall provide for 24-hour telephone contact capability;

5. Contact information for alternate operator and alternate rainfall and staff gage observer, if applicable;

6. Contact information for the local dispatch center nearest impounding structure including address and 24-hour telephone number;

7. City or county emergency services coordinator's name, mailing address, residential and business telephone numbers, and other means of communication;

8. A procedure and the responsible parties for notifying to the extent possible any known local occupants, owners, or lessees of downstream properties potentially impacted by the impounding structure's failure;

9. A discussion of the procedures for timely and reliable detection, evaluation, and classification of emergency situations considered to be relevant to the project setting and impounding features. Each relevant emergency situation is to be documented to provide an appropriate course of action based on the urgency of the situation;

10. A simple dam break inundation map acceptable to the director, demonstrating the general inundation that would result from an impounding structure failure. Such maps required pursuant to this section do not require preparation by a professional licensed engineer; however, maps prepared by a licensed professional engineer are preferred;

11. Identification of public roads downstream noting the highway number and distance below the impounding structure. If roads exist, contact information for the resident Virginia Department of Transportation engineer or city or county engineer including address and 24-hour telephone numbers;

12. Amount of rainfall that will initiate a Stage II Condition in inches per six hours, inches per 12 hours, and inches per 24 hours and a Stage III Condition in inches per six hours, inches per 12 hours, and inches per 24 hours;

13. Amount of flow in the emergency spillway that will initiate a Stage II Condition in feet (depth of flow) and a Stage III Condition in feet (depth of flow);

14. Staff gage location and description; the frequency of observations by the rainfall or staff gage observer under a Stage I Condition, and Stage II Condition, and a Stage III Condition; and a clear description of an access route and means of travel during flood conditions to the impounding structure;

15. Evacuation procedures including notification, monitoring, evacuation, and reporting processes and responsibilities;

16. Evidence that the required copies of such plan have been submitted to the local organization for emergency management and the Virginia Department of Emergency Management; and

17. Certification of the plan by the owner.

Statutory Authority

§ 10.1-605 of the Code of Virginia.

Historical Notes

Part IV

Procedures

4VAC50-20-180. Inspections.

A. The director may make inspections during construction, alteration or operation and maintenance as deemed necessary to ensure that the impounding structure is being constructed, altered or operated and maintained in compliance with the permit or certificate issued by the board. The director shall provide the owner a copy of the findings of these inspections. The department's inspection does not relieve the owner from the responsibility of providing adequate inspection during construction, alteration, or operation and maintenance. During the maintenance, construction, or alteration of any impounding structure or reservoir, the director shall require the owner to perform, at the owner's expense, such work or tests as necessary to obtain information sufficient to enable the director to determine whether conformity with the plans and specifications approved by the certificate is being secured.

B. Periodic inspections during construction or alteration shall be conducted under the direction of a licensed professional engineer who shall provide for monitoring, review of contractor submittals, and appropriate confirmatory testing of all facets of construction affecting the safety of the impounding structure in accordance with the construction or alteration permit issued by the board.

C. Required inspections during operation and maintenance shall be conducted under the supervision of a licensed professional engineer at intervals designated under 4VAC50-20-105.

D. Every owner shall provide for an inspection by a licensed professional engineer after overtopping of the impounding structure or after flows cause damage to the emergency spillway. A copy of the findings of each inspection with the engineer's recommendations shall be filed with the board within a reasonable period of time not to exceed 30 days subsequent to completion of the inspection.

Statutory Authority

§ 10.1-605 of the Code of Virginia.

Historical Notes

Derived from VR625-01-00 § 4.1, eff. February 1, 1989; amended, Virginia Register Volume 24, Issue 25, eff. September 26, 2008.

4VAC50-20-190. Right to informal fact-finding proceeding or hearing.

Any owner aggrieved by an action taken by the director or by the board without hearing, or by inaction of the director or the board, under the provisions of this chapter, may demand in writing an informal fact-finding proceeding pursuant to § 2.2-4019 of the Code of Virginia or a formal hearing pursuant to § 2.2-4020 of the Code of Virginia. A formal hearing may be granted only with the consent of the board.

Statutory Authority

§ 10.1-605 of the Code of Virginia.

Historical Notes

Derived from VR625-01-00 § 4.2, eff. February 1, 1989; amended, Virginia Register Volume 24, Issue 25, eff. September 26, 2008.

4VAC50-20-200. Enforcement.

The provisions of this chapter may be enforced by the board, the director, or both in any manner consistent with the provisions of the Dam Safety Act (§ 10.1-604 et seq. of the Code of Virginia).

Statutory Authority

§ 10.1-605 of the Code of Virginia.

Historical Notes

Derived from VR625-01-00 § 4.3, eff. February 1, 1989; amended, Virginia Register Volume 24, Issue 25, eff. September 26, 2008.

4VAC50-20-210. Consulting committee.

A. When the board needs to satisfy questions of safety regarding plans and specifications, construction, alteration, or operation and maintenance, or when requested by the owner, the board may appoint a consulting committee to report to it with respect to those questions of the impounding structure's safety. Such a committee shall consist of two or more consultants, none of whom have been associated with the impounding structure.

B. The costs and expenses incurred by the consulting committee, if appointed at the request of an owner, shall be paid by the owner.

C. The costs and expenses incurred by the consulting committee, if initiated by the board, shall be paid by the board.

Statutory Authority

§ 10.1-605 of the Code of Virginia.

Historical Notes

Derived from VR625-01-00 § 4.4, eff. February 1, 1989; amended, Virginia Register Volume 24, Issue 25, eff. September 26, 2008.

4VAC50-20-220. Unsafe conditions.

A. No owner shall maintain an unsafe impounding structure. Designation of an impounding structure

as unsafe shall be made in accordance with § 10.1-607.1 of the Code of Virginia.

B. Imminent danger.

1. If an owner or the owner's engineer has determined that circumstances are impacting the integrity of the impounding structure that could result in the imminent failure of the impounding structure, temporary repairs may be initiated prior to approval from the board. The owner shall notify the department within 24 hours of identifying the circumstances impacting the integrity of the impounding structure. Such emergency notification shall not relieve the owner of the need to obtain an alteration permit as soon as may be practicable, nor shall the owner take action beyond that necessary to address the emergency situation.

2. When the director finds that an impounding structure is unsafe and constitutes an imminent danger to life or property, he shall immediately notify the Virginia Department of Emergency Management and confer with the owner who shall activate the Emergency Action Plan or Emergency Preparedness Plan if appropriate to do so. The owner of an impounding structure found to constitute an imminent danger to life or property shall take immediate corrective action to remove the imminent danger as required by § 10.1-608 of the Code of Virginia.

C. Nonimminent danger. The owner of an impounding structure who has been issued findings and recommendations, by the board, for the correction of deficiencies that may threaten life or property if not corrected, shall undertake to implement the recommendations for correction of deficiencies according to a schedule of implementation contained in that report as required by § 10.1-609 of the Code of Virginia.

Statutory Authority

§ 10.1-605 of the Code of Virginia.

Historical Notes

Derived from VR625-01-00 § 4.5, eff. February 1, 1989; amended, Virginia Register Volume 18, Issue 14, eff. July 1, 2002; Volume 24, Issue 25, eff. September 26, 2008.

4VAC50-20-230. Complaints.

A. Upon receipt of a complaint alleging that the person or property of the complainant is endangered by the construction, alteration, maintenance or operation of an impounding structure, the director shall cause an inspection of the structure, unless the data, records and inspection reports on file with the board are found adequate to determine if the complaint is valid.

B. If the director finds that an unsafe condition exists, the director shall proceed under the provisions

of §§ 10.1-608 and 10.1-609 of the Code of Virginia to render the extant condition safe.

Statutory Authority

§ 10.1-605 of the Code of Virginia.

Historical Notes

Derived from VR625-01-00 § 4.6, eff. February 1, 1989; amended, Virginia Register Volume 24, Issue 25, eff. September 26, 2008.

Part V

Design Requirements

4VAC50-20-240. Design of structures.

A. The owner shall complete all necessary investigations prior to submitting the design report (Design Report for the Construction or Alteration of Virginia Regulated Impounding Structures). The design report shall contain those components outlined in 4VAC50-20-70 for construction activities or those outlined in 4VAC50-20-80 for alteration activities. The scope and degree of precision required is a matter of engineering judgment based on the complexities of the site and the hazard potential classification of the proposed structure.

B. Surveys shall be made with sufficient accuracy to locate the proposed construction site and to define the total volume of storage in the impoundment. Locations of center lines and other horizontal and vertical controls shall be shown on a map of the site. The area downstream and upstream from the proposed impounding structure shall be investigated in order to delineate the areas and extent of potential damage in case of failure or backwater due to flooding.

C. The drainage area shall be determined. Present and planned land-use conditions shall be considered in determining the runoff characteristics of the drainage area. The most severe of these conditions shall be included in the design calculations which shall be submitted as part of the design report.

D. The geotechnical engineering investigation shall consist of borings, test pits and other subsurface explorations necessary to adequately define the existing conditions. The investigations shall be performed so as to appropriately define the soil, rock and ground water conditions.

E. All construction materials shall be adequately researched and selected so as to ensure that their as constructed behavior will reasonably conform to design criteria. If on-site materials are to be utilized, they shall be located and determined to be adequate in quantity and quality.

Statutory Authority

§ 10.1-605 of the Code of Virginia.

Historical Notes

Derived from VR625-01-00 § 5.1, eff. February 1, 1989; amended, Virginia Register Volume 24, Issue 25, eff. September 26, 2008.

4VAC50-20-250. (Repealed.)

Historical Notes

Derived from VR625-01-00 § 5.2, eff. February 1, 1989; repealed, Virginia Register Volume 24, Issue 25, eff. September 26, 2008.

4VAC50-20-260. Spillway design.

A. Every impounding structure shall have a spillway system with adequate capacity to discharge the design flood without endangering the safety of the impounding structure.

B. Vegetated earth or an unlined emergency spillway may be approved when the applicant demonstrates that it will pass the spillway design flood without jeopardizing the safety of the impounding structure (such as by allowance of overtopping of a structure not designed to permit overtopping). In no case shall impounding structure owners permit the growth of trees and other woody vegetation in the emergency spillway area.

C. Lined emergency spillways shall include design criteria calculations, plans and specifications for suitable energy dissipators and for spillways that include crest control structures, chutes, walls, panel lining, sills, blocks, and miscellaneous details. All joints shall be reasonably water-tight and placed on a foundation capable of sustaining applied loads without undue deformation. Provision shall be made for handling under seepage and uplift pressures from the foundation which might adversely affect the structural integrity and structural stability of the impounding structure.

Statutory Authority

§ 10.1-605 of the Code of Virginia.

Historical Notes

Derived from VR625-01-00 § 5.3, eff. February 1, 1989; amended, Virginia Register Volume 24, Issue 25, eff. September 26, 2008.

4VAC50-20-270. Principal spillways and outlet works.

A. It will be assumed that principal spillways and regulating outlets provided for special functions will operate to normal design discharge capabilities during the spillway design flood, provided appropriate analyses show:

1. That control gates and structures are suitably designed to operate reliably under maximum heads for durations likely to be involved and risks of blockage by debris are minimal;

2. That access roads and passages to gate regulating controls would be safely passable by operating personnel under spillway design flood conditions; and

3. That there are no substantial reasons for concluding that outlets would not operate safely to full design capacity during the spillway design flood.

B. If there are reasons to doubt that any of the above basic requirements might not be adequately met under spillway design flood conditions, the "dependable" discharge capabilities of regulating outlets shall be assumed to be less than 100% of design capacities, generally as outlined in the following subsections C through G of this section.

C. Any limitations in safe operating heads, maximum velocities to be permitted through structures or approach channels, or other design limitations shall be observed in establishing "dependable" discharge rating curves to be used in routing the spillway design flood hydrograph through the reservoir.

D. If intakes to regulating outlets are likely to be exposed to significant quantities of floating debris, sediment depositions or ice hazards prior to or during major floods, the dependable discharge capability during the spillway design flood shall be assumed to be zero.

E. If access roads or structural passages to operating towers or controls are likely to be flooded or otherwise unusable during the spillway design flood, the dependable discharge capability of regulating outlets will be assumed to be zero for the periods of time during which such conditions might exist.

F. Any deficiencies in discharge performance likely to result from delays in the operation of gates before attendants could be reasonably expected to reach the control must be taken into account when estimating "dependable" discharge capabilities assumptions in routing the spillway design flood through the impoundment. Reports on design studies shall indicate the allowances made for possible delays in initiating gate operations. Normally, for projects located in small basins, where critical spillway design flood inflows may occur within several hours after intense precipitation, outflows through any regulating outlets that must be opened after the flood begins shall be assumed to be zero for an appropriate period of time subsequent to the beginning of intense rainfall.

G. All gates, valves, conduits and concrete channel outlets shall be designed and constructed to prevent significant erosion or damage to the impounding structure or to the downstream outlet or channel.

Statutory Authority

§ 10.1-605 of the Code of Virginia.

Historical Notes

Derived from VR625-01-00 § 5.4, eff. February 1, 1989; amended, Virginia Register Volume 24, Issue 25, eff. September 26, 2008.

4VAC50-20-280. Drain requirements.

All new impounding structures regardless of their hazard potential classification, shall include a device to permit draining of the impoundment within a reasonable period of time as determined by the owner's licensed professional engineer. Existing drains on impounding structures shall be kept operational. When practicable, existing impounding structures shall be retrofitted with devices to permit draining.

Statutory Authority

§ 10.1-605 of the Code of Virginia.

Historical Notes

Derived from VR625-01-00 § 5.5, eff. February 1, 1989; amended, Virginia Register Volume 24, Issue 25, eff. September 26, 2008.

4VAC50-20-290. Life of the impounding structure.

Components of the impounding structure, the outlet works, drain system and appurtenances shall be durable and maintained or replaced in keeping with the design and planned life of the impounding structure.

Statutory Authority

§ 10.1-605 of the Code of Virginia.

Historical Notes

Derived from VR625-01-00 § 5.6, eff. February 1, 1989; amended, Virginia Register Volume 24, Issue 25, eff. September 26, 2008.

4VAC50-20-300. Additional design requirements.

A. Flood routings shall start at or above the elevation of the crest of the lowest ungated outlet. Freeboard determination and justification must be addressed by the owner's engineer.

B. All elements of the impounding structure shall conform to sound engineering practice. Safety factors, design standards and design references that are used shall be included with the design report.

C. Inspection devices may be required by the director for use by inspectors, owners or the director in conducting inspections in the interest of structural integrity during and after completion of construction and during the life of the impounding structure.

Statutory Authority

§ 10.1-605 of the Code of Virginia.

Historical Notes

Derived from VR625-01-00 § 5.7, eff. February 1, 1989; amended, Virginia Register Volume 24, Issue 25, eff. September 26, 2008.

4VAC50-20-310. Plans and specifications.

The plans and specifications for a proposed impounding structure required in 4VAC50-20-70 for construction activities and in 4VAC50-20-80 for alteration activities shall consist of a detailed engineering design report (Design Report for the Construction or Alteration of Virginia Regulated Impounding Structures) and engineering drawings and specifications, with the following as a minimum:

1. The name of the project; the name of the owner; classification of the impounding structure as set forth in this chapter; designated access to the project and the location with respect to highways, roads, streams and existing impounding structures and impoundments that would affect or be affected by the proposed impounding structure.

2. Cross-sections, plans, profiles, logs of test borings, laboratory and in situ test data, drawings of principal and emergency spillways, impounding structures, outlet works, drain system and appurtenances, and other project components in sufficient detail to indicate clearly the extent and complexity of the work to be performed.

3. Contract drawings should include, but not be limited to, foundation and abutment treatment, stream or river diversion, excavation and material fill processes, phased fill and compaction and drainage devices.

4. The erosion and sediment control plan, as approved by the local government, which minimizes soil erosion and sedimentation during all phases of construction or alteration.

5. Technical specifications, as may be required to describe the materials, performance, and methods of the construction and construction quality control for the project.

Statutory Authority

§ 10.1-605 of the Code of Virginia.

Historical Notes

Derived from VR625-01-00 § 5.8, eff. February 1, 1989; amended, Virginia Register Volume 24, Issue 25, eff. September 26, 2008.

4VAC50-20-320. Acceptable design procedures and references.

To ensure consistency of approach, within the major engineering disciplines of hydrology, hydraulics, soils and foundations, structures, and general civil design, criteria and approaches from multiple sources shall not be mixed for developing the design of a given feature or facility without approval of the director. In all cases the owner's engineer shall identify the source of the criteria.

The following are acceptable as design procedures and references:

1. The design procedures, manuals and criteria used by the United States Army Corps of Engineers.

2. The design procedures, manuals and criteria used by the United States Department of Agriculture, Natural Resources Conservation Service.

3. The design procedures, manuals and criteria used by the United States Department of the Interior, Bureau of Reclamation.

4. The design procedures, manuals and criteria used by the United States Department of Commerce, National Weather Service.

5. The design procedures, manuals and criteria used by the United States Federal Energy Regulatory Commission.

6. Other design procedures, manuals and criteria that are accepted as current, sound engineering practices, as approved by the director prior to the design of the impounding structure.

Statutory Authority

§ 10.1-605 of the Code of Virginia.

Historical Notes

Derived from VR625-01-00 § 5.9, eff. February 1, 1989; amended, Virginia Register Volume 18, Issue 14, eff. July 1, 2002; Volume 24, Issue 25, eff. September 26, 2008.

4VAC50-20-330. Other applicable dam safety references.

A. Manuals, guidance, and criteria used by the Federal Emergency Management Agency, including the following:

1. Federal Guidelines for Dam Safety: Emergency Action Planning for Dam Owners, U.S. Department of Homeland Security, Federal Emergency Management Agency, October 1998, Reprinted January 2004; FEMA 64 or as revised.

2. Federal Guidelines for Dam Safety: Selecting and Accommodating Inflow Design Floods for Dams, U.S. Department of Homeland Security, Federal Emergency Management Agency, October 1998, Reprinted April 2004; FEMA 94 or as revised.

B. Manuals, guidance, and forms provided by the department. Such materials may be located on the department's website at: http://www.dcr.virginia.gov.

Statutory Authority

§ 10.1-605 of the Code of Virginia.

Historical Notes

Derived from Virginia Register Volume 24, Issue 25, eff. September 26, 2008.

Part VI

Fees

4VAC50-20-340. Authority to establish fees.

Under § 10.1-613.5 of the Code of Virginia, the board is authorized to establish and collect application fees for the administration of the dam safety program, administrative review, certifications, and the repair and maintenance of impounding structures. The fees will be deposited into the Dam Safety, Flood Prevention and Protection Assistance Fund.

Statutory Authority

§ 10.1-605 of the Code of Virginia.

Historical Notes

Derived from Virginia Register Volume 24, Issue 25, eff. September 26, 2008.

4VAC50-20-350. Fee submittal procedures.

A. Effective September 26, 2008, fees for all application submittals required pursuant to 4VAC50-20-370 through 4VAC50-20-390 are due prior to issuance of a certificate or permit. No application for an Operation and Maintenance Certificate or a Construction Permit will be acted upon by the board without

full payment of the required fee per § 10.1-613.5 of the Code of Virginia.

B. Fees shall be paid by check, draft or postal money order payable to the Treasurer of Virginia, or submitted electronically (if available), and must be in U.S. currency, except that agencies and institutions of the Commonwealth of Virginia may submit Interagency Transfers for the amount of the fee. All fees shall be sent to the following address (or submitted electronically, if available): Virginia Department of Conservation and Recreation, Division of Finance, Accounts Payable, 203 Governor Street, 4th Floor, Richmond, Virginia 23219.

C. All fee payments shall be accompanied by the following information:

1. Applicant name, address and daytime phone number.

2. The name of the impounding structure, and the impounding structure location.

3. The type of application or report submitted.

4. Whether the submittal is for a new permit or certificate issuance or permit or certificate reissuance.

5. The amount of fee submitted.

6. Impounding structure identification number, if applicable.

D. No permit fees remitted to the department shall be subject to refund except as credits provided for in 4VAC50-20-390 C.

Statutory Authority

§ 10.1-605 of the Code of Virginia.

Historical Notes

Derived from Virginia Register Volume 24, Issue 25, eff. September 26, 2008.

4VAC50-20-360. Fee exemptions.

Impounding structures owned by Virginia Soil and Water Conservation Districts shall be exempt from all fees associated with this part in accordance with § 10.1-613.5 of the Code of Virginia. There will be no fee assessed for a low hazard impounding structure exempted from fees pursuant to 4VAC50-20-51 or for the decommissioning of an impounding structure.

Statutory Authority

§ 10.1-605 of the Code of Virginia.

Historical Notes

Derived from Virginia Register Volume 24, Issue 25, eff. September 26, 2008.

4VAC50-20-370. Construction Permit application fees.

A. Any application form submitted pursuant to 4VAC50-20-70 for permitting a proposed impounding structure construction after September 26, 2008, shall be accompanied by a payment as determined in subsection B of this section.

B. Fees shall be as follows:

1. $2,500 for High or Significant Hazard Potential impounding structures.

2. $1,000 for Low Hazard Potential impounding structures.

Statutory Authority

§ 10.1-605 of the Code of Virginia.

Historical Notes

Derived from Virginia Register Volume 24, Issue 25, eff. September 26, 2008.

4VAC50-20-380. Regular Operation and Maintenance Certificate application fees.

A. Any application for a six-year Regular Operation and Maintenance Certificate after September 26, 2008, except as otherwise exempted, shall be accompanied by a payment as determined in subsection B of this section.

B. Fees for High, Significant, or Low Hazard Potential impounding structures shall be as follows:

1. $600 for High Hazard Potential.

2. $600 for Significant Hazard Potential.

3. $300 for Low Hazard Potential.

C. Fees for extension of Regular Operation and Maintenance Certificates shall be $250 per year or portion thereof.

Statutory Authority

§ 10.1-605 of the Code of Virginia.

Historical Notes

Derived from Virginia Register Volume 24, Issue 25, eff. September 26, 2008.

4VAC50-20-390. Conditional Operation and Maintenance Certificate application fee.

A. Fees for issuance of a Conditional Operation and Maintenance Certificate shall be as follows:

1. For a certificate for more than one year but no more than two years: $300.

2. For a certificate for one year or less: $150.

B. The fee for an extension of a Conditional Operation and Maintenance Certificate shall be $250 per year or portion thereof.

C. The board may allow a partial credit towards the Regular Operation and Maintenance Certificate fee if the owner of the impounding structure has completed, to the director's satisfaction, the conditions of the Conditional Certificate prior to its expiration.

Statutory Authority

§ 10.1-605 of the Code of Virginia.

Historical Notes

Derived from Virginia Register Volume 24, Issue 25, eff. September 26, 2008.

4VAC50-20-400. Incremental Damage Analysis review fees.

Should the department determine that outside expertise to assist with the review of an incremental damage analysis is necessary, the applicant shall be responsible for the cost of such outside expertise. Such costs shall be agreed upon in advance by the department and the applicant.

Statutory Authority

§ 10.1-605 of the Code of Virginia.

Historical Notes

Derived from Virginia Register Volume 24, Issue 25, eff. September 26, 2008.

NAVIGATING DAM SAFETY RULES IN VIRGINIA

Greg Zamensky, P.E., Black & Veatch Corporation

Introduction

For decades, the probable maximum flood (PMF) and fractions thereof have been the dominant spillway design criterion used by state dam safety agencies for high and significant hazard potential dams throughout the United States. The methodologies used to compute the PMF vary with topography and climate and were last updated in the late 1980s. Regardless, the PMF has always been a theoretical event. As such, the PMF does not have a definable recurrence interval (i.e., 100-year event, 500-year event, etc.), however, some estimates put the recurrence interval of the PMF at between a 100,000 and 1,000,000-year event. The immense size of the PMF and the lack of an understandable return period lead most dam owners and many engineers to question the reasonableness of the criterion.

In Virginia, the use of the PMF led one politically connected dam owner to nearly undermine the entire state dam safety program. Along the way, the dam safety legislation and regulations underwent several iterations of extensive revisions; some laws were clearly positive while others left the dam safety community perplexed. Since then, dam owners as well as engineering consultants have scrambled to stay abreast of the regulatory changes to understand how the regulations affect their dams.

Virginia has maintained a strong dam safety program for over 20 years, beginning with the inception of dam safety legislation in 1989. The Department of Conservation and Recreation, Dam Safety Division (DCR) oversees dam safety in the Commonwealth and administers the applicable regulations. In September 2008, the Virginia Impounding Structure Regulations were revised from top to bottom after several years of debate between regulators, legislators, engineers, and the public. Between September 2008 and April 2009, before the ink was even dry on these revised regulations, several pieces of new legislation were drafted that once again changed the dam safety landscape in Virginia. As of June 2010, the dam safety community in Virginia continues to monitor the situation as regulators struggle to provide updated regulations and guidance documents to clarify the application of these new laws.

In the meantime, dam owners and consultants cautiously try to navigate the obscure regulations and hope that future guidance includes insightful discussion across the industry—discussion that focuses on setting reasonable standards for selection of appropriate spillway design floods.

Regulatory and Legislative Changes

The Virginia Dam Safety Act was originally passed in to law under Article 2, Chapter 6, Title 10.1 of the Code of Virginia. The Virginia Impounding Structure Regulations (§4VAC50-20) became effective February 1, 1989. These regulations were recodified in 1997 and reprinted 2004.

Until the September 2008 revisions, no changes to the impounding structure regulations had occurred since the late 1980s except to update the definition of "regulated dams" to conform to the 2001 legislative change in definition (Chapter 92 (SB1166) of the 2001 Virginia Acts of Assembly). Over the decades, the management of dams evolved to include factors that were not considered in the 1980 legislation. For example, the residential and commercial populations near existing dams have increased, which in turn increased public safety concerns. Similarly, engineering and technology and methodologies have advanced over the decades, creating a host of approaches that were unavailable at the time the current law was drafted. Given the evolution of the dams practice and the community issues surrounding existing dams, it was determined that a substantive review of these regulations would be prudent, and that amendments may be necessary.

The significant revisions to the Virginia Dam Safety Act during the 2006 legislative session (Chapter 30 (HB597) of the 2006 Virginia Acts of Assembly) necessitated updates to the regulations to reflect the revised and enhanced powers and authorities. It has also been determined that the administration and implementation of the Dam Safety Program could be improved through regulatory updates and that the intent and procedures embodied within the regulations could be clarified to benefit the regulated community and the public.

A Technical Advisory Committee (TAC) composed of public and private dam owners, regulators, consultants, and contractors was impaneled in 2006 to develop the revised Impounding Structure Regulations. Formation of the TAC was influenced by a politically connected, private dam owner who was faced with costly spillway upgrades necessitated by building downstream that resulted in a change to the hazard potential classification. Although the dam was well maintained, construction of homes downstream, resulted in a high hazard potential classification, requiring that the spillway pass the full PMF versus the previous requirement of about 50 percent of the PMF.

While the TAC and DCR considered changes to the Impounding Structure Regulations, the Virginia legislature focused on protecting dam owners whose dams are located upstream from large, newly constructed communities. Developers' actions downstream affect dams upstream, often requiring dam owners to undergo costly upgrades to protect newly established downstream populations. In March 2008, the Governor signed House Bill 837 that provided

this protection, to a point. The bill requires dam owners to submit dam break inundation maps to their local jurisdiction's planning and zoning group. The bill provides localities with the authority to address development in dam break inundation zones. The bill directs developers to assist dam owners with dam upgrades (100 percent of the design cost and 50 percent of the construction cost) that are required as a direct result of the developer's proposed building in the dam break inundation zone.

After nearly three years, numerous public input periods, and several draft documents, the TAC and DCR produced revised regulations. Released in September 2008, the changes were substantial and affected nearly every regulated dam in the Commonwealth. Some of the more substantial issues affecting dam owners include:

1. Revising the dam hazard potential classification system;
2. Specifying that spillway design requirements are applicable to all state regulated dams;
3. Modifying the spillway design requirements to enhance public safety and reduce subjectivity (eliminate Section 130 exception from previous regulations);
4. Allowing for the potential reduction of the spillway design flood requirement through an incremental damage assessment (IDA) for all qualified dams;
5. Establishing dam break inundation zone mapping requirements;
6. Expanding emergency action plan requirements for High and Significant Hazard Potential dams and emergency preparedness plan requirements for Low Hazard Potential dams;
7. Establishing permit application fees for the administration of the Dam Safety Program that will create a stream of revenue sufficient to support an additional dam safety engineer;
8. Removing the forms that are incorporated by reference and move reporting standards into the regulations;
9. Creating new definitions or modifying current definitions;
10. Reorganizing, clarifying, and expanding sections related to permitting procedures; and
11. Updating sections related to inspections, enforcement, and unsafe conditions.

Most thought these changes were wholly appropriate; however, they did not relieve the aforementioned private dam owner of his responsibility to upgrade their spillway. Under the revised regulations, the private dam owner remained obligated to safely pass the full PMF. Further, the prospect of an IDA resulting in a lowered spillway design flood was negligible given the location of the homes downstream. So, once again, changes to the dam safety laws were sought.

Not surprisingly, the dam safety landscape in Virginia changed again in January 2010 when two new dam safety bills were introduced to the Virginia legislature: Senate Bill 276 and House Bill 438. The original version of Senate Bill 276 would have allowed dam owners to ignore safety concerns issued by DCR until the Commonwealth was able to fund any and all repairs needed to satisfy the dam safety regulations. Inexplicably, Senate Bill 276 passed both the Virginia House and Senate and was sent to the Governor's office for his signature. The original text was as follows:

> *"Until such time as adequate funding is available through the Dam Safety….Fund…., the [Board] shall continue to issue conditional operation and maintenance certificates for any existing impoundment that does not comply with dam safety regulations so long as the owner of the impoundment has adopted a dam safety emergency action plan…."*, Senate Bill 276, January 27, 2010

As written, the law would have completely undermined dam safety in Virginia. Justifiably, the Governor's office received intense pressure to reject the bill, including pleas from the American Society of Civil Engineers and the Association for State Dam Safety Officials. The Governor elected to send the bill back to the House for revision based on these and other comments. The amended Senate Bill 276 and House Bill 438, as signed by the Governor, provide potentially significant relief from the 2008 regulations for some dam owners. In summary, these bills provide the following major elements:

Senate Bill 276 – The maximum rainfall event to be used for evaluating all impounding structures and spillways built or permitted prior to July 1, 2010, shall be 90 percent of the probable maximum precipitation (PMP), reduced from 100 percent of the PMP. The maximum precipitation can be further reduced (to 60 percent of the PMP) for some qualified structures, if the owner can satisfy eight provisions including having a DCR-accepted EAP that is tested; daily inspections of the impounding structure; and insurance in an amount that will substantially cover property losses due to a dam failure. It is the insurance provision of the bill that the vast majority of dam owners can not satisfy.

The last line of the one page bill indicates "that this act is in force from its passage". As a result, DCR did not have the opportunity to interpret the legislation and modify the Impounding Structure Regulations accordingly. Therefore, interested dam owners must approach not just their Regional Dam Safety Engineer from DCR, but others including the Dam Safety Manager and the DCR Director to discuss their opportunity to apply the bill. As fate would have it, the aforementioned private dam owner can satisfy these provisions and, therefore, can take advantage of the relief provided.

House Bill 438 – The minimum spillway design flood for high hazard potential dams as identified through an IDA is reduced from 0.50PMF to the 100-year storm event. Limited-use or private roadways with low traffic volume shall be considered when determining the hazard potential classification of an impounding structure.

In January 2010, DCR issued a series of guidance documents to help owners and engineers interpret the rule changes including Dam Break Inundation Zone and Incremental Damage Analysis and Mapping Procedure; Roadways on or Below Impounding Structures; Special Low Hazard Impounding Structure Requirements; and Impounding Structure Hazard Potential Classifications. Given a date of January 14, 2010, these documents do not yet consider the implications of Senate Bill 276 or House Bill 438. Although these "Working Drafts" are available on DCR's website, they are not yet approved by the Virginia Soil and Water Conservation Board. Revised guidance documents are currently being reviewed by DCR. Release of the guidance documents is expected to occur sometime in the summer of 2010.

Dam Owner's Perspectives

Every owner in Virginia with a regulated impounding structure is affected by the aforementioned legislative and regulatory changes. The following section describes three cases studies of owners and their situation relative to the changing dam safety landscape. Considering none of these owners have fully navigated the process, the owner and dam names will be kept anonymous.

DAM A

Dam A and the impoundment are owned and operated by a city's utilities department as a surface water supply source. DCR classified Dam A as Class II structure, or having a significant hazard potential classification. Dam A, built in 1960, is a mass concrete structure with a central spillway capable of passing about 25 percent of the PMF before overtopping the remainder of the dam. The dam is well maintained and, as a result of the Section 130 Exception in the older dam safety regulations, the city held a Regular Operation & Maintenance (O&M) Certificate that expired in 2009. In late 2008, the city began planning for renewal of their O&M Certificate and contracted Black & Veatch to provide a comprehensive safety evaluation of the impounding structure that included hydrologic modeling, hydraulic modeling, stability evaluation, hazard classification, and foundation scour analysis.

The city was provided a Regular Certificate in 2003 through the Section 130 Exception of the dam safety regulations even though the spillway capacity was considerably less than the allowed range for a Class II structure (e.g., 0.50PMF to PMF). The revised regulations promulgated in 2008 removed the Section 130 Exception. Therefore, the city recognized that their next certificate renewal submission would not only require documentation demonstrating

a Significant Hazard Potential classification, but would also require justification for a lesser spillway capacity than required (e.g., an IDA).

Black & Veatch studies revealed that Dam A should be classified as a high hazard potential structure with more than 20 homes within the dam break inundation limits. Stability analyses indicated the mass concrete dam was stable even under the PMF loading condition. However, foundation scour evaluations revealed an erodible zone at the dam foundation if the dam were overtopped. Based on hydrologic modeling, precipitation in excess of the 500-year storm event is necessary to create sufficient overtopping to cause potential foundation scour. Nonetheless, relatively minor upgrades were needed to protect the foundation materials from potential scour to satisfy dam safety requirements.

The city accepted the study's conclusions and submitted a certificate renewal package in accordance with the 2008 dam safety regulations with provisions for installing the upgrades in the near future. Considering the new regulations and legislative changes, the city's choices to navigate the dam safety rules included:

Table 1: Dam A - City Regulatory Decisions

Choice Presented to the City	Source	City's Decision
Hazard potential classification determination. Hazard classification process not clearly defined in regulations.	Draft guidance for hazard potential classification, January 14, 2010 (not available at the time). Dam owners partially protected from downstream construction changing the SDF (House Bill 837, 2008)	Due to the potential for additional building downstream, the city chose to rehabilitate the dam as a High Hazard structure to avoid any future changes.
Perform IDA to potentially reduce the SDF from the PMF to as low as the 0.50PMF	IDA permitted by the 2008 regulations (4VAC50-20-52)	Based on review of the PMF dam break inundation maps, the city elected to not pursue an IDA.
Perform IDA to potentially reduce the SDF from the PMF to as low as the 100-year storm	SDF as low as the 100-year storm for high hazard structure by House Bill 438	Based on review of the PMF dam break inundation maps, the city elected to not pursue an IDA.
Reduce the extent of the upgrade at the dam from the PMF to 90 percent of the PMP	Reduced maximum storm for structures permitted before July 1, 2010 by Senate Bill 276	The city is considering, but the reduction is small
Reduce the extent of the upgrade at the dam from the PMF to 60 percent of the PMP	Reduced SDF allowed if other provisions are met by Senate Bill 276	The city is not willing to insure downstream property owners

DAM B

Dam B and the impoundment are owned and operated by a private home owners association as a recreational facility. DCR classified Dam B as a Class I impounding structure, or having a high hazard potential based on the 2008 regulations. Built in 1971, Dam B is a 100-foot-high zoned embankment dam with an off-channel spillway. The spillway is capable of passing about 20 percent of the PMF before dam overtopping begins. Considering the default SDF is the PMF (as defined in the 2004 regulations and the 2008 regulations), DCR issued the owner a Conditional O&M Certificate based on an inadequate spillway.

Due to very limited funding and continuous attrition of their board members, the owner struggled to develop or execute a definitive plan to address the spillway inadequacy. Consulting engineering firms had been working with the owner regarding the dam and spillway since 2006. Cognizant of the owner's financial situation, DCR provided several extensions to the Conditional Certificate and the 2008 regulation changes provided the owner even more time to develop a way forward.

In 2009, the owner engaged Black & Veatch to evaluate spillway upgrade alternatives to manage the PMF and satisfy dam safety regulations. In November 2009, the owner selected their preferred option; in January 2010, with a wary eye to the proposed legislative changes, Black & Veatch began final design. In April 2010, Senate Bill 276 was signed by the Governor causing the owner and Black & Veatch to mutually stop work to assess the applicability of the bill's provisions. After several discussions, DCR told the owner that they could apply for the large reduction in SDF described in Senate Bill 276. Although the owner has received no official paperwork from DCR, all correspondence with DCR indicate acceptance of the application. Based on these correspondences, in May 2010, the owner directed Black & Veatch to redesign the preferred alternative to meet the provisions of Senate Bill 276.

Table 2: Dam B - Owner Regulatory Decisions

Choice Presented to the Owner	Source	Owner's Decision
Perform IDA to potentially reduce the SDF from the PMF to as low as the 0.50PMF	IDA permitted by the 2008 regulations (4VAC50-20-52)	The owner elected to fund a preliminary IDA that revealed reduction of the SDF was not likely due to location of downstream occupied structures.
Perform IDA to potentially reduce the SDF from the PMF to as low as the 100-year storm	SDF as low as the 100-year storm for high hazard structure by House Bill 438	Preliminary IDA (above) revealed SDF reduction not likely.
Reduce the extent of the upgrade at the dam from the PMF to 90 percent of the PMP	Reduced maximum storm for structures permitted before July 1, 2010 by Senate Bill 276	The owner is automatically granted this reduction and accepts it.
Reduce the extent of the upgrade at the dam from the PMF to 60 percent of the PMP	Reduced SDF allowed if other provisions are met by Senate Bill 276	The owner elected to take the opportunity to potentially reduce the size (i.e., cost) of the spillway upgrades.

DAM C

Dam C is owned and operated by a city's public works department because a major roadway passes across the dam's crest. The reservoir is owned by a private institution. DCR classified Dam C as Class II structure, or having a significant hazard potential classification. Dam C, built in 1934, is a zoned embankment, about 35 feet high, with an off-channel spillway capable of passing about 10 percent of the PMF before overtopping of the dam. Even with an inadequate spillway according to the regulations, the city held a Regular O&M Certificate that expired in 2010 as a result of the Section 130 Exception from the 2004 dam safety regulations. An O&M Certificate renewal application is due to DCR by the end of 2010.

The city recognized that the 2008 regulations require a certificate renewal submission to include background data and computations supporting a reduced SDF that they did not have. In addition, the submission requires verification of the hazard potential classification. Due to downstream construction over the past 20 years, the city suspected that Dam C should be classified as a high hazard potential structure rather than a significant hazard structure. In 2009, the city began planning for renewal of their O&M Certificate by contracting Black &

Veatch to provide a safety evaluation of the impounding structure that included hydrologic modeling, hydraulic modeling, hazard classification, and rehabilitation alternatives development, if needed.

Black & Veatch completed the studies confirming Dam C as a high hazard potential structure with a spillway capacity significantly less than that required—10 percent of the PMF versus 50 to 100 percent of the PMF. An IDA requested by the city re-established the SDF to be the PMF; no reduction in the SDF was possible. Therefore, Black & Veatch prepared dam and spillway upgrade alternatives including embankment armoring, spillway expansion, and decommissioning.

By the end of 2010, the city will submit an O&M Certificate renewal package that describes the dam's issues, most notably an inadequate spillway, and their planned way forward in addressing the issues.

Table 3: Dam C - City Regulatory Decisions

Choice Presented to the City	Source	City's Decision
Perform IDA to potentially reduce the SDF from the PMF to as low as the 0.50PMF	IDA permitted by the 2008 regulations (4VAC50-20-52)	The city elected to fund a preliminary IDA that revealed reduction of the SDF was not likely due to location of downstream occupied structures.
Perform IDA to potentially reduce the SDF from the PMF to as low as the 100-year storm	SDF as low as the 100-year storm for high hazard structure by House Bill 438	Preliminary IDA (above) revealed SDF reduction not likely.
Reduce the extent of the upgrade at the dam from the PMF to 90 percent of the PMP	Reduced maximum storm for structures permitted before July 1, 2010 by Senate Bill 276	The city is automatically granted this reduction and accepts it, although the reduction provides only minor relief.
Reduce the extent of the upgrade at the dam from the PMF to 60 percent of the PMP	Reduced SDF allowed if other provisions are met by Senate Bill 276	The city is not willing to insure downstream property owners.

Conclusions

Through the influence of one local, politically connected, private dam owner, the dam safety rules in Virginia changed significantly in September 2008 and have continued to evolve since that point. In fact, the landscape is changing so rapidly that DCR representatives have been unable to compose guidance documents that provide their interpretation of the new rules.

Dam owners are left to wander through the collection of regulations, legislation, and draft guidance documents to find the optimal way forward considering their specific situation. Some dam owners are waiting for the dust to settle regarding DCR's interpretation of the new rules. Others are forging ahead with decisions trusting that the rules won't change again.

When you step back through the legislative changes and regulatory changes over the past five years and the reasonable or unreasonable justifications of the single dam owner, you find the core issue – the PMF. The PMF is a standard long used by the dam safety industry, but rarely brought to the forefront of political discourse.

Faced with shrinking budgets, many dam owners need to make difficult decisions and prioritize their expenditures based on public safety considerations. Some dam owners are questioning the reasonableness of regulations that require protection against the 100,000-year storm event (PMF) and only a 2,500-year earthquake event. The debate will continue and amplify in the upcoming years as states are faced with dam owners unable to pay for large spillway expansions. Public policy meets public safety.

ABSTRACT

Regional analyses were conducted on data from extreme storms for each of three storm durations and five climatologically homogeneous regions within Washington State. The primary objective of the study was to obtain probabilistic information about the temporal and spatial characteristics of extreme precipitation events for use in constructing synthetic storms for rainfall-runoff modeling.

Probabilistic analyses were conducted on those storm characteristics which are needed either to construct synthetic storms or to provide initial conditions for rainfall-runoff modeling. Those characteristics which were investigated included: seasonality of occurrence, macro storm patterns, precipitation depth-duration relationships, time of occurrence and temporal distribution of high intensity storm segments and the magnitude and frequency of occurrence of antecedent storms. Particular emphasis was placed on the analysis of the cross-correlation structure of the incremental precipitation amounts within storms. These analyses allowed the development of dimensionless probabilistic depth-duration curves which exhibited the statistical characteristics of observed extreme storms.

Methodologies were developed for assembly of synthetic storms using the probabilistic depth-duration data and associated storm characteristics for each of the five regions and three storm durations.

INTRODUCTION

The occurrence of an extreme precipitation event and the resultant flood are critical considerations in the design of many types of hydraulic structures. Dams for water resource projects, large stormwater conveyance and/or detention facilities, bridges for important transportation links and flood barriers such as major dikes and levees are examples of structures which must accommodate extreme floods to function properly.

Estimation of the flood peak discharge or the entire flood hydrograph for the design of these facilities is commonly accomplished using rainfall-runoff models. While numerous factors can affect the magnitude of an extreme flood, the magnitude of the precipitation event and its associated temporal and spatial characteristics are often dominant factors. Successful rainfall-runoff modeling of extreme floods is, therefore, highly dependent upon the use of realistic storm characteristics in the modeling process.

Given these considerations, a program of study was developed to analyze the characteristics of extreme storms. One study element was the development of methodologies to provide at-site precipitation magnitude-frequency information. Particular emphasis was placed on obtaining reasonable estimates of extreme events with annual exceedance probabilities in the range of 10^{-2} to 10^{-4}. Regional analyses techniques were selected to meet that objective and they are the subject of a separate paper titled "Regional Analyses of Precipitation Annual Maxima in Washington State" [Schaefer, 1990].

Another study element was the probabilistic examination of the temporal and spatial characteristics of extreme storms and that is the subject of this paper.

In the Pacific Northwest, minimal information previously existed on many aspects of extreme storms which are needed to properly model extreme floods. It is intended that the findings from these studies will further the understanding of extreme storms and will allow improved modeling of extreme floods.

O V E R V I E W

METHOD OF ANALYSIS

When an extreme storm occurs, it is the result of the interaction of a number of complex meteorological processes. The magnitude and/or intensity of any given meteorological process, which produces precipitation, is ultimately governed by atmospheric conditions having both random and deterministic components. This results in the measurable physical characteristics of a storm, such as the temporal and spatial distribution of the precipitation amounts, being highly variable and complex. It is, therefore, important that methods of analysis be used which recognize the stochastic nature of storms. For this reason, probabilistic methods of analysis have been used throughout this study.

OBJECTIVES AND STUDY CONTENTS

The primary objective of the study was to develop probabilistic information about the characteristics of extreme storms for use in the computer modeling of extreme floods. Specifically, information was needed for the construction of synthetic storm hyetographs which have the statistical properties of observed extreme storms. This required that information be obtained and probabilistic analyses be conducted on numerous aspects of observed storms. In addition, many of the meteorological characteristics associated with extreme storms have hydrologic implications in the modeling process. For example, knowledge about the season of occurrence of extreme storms allows inferences to be made about likely antecedent soil moisture conditions, initial streamflow magnitudes and, if appropriate, concurrent snowpack conditions. Thus meteorological characteristics, such as season of occurrence and the magnitude of antecedent storms, were also included in the study.

It was anticipated that the majority of applications of the information produced by this study would be on small watersheds.

Small watersheds are taken to be those having less than 50 square miles in drainage area, with most applications on watersheds having less than 10 square miles in drainage area. Because of the small size of the watersheds of interest, relative to the typical areal coverage of extreme storms, the emphasis of the study was directed towards at-site storm characteristics. Precipitation depth-area information has been excerpted from other sources to allow application of the results of this study on larger watersheds.

Given the aforementioned considerations, the following storm characteristics were selected for investigation:

Temporal Characteristics

- season of occurrence
- macro storm patterns
- time of occurrence and temporal distribution of high intensity segments within the storm
- correlation structure between incremental precipitation amounts within the storm and resultant depth-duration relationships
- magnitude and frequency of occurrence of storms antecedent to the extreme storm

Spatial Characteristics

- precipitation depth-area relationships
- areal coverage of thunderstorms in eastern Washington
- direction of storm movement and storm shape for thunderstorms in eastern Washington

HOMOGENEITY AND REGION DEFINITION

Inherent in the use of statistical methods is the desirability of obtaining representative samples of the data. Extreme storms, are, as the name implies, rare events. As such, insufficient data exists at any given station to produce a representative sample. To obtain sufficient data for a representative sample, data from numerous stations must be pooled for use in a "regional" analysis.

The validity of any regional analysis is dependent upon the actual homogeneity of the regional data. Herein, homogeneity refers to the condition that the particular data under analysis, either as directly observed or after some transformation, have common statistical properties. The statistical properties of interest in a particular analysis may refer to any or all of the following: mean; variance; coefficient of skew; probability distribution - and for data observed in pairs, the covariance and correlation coefficient could also be of interest.

The issues of region delineation and climatic homogeneity were a topic of much discussion and analyses in the companion paper on Regional Analyses of Precipitation Annual Maxima [Schaefer, 1990]. In that study, Washington State was subdivided into 13 climatically homogenous regions, where each region was comprised of recording stations within a small range of Mean Annual Precipitation (MAP). That produced a continuum from arid to rainforest climates where MAP ranged from 7 to 200 inches/yr, respectively. Extreme storms are a subset of the annual maxima and, thus, the aforementioned region formulation posed a logical starting point for defining homogeneous regions. However, a database of extreme storms is much smaller than a database of annual maxima. Thus, if regions were to be defined in terms of MAP it would be necessary to pool the extreme storm data over larger ranges of MAP which would result in a smaller number of regions.

A competing scheme for region definition was the formulation used by the National Weather Service (NWS) in their precipitation magnitude-frequency study, NOAA Atlas 2 [Miller et al, 1973].

In that scheme, four geographic regions were defined; comprised of the mountainous areas and central basin of eastern Washington and the lowlands and mountainous areas of western Washington (Figure 1a).

Comparison of the two schemes indicated compatibility in several areas. Regions defined geographically by the NWS were found to occupy reasonably distinct, although somewhat broad, ranges of MAP. In addition, preliminary analyses indicated homogeneity of seasonality and depth-duration characteristics from stations having either similar MAP or representing a specific geographic area.

Given the limitations of the database size, a formulation of 5 regions was proposed (Table 1) which had characteristics of both geographic delineation and definition by ranges of MAP (Figure 1b).

Table 1. Formulation for Region Definition

REGION	RANGE OF MEAN ANNUAL PRECIPITATION FOR REGION (inches)	AVERAGE VALUE OF MEAN ANNUAL PRECIPITATION OF RECORDING STATIONS (inches)	CORRESPONDS TO NWS REGION DESIGNATION	GEOGRAPHIC DESCRIPTION AND METEOROLOGIC COMPONENTS *
2	7 - 20	9.5	2	EASTERN WASHINGTON - CENTRAL BASIN Convergence
1	15 - 70	23.5	1	EASTERN WASHINGTON - MOUNTAINS Convergence and Orographic
3	20 - 70	42.0	3 partial region	WESTERN WASHINGTON - PUGET SOUND LOWLANDS Convergence
4	50 - 200	86.5	4	WESTERN WASHINGTON - MOUNTAINS Convergence and Orographic
5	70 - 120	89.0	3 partial region	WESTERN WASHINGTON - COASTAL LOWLANDS Convergence and Onshore Stimulation

* Convergence, Orographic, and Onshore Stimulation are Described in Definitions Section

Review of Table 1 reveals that the proposed regions occupy reasonably distinct ranges of MAP. Each region represents a different geographic area and is generally associated with a different mix of meteorologic components which produce precipitation.

Verification of the suitability of this formulation was accomplished by examining data homogeneity during the various analyses. In some cases, data from several regions were found to be homogeneous and were pooled for analyses. In other cases, separate analyses were conducted for each of the five regions.

In summary, the five region formulation, as described in Table 1 and delineated in Figure 1b, was found to yield reasonably homogeneous data and was accepted for use in the study.

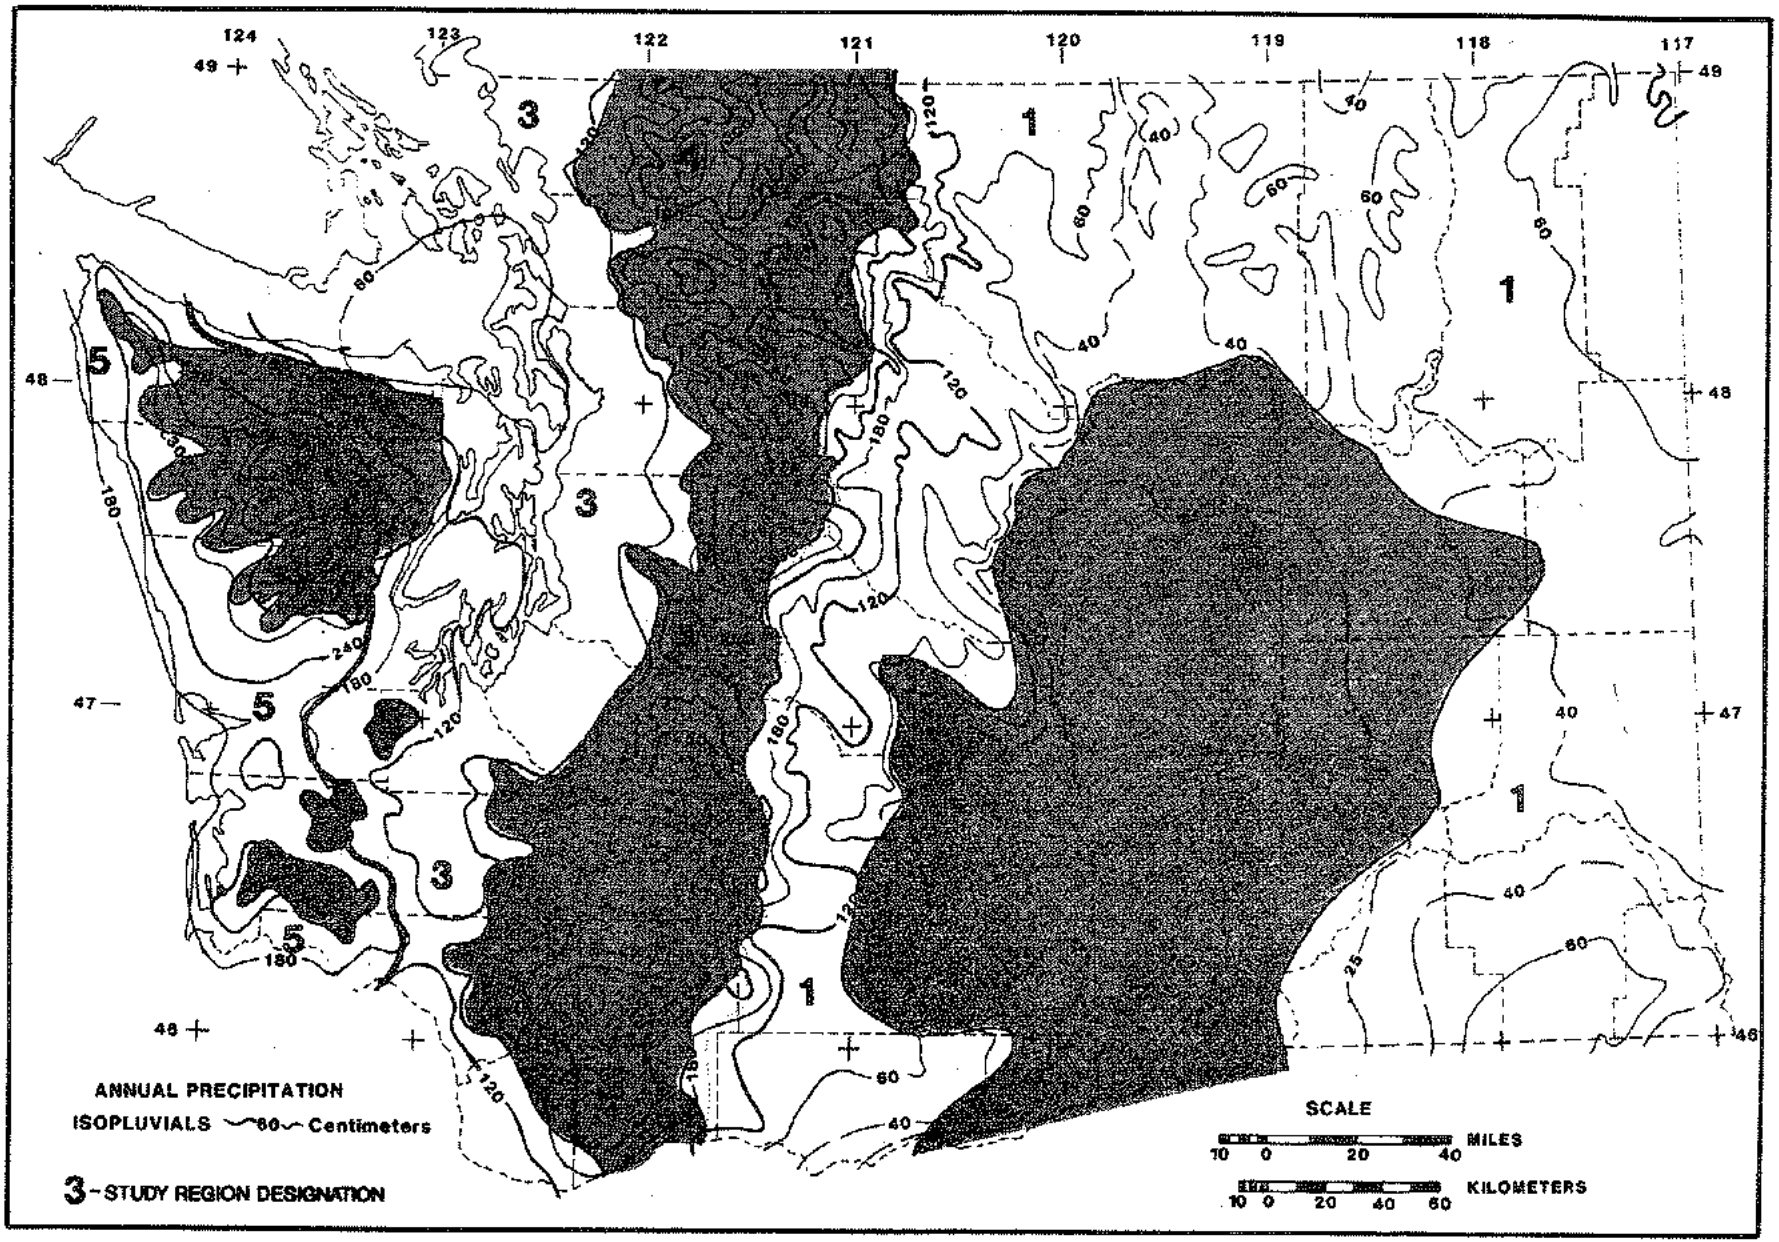

Figure 1b. Mean Annual Precipitation in Washington State and Delineation of Climatic Regions

EXTREME STORM CATALOG

To investigate the various storm characteristics, it was necessary to assemble a database of extreme storms for each of the five regions. The list of these databases is contained in Appendices 1A through 1E and is labeled the Extreme Storm Catalog.

PROCESS FOR SELECTION OF EXTREME STORMS

The term "extreme" as applied to precipitation events does not have a generally accepted meaning among the engineers and scientists who analyze and/or use the data. The selection of a threshold for defining extreme storms was made based on the needs of this study. There were three primary considerations. First, similitude considerations suggest that storms chosen for analyses should be of a similar magnitude/intensity to those which are desired for modeling of extreme floods. Second, prior studies by the NWS [Frederick et al, 1981] have shown that there are statistical differences between the characteristics of extreme events and common events. Based on these two considerations, the chosen threshold should certainly preclude the use of common events and should be set as high as practicable. Third, the threshold should be set at a level which yields databases of sufficient size to provide representative samples and thus allow valid statistical analyses.

These considerations resulted in setting the threshold for defining an extreme storm at an annual exceedance probability of 5%. Thus, any storm which contained precipitation amounts representing an at-site return period of 20 years or greater would be a candidate for inclusion in the catalog.

The following procedures were used to screen the storm data from each region and to assemble the extreme storm catalog:

- Three specific durations were selected for analyses; 2 hrs, 6 hrs, and 24 hrs.

- An annual maxima series was assembled for the precipitation data at each recording station (Figure 1a) for each of the three durations.

- Exceedance probabilities were computed for the annual maxima at each station for each duration using the Generalized Extreme Value distribution and regional analysis procedures as described by Schaefer [1990].

- The annual maxima and associated annual exceedance probabilities at each duration were then examined to identify the "extreme" storms and corresponding dates of occurrence.

- When an event, having extensive areal coverage, produced precipitation amounts which exceeded the extreme storm threshold at two or more stations within a region, only the station representing the rarest amount was retained in the catalog.

A review of the selected storm data disclosed that, occasionally, an individual event exceeded the extreme storm threshold at two or more durations. To avoid duplicity, it was decided that a storm event should only be contained in the database for a region at one of the three specified durations. Further, it was important for homogeneity considerations that storms of similar duration be grouped together in the analyses of storm characteristics. This necessitated that the databases be further screened to meet these two additional considerations.

Additional screening was accomplished wherein an extreme storm (storm date) could only appear in the catalog at one of the three durations. The selection of the duration which best represented the observed storm event was made using the following criteria:

- When a storm event was identified as extreme at two or more durations, it was placed in the database for the duration at which the corresponding precipitation amount was markedly the most rare (smallest annual exceedance probability).

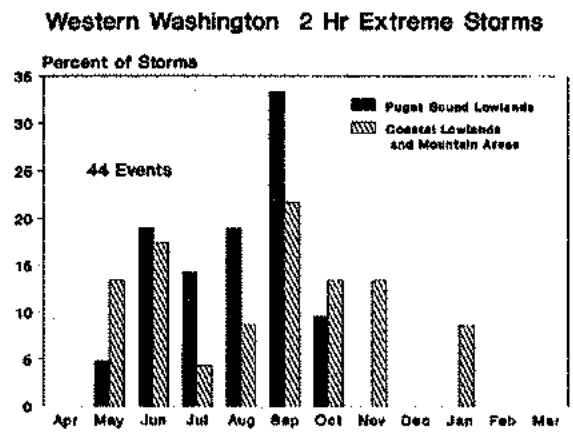
- If a storm event was not markedly more rare at any specific duration, then the storm was examined to determine the effective duration [NWS, 1984]. The effective duration was defined as being the time period during which the bulk of the precipitation occurred; i.e., 90% of the total precipitation. The effective duration was then compared to the three durations under study and the criteria shown in Table 2 were used as a general guideline in selecting the representative duration.

Table 2 General Guideline for Selection of the Duration Most Representative of a Given Storm Event

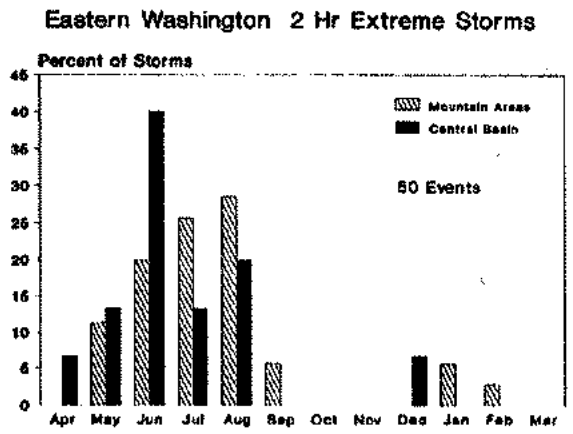
REPRESENTATIVE STORM DURATION	SELECTION GUIDELINE
2 hours	effective duration < 3 hrs
6 hours	4 hrs < effective duration < 12 hrs
24 hours	15 hrs < effective duration

These procedures resulted in the selection of 252 extreme storms from 11,200 annual maxima. The 252 storms are listed in the storm catalog in Appendices 1A through 1E. These storms provided the databases which were used for all analyses on storm characteristics.

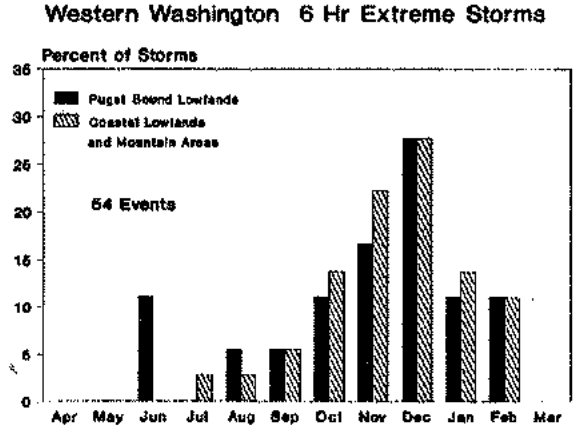
SEASONALITY OF EXTREME STORMS



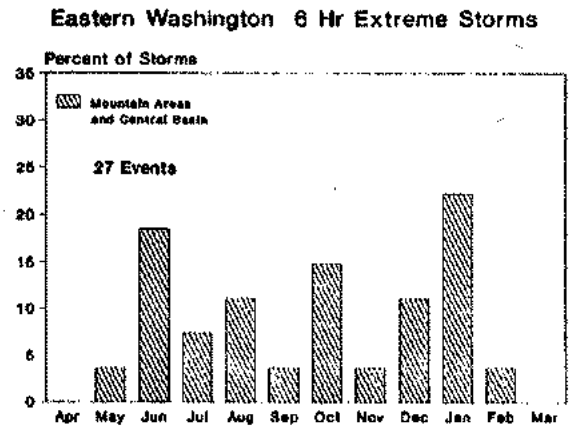
It is common knowledge that the majority of the precipitation that falls annually in the Pacific Northwest occurs in the winter months. However, only limited study [Frederick et al, 1981] has been conducted on the season of occurrence (seasonality) of extreme storms.



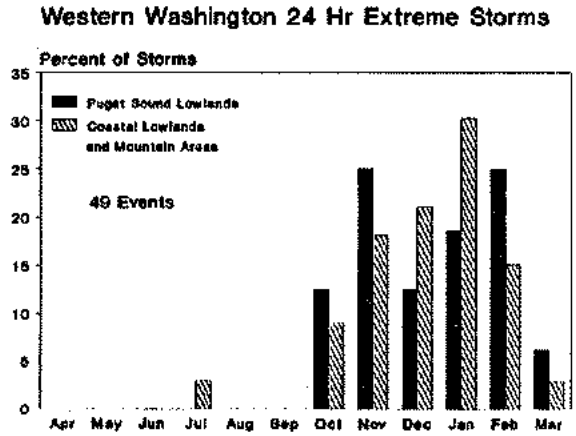
The principal application of seasonality information is in selecting the likely climatological and hydrologic conditions which will accompany an extreme storm event at a specific geographic location. Use of published climatological data [NCDC] and streamflow data [USGS] in combination with seasonality information can aid in the selection of antecedent soil moisture conditions, runoff characteristics, initial streamflow magnitudes, initial reservoir levels, etc. Where flood events produced by rain on snow are a consideration, selection of snowpack conditions can be made based on the historical record of snowfall in combination with seasonality information.



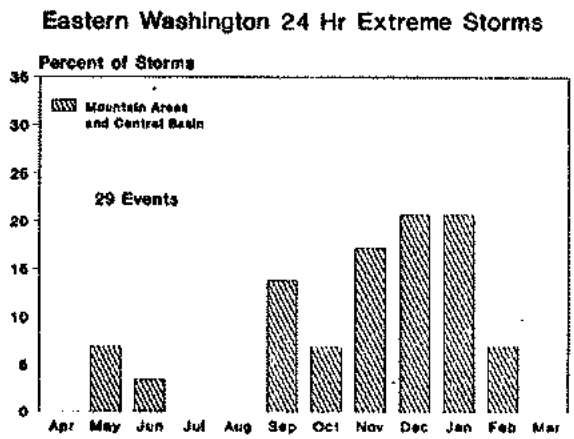
The seasonality of extreme storms was investigated in each region by constructing frequency histograms of the storm dates. In eastern Washington, there was insufficient data for the central basin at the 6 hour and 24 hour durations to provide representative samples. It was necessary to combine the central basin data (Region 2) with the data from the mountain areas (Region 1) for the seasonality analyses.



In western Washington, the amount of coastal data was marginally adequate to provide representative samples. Analyses of the coastal data (Region 5) indicated similarity to the data from the mountain areas (Region 4) at all three durations. Thus, the data from the two regions were combined in the seasonality analyses.



It can be seen in Figures 2a through 2f that, for each region and each duration, extreme storms occur in reasonably well-defined periods of the year. The short duration, 2 hour events, occur predominately in the warm season while the long duration, 24 hour events, occur in the late fall and winter months.



Figures 2a,2d
2b,2e
2c,2f

Frequency Histograms for Seasonality of Extreme Storms in Washington State

In general, the long duration extreme storms are produced by synoptic scale cyclonic weather systems and associated fronts. These storms are characterized by large precipitation amounts and contain moderate and relatively uniform rainfall intensities.

The short duration extreme storms are commonly produced by strong convective activity which may or may not be associated with a precipitation producing weather feature identifiable at the synoptic scale. The short duration events are characterized by high intensity, but short lived rainfall. They are a warm weather phenomenon, deriving much of the needed energy from the sun. The importance of insolation in the development of convective cells can be seen in Figure 3 where the short duration storms are seen to occur predominately in the late afternoon and early evening during the warm season.

The intermediate duration extreme storms have seasonality characteristics reflecting the causative storm types. In eastern Washington, some 6 hour events are hybrids of the 2 hour storms occurring in the warm season. Other 6 hour storms occur in the cool season and have similarities to the 24 hour storms. In western Washington, the 6 hour storms are almost always associated with cyclonic weather systems and the cool season.

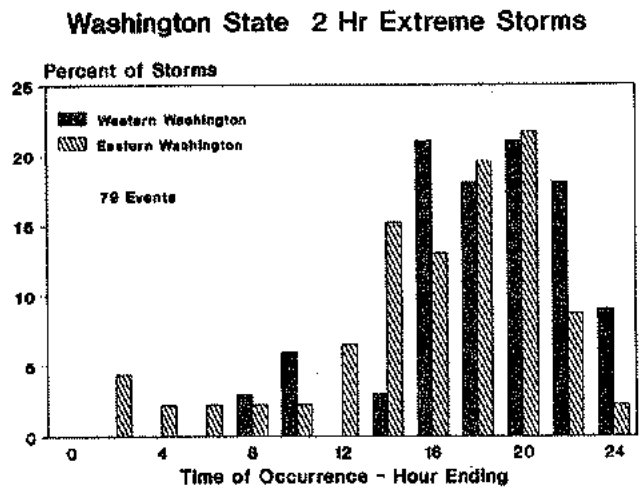


Figure 3. Frequency Histogram for Occurrence of 2 Hour Extreme Storms versus Time of Day

TEMPORAL DISTRIBUTION OF STORMS

The purpose of this component of the study was to develop probabilistic information about the temporal distribution of precipitation amounts during extreme storms. Elements of this component include probabilistic assessments of: macro storm patterns, depth-duration relationships and the time of occurrence and arrangement of high intensity storm segments.

DEFINITIONS - GLOSSARY OF TERMS

Storms are inherently complex. A discussion of the characteristics of extreme storms and the methods of analysis requires that a comprehensive nomenclature be utilized. Many of the terms used in this study are common to either meteorology or to statistical analyses. Other terms were created specific for use in this study. Most of the important terms are listed below. Those terms which are used in the study but not listed below should be found in most reference books on meteorology or statistics.

The reader may choose to review these terms now or may find it advantageous to wait until the terms are referenced in the paper.

At-site:

The term at-site is used in various ways. It may be used to distinguish analyses/data at a specific station (site) from regional analyses/data. It may be used in reference to a recording station and/or a specific geographic location. Observed at-site precipitation may be used synonymous with observed point rainfall.

Convergence Precipitation:

Convergence is intended to encompass all precipitation producing processes associated with the circulation of a cyclonic weather system.

Dependent Duration (DD):
Any specified period of time, internal to or exterior to the independent duration. The term dependent is used in the statistical sense of dependency. Precipitation during this period is dependent upon (correlated with) precipitation for the independent duration.

Depth-Duration Curve:
A precipitation mass curve created by rearrangement of observed incremental precipitation amounts in a manner which contains the largest incremental amounts at the start of the mass curve. See Appendix 2.

Effective Duration:
The period of time during which 90% of the total precipitation accumulated. This term assists in identifying the elapsed time during which the bulk of the precipitation occurred and eliminates periods of trace or small amounts which may precede or follow the period of heavy storm activity.

Extreme Storm:
An at-site precipitation amount, for a specified independent duration, which has an annual exceedance probability of 0.05 or less.

Hyetograph:
The hyetograph is a graphical representation of precipitation as it occurred with time. The graph may be discretized or continuous, displaying either incremental or accumulated (mass) precipitation or precipitation intensities.

Independent Duration (ID):
A continuous period of time during which extreme storm precipitation has occurred. Precipitation may have been continuous or intermittent during this period and precipitation may have also occurred prior to or following this period. Independent durations in these analyses are for the specific durations of 2 hrs, 6 hrs and 24 hrs.

Kernel Duration:
The dependent duration associated with the kernel ordinate.

Kernel Ordinate:
The initial dimensionless ordinate value selected in the development of probabilistic depth-duration curves. All other ordinates of the depth-duration curve are obtained by way of correlation relationships with the kernel value.

Local Storm:
A storm comprised of an isolated convective cell or group of cells, commonly referred to as a thunderstorm. Its occurrence is unrelated to any precipitation producing synoptic weather feature such as a cyclone or associated front.

Macro Storm Pattern:
A histogram describing the general shape of the incremental precipitation amounts during the total duration of the storm event.

Onshore Stimulation:
Precipitation which occurs from vertical instability and resultant lifting of atmospheric moisture in response to increased surface friction which accompanies the onshore movement of marine air.

Orographic Precipitation:
Precipitation which occurs from lifting of atmospheric moisture over mountain barriers.

Regional Analyses:
Analyses which are conducted on data collected from, and representative of, various sites within a specified region. Distinguished from at-site analyses which are conducted on data from a specific site.

Seasonality of Storms:
Frequency characteristics for the time of year (month) during which storms have been observed to occur.

Sequence:
Refers to the ordered arrangement of data. A sequence of 1342 indicates the largest data value occurred first, followed by the third, fourth and second largest values respectively.

Storm:
The term storm may be used in several ways. It may be used synonymous with the definition of "extreme storm" or it may be used generically in reference to the amount, total duration, temporal distribution or the areal coverage of precipitation.

Storm Segment:
Any selected time period and associated precipitation amount or dimensionless value.

Total Duration (TD):
A dependent duration representing a time period three times larger than the independent duration. The total duration would include the period of time containing the independent duration. The total duration must begin with precipitation, although precipitation need not be occurring at the end of the total duration.

Trisector:
Trisectors are used to subdivide the total duration into three equal periods of time. Each trisector has a duration equal in magnitude to the independent duration. Trisectors aid in categorizing and describing macro storm patterns.

MACRO STORM PATTERNS

This first element of the study investigated the temporal distribution of storms by examining the general arrangement (macro pattern) of the incremental precipitation amounts for each storm. The goal was to describe probabilistically the observed macro patterns for a given independent duration (ID) and region of occurrence.

In order to investigate the temporal characteristics of extreme storms, it was necessary to first establish a uniform approach for describing and categorizing the storms. The period of interest for investigation of storm activity was expanded to a total duration (TD) equal to three times the independent duration to include precipitation which may have preceded or followed the extreme event. The starting and ending times of the TD were selected such that precipitation was occurring at the start of the TD and the precipitation amount for the TD was the greatest for any window of time containing the ID. To facilitate the categorization of macro patterns, the total duration was subdivided into three equal time segments, called trisectors (Figure 4).

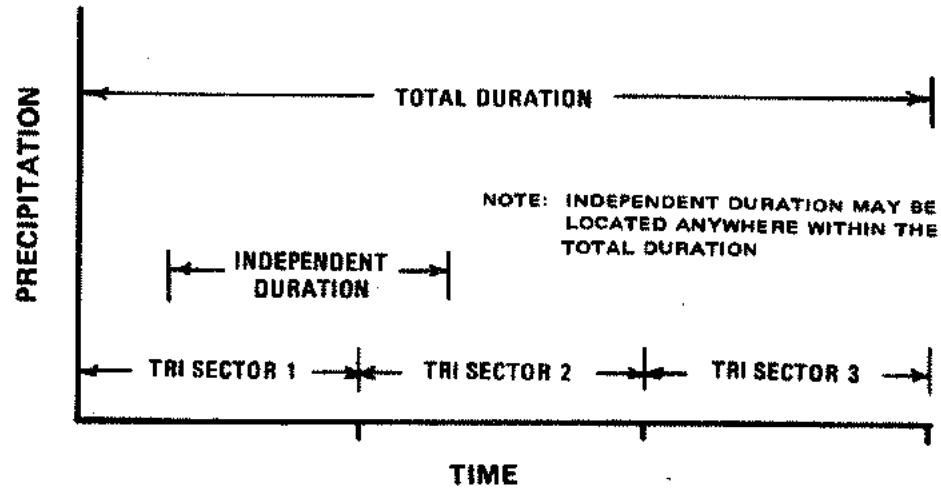

Figure 4 Example of Relationships between Independent Duration, Total Duration and Trisectors

The use of the trisector system allowed for 6 permutations in the storm pattern sequences. Consideration of both continuous and intermittent patterns produced the twelve generalized macro patterns which were used for categorizing storms (Figure 5).

To apply this categorization system, the precipitation amounts from a given storm were computed for each trisector and the amounts were compared and ordered in relative magnitude to form a sequence; i.e.: 312, 123, 213 etc. The effective duration and time of occurrence of the highest intensity were recorded and the precipitation was identified as either continuous or intermittent. Using the above information, the storm was categorized as one of the twelve macro patterns shown in Figure 5. Frequency histograms were then constructed (Figures 6a-6f) of the observed macro patterns for the various regions and independent durations.

Statistics were then compiled on the aforementioned storm characteristics. The percentage of storms which were continuous or intermittent are shown in Table 3. The typical values of the effective duration, time of highest intensity and macro storm patterns are shown in Table 4.

Table 3. Percentage of Extreme Storms which had Continuous or Intermittent Precipitation

REGIONS	INDEPENDENT DURATION (hours)	MACRO PATTERNS	
		CONTINUOUS %	INTERMITTENT %
1 & 2	2	100	0
3 & 4 & 5	2	93	7
1 & 2	6	90	10
3 & 4 & 5	6	93	7
1 & 2	24	75	25
3 & 4 & 5	24	67	33

REGION	INDEPENDENT DURATION (hours)	TOTAL DURATION (hours)	MACRO STORM CHARACTERISTICS			
			TIME OF HIGHEST INTENSITY (hours)		EFFECTIVE DURATION (hours)	TYPICAL MACRO PATTERN
			MEAN	STND. DEVIATION	MEAN	
1 & 2	2	6	0.7	0.7	1.3	I
3 & 4 & 5	2	6	0.9	0.6	2.6	I
1	6	18	6.3	3.7	10.5	VI
2	6	18	6.3	3.7	9.0	VI
3	6	18	9.2	4.3	10.1	VI
4	6	18	9.2	4.3	12.5	VI
5	6	18	9.2	4.3	12.1	VI
1	24	72	23.7	16.7	40.8	I
2	24	72	15.6	13.5	30.4	I
3	24	72	25.5	14.2	38.1	I
4	24	72	33.6	14.5	45.3	VI
5	24	72	30.6	17.2	49.5	VI

A review of the results displayed in the frequency histograms and contained in Tables 3,4 reveals several trends. The 2 hour ID events, in all regions, had predominately Type I macro patterns with the high intensity segment near the beginning of the storm. Frequently, these storms were quite localized, convective events which dissipated rapidly after the occurrence of the high intensity segment. Storms of this type would carry the generic label of "thunderstorm".

Comparison of characteristics for mountain areas versus lowlands for the 6 hour and 24 hour ID storms, in either eastern or western Washington, revealed the mountain areas to always have larger effective durations. This results from persistence of the storm in mountain areas due to the orographic lifting of atmospheric moisture which is not present in lowland areas. The persistence of precipitation due to orographic effects will be quantified in the section on depth-duration relationships.

The short duration storms occurred almost exclusively as continuous events. As the duration of the storm increased, there was an increase in the percentage of intermittent macro patterns. Likewise, there was a tendency for greater variability in observed macro patterns as the storm duration became longer. While, the short duration events occured primarily as Type I macro patterns, the longer duration events exhibited a number of macro patterns which were nearly equally likely.

It will be seen later that a macro pattern for use in developing a synthetic storm will not be selected directly. Instead, the determination of an appropriate macro pattern will be governed by the selection of the time of occurrence and sequence of incremental precipitation amounts surrounding the high intensity segment. This issue will be discussed in the section on Assembly of Synthetic Storms.

ANALYSIS OF DEPTH-DURATION CURVES

The depth-duration curve [Chow, 1964], [WMO, 1974] is an analytical tool originally developed by meteorologists to allow precipitation depth and duration comparisons to be made between observed storms. In simple terms, the depth-duration curve is a precipitation mass curve created by rearrangement of observed storm precipitation in a manner which contains the largest incremental precipitation amounts at the start of the new mass curve. The primary application of depth-duration data is in the construction of synthetic storms for use in rainfall-runoff modeling.

Historically, depth-duration data have been used in a deterministic manner which does not incorporate the stochastic nature of storms. Depth-duration curves have usually been obtained from only a small number of "representative" storms and then scaled to the magnitude necessary for a specific application. An alternative procedure has been to prepare an "envelope" curve which envelopes all observed storms and which is intended to represent the most severe manner in which the storm might occur. Neither of these two procedures exploit the full amount of information contained in the observed storm data.

In this element of the study, regional analyses techniques will be utilized to statistically examine a large number of extreme storms. This procedure will allow the development of a family of probabilistic depth-duration curves which have the statistical characteristics of depth-duration data exhibited by observed extreme storms. The probabilistic framework employed herein will provide a methodology to predetermine the likelihood of the depth-duration characteristics which are used to assemble a given synthetic storm. Thus, a synthetic storm can be constructed which both suits the needs of a particular application and for which the likelihood of occurrence is reasonably known.

In the following sections, it is assumed that the reader is familiar with precipitation mass curves and with the construction of depth-duration curves. If needed, the reader may refer to Appendix 2 for a detailed discussion of depth-duration curves.

Methods of Analysis

Analyses of depth-duration curves/data were accomplished on a regional basis. Separate analyses were conducted on the collection of extreme storms at each of the three Independent Durations (IDs) for each region. A significant amount of data preparation was required prior to analysis and for sake of clarity, the progression of data preparation is listed below.

- For each storm, precipitation amounts were recorded at the time intervals shown in Table 7. A depth-duration curve was then assembled by accumulation of the incremental precipitation amounts using procedures contained in Appendix 2. Each duration for which mass precipitation was tabulated, except the ID, was labeled a Dependent Duration (DD).

Basic data needed to compute the curves were obtained either from weighing bucket charts from the National Climatic Data Center (NCDC), [NOAA, 1940-1986] or from incremental precipitation data contained in the Hourly Precipitation Data periodicals published by NCDC [NOAA, 1951-1986].

- The tabulated mass precipitation amounts at each dependent duration were made dimensionless by division by the precipitation amount for the independent duration.

- For curves which were based on incremental precipitation amounts obtained from NCDC periodicals, corrections were applied (Table 5) to the dimensionless tabulated amounts (ordinates) to account for systematic errors produced by recording precipitation at fixed intervals (Weiss, 1964).

These procedures transformed all mass precipitation amounts from the collection of extreme storms to a common scale. The dimensionless ordinates at each dependent duration could then be grouped together for analysis.

Table 5. Corrections Applied to Dimensionless Ordinates in Depth-Duration Curves

Stage 1 of Analyses

Probabilistic analyses were accomplished in two stages for the depth-duration data for each ID within each region. The first stage was patterned after techniques used by the NWS [Frederick et al, 1981] wherein frequency analyses were conducted on the dimensionless ordinates at each of the dependent durations. In the NWS study, the Extreme Value Type I distribution [Fisher and Tippett, 1929] was used to model the magnitude-frequency characteristics of the ordinate data. Upon review of the ordinate data it was determined that the Beta Distribution [Benjamin and Cornell, 1970] would be a better choice. The four parameter Beta distribution was selected because it is extremely flexible, being capable of modeling data with either a positive or negative skew as exhibited by the ordinate data at various dependent durations.

The Beta distribution also incorporates both an upper and lower bound which is consistent with the physical constraints inherent in the construction of depth-duration curves (Figure 7).

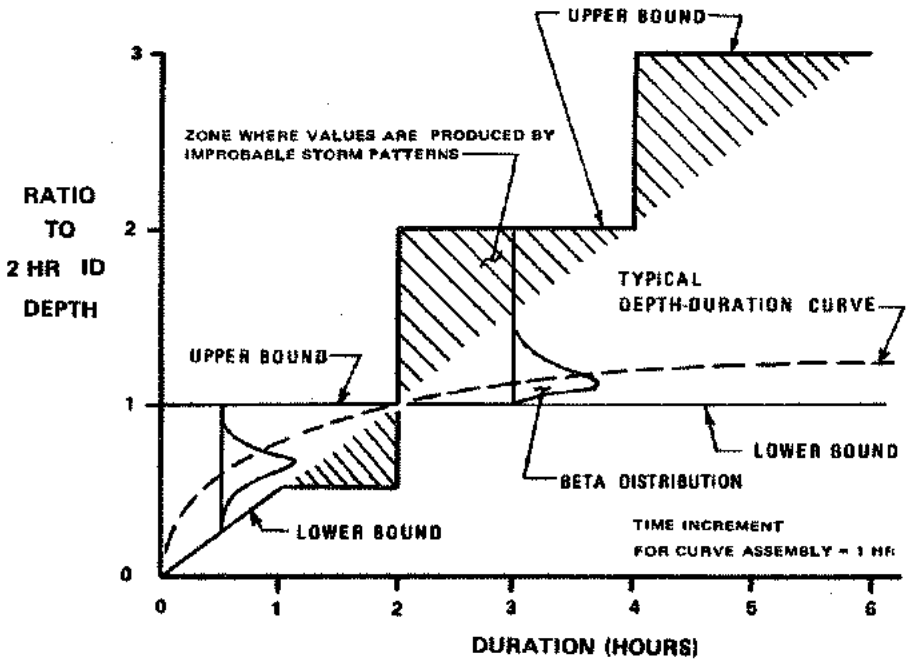

Figure 7. Depth-Duration Curve for 2 Hour ID Extreme Storm Depicting Typical Characteristics and Physical Boundaries

The probability density function for the Beta distribution is:

$$f(x) = \frac{\Gamma(\alpha+\beta)}{\Gamma(\alpha)\ \Gamma(\beta)} \left[(\delta_2-\delta_1)^{1-\alpha-\beta} \right] (x-\delta_1)^{\alpha-1} (\delta_2-x)^{\beta-1} \qquad (1)$$

where:

δ_1 and δ_2 are the lower and upper bounds respectively
α and β are distribution parameters
$\Gamma(\ )$ is the Gamma function

The conventional moments for the Beta distribution are:

$$\mu_x = \delta_1 + (\delta_2 - \delta_1) \left[\frac{\alpha}{(\alpha+\beta)} \right] \quad \ldots\ldots\ldots\ldots\ldots\ldots (2)$$

$$\sigma_x^2 = (\delta_2 - \delta_1)^2 \left[\frac{\alpha\beta}{(\alpha+\beta)^2 (\alpha+\beta+1)} \right] \quad \ldots\ldots\ldots\ldots\ldots\ldots (3)$$

$$\gamma_x = \frac{\alpha}{\sigma_x^3 (\alpha+\beta)} \left[\frac{(\alpha+2)(\alpha+1)}{(\alpha+\beta+2)(\alpha+\beta+1)} - \frac{3\alpha(\alpha+1)}{(\alpha+\beta)(\alpha+\beta+1)} + \frac{2\alpha^2}{(\alpha+\beta)^2} \right] \quad (4)$$

where:

μ_x, σ_x^2 and γ_x are the mean, variance and skew coefficient respectively

The method of moments was used to estimate the distribution parameters and quantile estimates where obtained for the ordinate values by numerical integration of the density function.

The results of the magnitude-frequency analyses are displayed in Figures 8a,b,c,d,e,f. It should be noted that the analysis of the ordinate data at each of the dependent durations is accomplished separately and without consideration of the ordinate data at other DDs. Thus, while this type of analysis provides valid magnitude-frequency information at a given DD, this information, alone, is insufficient to assemble synthetic depth-duration curves. For there are innumerable combinations in which the ordinate values, and a resultant depth-duration curve, can be assembled.

Further information is needed on the interrelationships between the ordinate values to determine the statistical dependencies. This type of analysis will be conducted in Stage 2 and will ultimately allow decisions to be made regarding which combinations are "best" and reflect observed storm characteristics.

Stage 2 of Analyses

The second stage of analysis was employed to determine the interrelationships between the ordinates at the various Dependent Durations (DDs). This required an investigation of the correlation structure of the DD ordinate values. Use of the correlation structure provided information by which selection of the ordinate value for a specific DD would allow realistic selection of the ordinate values at other DDs.

The analysis was initiated by computing correlation coefficients for all DD ordinate pairs at each of the three IDs in each of the five regions. Cross-correlation matrices were then assembled for inspection. A review of the magnitude of the correlation coefficients for some typical cross-correlation matrices (Tables 6a,b,c) reveals that the DD ordinates are highly correlated. In addition, given any specific DD, the correlation coefficients are seen to decay in absolute magnitude with DDs progressively further from the starting DD. Strong correlation interrelationships exist for the short duration 2 hour ID events and there is a movement towards weaker correlation structure for the longer duration 24 hour ID events where the time increment between DDs becomes greater.

To properly utilize this information, a methodology was needed to allow the correlation structure to be incorporated into the selection of DD ordinates values for the development of the depth-duration curves. One approach available was to develop a stochastic model for generating synthetic storms. The correlation decay characteristics of the depth-duration data were indicative that models such as the Auto Regressive (AR) or Auto Regressive Moving Average (ARMA) models [Box and Jenkins, 1976] might be applicable. Variations of models of precipitation point processes such as those discussed by Woolhiser and Osborn [1985] or Istok and Boersma [1989] could also provide suitable alternatives.

After due consideration, it was determined that nothing as sophisticated as these models was needed. The primary objective of this element of the analyses was to develop a finite number of depth-duration curves which would span the range exhibited in observed storms. Therefore, a simple way to include the correlation structure would be to use disaggregation techniques

[Valencia and Schaake, 1973] and standard correlation methods to preserve the correlation structure. Specifically, this could be accomplished by selecting a representative DD and using the appropriate regression parameters of slope and intercept from the cross-correlation analyses to estimate the "expected values" of the ordinates at all other DDs.

The selection of a representative DD for each of the IDs was made with consideration of several factors. First, estimation of the flood peak discharge is often the item of primary interest in rainfall-runoff modeling. And, the occurrence of the high intensity segment of a storm normally produces the flood peak discharge. Therefore, the representative DD should be a relatively short duration DD within the ID. Second, a review of the cross-correlation matrices revealed the short duration DDs to be highly correlated. Thus, the selection of a specific DD among the shorter duration DDs was not critical. Based on these considerations, the

representative DD for use in developing probabilistic depth-duration curves for each ID was chosen such that it was from 1/4 to 1/3 the duration of the IDs. These representative durations were labeled as "Kernels" (Table 7) because they defined the initial ordinate from which all other DD ordinates would be obtained.

Table 7. Time Increments Used in Various Elements of the Study of the Temporal Distribution of Extreme Storms

INDEPENDENT DURATION (hours)	ASSEMBLY OF DEPTH DURATION CURVES (minutes)	KERNEL DEPENDENT DURATION (minutes)	HIGH INTENSITY STORM SEGMENTS (minutes)
2	60	30	15
6	180	120	60
24	360	360	60

After selection of the kernel DDs, the next step was to refine the estimates of the regression parameters obtained from the cross-correlation analyses. Improved estimates of the regression parameters were made based on a smoothing of either the correlation coefficients or the slope parameters. In either instance, the parameters to be smoothed were obtained from the cross-correlation analyses for the case where the kernel duration was the independent variable (see for example, graytone blocks in Tables 6a,b,c).

Three separate smoothing functions were employed (Figure 9). A first order polynomial was fit to the correlation coefficient data for DDs less than the kernel DD and a second order polynomial was fit to the data for DDs greater than the kernel DD but less than the ID. In both cases, the solution polynomials were constrained to a value of unity at the kernel DD. Improved estimates of the regression parameters were then made based on the new estimates of the cross-correlation coefficients and the observed sample statistics for the kernel and DD ordinate data.

Thus, for linear correlation where: $Y = a + bX$ . . . . (5)
Improved estimates of the regression parameters a and b are:

$$\bar{Y} = \hat{a} + \hat{b}\bar{X} \qquad \text{or} \qquad \bar{Y} = \hat{a} + \hat{\rho}(S_y/S_x)\,\bar{X} \quad . \ . \ . \ . \ (6)$$

where:

$\hat{\rho}$ is the improved estimate of the correlation coefficient
$\hat{a}$ and $\hat{b}$ are the improved estimates of the intercept and slope
$\bar{X}$ and S_x are the mean, standard deviation of the Kernel ordinate data
$\bar{Y}$ and S_y are the mean, standard deviation of some specified DD data

For DDs greater than the ID, the slope parameters from the regression analyses were plotted against the DDs and a second order polynomial was fit to the coefficients (Figure 9). The slope parameters were used in lieu of the correlation coefficients because they generally allowed a simpler function description. The solution for this case was constrained to a value of zero slope at the ID. Improved estimates of the intercept parameters were then made based on the new estimates of the slope parameters and the observed sample statistics for the kernel and DD ordinate data (equation 6).

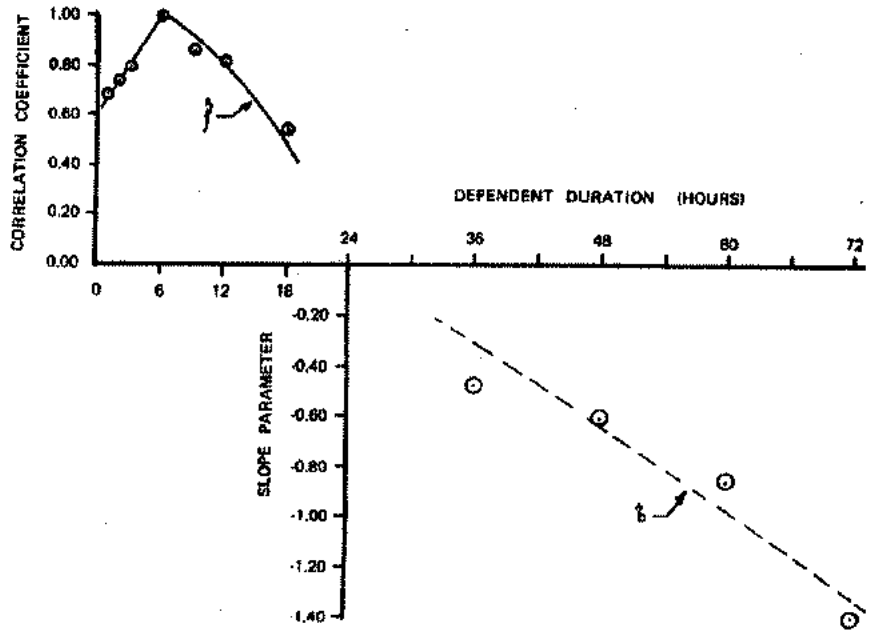

Figure 9. Smoothing Functions for Improving Regression Parameters
Example - 24 Hour ID Storms for Puget Sound Lowlands

CONSTRUCTION OF PROBABILISTIC DEPTH-DURATION CURVES

The stage 1 and 2 solutions provided the framework for the construction of the probabilistic depth-duration curves. Curves were generated for each ID and region as follows:

- Nine levels of exceedance probability were selected for use in developing probabilistic depth-duration curves.

- The kernel ordinate was computed for each of the nine exceedance probabilities based on the results of fitting the Beta distribution to the ordinate data for the kernel DD. (Stage 1 solution).

- The ordinate values of each probabilistic depth-duration curve were then computed using the previously computed kernel ordinate and the improved estimates of the regression parameters from the cross-correlation analyses. (Stage 2 solutions).

The resultant depth-duration curves were then examined to verify the existence of a reasonably smooth monotonically increasing function with the the first derivative, the slope of the curve, exhibiting a continuously decreasing positive magnitude over the initial period of time equal to the ID. Both of these characteristics are desirable properties of synthetic depth-duration curves. For some curves, minor adjustments of the ordinate values were made to produce the characteristics described above.

Probabilistic depth-duration curves generated by these procedures are shown in Tables 8a,b,c,d,e,f,g,h,i,j,k,l. After developing these curves, it is appropriate to examine their characteristics. A review of typical correlation matrices (Tables 6a,b,c) in combination with the curves in Tables 8a to 8l, reveals several common characteristics. For DDs which are shorter than the ID, there is positive correlation between DDs: i.e. above average ordinates are associated with above average ordinates; below

average ordinates are associated with below average ordinates. For DDs which are longer than the ID, there is negative correlation with ordinates for DDs which are less than the ID. This produces synthetic depth-duration curves having certain characteristic shapes regardless of the ID. Curves with sharp rising limbs have predominately flat tails. Conversely, curves with more flattened rising limbs have heavier (steeper) tails (Figure 10). These characteristic shapes simply reflect the observed correlation structure of observed storms - it is quite rare to have the dimensionless depth-duration curve from an observed storm with an unusually steep rising limb and an unusually heavy tail.

With those thoughts in mind, an interpretation can be made of the probabilistic labels attached to the curves. In general, for a curve with a 0.20 exceedance probability, there would be a 20% chance that any given extreme storm would have a steeper rising limb, reflecting more severe rainfall intensities, than that for the 20% curve. In addition, these curves are comprised of expected values for all DD ordinates conditioned on the magnitude of the kernel ordinate. Thus, the depth-duration curve with a 20% label represents the most likely manner in which the curve will occur, given that the 20% kernel ordinate has occurred.

In actual application, these procedures will preserve the three most important statistical characteristics of depth-duration curves, namely: the marginal distribution at the kernel duration (Stage 1); the correlation relationships between ordinate values, through the use of expected values of the ordinates at the various dependent durations (Stage 2); and the desired storm magnitude, through its use to directly scale the dimensionless ordinates.

In summary, the probabilistic depth-duration curves produced by these procedures, and displayed in the previous Tables, are descriptive of a wide range of observed depth-duration curves. These curves should be useful in rainfall-runoff modeling for examining the flood response of a watershed for a wide range of storm characteristics.

Depth-Duration Curves Conditioned on the Total Storm Depth

The depth-duration curves discussed up to this point have all been constructed conditioned on the magnitude of a high intensity storm segment. This was done because the high intensity segment of the storm is primarily responsible for producing the flood peak discharge. However, there are design cases where the volume of the flood is more important than the flood peak discharge. If the design of a facility is dependent on flood volume, then the 24 hour ID event (largest precipitation depth) would be the extreme storm of interest. A depth-duration curve for use in flood volume critical cases should, therefore, be conditioned on the magnitude of an ordinate for a long duration DD from the 24 ID storm.

The procedures for generating depth-duration curves conditioned on a long duration DD were essentially the same as those discussed previously. The following procedures were employed:

- The 48 hour duration was selected as the kernel DD.

- Nine levels of exceedance probability were selected to describe characteristic depth-duration curves.

- The 48 hour kernel ordinate was computed for each of the nine exceedance probabilities based on the results of fitting the Beta distribution to the ordinate data for the kernel DD (Stage 1 solution, Figures 8e,f).

- Improved estimates of the regression parameters from the cross-correlation analyses at the 48 hour DD were obtained using smoothing functions in a manner similar to that used in the Stage 2 solutions. A first order polynomial was fit to the correlation coefficients for DDs longer than the 48 hour kernel DD. The correlation coefficient at the 36 hour DD was retained as originally computed. A second order polynomial was fit to the slope parameters for DDs between 6 hours and 24 hours. For DDs less than 6 hours, the 6 hour ordinate amount was disaggregated in the same manner as was accomplished in Stage 2.

- The ordinate values of each probabilistic depth-duration curve were then computed using the previously computed 48 hour kernel ordinate and the improved estimates of the regression parameters from the cross-correlation analyses.

The depth-duration curves generated by these procedures are contained in Tables 9a,b,c,d,e. Differences between these curves and those curves containing ordinates conditioned on a high intensity segment (Tables 8h,i,j,k,l) are readily apparent (Figure 11). For curves at the same exceedance probability: a curve which was conditioned on the magnitude of a high intensity segment has a steeper rising limb (contains larger rainfall intensities) and a flatter tail. Conversely, if the depth-duration curve is conditioned on the magnitude of an ordinate for a DD longer than the ID, then it has a steeper tail (contains larger total depth) and a flatter rising limb.

Curves contained in Tables 8a to 8l and 9a to 9e obviously do not contain all ordinate combinations which could comprise depth-duration curves. They do, however, represent the most likely curves conditioned on the magnitude of high intensities or total storm depth, whichever is of primary interest.

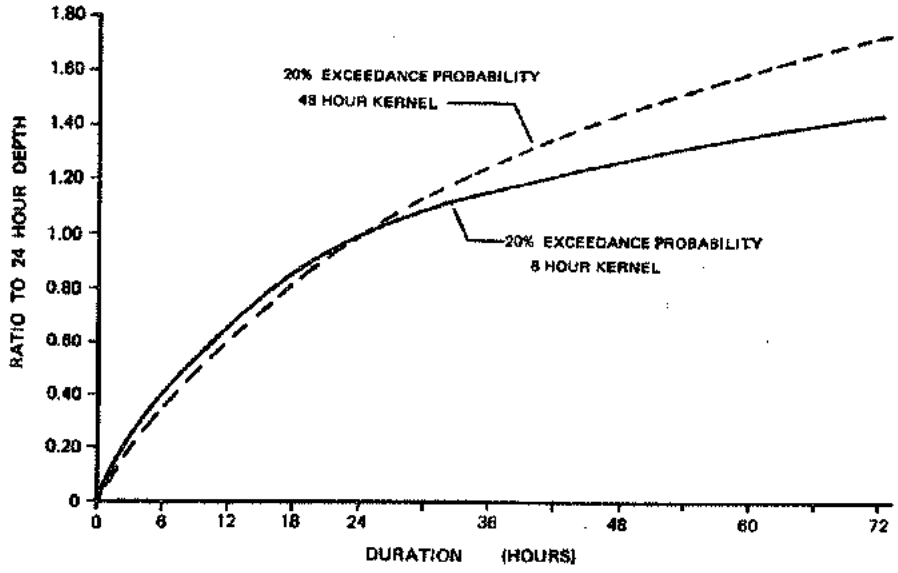

Figure 11. Comparison of Depth-Duration Curves for 24 Hour ID Storms Example - Western Washington Mountains

VERIFICATION OF VALIDITY OF USING DIMENSIONLESS ORDINATES IN DEPTH-DURATION CURVES

The use of dimensionless depth-duration curves for analysis and design has been a standard technique for decades. An underlying assumption in the use of dimensionless depth-duration curves is that the curve ordinates are independent of scale. This infers that the probabilistic characteristics of the ordinate values are independent of the magnitude of the ID storm. Although dimensionless depth-duration and dimensionless precipitation mass curves are "well accepted", the author is unaware of any detailed theoretical discussion or an investigation of historical data to demonstrate the validity of the scale independence assumption.

An investigation of this assumption can be made by examination of the ordinate values for the kernel DDs relative to the ID storm magnitude. If the independence assumption is valid, then the sample correlation coefficient for the two variables would approach zero and there would be no trend for the ordinate values to increase or decrease with storm magnitude.

The 6 hour ID storm data set for western Washington is one case where there is both a sufficient number of storms and range of storm magnitude to examine the assumption of scale independence. Referring to Figure 12a, it is seen that for the range of 6 hour ID extreme storm data available, the kernel ordinates do not appear to vary with storm magnitude (correlation coefficient = 0.06). Additional analyses were conducted for the 2 hour ID data in eastern and western Washington and the results were similar. In both cases, correlation coefficients had absolute values less than 0.12.

An alternative way to examine the linear scaling assumption is to perform correlation analyses using a logarithmic transform of the original precipitation amounts at various DDs. The logarithm of the precipitation amounts for the ID would be used as the independent variable. In this type of procedure, the scaling is assumed to be a power function (equation 7) and if, in fact the scaling is linear, then the scaling equation simplifies to a linear form. A graphical depiction of this approach is shown in Figure 12b for the 6 hour extreme storm data in western Washington.

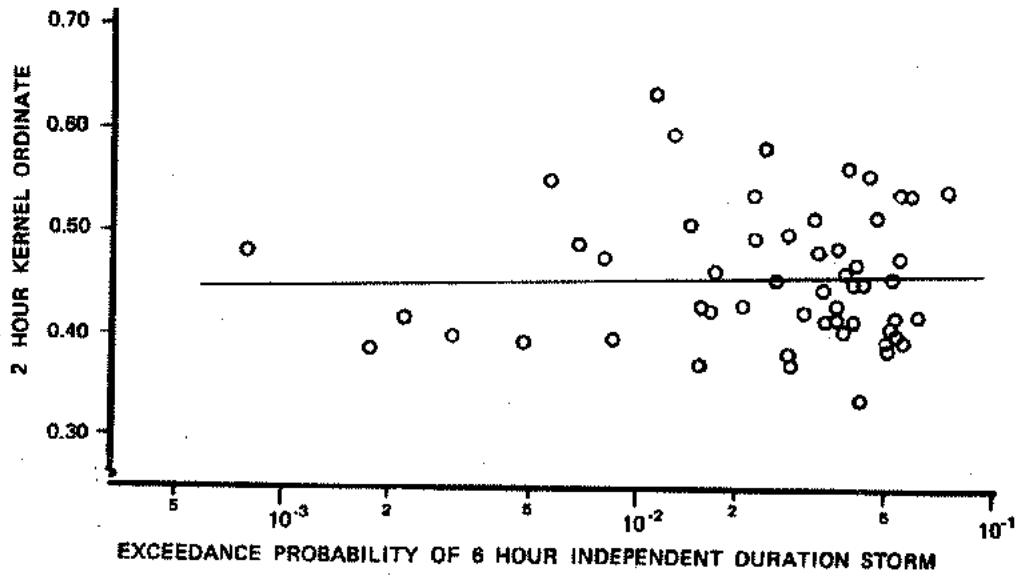

Figure 12a. Variation of Kernel Ordinates with Storm Annual Exceedance Probability
Example - 6 Hour ID Events Western Washington

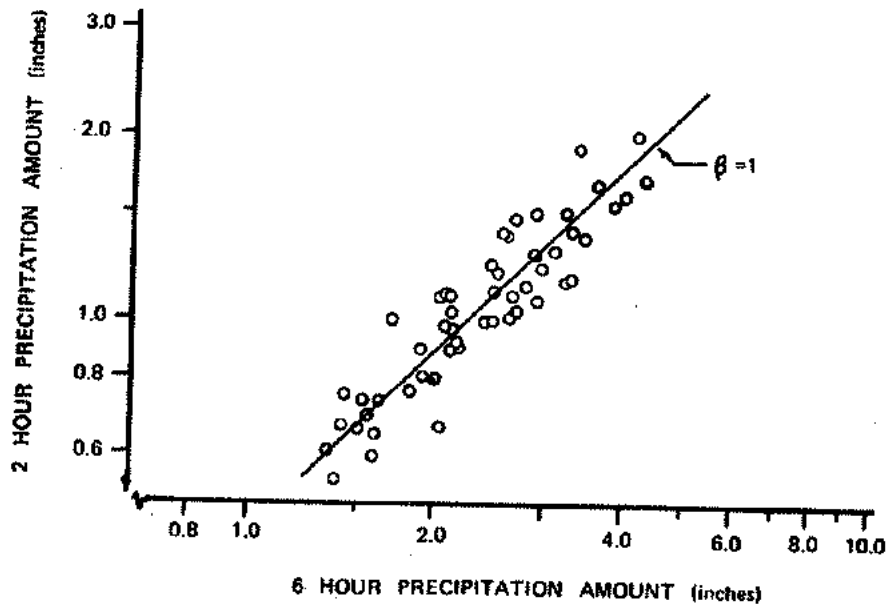

Figure 12b. Relationship of Kernel Duration Precipitation Amounts to Independent Duration Precipitation Amounts
Example - 6 Hour ID Events Western Washington

The scaling relationship for this approach is a simple power function. The solution equation follows directly from the use of log-log correlation and takes the form:

$$P_{dd} = \alpha P_{id}^{\beta} \quad \ldots\ldots\ldots\ldots\ldots\ldots (7)$$

where:

P_{dd} is the precipitation amount for a specified DD
P_{id} is the precipitation amount for the ID
α and β are intercept and slope parameters, respectively

If the linear scaling assumption is applicable, then the slope should have a value of near unity. Rearrangement of equation 7 for a slope of unity results in the equation simplifying to a linear scaling equation. Wherein, the ordinate value (P_{dd}/P_{id}) is equal to the constant α and is not scale (storm magnitude) dependent. If the slope takes on a value other than unity, then the scaling is non-linear and a function of storm magnitude as shown below:

$$\frac{P_{dd}}{P_{id}} = \alpha P_{id}^{\beta-1} \quad \ldots\ldots\ldots\ldots\ldots\ldots (8)$$

Log-log correlation analyses for the western Washington 6 hour extreme storms resulted in slope parameters near unity and ranging from 1.08 to 0.92 for DDs between 1 hour and 18 hours, respectively. Analyses for the short duration 2 hour extreme storm events in both eastern and western Washington produced similar results. Slope values ranged between 1.12 and 0.92 with the larger values generally associated with DDs within the ID and smaller values associated with DDs exterior to the ID.

Thus, based on the information available, it appears that the use of the ID precipitation depth to scale up or down a storm of interest, is a reasonable approximation of the meteorologic process.

TIMING CHARACTERISTICS OF HIGH INTENSITY SEGMENT

The time of occurrence of the high intensity segment within a storm is an important element in the analysis of observed storms and in the development of synthetic storms. The time of occurrence of the high intensity segment within a storm often affects the magnitude of the flood peak which will be generated by the storm. Storms with the high intensity segment near the end of the storm will generally produce larger flood peaks than similar storms where the high intensity segment occurs near the beginning of the storm. This outcome is attributable to both the manner in which runoff collects from the tributary drainage of a watershed, and to the infiltration properties of soils. With regard to the soils, near the end of a storm, the surficial soils are at a wetter state than at the beginning, and thus they have lower infiltration capacity. This results in higher runoff rates and larger flood peaks when the high intensity segment occurs near the end of the storm period. In the design of reservoir projects, the occurrence of the flood peak near the end of the flooding period is often a more stringent design consideration because the reservoir volume allocated to flood control is partially filled prior to the arrival of the flood peak. Information on the observed timing characteristics of the high intensity segment of storms is, therefore, an important and necessary element in the assembly of synthetic storms.

In general, observed storms had only one period of high intensity. This was particularly true for the shorter duration events. In those cases where there were two distinct periods of high intensity, they were usually found in intermittent macro patterns for long duration events and represented the passage of separate fronts during a period of several days. When two periods of high intensity occurred, only the highest intensity segment was included in the data for analysis.

Analysis of the frequency characteristics for the time of occurrence of the high intensity segment was accomplished by fitting the data to the Beta distribution [Benjamin and Cornell, 1970]. The method of moments was used to solve for the distribution parameters

for the Beta distribution (equations 2,3) for each of the three IDs in each of the five regions. The lower and upper bounds for the distribution (equation 1) were δ_1=0 and δ_2 equal to the total duration. The results of the analyses are shown in Table 10 and are an expansion of the information contained in Table 4.

The timing data were also examined to determine if the values were related to the magnitude of the kernel ordinates. In simple terms, if a storm exhibited an unusually long (short) timing value, would the magnitude of the kernel ordinate also be more likely to be above (below) average? Alternatively, are the two values unrelated? Correlation analyses of the two variables were performed for each of the three IDs and various region combinations. All correlation coefficients had absolute values less than 0.10 and it was concluded that the correlation coefficients were not significantly different from zero. Therefore, during the assembly of a synthetic storm, the kernel ordinate and the time of occurrence of the high intensity segment can be selected independent of each other.

Table 10. Frequency Characteristics for Time of Occurrence of High Intensity Segment of Extreme Storms

REGIONS	INDEPENDENT DURATION (hours)	TIME OF HIGHEST INTENSITY - HOURS								
		MEAN (hours)	EXCEEDANCE PROBABILITY							
			0.95	0.90	0.80	0.67	0.50	0.33	0.20	0.10	0.05
1 & 2	2	0.70	0.03	0.06	0.12	0.25	0.50	0.80	1.20	1.70	2.15

5	24	30.6	8.4	11.9	17.2	22.9	29.9	37.1	43.7	50.4	55.3

SEQUENCING OF INCREMENTAL PRECIPITATION SEGMENTS

The sequencing (arrangement) of incremental precipitation amounts surrounding the high intensity segment is another element of an extreme storm which can have an affect on the magnitude of the flood peak discharge. Those sequences which have the high intensity segment near the end of the sequence generally produce larger flood peaks. This applies to both the high intensity sequences immediately surrounding the high intensity segment, and to trisector sequences which describe the storm macro pattern. This phenomenon occurs as a result of the hydraulic response of watersheds and the runoff properties of surficial soils which were discussed in the previous section.

The sequencing characteristics of the incremental precipitation segments within storms can be seen as a companion element to the timing characteristics. Probabilistic information on observed sequences is, therefore, needed to allow realistic development of synthetic storm hyetographs.

Sequencing of High Intensity Segments Within Storms

To investigate the sequencing characteristics of the high intensity segments, each storm was examined to identify the incremental precipitation amounts during the time intervals surrounding the occurrence of the highest intensity. The time increments that were used in this phase of the analysis for each of the three IDs are shown in Table 7. Consideration of the three largest incremental precipitation amounts in a storm resulted in six possible sequences: 123; 132; 213; 312; 231; 321 (see definitions section).

Table 11 contains the results of the analysis on the frequency of occurrence of the six sequences. It should be noted that those sequences, 132 and 231, which separate the two largest increments are fairly rare at all three IDs. In eastern Washington at the 2 hour ID, the sequence 123 occurred most frequently. In all other regions and durations, those sequences, 213 and 312, which

sandwich the highest intensity segment in the middle were the most common and should be preferred in the development of synthetic storms.

No trends were identified which would indicate that the sequencing characteristics are statistically dependent on either the kernel ordinate or on the time of occurrence of the high intensity segment.

Table 11. Sequencing Characteristics of High Intensity Segments

REGIONS	INDEPENDENT DURATION (hours)	NUMBER OF EVENTS	HIGH INTENSITY SEGMENTS					
			FIRST BLOCK SEQUENCES		SECOND BLOCK SEQUENCES		THIRD BLOCK SEQUENCES	
			1 2 3	1 3 2	2 1 3	3 1 2	2 3 1	3 2 1
1 & 2	2	32	11	1	7	6	3	4
			38%		41%		21%	
3 & 4 & 5	2	22	5	0	9	8	0	0
			23%		77%		0%	
1 & 2	6	23	5	2	4	8	1	3
			30%		52%		18%	
3 & 4 & 5	6	56	13	2	12	18	4	7
			27%		54%		19%	
1 & 2	24	28	3	1	9	13	0	2
			14%		79%		7%	
3 & 4 & 5	24	49	3	3	13	19	3	8
			12%		65%		22%	

Sequencing of 6 Hour Segments Within 24 Hour ID Storms

At the 2 hour and 6 hour IDs, information on time of occurrence and sequencing of the high intensity segments, in combination with information on macro storm patterns, is usually adequate to describe a storm hyetograph. Additional information, however, is needed to describe a hyetograph for the longer duration 24 hour ID events. To describe the longer duration storm, the 24 hour ID was broken into four time segments with each segment being 6 hours in duration. As before, the sequence 1234 would represent the first,

second, third and fourth largest incremental precipitation segments, respectively. With four segments, there are 24 separate sequences which can occur. Unfortunately, there were an insufficient number of extreme storms in any region to properly investigate the frequency characteristics. Nonetheless, there was sufficient data to identify some of the more common sequences. Referring to Table 12, it can be seen that the first and second largest precipitation segments occur adjacent to each other in about 80% of the cases. Therefore, regardless of the final sequence selected for use in a synthetic storm, it would be appropriate to keep the two largest 6 hour segments adjacent to each other.

Table 12. Frequency that the First and Second Largest 6 Hour Precipitation Segments Occur Adjacent to Each Other Within 24 Hour ID Extreme Storms

REGION	NUMBER OF EVENTS	SEQUENCE 12.. 21..	SEQUENCE .12. .21.	SEQUENCE ..12 ..21	TOTAL
1	21	24%	14%	33%	71%
2	7	43%	14%	29%	86%
3	16	13%	44%	31%	88%
4	22	18%	36%	32%	86%
5	11	27%	55%	9%	91%

Another sequencing characteristic was investigated by examining the sequence location of the largest 6 hour precipitation segment within the 24 hour ID storms. The frequency of occurrence of the sequence location of the largest segment can be seen in Table 13. There was a general tendency for the largest 6 hour segment to be located in the middle of the 24 hour ID.

Table 13. Sequencing Characteristics of the Largest 6 Hour Precipitation Segment Within 24 Hour ID Extreme Storms

REGION	NUMBER OF EVENTS	SEQUENCE 1...	SEQUENCE .1..	SEQUENCE ..1.	SEQUENCE ...1
1	21	14%	48%	0%	38%
2	7	29%	43%	14%	14%
3	16	0%	50%	31%	19%
4	22	9%	32%	45%	14%
5	11	9%	55%	36%	0%

In each region, several sequences were observed to occur frequently. Those sequences (Table 14) exhibited the tendencies identified in Tables 12 and 13 and are logical choices for use in constructing synthetic storms. The more commonly occurring sequences are ordered from left to right in the table, but the ranking is not necessarily significant. Any of the sequences shown, or minor variations thereof, should be acceptable.

Table 14 Commonly Occurring Sequences for 6 Hour Precipitation Segments Within 24 Hour ID Extreme Storms

REGION	COMMONLY OCCURRING SEQUENCES		
1	4321	3124	2134
2	3124	4321	2134
3	4123	4312	4213
4	4312	4213	4123
5	4123	4312	4213

ANTECEDENT STORMS

The meteorological conditions in the days and weeks prior to the occurrence of an extreme storm predetermine the hydrologic conditions which will prevail in a watershed when the extreme storm occurs. Initial streamflow, antecedent soil moisture conditions and initial reservoir levels are all dependent on prior meteorological conditions. The runoff volume and flood peak discharge produced by an extreme storm are in turn affected by the antecedent hydrologic conditions. Thus, information on antecedent conditions is necessary for proper rainfall-runoff modeling.

An investigation was conducted to examine the precipitation events which occurred antecedent to the extreme storm. Specifically, the 14 day period prior to each extreme storm was examined. The largest precipitation amount for any 24 hour period was recorded along with the number of days elapsed between antecedent and extreme events. Sample statistics were computed for the recorded data and the results are shown in Table 15.

A review of the contents of Table 15 reveals that, typically, extreme storms are <u>not</u> preceded by an unusual storm. In the case of the 2 hour ID storms, which occur predominately in the warm season, the antecedent storms are of a magnitude which occur from 10 to 20 times during any given year. Likewise, for the 6 hour and 24 hour ID storms, which are cool season events, antecedent storms are of a magnitude which occur numerous times during a given year.

In the particular case of the 24 hour ID extreme storms, a plot was made (Figure 13) depicting the relationship between the return period for a given 24 hour ID event and its associated antecedent storm. Partial duration return periods were used in lieu of annual return periods to allow a more direct interpretation of the frequency characteristics of the antecedent storms. Estimates of the return periods of the antecedent storms were based on climatic and precipitation-frequency information contained in publications prepared by Phillips [1964-1970] for Washington State precipitation stations.

Table 15. Characteristics of Storms Antecedent to Extreme Storms

REGION	INDEPENDENT DURATION (hours)	NUMBER OF EVENTS	ANTECEDENT STORM	
			AVERAGE 24 HOUR DEPTH (inches)	AVERAGE # DAYS PRIOR
1	2	32	0.35	8.5
2	2	15	0.45	7.5
3	2	18	0.60	7.5
4	2	17	0.70	6.5
5	2	5	0.65	6.0
1	6	17	0.45	7.5
2	6	6	0.40	7.0
3	6	17	0.80	8.5
4	6	25	1.70	5.5
5	6	11	2.40	4.5
1	24	21	0.60	8.0
2	24	9	0.25	10.0
3	24	16	1.05	8.0
4	24	22	1.60	7.0
5	24	11	1.25	8.5

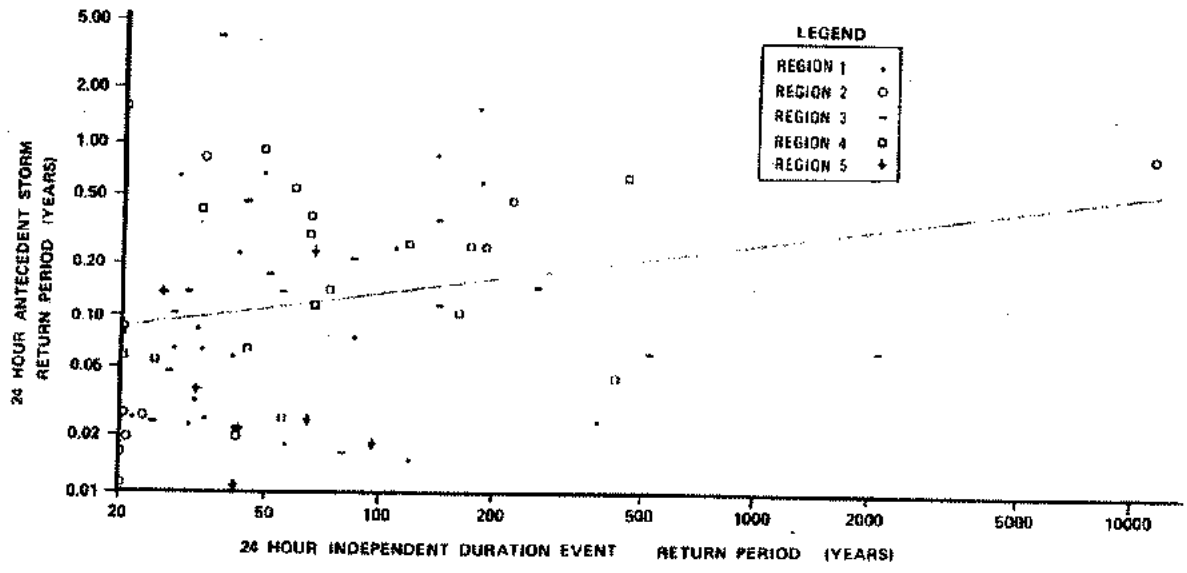

Figure 13. Relationship of Antecedent 24 Hour Duration Storms to 24 Hour ID Extreme Storms

A review of the data in Figure 13 reveals the antecedent storms to be highly variable and nearly independent of the associated extreme storm. The weak trend line depicted on the graph (correlation coefficient 0.24) indicates that for the 24 hour ID storms, there is some small tendency for the rare events to have slightly larger antecedent storms. However, even for extraordinarily rare events, the antecedent storms would not be expected to have a significant magnitude.

The average antecedent storm contained in Figure 13 corresponds to a partial duration return period of 0.11 years (occurs an average of 9 times per year.). This result roughly corresponds to storm magnitudes to be expected during any 14 day period during the cool season. As a practical matter, it would appear reasonable to conclude that the time period preceding a given extreme storm is not significantly different than that same (calendar) time period during any given year.

Based on the foregoing, selection of antecedent conditions, such as individual storm amounts, soil moisture conditions, streamflow, snowpack, initial reservoir levels, etc., can be reasonably made by consideration of the seasonality of the extreme storm and a review of the historical record on the desired items. Selection of a more or less conservative value can then be made on a probabilistic basis when considering each item.

For example, while the antecedent storms for the 24 hour ID storms in western Washington were not large, it was quite common to have extreme storms preceded by a series of small precipitation events. These events undoubtedly produced elevated streamflows and wet soils. These conditions are typical of the winter months and would be expected from a simple review of the historic meteorologic and hydrologic data for the winter months.

SPATIAL CHARACTERISTICS

Investigation of the spatial characteristics of extreme storms was not a major element in this study. This decision was made because the principal applications for the results of this study are on small watersheds. Small as used herein refers to watersheds with a drainage area less than 50 square miles with most applications on watersheds having areas less than 10 square miles. Small also is appropriate as a relative term for the size of the watersheds of interest compared to the extensive areal coverage of extreme storms at the 6 hour and 24 hour ID. Thus, for the longer duration storms, more detailed depth-area and other spatial information was not of great importance. For completeness, conventional depth-area duration curves have been obtained from other sources [NWS Hydrometeorological Report 43, 1966], [NOAA Atlas 2, Miller et al, 1973] and are presented later.

The main objective of this element of the study was to investigate the spatial characteristics of the short duration, warm season, convective events, in eastern Washington. These events are usually localized but may be associated with an organized weather system which can be identified at the synoptic scale. Thunder, lightning and hail often accompanied these storms and the storms have been given the generic label of "thunderstorm" to avoid problems associated with categorizing the causative storm type.

There has been controversy among meteorologists and hydrologists for many years on the typical and potential maximum areal coverage of thunderstorms in eastern Washington. The thunderstorms which are large enough to attract public and news media attention, often have areal coverages of less than 20 square miles. In contrast, the NWS [1966] has estimated an areal coverage of about 500 square miles to be used in association with thunderstorm Probable Maximum Precipitation (PMP) events. Thus, there was a need to investigate the probabilistic characteristics of thunderstorm areal coverage.

THUNDERSTORM CHARACTERISTICS - EASTERN WASHINGTON

The scarcity of recording precipitation gauges in eastern Washington restricted the ability to make detailed analyses of thunderstorm characteristics. It was not possible to examine more complex characteristics, such as the spatial correlation structure of precipitation amounts or the depth-area relations. The study was restricted by data limitations to: investigation of the areal coverage of observed extreme storms; the direction of storm movement; and the general physical shape of the areal distribution. Those elements will be presented in the following sections.

Thunderstorm Areal Coverage

The areal coverage characteristics of eastern Washington thunderstorms were investigated by reviewing the storm catalog and selecting those events for which additional storm information was available. Outside sources which were used to estimate the limits of precipitation included:

- observers notes at precipitation stations
- newspaper accounts
- crop damage reports
- county highway department damage surveys
- U.S. Geological Survey (USGS), continuous recording streamflow records and miscellaneous streamflow measurements
- published accounts of storm events (NWS & USGS)

The areal coverage of a given storm was determined by defining the outer boundary of the storm to be the precipitation amount corresponding to approximately 10% of the maximum observed point rainfall amount. Using the information sources discussed above, considerable judgment was applied in delineating the storm boundary. The delineated area was then measured and the results are listed in Table 16 and displayed in Figure 14. While the

accuracy of any individual areal estimate is questionable, it can still be seen that there is considerable variability in the areal coverage of the storms that have occurred.

Based on these results, it appears that thunderstorm areal coverage on the order of the NWS [1966] estimate of 500 square miles is indeed possible. Also, it appears that little correlation exists between maximum point rainfall and areal coverage. Consideration of meteorological physics would suggest that a larger point rainfall is likely produced by a larger, more organized, more intensive convective cell or cells. This infers that there should be a tendency for storms with greater point rainfall to produce larger areal coverage. However, there is insufficient data to either confirm or refute this trend.

Table 16. Database of Selected Pacific Northwest Thunderstorms

STORM LOCATION	DATE	MAXIMUM MEASURED POINT RAINFALL (inches) *	MAXIMUM REPORTED/ESTIMATED POINT RAINFALL (inches) *	EFFECTIVE DURATION (minutes)	AREAL COVERAGE (sq miles)	DIRECTION OF STORM MOVEMENT (from)

* Duration of rainfall 2 hours or less

Thunderstorms - Direction of Movement

Although there were only 13 events for which the direction of storm movement could be determined, the storm vectors occupied a relatively small sector of the wind rose. Review of Table 16 reveals that nearly all the storms originated from the southwest or west.

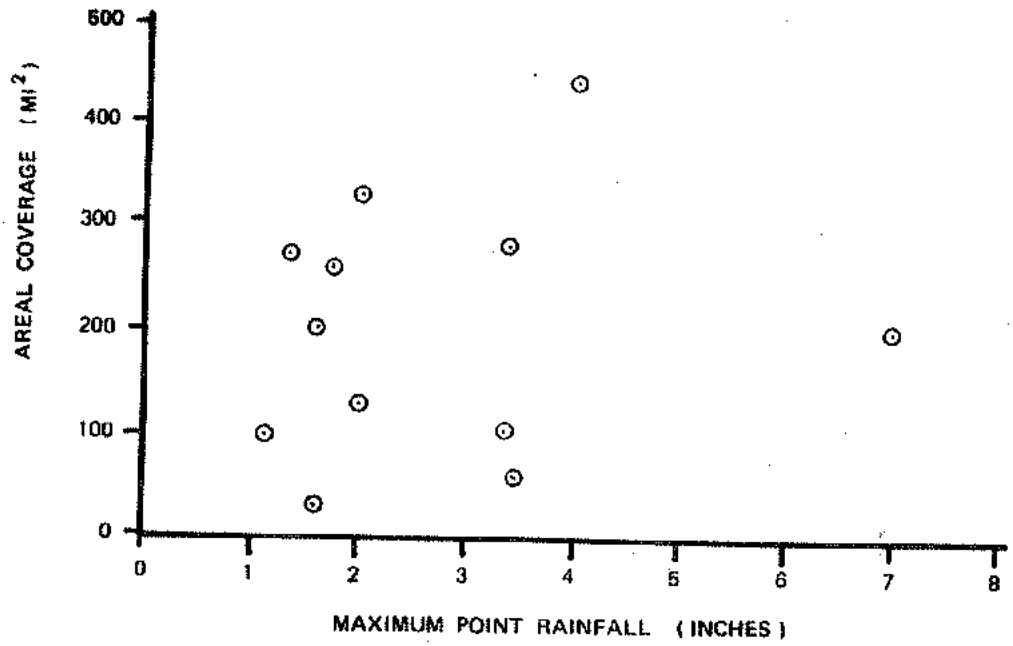

Figure 14. Variation of Areal Coverage with Maximum Point Rainfall for 2 Hour ID Pacific Northwest Thunderstorms

Thunderstorm - Storm Shape

The inability to accurately define the outer boundaries of precipitation (ground print) resulted in "smoothed" storm shapes. Nearly all shapes were ovals with the majority being elongated ovals. Based on newspaper accounts, many of the elongated ovals resulted from storm movement across the area. Measurement of the lengths of the major and minor axes of the ovals produced an average ratio of 2.45:1. The axes ratios ranged from a minimum of 1.15 to 3.33. Based on these results, an elliptical isohyetal pattern with an axes ratio of 2.5:1 would appear to be a reasonable approximation of the storm ground print. Information on storm shape and direction of movement could be important considerations for watersheds which are oriented in such a manner where only partial storm coverage of the basin is likely. This information should be taken into account when applying the depth-area curves discussed in the next section.

DEPTH-AREA RELATIONSHIPS

As discussed previously, the results of this study are intended for use primarily on small watersheds. Therefore, minimal efforts were made to conduct a probabilistic study of the spatial characteristics of extreme storms. In those cases where spatial information is needed for application on large watersheds, conventional depth-area-duration curves can be used to estimate the spatial and temporal distribution of the storm amounts.

The depth-area curves (Figure 15) recommended for use with the 6 hour and 24 hour ID storms were obtained from procedures contained in NWS Hydrometeorological Report 43 [1966] and are similar to curves contained in NOAA Atlas 2 [Miller et al, 1973]. Use of these curves are for watersheds larger than 10 square miles, because at-site precipitation depths are taken to represent an area of 10 square miles for the 6 hour and 24 hour ID cool season extreme storms.

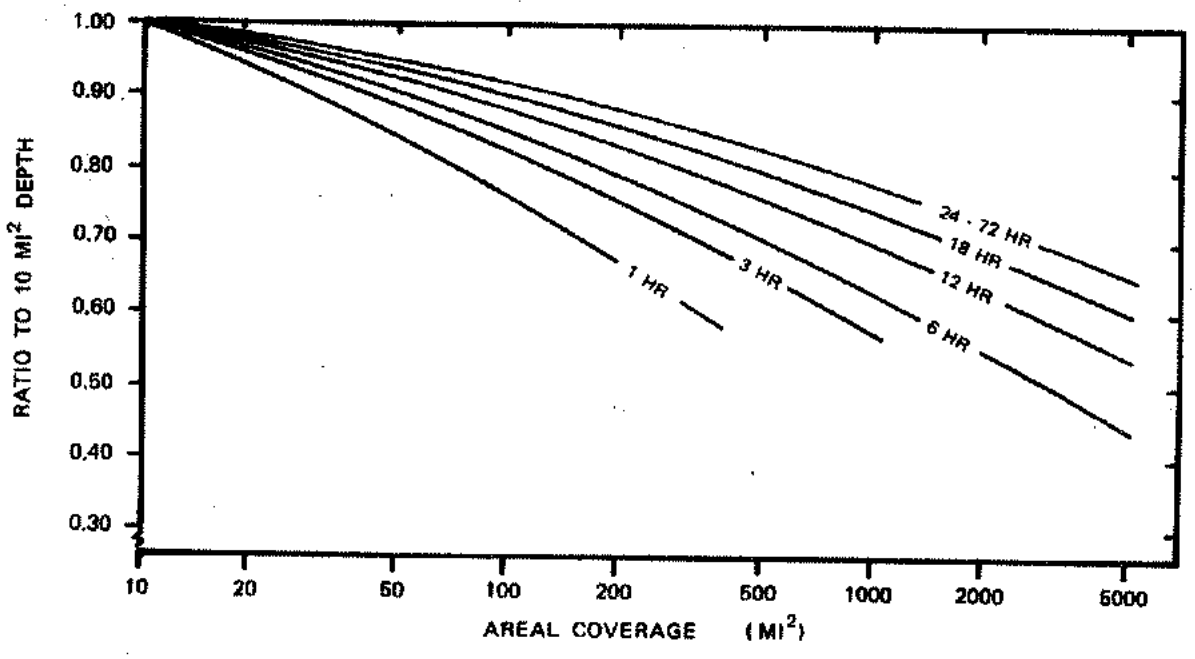

Figure 15. Depth-Area Curves for 6 Hour and 24 Hour ID Storms

The depth-area curves (Figure 16) for use with the 2 hour ID storms in eastern Washington were taken from NWS Hydrometeorological Reports 49 and 55 [1977, 1984]. The original curves were modified for use in Washington and reflect a reduced areal coverage for a nominal 250 square mile coverage versus the 500 square mile coverage of the original. This reduction was based on the finding that the areal coverage of the 2 hour ID storms were typically about 250 square miles. At-site precipitation depths are taken to represent an area of 1 square mile for the 2 hour ID warm season extreme storms.

In western Washington, no specific studies were conducted for the areal coverage of 2 hour ID storms. It is anticipated that the primary application of 2 hour ID storms will be on very small urban watersheds where the depth-area characteristics will not be of great importance. Figure 16 values are recommended for interim usage in western Washington until detailed information becomes available.

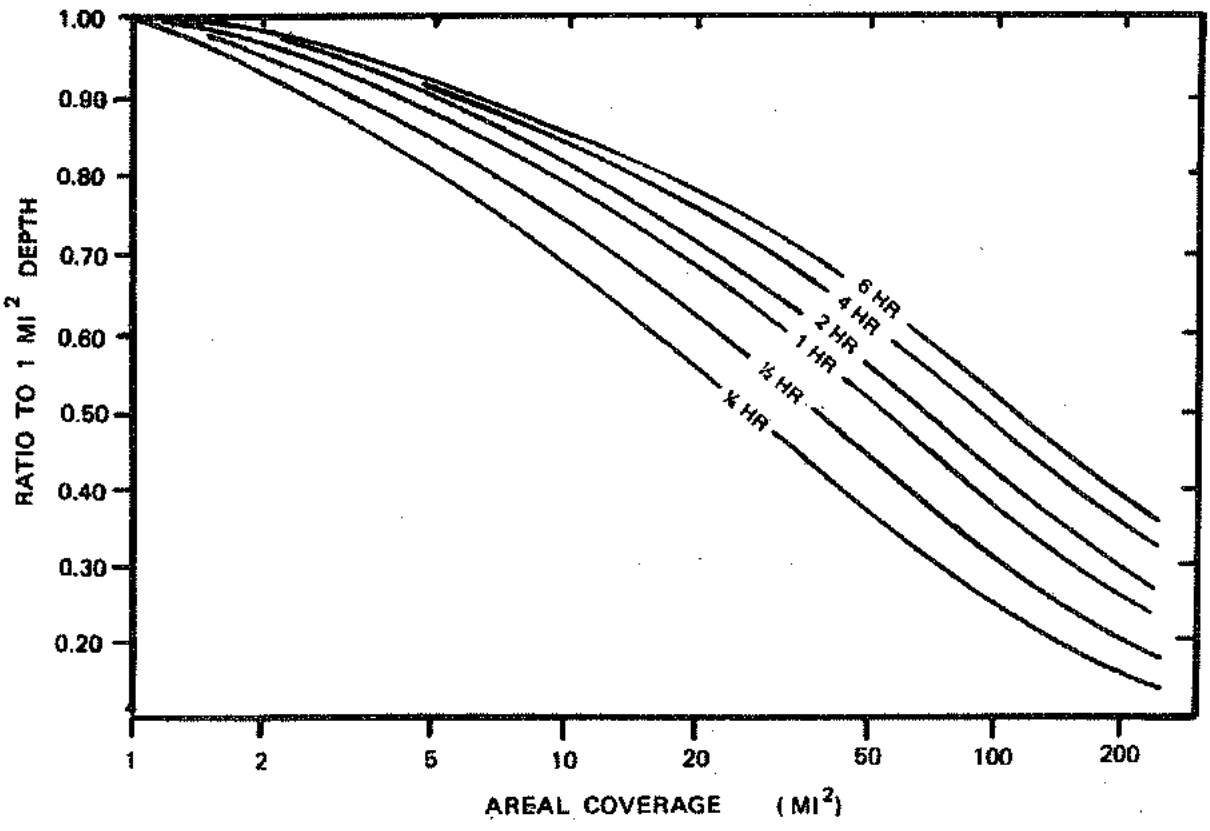

Figure 16. Depth-Area Curves for 2 Hour ID Storms

The following procedures would be employed to apply the depth-area curves to produce a basin-average depth-duration curve for a given ID storm magnitude on a specific watershed:

- Prepare a grid network and overlay the grid on the watershed. Estimate an at-site precipitation depth for the chosen ID and specified exceedance probability for each node point on the grid network of points.

- Compute an average precipitation depth for the watershed from the collection of at-site values for the grid nodes.

- Use the average precipitation depth computed above, in combination with the chosen dimensionless depth-duration curve, to scale the dimensionless ordinates to the desired storm magnitude.

- Compute the basin-average depth-duration curve by using the areal reduction factors from Figure 15 or 16 to adjust the curve computed above for the effects of storm spatial distribution.

In using data from both Figures 15 and 16, it should be recognized that these values represent the average spatial characteristics from a limited pool of data. At the present time, the author is unaware of any published regionalized information or study which addresses the stochastic nature of the spatial characteristics of extreme storms in the Northwest. Until further information is available, these depth-area curves represent the only practical approach to account for the spatial distribution of extreme storm precipitation.

ASSEMBLY OF SYNTHETIC STORMS

The primary objective of this study was to collect sufficient information on the characteristics of extreme storms to allow development of synthetic storm hyetographs for use in rainfall-runoff modeling. In this section, a methodology is presented for the assembly of synthetic storms which incorporates the probabilistic information on storm elements developed in the previous sections.

Assembly of a synthetic storm hyetograph can be viewed as a reversal of the depth-duration analysis process. The incremental precipitation amounts from a depth-duration curve are rearranged to produce a storm mass hyetograph. An important component in the assembly of synthetic storms is that conscious decisions must be made on the level of conservatism to be applied in the selection of the various storm elements. Every storm element discussed previously has been described in probabilistic terms and thus it is possible to reasonably predetermine the likelihood of occurrence of each element being built into the storm. This affords the opportunity to construct storms suited to site specific or commonly encountered types of applications.

In some applications, the selection of individual storm elements representing typical or mean values is appropriate. This is usually the case when attempting to synthetically generate a flood frequency curve of flood peak discharges. Typical storm elements would also be used in the calibration of soil or watershed response parameters in flood modeling when attempting to recreate a flood frequency curve obtained from other sources. In applications involving the design of hydraulic structures, somewhat more conservative values may be desirable.

The term conservative, as used here, refers to the procedure of selecting a more unusual magnitude or sequence of a storm element in order to produce a larger flood. This acts as a hedge against underestimation of the design flood when faced with the ever present uncertainty of obtaining the "correct" flood magnitude for the desired flood frequency. Although this procedure does provide

protection from underdesign, it often results in more expensive construction to accommodate the larger flood. Ultimately, the selection of an acceptable level of conservatism resides with the project manager or the responsible regulatory agency.

In general, the selections of the exceedance probability for the depth-duration curve and the time of occurrence of the high intensity segment have the greatest influence on the resultant flood peak discharge. Variations of sequences for the high intensity segment or for the four 6 hour segments in the 24 hour ID event are of lesser importance. Where appropriate, sensitivity analyses may be used to examine the effects that alternative decisions on the selection of storm elements would have on the resultant flood.

METHODOLOGY FOR ASSEMBLY OF SYNTHETIC STORMS

The assembly of a synthetic storm mass hyetograph begins with the selection of a specific depth-duration curve, the time of occurrence of the high intensity segment and sequences for storm segments. Incremental precipitation amounts from the specified depth-duration curve are then arranged in a manner consistent with the chosen storm characteristics and macro storm pattern. The following list describes the general methodology to be used in storm assembly:

Step 1. Estimate the at-site precipitation depth for the desired Annual Exceedance Probability (AEP) and Independent Duration (ID) of the extreme storm. This can be accomplished using information contained in either NOAA Atlas 2 [Miller et al, 1973] or Schaefer [1989].

Step 1a. If the watershed of interest is larger than 1 square mile at the 2 hour ID, or larger than 10 square miles at the 6 hour or 24 hour IDs, then computation of an average precipitation depth for the watershed is necessary. The average depth can be computed using the grid network

procedures presented in the section on depth-area relationships.

Step 2. Select a dimensionless depth-duration curve from Tables 8a-8l or Tables 9a-9e for the desired level of exceedance probability and appropriate climatic region. Scale the dimensionless depth-duration ordinates to the desired storm magnitude by multiplying the ordinates by the precipitation depth from Step 1 or 1a.

Step 3. Select the time of occurrence of the high intensity segment using information contained in Table 10.

Step 4. Select the sequence for the three high intensity storm segments using information contained in Table 11. The time interval associated with each of the three segments is listed in Table 7.

Step 5. If the extreme storm is a 24 hour ID event, then select the sequence for the four 6 hour storm segments within the ID. Necessary information is contained in Tables 13 and 14.

Step 6. Select a macro storm pattern from Figures 6a-6f which is consistent with the timing and sequencing selections made previously. Choose a six segment macro sequence.
Note: The choice of the number of segments for the macro pattern sequence is arbitrary. The macro patterns in Figure 5 are shown using trisector sequences comprised of three segments. However, this was done to simplify the categorization of observed storms. It is recommended that macro patterns and associated sequences with six segments be used for storm assembly. This is consistent with the time intervals (Table 7) used in the original development of the depth-duration curves and will simplify construction.

Step 7. If Step 1a is utilized above, then the watershed is sufficiently large that the spatial characteristics of the storm must be incorporated. The basin-average depth-duration curve can be computed using the areal reduction factors from Figures 15 or 16 as described in the section on depth-area relationships.

The storm can now be assembled in a manner which incorporates the storm elements chosen in Steps 2 - 6. Worksheets are provided in Appendix 3 which should aid in the bookkeeping aspects of storm assembly. While the methodology for storm assembly appears straightfoward, actual applications will reveal subtleties and possible permutations which may raise questions regarding appropriate procedures. Therefore, a series of examples are provided to demonstrate the assembly of a few synthetic storm mass hyetographs. As mentioned above, there is room for reasonable latitude in determining the manner in which a hyetograph incorporates the various storm characteristics. Minor variations in the completed hyetograph may be expected from separate practitioners even though the same values for the storm elements are employed. In general, these minor variations of the hyetograph would not be anticipated to have significant effects on the resultant flood. Where deemed appropriate, sensitivity analyses may be used to explore the differences in the floods produced by the various hyetographs.

The following examples are presented to clarify the methodology that is used to assemble synthetic storm hyetographs.

Example 1. Development of a typical mass hyetograph for a 2 hour ID event, with an Annual Exceedance Probability (AEP) of 0.01 for a 1 square mile watershed near Olympia, WA in the Puget Sound lowlands.

Given: For a 100 year recurrence interval event (AEP=0.01), the precipitation depth from NOAA Atlas 2 is 1.30 inches. Interpret **typical** event to be median or mean values for all storm elements.

Step 1:

The 2 hour ID precipitation depth is 1.30 inches.

Step 2:

Use the dimensionless depth-duration ordinate values for the 50% exceedance probability (median value) from Table 8b. Multiply the dimensionless ordinates by the 2 hour ID depth to scale the storm to the proper magnitude.

Step 3:

Select the mean value (0.9 hours, 54 minutes) from Table 10 for the time of occurrence of the high intensity segment.

Step 4:

Select the most likely sequence for the three high intensity segments of the storm. Referring to Table 11, this corresponds to either sequence 213 or 312. Choose sequence 213 at 15 minute increments per Tables 7 and 11.

During storm assembly, the incremental precipitation amounts corresponding to this sequence are inserted into the storm mass curve so the largest segment spans the time increment from 45 to 60 minutes of elapsed time (per Step 3).

It should be noted that Table 8b also contains ordinate values for precipitation amounts for three 5 minute segments. These segments are internal to the largest 15 minute high intensity segment and should be inserted within the largest 15 minute increment.

A sequence of 213 may also be used for these segments.

Step 5:

Not applicable.

Step 6:

Select macro pattern Type I based on Figure 6a and selections in Steps 3 and 4. Choose sequence 123456 for the six 1 hour segments.

Step 7:

No corrections for areal coverage are required since the watershed is not larger than 1 square mile.

Examination of the resultant synthetic storm (Table 17, Figure 17) reveals that it contains all of the storm elements described above.

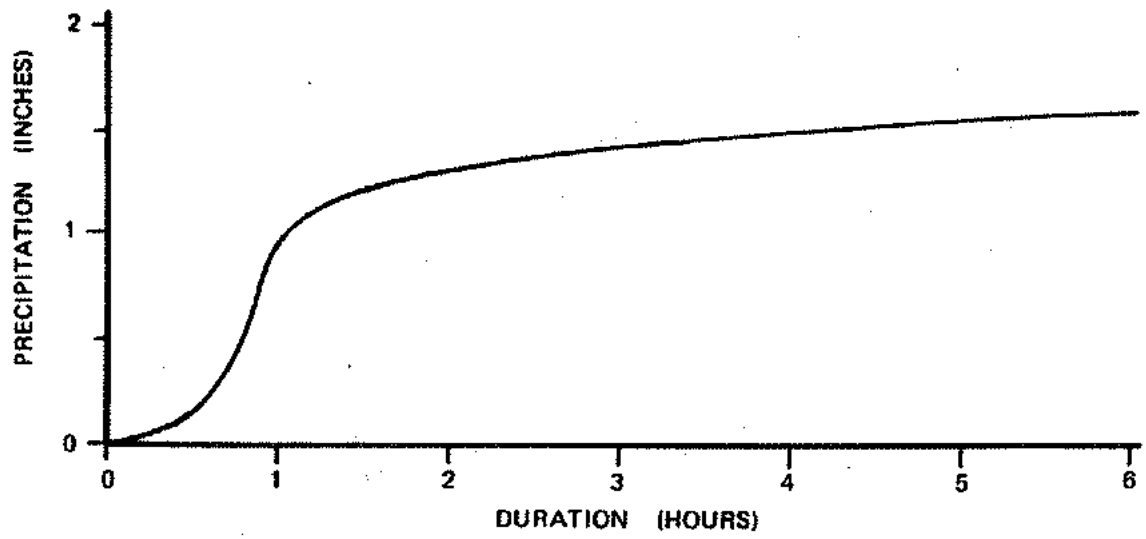

Figure 17. Synthetic Mass Hyetograph for 2 Hour ID Extreme Storm for a 1 Square Mile Watershed near Olympia, WA.

Example 2. Development of a conservative mass hyetograph for a 6 hour ID event, with an AEP of 0.01 for a 5 square mile watershed near Olympia, WA in the Puget Sound lowlands.

Given: For a 100 year recurrence interval event (AEP=0.01), the precipitation depth from NOAA Atlas 2 is 2.40 inches. Interpretation of a **conservative** temporal distribution is taken to mean storm elements having exceedance probabilities of 0.20 - one chance in five of being exceeded:

Step 1:
The precipitation depth is 2.40 inches.
Step 2:
Use the dimensionless depth-duration ordinate values for the 20% exceedance probability (conservative occurrence) from Table 8e. Multiply the dimensionless ordinates by the 6 hour ID depth to scale the storm to the proper magnitude.
Step 3:
Select the 20% exceedance probability value (13.4 hours) from Table 10 for the time of occurrence for the high intensity segment. Remember that the occurrence of the high intensity segment nearer the end of the storm generally produces a larger flood peak discharge. Thus, a longer timing value is conservative relative to a value nearer the start of the storm.
Step 4:
Select a conservative sequence for the three high intensity segments of the storm. The sequence chosen should be one with the larger precipitation segments nearer the end of the sequence.
In consideration of the above, choose sequence 312 at 60 minute increments per Tables 7 and 11. The incremental precipitation amounts corresponding to this sequence are inserted into the storm so the largest amount spans the time increment from 13 to 14 hours of elapsed time (per Step 3). Table 8e also contains high intensity ordinates for two 15 minute segments and one 30 minute segment. These segments should be inserted within the largest 60 minute segment to have the greatest intensity occurring around 13.4 hours.

Step 5:

Not applicable.

Step 6:

Select macro pattern Type IX based on selections in Steps 3,4 and Figure 6c. Use of a six segment sequence for the macro pattern (3 hour time intervals) does allows some latitude in the selection of a sequence which incorporates the previously chosen timing and sequencing elements. Logical choices would include: 654213 and 654312. Choose macro pattern sequence 654213 based on the timing of the high intensity segment at 13.4 hours which is near the boundary between macro segments 4 and 5 (boundary at 12 hours).

Step 7:

No corrections for areal coverage are necessary since the watershed is less than 10 square miles.

The resultant synthetic storm is shown in Figure 18 and the supporting computations for storm assembly are contained in Table 18.

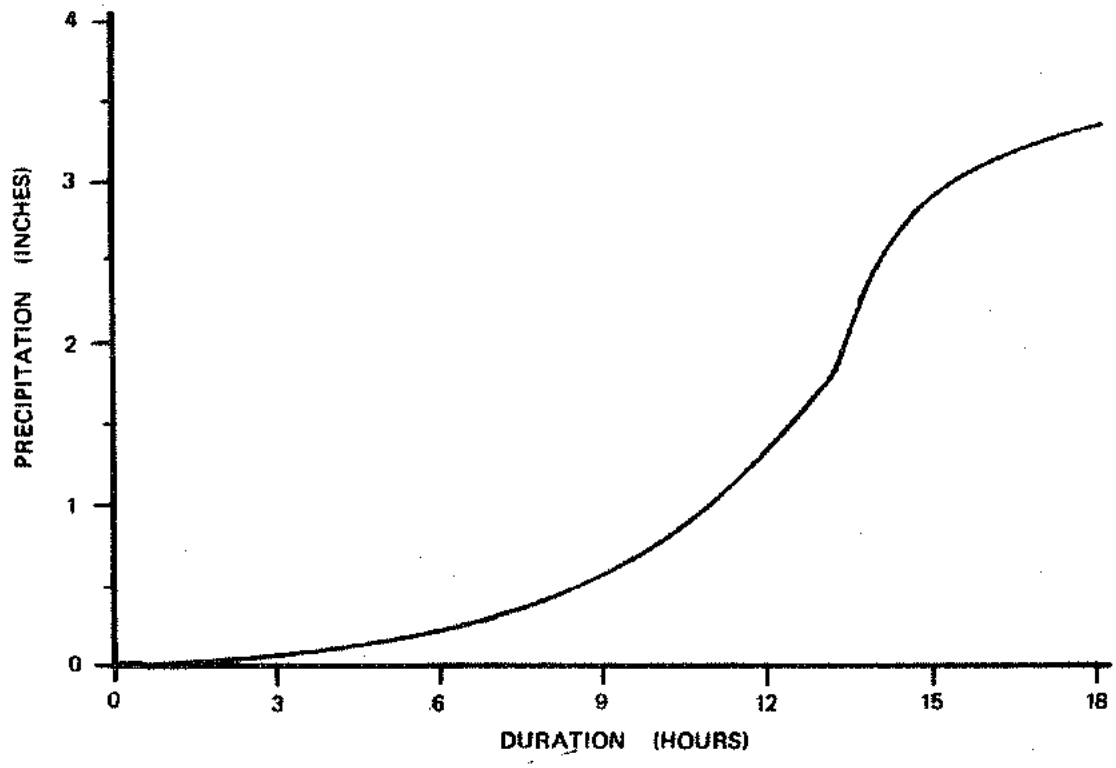

Figure 18. Synthetic Mass Hyetograph for 6 Hour ID Extreme Storm for 5 Square Mile Watershed near Olympia, WA.

Table 18. Assembly of Synthetic Mass Hyetograph for 6 Hour ID Extreme Storm for 5 Square Mile Watershed near Olympia, WA.

Example 3. Development of a very conservative mass hyetograph for a 24 hour ID event, with an AEP=0.01 for a 100 square mile watershed near Olympia, WA. in the Puget Sound lowlands.

Given: For a 100 year recurrence interval event (AEP=0.01), the average precipitation depth for the watershed was computed using the collection of at-site values from NOAA Atlas 2 at nodes on a rectangular grid which encompassed the watershed. The average depth was computed to be 5.40 inches.

Interpretation of a **very conservative** temporal distribution is taken to mean storm elements having exceedance probabilities of 0.05 - one chance in twenty of being exceeded. For purposes of this example, assume flood peak discharge is the primary concern, rather than flood volume. Therefore, use a depth-duration curve developed from a 6 hour kernel.

Step 1a:

The 24 hour average precipitation depth for the watershed was determined to be 5.40 inches.

Step 2:

Use the dimensionless depth-duration ordinate values for the 5% exceedance probability from Table 8j. Multiply the dimensionless ordinates by the 24 hour ID average depth to scale the storm to the proper magnitude.

Step 3:

Select the 5% exceedance probability value (51.3 hours) from Table 10 for the time of occurrence for the high intensity segment.

Step 4:

Select a sequence for the three high intensity segments of the storm. As discussed previously, a more conservative sequence would have the larger precipitation amounts nearer the end of the sequence. In consideration of the above, a very conservative sequence would be represented by sequence 321 at 60 minute increments per Tables 7 and 11.

The incremental precipitation amounts corresponding to this sequence are inserted into the storm so the largest amount spans the time increment from 51 to 52 hours of elapsed time. Table 8j also contains ordinate values for precipitation amounts for two 30 minute high intensity segments. These segments should be inserted within the largest 60 minute segment.

Step 5:

Select a sequence for the four 6 hour segments within the 24 hour ID. As before, a conservative sequence should have the larger precipitation amounts nearer the end of the sequence. Chose sequence 4312 based on information in Tables 13 and 14. The largest 6 hour precipitation amount should include and be centered around the 1 hour high intensity segment at 51.3 hours. This results in the 24 hour ID occurring between 36 and 60 hours of elapsed time.

Step 6:

Select macro pattern Type IX based on selections in Steps 3,4 and 5. Choose macro pattern sequence 654213 for the six segment macro pattern sequence (12 hour time intervals) based on previous selections in Steps 3,4 and 5.

Step 7:

Multiply the scaled ordinate values from Step 2 by the appropriate areal reduction factors in Figure 15 to produce the final ordinates for the basin-average depth-duration curve.

The resultant synthetic storm is shown in Figure 19 and the supporting computations are contained in Table 19. For comparison purposes, a second storm mass hyetograph was computed (computations not shown) using a 48 hour DD kernel (Table 9c) in conjunction with the same characteristics used in Example 3. It can be seen in Figure 19 that the storms have similar mass curves. The primary differences being that the storm generated from the 6 hour DD kernel contains higher intensities and the storm generated from the 48 hour DD kernel has significantly larger total depth. The selection of the appropriate storm for the design of a specific hydraulic structure would depend on whether flood volume or flood peak discharge was the critical consideration.

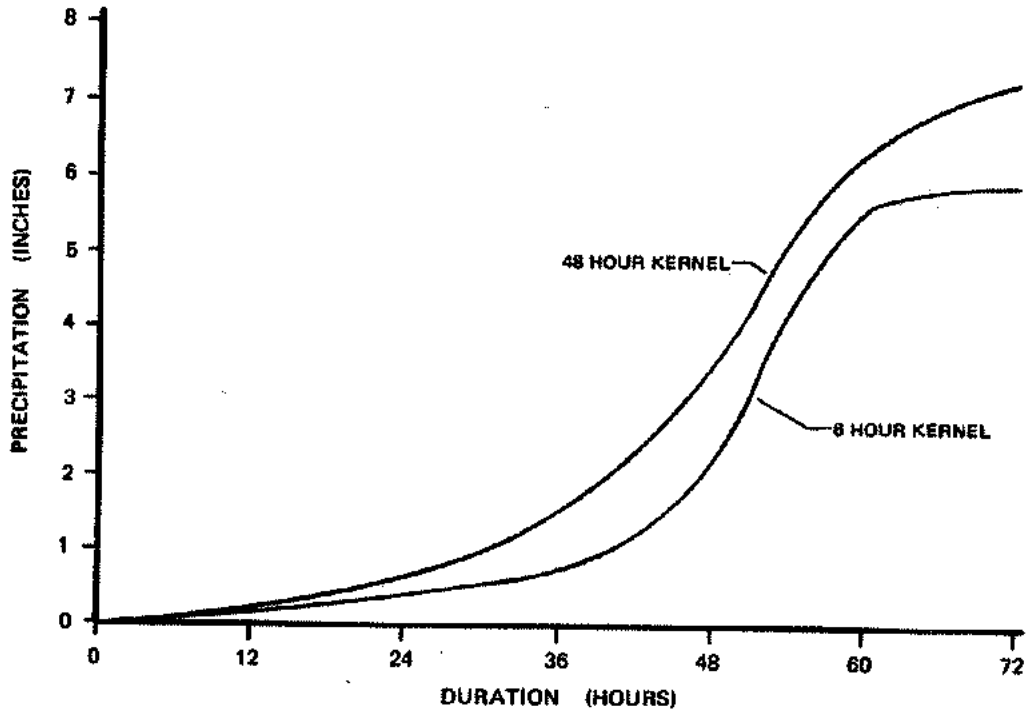

Figure 19. Synthetic Mass Hyetographs for 24 Hour ID Extreme Storms for 100 Square Mile Watershed near Olympia, WA.

One of the findings identified earlier in this study was the general relationship between storm seasonality, precipitation intensity and duration. To reiterate, short duration 2 hour ID extreme storms occur predominately in the warm season and typically contain high intensities but relatively small total depth. By comparison, the long duration 24 hour ID extreme storms are cool season events which contain relatively moderate and uniform intensities and a much larger total depth. The 6 hour ID extreme storms exhibit characteristics intermediate between the two. The general relationship between storm duration and the magnitude of the high intensities contained within the storm can be seen by reviewing the results from the three examples. The highest intensities in the example storms, for the 15 minute DD and no areal reduction, are 2.00 in/hr, 1.32 in/hr and 0.90 in/hr for the

2 hour ID, 6 hour ID and 24 hour ID storms respectively. **This complexity between storm magnitude, duration and the magnitude of the high intensity segments warrants that several synthetic storms be developed at each duration when investigating the flood characteristics of a specific watershed.** This will allow a proper determination of the storm duration and temporal components which have the characteristics to generate the flood which will govern the design of a given hydraulic structure.

SUMMARY AND CONCLUSIONS

Analyses were conducted to describe the probabilistic characteristics of extreme storms in Washington State. An extreme storm was defined as being a precipitation event whose depth for a specified duration, the Independent Duration (ID), represented a return period of 20 years or greater. For purposes of the study, a catalog of extreme storms was developed for three specific IDs, 2 hours, 6 hours and 24 hours, for each of five reasonably homogeneous climatic regions. Storms which exceeded the extreme storm threshold had to meet certain selection criteria to be included in the catalog. For each region, a specific storm (date) could appear at only one of the three IDs. In addition, only the recording station where the storm amount was the rarest was retained in the catalog.

The catalog created by the storm selection process formed the database for the probabilistic analyses. As a result of those analyses, the following observations and conclusions were made:

Seasonality

The season of occurrence of the extreme storms was strongly related to storm duration. The 2 hour ID events, in both eastern and western Washington, were found to occur primarily in the warm season; typically May through September. The influence of solar heating in initiating these convective events is evidenced by the fact that the vast majority of storms occurred between noon and early evening.

The 6 hour and 24 hour ID storms in western Washington were found to occur almost exclusively in the cool season; typically October through February. These storms were characterized by relatively moderate and uniform intensities. The high intensity segments of these storms rarely contained intensities as large as those found in the shorter duration 2 hour ID events.

The 24 hour ID storms in eastern Washington were found to occur primarily in the cool season; typically September through February.

The seasonality of occurrence of the 6 hour ID storms in eastern Washington had a bimodal distribution. Common seasons of occurrence were in spring and in late fall and winter.

Temporal Storm Characteristics

Twelve generalized macro storm patterns (incremental precipitation histograms) were created and used to categorize extreme storms. Six patterns were for storms which contained continuous precipitation and six patterns were for intermittent storms. Continuous patterns were always in the majority, although the percentage of intermittent storms tended to increase with storm duration. Likewise, a greater variety of macro patterns were observed as the ID of the storm increased.

The short duration 2 hour ID storms, in both eastern and western Washington, exhibited predominately Type I macro patterns. This pattern has the high intensity segment near the beginning of the storm.

In eastern Washington, the 6 hour and 24 hour ID storms typically exhibited a Type I macro pattern. In western Washington, the 6 hour and 24 hour ID storms typically occurred with a macro pattern where the high intensity segment was near the middle of the storm.

Probabilistic dimensionless depth-duration curves were developed for each of the three durations and five climatic regions. The depth-duration curves were found to be essentially independent of storm magnitude. Thus, selection of a design storm magnitude and a depth-duration curve are to be considered as independent decisions in the development of synthetic storms for rainfall-runoff modeling.

The cross-correlation structure of the dependent duration (DD) ordinates within the depth-duration curves was investigated for the three IDs in each region. In all cases, a definitive decay structure was observed, wherein, the magnitudes of the cross-correlation coefficients decreased as the time between DD pairs increased in magnitude. The cross-correlation structure resulted in probabilistic dimensionless depth-duration curves having certain characteristic shapes. For all three durations, dimensionless

curves with steeper than average rising limbs had flatter than average upper tails. Conversely, curves having steeper than average upper tails had flatter than average rising limbs. Thus, it was quite rare to see a storm whose dimensionless depth-duration curve ordinates exhibited significantly higher than average values at the high intensity segment of the storm and which exhibited unusually large ordinate values at the total duration.

Probabilistic information was developed on the sequencing (arrangement) characteristics of the incremental precipitation amounts within storms and on the time of occurrence of the high intensity storm segment for each of the three IDs and five regions. The sequencing characteristics were found to occur in a wide variety of possible combinations. Likewise, the timing characteristics of the high intensity segment were highly variable.

Antecedent Storms

Investigations were conducted to examine the largest antecedent precipitation events which occurred in the 14 day period prior to the extreme storms. For all three IDs, it was found that extreme storms are not preceded by an unusual storm.
In particular, antecedent storms are typically of a magnitude which occur numerous times during a given year.

Spatial Characteristics

The areal coverage characteristics of the 2 hour ID "thunderstorms" in eastern Washington were examined. Observed areal coverages were found to be highly variable, ranging from 35 to 500 square miles, and were nearly independent of the storm magnitude. The majority of storms originated out of the southwest or west. Storm movement resulted in areal coverages having an elliptical shape with an average major to minor axis ratio of about 2.5:1.

Assembly of Synthetic Storms

A methodology was presented for assembly of synthetic storms for each of the three IDs and five regions. The assembly methodology contained procedures which allowed decisions to be made regarding the manner in which the observed statistical characteristics could be incorporated in a synthetic storm.

In conclusion, it is intended that the findings from this study will allow engineers, hydrologists, meteorologists and other practitioners of rainfall-runoff modeling to make informed decisions in the selection and development of synthetic storms. Ultimately, it is hoped that this study will result in improved estimates of floods in Washington State.

ACKNOWLEDGMENTS

The author is deeply appreciative of the support provided by the Department of Ecology and in particular by M. Edward Garling while this study was being conducted. Data collection and compilation by Mr. Joe Cason was instrumental to the completion of this study and his efforts are appreciated.

APPENDIX 2

CONSTRUCTION OF DEPTH-DURATION CURVES

The depth-duration curve is an analytical tool developed by meteorologists [Chow, 1964] [WMO, 1969] to allow comparisons to be made between storms of the amount of precipitation which occurred during a given time period. Simply stated, the depth-duration curve is a precipitation mass curve created by rearrangement of the incremental precipitation amounts from an observed storm. The new mass curve is constructed in a manner which contains the largest incremental precipitation amounts at the start of the new mass curve. Slight variations exist in the procedures used by various meteorologists, hydrologists and engineers in the construction of depth-duration curves.

Depth-duration curves can be developed for at-site precipitation, representing storm areal coverage for some nominal area such as 1 square mile or 10 square miles, or for a specific area. In the latter case, spatial averaging techniques are first used to define the average temporal distribution of the storm for the given area.

The following list describes procedures for construction of at-site depth-duration curves:

- A time increment for analysis is selected based on the needs of the specific study.

- The precipitation record is examined to determine the largest precipitation amount which occurred in a "window of time" equal to the time increment. This incremental precipitation amount is ranked first and forms the beginning of a new series of reordered amounts from the observed storm.

- The precipitation record is then reexamined to determine the largest precipitation amount which has occurred in a window of time equal to twice the time increment and which includes the initial precipitation amount chosen previously. The precipitation amount which occurred in this second incremental period of time is listed second in the new series being formed. The term "nested" is often applied to the requirement that the duration (time window) being examined must include the entire time period which contained the previously selected amounts.

- The process of expanding the time window by one time increment and selecting the largest nested precipitation amount is continued until the original storm is completely reordered.

- The reordered mass curve is labeled a depth-duration curve.

- A dimensionless depth-duration curve is produced by dividing the ordinates of the curve by the observed precipitation amount corresponding a specic duration of interest.

EXAMPLE: Extreme Storm of October 14, 1945 - Snoqualmie Pass, WA.
6 hour Precipitation Depth= 3.87 inches
Independent Duration= 6 hours, Time Increment= 3 hours
Macro Pattern= Type VI

Solution: Use previously discussed steps to reorder observed storm mass curve into dimensionless depth-duration curve. Incremental precipitation amounts are listed and reordered in Table 20 and displayed in Figure 20.

Mission

The mission of the Department of Ecology is to protect, preserve and enhance Washington's environment and promote the wise management of our air, land and water for the benefit of current and future generations.

12–Point Strategy

To accomplish this mission, the department will:

- Recognize its most valuable asset is its dedicated and committed employees and it will provide necessary support, training and professional development.
- Promote prevention and conservation as the most effective ways to preserve our natural resources and protect the environment.
- Enforce environmental laws and regulations in a fair and firm manner.
- Provide public education programs to promote wise use of our natural resources and encourage environmental protection.
- Offer information, technical and financial assistance to help the public, governments, businesses and industries comply with environmental laws and regulations.
- Promote the recognition that compliance with environmental laws and regulations is compatible with a sound economy.
- Provide meaningful public involvement in the development of rules, regulations and new initiatives.
- Provide leadership in addressing emerging problems and strive to bring public agencies and diverse interest groups together to address environmental issues.
- Use an integrated approach to resolve environmental issues.
- Place special emphasis on educating and working with youth to create a strong environmental ethic.
- Help state agencies set an example in environmental protection.
- Work with the executive and legislative branches to promote sound environmental policy.

DETERMINING DESIGN/PERFORMANCE GOALS FOR SPILLWAY ADEQUACY: THE WASHINGTON STATE APPROACH

by Douglas L. Johnson, P.E.[a]

A. Introduction

This paper summarizes the conclusions from many years of work by the Washington State Dam Safety Section towards developing a risk-based approach to spillway adequacy. Historically, spillway design for dams with population at risk has been based on deterministic methods (i.e. Probable Maximum Precipitation). This level of protection is widely recognized as appropriate for the design of large dams located above densely populated areas. However, the vast majority of dams regulated by state dam safety programs are small to intermediate in size, where the downstream hazard setting typically includes fewer than 10 homes. These types of projects and downstream hazard settings typically represent situations where the extreme storm used in flood analysis can often be justified as being something less than PMP. However, the key question arises - *What is an acceptable level of safety for these projects?* Our studies in extreme storms and risk-based methods attempt to answer this question.

The key elements to the Washington State approach to spillway design are contained in Technical Note 2: *Selection of Design/Performance Goals for Critical Project Elements*[1], along with its companion paper, Technical Note 3: *Design Storm Construction*[2]. Technical Note 2 is an application of the probability-based extreme storm studies developed by Dr. Mel Schaefer in *Regional Analysis of Precipitation Annual Maxima in Washington State*[3], and applied in Technical Note 3. Technical Note 2 takes a probabilistic approach to design levels for dams vs. a deterministic approach (i.e. PMP). However, the design levels discussed in Technical Note 2 were not intended to replace PMP, but to compliment it. PMP which is a "maximum" event, is still used as an upper limit for large dams with a large population at risk downstream. For smaller dams with less population at risk, however, a probabilistic or "risk-based" approach was developed.

B. Balanced Protection Concept

Historically, the various engineering disciplines involved in dam design/safety evaluation used different methodologies that have resulted in various elements of the project being designed to different standards, resulting in widely dissimilar levels of protection from failure. For example, a spillway may be designed for PMP/PMF, while the outlet conduit is designed using methods common for roadway drainage structures. The *Balanced Protection Concept* sets a common design/performance goal for the design or evaluation of each critical project element to assist in providing reasonably consistent levels of protection. A design/performance goal is simply a goal for the performance of critical project elements (e.g. spillway, embankment stability), which may be used in design or evaluation. It is expressed as an Annual Exceedance Probability (AEP) and is a measure of the chance of adverse behavior, or failure of a critical project element. Technical Note 2 presents a methodology for determining a common design/performance goal for a given level of protection of any critical element of a project, including spillways.

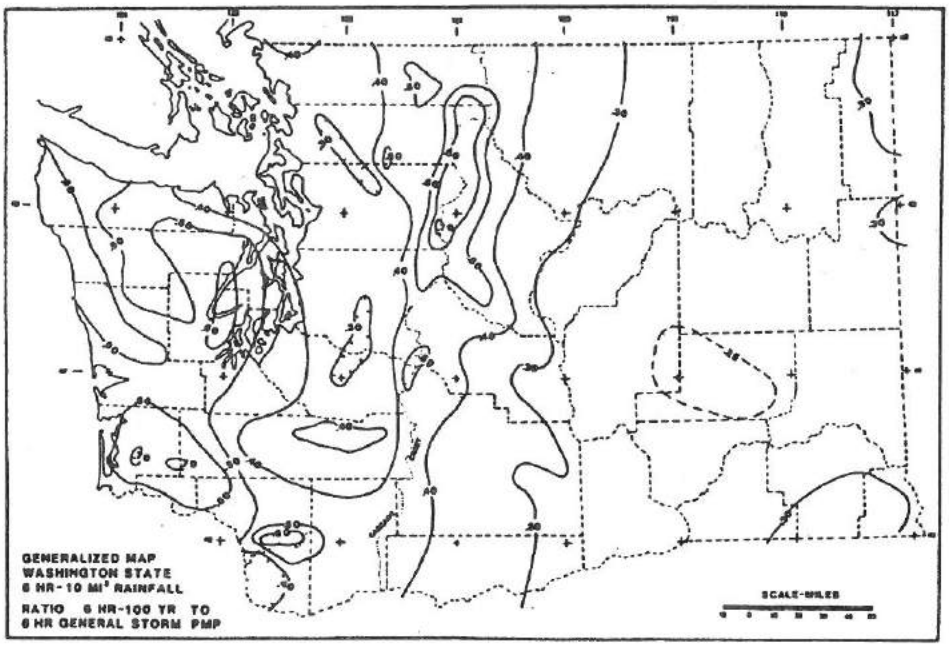
C. Consequence Dependent Design Levels

It is standard practice in civil engineering that the degree of conservativism in design should correspond with the consequences of failure of a given element. If failure of the element poses no public safety concern, the design level is usually based on economic considerations. However, if failure of a given element could pose threat to loss of life, design levels are typically much more conservative to protect from consequences of failure. Also, as the magnitude of loss of life and

---

[a] Dam Inspection Specialist, Dam Safety Section, Washington Department of Ecology

property damage resulting from a failure increases, design levels become more stringent. This concept is called *Consequence Dependent Design Levels.*



D. Selection of Probabilistic Approach

In the past, the standard design storm in the dam safety community for the design of intermediate and large high hazard projects (3 or more homes) has been the Probable Maximum Precipitation (PMP). PMP is theoretically *the greatest depth of precipitation for a given duration that is physically possible over a given storm area at a particular geographical location at a certain time of year*[4,5]. In the engineering community, it is commonly assumed that PMP provides a consistent level of protection and a "zero risk" design level. However, it is not possible to compute theoretical PMP directly, and numerous procedures and judgements must be used to estimate PMP. Thus, in reality, computed PMP approaches, rather than meets, the theoretical upper limit. This implies that real world precipitation can exceed computed PMP estimates, and use of these values does not carry zero risk.

Further studies by Dr. Schaefer showed that in Washington (as well as across the U.S.), the annual exceedance probability for PMP can vary widely across the state. On the Coast, where the moisture source is near at hand and the rainfall processes are very efficient, PMP (based on HMR-43) has an exceedance probability of about 10^{-5}. In the Puget Sound Area, PMP has an exceedance probability of 10^{-6}, while in Eastern Washington, where the sources of moisture are remote, PMP's exceedance probability approaches 10^{-9} for some locations. Thus using PMP as a design event can provide widely different levels of protection, depending on location within the State.

The situation is further complicated when we look at smaller dams where only a few lives may be at risk. The standards used by many regulatory organizations dictated that ratios of the PMP be used for the design of these facilities, with 50% PMP commonly used as the lower bound when any lives are at risk. However, when we use ratios of the PMP, we know nothing of the level of protection afforded. This is illustrated in Figure 1, which shows that a 100-year event is about 50% to 70% of the 6 hour PMP in coastal areas, while in Eastern Washington, the 100-year precip is only 15% to 20% of PMP.

FIGURE 1 - RATIO OF 6 HR 10 MI² PRECIPITATION TO 6 HR 10 MI² GENERAL STORM PMP (HMR-43) IN WASHINGTON

Recognizing that the PMP (and % PMP) approach is not zero risk, provides different levels of protection, and de facto has an associated exceedance probability and risk, the Dam Safety Section elected to pursue a probabilistic or risk-based approach to spillway design. The PMP was not, however, completely eliminated from consideration. Rather, it was selected as an upper bound for design events, to be used for large dams where the consequences of failure are great. The probabilistic approach was employed for the many small and intermediate sized dams with few to no homes at risk. This approach is termed the Design Step Format and is described in the following section.

E. Design Step Format

The concepts of Balanced Protection and Consequence Dependent Design are implemented through a Design Step Format. The Design Step Format utilizes 8 steps, where the design events become increasingly more stringent as the consequences of a dam failure become more severe. Figure 1 shows the 8-step format employed by the Dam Safety Section.

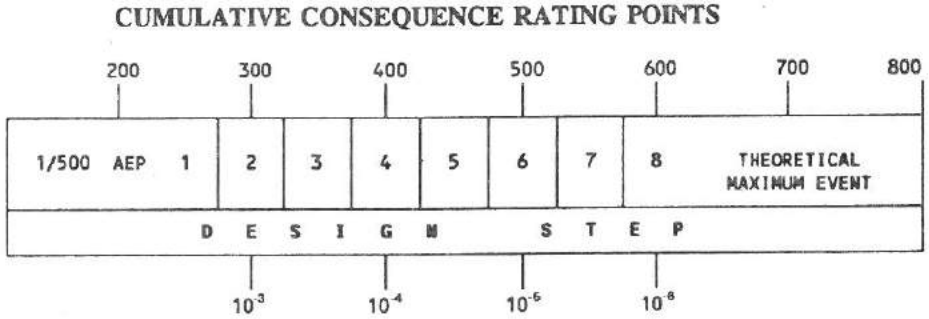


FIGURE 2

Design Step 1 would apply where consequences of a dam failure would be minimal and there would be no chance for loss of life. Step 1 has an annual exceedance probability (AEP) of 1 in 500, one chance in 500 of being exceeded in any given year. This design level is consistent with engineering design practice for dams in similar low hazard settings (National Research Council[6], ICE[7], ICOLD[8], BC Hydro[9]). Design Step 8 applies where a dam failure would be catastrophic with hundreds of lives at risk. In this situation, extreme design events and design loads are used to provide the extremely high levels of reliability needed to properly protect the public. For Design Step 8, the maximum design level is set at an AEP of 10^{-6} (1 chance in 1 million). Step 8 corresponds to theoretical maximum design events (PMP, MCE) and loading conditions. The use of a design/performance goal with an AEP of 10^{-6} is based on existing design standards (EPRI[10]) and review of recommendations for engineered structures with similar extremely serious consequences of failure (CSS[11], Kennedy[12], BC Hydro[9], Nuclear Regulatory Commission[13], Newton[14])

The design step format was completed by providing uniform performance increments between the design steps such that the AEP's for the design/performance goals decrease tenfold for every two design steps. Thus, this format strives to provide a reliability of design with a tenfold increase in protection for every 2 step increase.

F. Benchmarks for Design Step Format

The next step in developing the design step format was the selection of benchmarks for setting design levels which would be consistent with levels of safety provided by other engineering disciplines and governmental regulation.

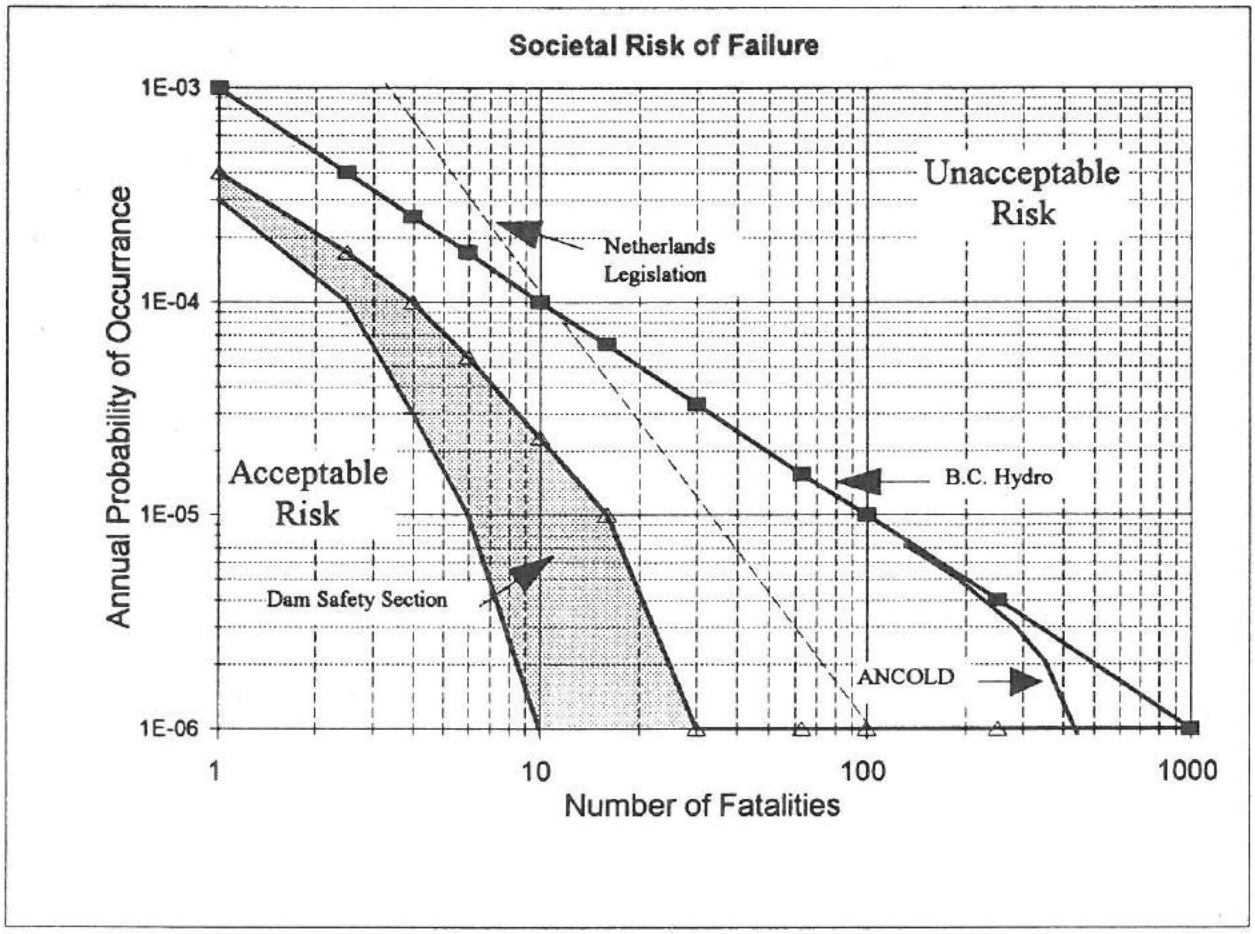
In many engineering applications, design levels are set by standards or codes which provide guidance or set design minimums. This obscures the actual levels of protection afforded by standards/codes. This result is not entirely unintentional, as governing bodies and standards boards are often hesitant to openly discuss acceptable levels of risk and probabilities of failure, where system failure could pose a threat to loss of life. This situation requires that design levels and probabilities of failure must be back-calculated for standards and codes. This back-calculation has been done for the establishment of design/performance goals in the design and evaluation of Department of Energy Facilities[12]. That information, as well as other sources provided background information for setting the benchmarks shown in Figure 3.

FIGURE 3 - BENCHMARKS FOR CALIBRATING POINT RATING ALGORITHM FOR USE IN DECISION FRAMEWORK

BENCHMARK	CHARACTERISTICS OF IDEALIZED PROJECTS	MINIMUM DESIGN STEP	DESIGN/PERFORMANCE GOAL AEP
1	1 or More Lives at Risk	3	3×10^{-4}
2	Large Dam, over 50 feet High No Downstream Hazard	3	3×10^{-4}
3	Intermediate Dam No Commercial Development 10 Residences at Risk	4	10^{-4}
4	Large Dam Limited Commercial Development 34 Residences at Risk	6	10^{-5}
5	Large Dam Significant Commercial Development 100 Residences at Risk	8	10^{-6}

Note: AEP - Annual Exceedance Probability

Additional guidance in setting design/performance goals was obtained by examining the levels of risk to which the public is exposed in ordinary life. Several of these risks are shown in Figure 4.



A review of the data in Figure 4 shows a basic trend. In those activities where few lives are at risk and the activity is voluntary in nature, nominal values of protection are accepted by the general public. Conversely, as the number of persons at risk and the level of hazard to the public from a certain activity increases, the level of protection expected by society and the engineering profession increases significantly. This viewpoint is called "risk averse" with regard to loss of life. This is illustrated in Figure 5, which shows the DSS criteria in comparison to other risk-based criteria, such as B.C. Hydro's, which is considered risk neutral.

FIGURE 4 - LISTING OF RISKS FOR VARIOUS ACTIVITIES AND PERFORMANCE LEVELS FOR VARIOUS ENGINEERED SYSTEMS

ACTIVITY/ITEM	TYPICAL NUMBER OF PERSONS AT RISK	RISK LEVEL	PERFORMANCE LEVEL
NATIONAL FLOOD INSURANCE PROGRAM • Risk from Natural Flooding	Varies Widely		1/100 AEP 100 Year Flood

Note: AC - Annual Chance of Occurrence AEP - Annual Exceedance Probability ** - Based on an "Average Traveller"

FIGURE 5 - COMPARISON OF SOCIETAL RISK CRITERIA

G. Additive Point Rating Scheme for Determining Design/Performance Goals

An additive weighting scheme was developed to determine numerical ratings of the consequences of dam failure, which reflects the relative importance of each consequence, and the range of severity of the impacts posed by each consequence. Cumulative consequence rating points with values between 200 and 600 points were used to define the working range for the eight step format. Factors were selected within the 3 general categories shown in Figure 6, which described the nature of the consequences that could be quantified.

FIGURE 6. NUMERICAL RATING FORMAT FOR ADDITIVE WEIGHTING SCHEME FOR ASSESSING CONSEQUENCES OF DAM FAILURE

CONSEQUENCE CATEGORIES	CONSEQUENCE RATING POINTS	INDICATOR PARAMETER	CONSIDERATIONS
CAPITAL VALUE OF PROJECT	0 - 150	DAM HEIGHT	Capital Value of Dam
	0 - 75	PROJECT BENEFITS	Revenue Generation or Value of Reservoir Contents
POTENTIAL FOR LOSS OF LIFE	0 - 75	CATASTROPHIC INDEX	Ratio of Dam Breach Peak Discharge to 100 Year Flood
	0 - 300	POPULATION AT RISK	Population at Risk Potential for Future Development
	0 - 100	ADEQUACY OF WARNING	Likely Adequacy of Warning in Event of Dam Failure
POTENTIAL FOR PROPERTY DAMAGE	0 - 250	ITEMS DAMAGED OR SERVICES DISRUPTED	Residential and Commercial Property Roads, Bridges, Transportation Facilities Lifeline Facilities Community Services Environmental Degradation from Reservoir Contents (Tailings, Wastes, etc.)

Utility Curves and consequence rating tables were developed for each of the indicator parameters in Figure 6 to implement the additive weighting scheme. A worksheet was then developed for compiling the rating points and selecting an appropriate design step. A typical utility curve is shown in Figure 7, and a rating table is shown in Figure 8.

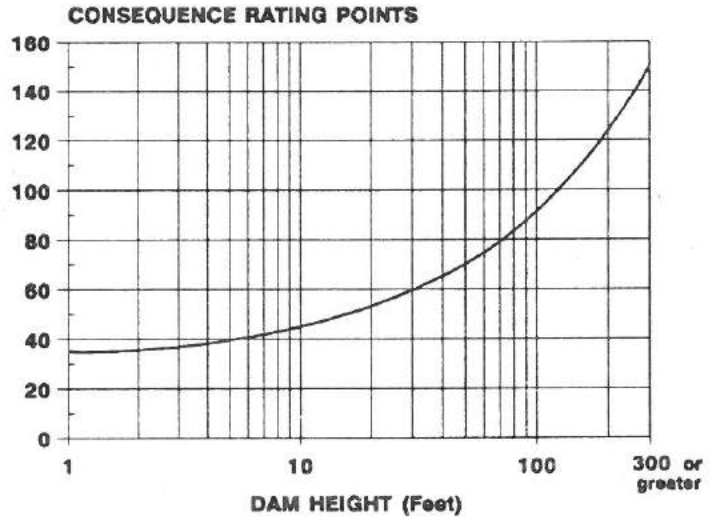

FIGURE 7. CONSEQUENCE RATING POINTS FOR DAM HEIGHT INDEX

FIGURE 8. CONSEQUENCE RATING TABLE FOR LOSS OF PROJECT BENEFITS

CONSEQUENCE SUB CATEGORY	CONSIDERATION	TYPICAL EXAMPLES	RATING POINTS
LIMITED RESOURCE LOSS WOULD AFFECT GENERAL PUBLIC	MANDATORY	PUBLIC WATER SUPPLY RESERVOIR	25 - 75
PRIVATE ENTERPRISE LOSS WOULD NOT AFFECT GENERAL PUBLIC	DISCRETIONARY	IRRIGATION OR INDUSTRIAL WATER SUPPLY	10 - 75
		HYDROPOWER GENERATION	10 - 75
		MINING OR MANUFACTURING	10 - 75
		AESTHETICS, RECREATION OR WILDLIFE HABITAT	10 - 25

H. Selection of the Design Step

Cumulative rating points are used to select an appropriate design step using Figure 2. The design step and corresponding annual exceedance probability are then used to determine a design event/loading for a critical project element. Typical applications of the design step would include:

1. Computation of Inflow Design Floods
2. Assessing the Seismic Stability of Embankments
3. Design of Outlet Conduits
4. Reliability Levels for Critical Electrical and Mechanical Systems

There are several additional issues that need to be considered when applying decision framework to the selection of a design step.

1. **Modes of Failure for Various Critical Project Elements**
   Since procedures are applied for each critical element of project, it is possible to come up with different design steps for each element, due to different reservoir levels, dam break floods, etc. for different failure modes. However, a reasonable approach would be to use the design step for failure mode that would produce the worst consequences, and to use that step for the design of all critical project elements. This follows *the Balanced Protection* concept, and achieves reasonably similar design levels of conservatism and reliability. Under most circumstances, a dam failure by overtopping usually the worst case, and should be examined first in determining the design step.

2. **Projects with Multiple Dams**
   With multiple dam projects, dams are often of different size and have different consequences should they fail. It is reasonable and acceptable that design levels and loadings for each dam can be different. Thus the design loadings and protection afforded at the main dam could be greater than at a saddle dam.

3. **Dams in Series**
   When several dams are located in series on a stream, the failure of upper dam could cause failure of one or more lower dams. Consequently, the design step for any upstream dam which

can cause failure of downstream dam must be equal to or greater than the design step for the downstream dam.

4. **Engineering Judgement**
The Design Step Worksheet is an aid to decision making, and should not replace sound engineering judgement. Prudent reasoning may indicate that a higher or lower Design Step is appropriate.

5. **Design Step Minimum**
For small dams with only a few people at risk downstream, the numerical value of the rating points may not correspond to an adequate design step. Thus, **Design Step 3 is the minimum design step when <u>any</u> lives are at risk.**

I. Relationship of Design Step to Downstream Hazard Classification

Oftentimes during the planning stage of a project there is a need to make a quick assessment of the value of the design step. This can be accomplished by utilizing the Downstream Hazard Classification for the project as a rough indicator for the design step. Experience has shown that the value of the design step typically falls within a small range for each of the Downstream Hazard Classes as shown in Figure 9.

FIGURE 9. RELATIONSHIP OF DESIGN STEP TO DOWNSTREAM HAZARD CLASSIFICATION

DOWNSTREAM HAZARD POTENTIAL	DOWNSTREAM HAZARD CLASSIFICATION	POPULATION AT RISK	ECONOMIC LOSS GENERIC DESCRIPTIONS	ENVIRONMENTAL DAMAGES	TYPICAL DESIGN STEP
LOW	3	0	Minimal. No inhabited structures. Limited agriculture development.	No deleterious materials in reservoir	1 - 2
SIGNIFICANT	2	1 to 6	Appreciable. 1 or 2 inhabited structures. Notable agriculture or work sites. Secondary highway and/or rail lines.	Limited water quality degradation from reservoir contents and only short term consequences	3 - 4
HIGH	1C	7 to 30	Major. 3 to 10 inhabited structures. Low density suburban area with some industry and work sites. Primary highways and rail lines.	Severe water quality degradation potential from reservoir contents and long term effects on aquatic and human life	3 - 6
HIGH	1B	31-300	Extreme. 11 to 100 inhabited structures. Medium density suburban or urban area with associated industry, property and transportation features.		4 - 8
HIGH	1A	More than 300	Extreme. More than 100 inhabited structures. Highly developed, densely populated suburban or urban area with associated industry, property, transportation and community life line features.		8

J. Summary

This paper summarized the approach used by the Washington State Dam Safety Section for the design/evaluation of spillways for dams. The concepts of *Consequence Dependent Design Levels* and *Balanced Protection* are the cornerstones of the decision framework discussed herein. The decision framework utilizes probabilistic methods rather than deterministic methods (such as PMP), for the selection of design/performance goals for spillways and other critical project elements. However, the design approach discussed is not intended to replace PMP but to augment it. PMP is still used as an upper limit for the design of large dams with large populations at risk. The probabilistic design step approach discussed herein attempts to provide a method for determining design/performance goals for smaller projects with less population at risk, where something less than PMP is justified. The design step approach represents an answer for the question - *What is an acceptable level of safety for these smaller projects?*

RISK IS NOT A FOUR LETTER WORD: TEN YEARS OF SUCCESS USING A RISK-BASED DAM SAFETY APPROACH IN WASHINGTON

Doug Johnson
Washington State Dam Safety Supervisor

INTRODUCTION

This paper discusses the application of probability and risk concepts in the state of Washington's dam safety program. Our approach can be characterized as employing risk concepts in a standards-based framework, and using a risk-based prioritization scheme to correct dam safety deficiencies. Under this approach, probability methods, risk concepts, and elements of risk assessment are combined with decision making in setting performance standards that provide acceptable minimum levels of protection. This approach has been quite successful since its implementation in 1990. For similar downstream hazard settings, it has provided consistent levels of protection against flood induced overtopping failures across diverse climatic regions. It has been less successful in addressing the difficult, rapidly evolving seismic concerns confronting the Pacific Northwest. Furthermore, this approach has allowed us to make great progress in repairing the backlog of dams with identified safety deficiencies, as well as design new dams to more consistent standards across the State of Washington.

Why Choose Probabilistic Over Deterministic Approach?

The use of risk-based approaches in the dam safety community is still highly controversial. There is much fear and trepidation among dam safety engineers when "risk" is mentioned in conjunction with dam safety. To many, the word risk implies that we would be designing to accept failure and loss of life, or more insidiously that risk assessment is a way of avoiding making expensive structural repairs to a dam. In addition, many think that using risk entails quantitative risk assessment, a highly complex and time-consuming analysis. Conversely, many dam safety professionals believe that using deterministic standards imply that a dam can pose zero risk to the public (as well as no liability risk to the engineer). Unfortunately, this viewpoint is based on misconceptions in the engineering community about the Probable Maximum Precipitation (PMP) and the Maximum Credible Earthquake (MCE). In reality, these values are estimates of the theoretical maxima that commonly approach, rather than meet, the theoretical upper limits. For example, studies have shown[1] that the annual exceedance probabilities (AEPs) of PMP events vary widely across the nation, from about 10^{-5} to perhaps 10^{-9}. In the Pacific Northwest, PMP events have AEPs that vary from about 10^{-5} on the coast, to 10^{-6} in the Puget Sound region to 10^{-9} in some areas of Eastern Washington[1]. Thus, the use of these values may not only not provide zero risk, they likely do not provide consistent levels of protection across broad geographic areas.

The situation is further complicated when we look at smaller dams where only a few lives would be at risk. This situation represents the majority of dams regulated by Washington and, we believe, most other states (Figure 1). Regulatory organizations have long recognized that PMP and MCE loadings are too stringent for the design/analysis of these smaller projects. Consequently, some percentage of the theoretical maximum PMP is used for hydrologic assessment. An earthquake with a larger probability of exceedance is utilized in the seismic stability assessment. For example, 50% of the PMP is frequently used by many regulatory agencies as the lower bound for smaller dams

where only a few lives are at risk. However, when ratios of the PMP are taken, wildly differing levels of protection may result. For example, based on a regional analysis of some 10,000 station-years of precipitation data covering the Pacific Northwest, 50% of the PMP is only about a 100-year event in the marine climate on the Pacific Coast, while being closer to a 10,000-year event in parts of the arid eastern half of the state. Thus, by using ratios of PMP for design or repair of smaller, lower hazard dams, not only are we accepting that the dam is not zero risk, we often have no idea what the level of risk is!

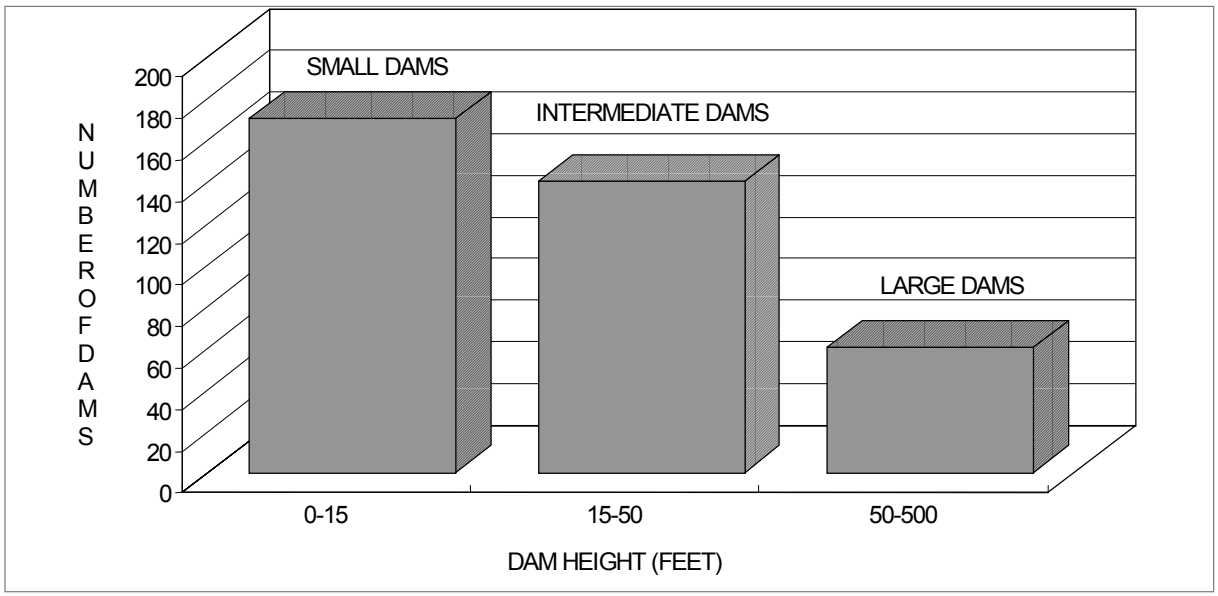

Figure 1 – Dams Sited Above Populated Areas in Washington State

Selection of Risk Based Approach

Recognizing that the PMP/MCE (much less % PMP) approach is not zero risk and provides unbalanced protection across the state, the Dam Safety Office elected to employ a risk-based design approach. This approach was selected based on a number of considerations. The first consideration was the need to provide consistent minimum levels of protection across the state for similar downstream hazard settings. There was also a need to provide methods of analysis that were manageable with limited resources. The state is responsible for over 800 dams, and has limited staffing and resources to apply toward detailed risk assessment. Likewise, most of the regulated community has smaller dams with limited project budgets. Finally, we needed an approach that could be used for the design of new projects as well as for analysis of existing dams. Performing quantitative risk assessments for every project would not be feasible given these considerations. However, employing risk concepts and procedures in a standards-based framework allowed us to address these issues, while realizing the benefits of using a risk-based approach in a relatively simple and inexpensive manner.

We decided to utilize probability and risk concepts in two main areas. The first was to develop risk-based standards for dam design and evaluation of existing dams. These standards were applied through the design step format, which is detailed later in this paper. The second area where these concepts were applied was in the development of a risk-based ranking scheme to prioritize compliance and enforcement efforts on existing dams with identified safety deficiencies.

The combination of both areas was integral to the success of Washington's dam safety program and is detailed in the following sections.

Design Philosophy

The philosophy of the Washington dam safety program utilizes several design principles that provide a framework for evaluating and establishing what design/performance levels are appropriate for the various elements of a dam project. The primary principles related to risk are *Balanced Protection* and *Consequence Dependent Design Levels.*

Balanced Protection - A dam is comprised of numerous critical elements, and like the old chain adage, "is only as strong as the weakest link". The goal of the *Balanced Protection* concept is to establish an appropriate common Annual Exceedance Probability (AEP) as the minimum design level for the evaluation of each critical project element. The term critical project element refers to an aspect of the structure, whose failure could precipitate an uncontrolled release of the reservoir. This office has only achieved partial success in this endeavor. As is noted below, the seismic design aspects lag behind the progress made in the hydrology arena.

Consequence Dependent Design Levels – Standard practice in the civil engineering community is that the degree of conservatism in design should correspond with the consequences of failure of a given element. If failure of a given element could pose a threat of loss of life, design levels are typically much more conservative. That conservatism increases with an increase in the potential magnitude of loss of life and property at risk. This concept is called *Consequence Dependent Design Levels*.

Design Step Format

The philosophies of Balanced Protection and Consequence Dependent Design are implemented through the Design Step Format. This format utilizes eight steps, where the design events become increasingly more stringent as the consequences of failure become more severe. Design Step 1 has an annual exceedance probability of 1 in 500, and would apply where the consequences of dam failure are minimal and there would be no chance for loss of life. Design Step 8 applies to large dams where a dam failure would be catastrophic, with hundreds of lives at risk. In this situation, extreme design loads are used to provide the extremely high levels of reliability needed to properly protect the public. Thus, the AEP of Step 8 is set at 1 in 1,000,000, or the theoretical maximum events (PMP, MCE), whichever is smaller. The design Step 8 AEP of 10^{-6} is based on existing design standards (EPRI[2]) and a review of recommendations for engineered structures with extreme consequences of failure, such as nuclear power plants.

The design step format was completed by providing uniform performance increments between the design steps such that the AEP's decrease tenfold for every two design steps. Figure 2 shows the 8-step format employed by the Washington dam safety program.

Figure 2. Design Step Format

Design Step	Exceedance Probability	Consequence Rating Points
1	1 in 500	< 275
2	1 in 1000	275 - 325
3	1 in 3000 (actually 3160)	326 - 375
4	1 in 10,000	376 - 425
5	1 in 30,000	426 - 475
6	1 in 100,000	476 - 525
7	1 in 300,000	526 - 575
8	1 in 1,000,000 (or theoretical maximum)	> 575

Benchmarks for Selecting Design Steps

A critical question when using risk-based design is "what is 'acceptable' (or tolerable) risk?" This is probably the most controversial aspect of using risk assessment in dam safety. This implies that above some threshold design event/performance level, loss of life would be tolerated. This is actually a common engineering precept used in bridge design, the UBC, and other engineering codes and standards. At the time we were developing our standards, there was very little guidance on tolerable risk criteria in the dam safety field. Thus, rather than try to come up with a definition of tolerable risk on our own, we decided to utilize design levels that would be consistent with the levels of safety provided by other engineering disciplines and governmental regulation. Because the actual levels of protection in many engineering applications are obscured by standards and codes (sometimes intentionally), the actual design levels and probabilities of failure had to be back calculated. This back calculation had been done for the establishment of performance goals in the design and evaluation of Department of Energy facilities[10]. That information, as well as other sources provided background information for setting the benchmarks shown in Figure 3.

Figure 3 – Benchmarks for Calibrating Point rating Algorithm For Use in Decision Framework

BENCHMARK	CHARACTERISTICS OF IDEALIZED PROJECTS	MINIMUM DESIGN STEP	DESIGN/PERFORMANCE GOAL AEP
1	1 or More Lives at Risk	3	3×10^{-4}
2	Large Dam, over 50 feet High No Downstream Hazard	3	3×10^{-4}
3	Intermediate Dam No Commercial Development 10 Residences at Risk	4	10^{-4}
4	Large Dam Limited Commercial Development 34 Residences at Risk	6	10^{-5}
5	Large Dam Significant Commercial Development 100 Residences at Risk	8	10^{-6}

Note: AEP - Annual Exceedance Probability

Additional guidance in setting design levels was obtained by examining the levels of risk to which the public is exposed to in ordinary life. Several of those risks are shown in Figure 4.

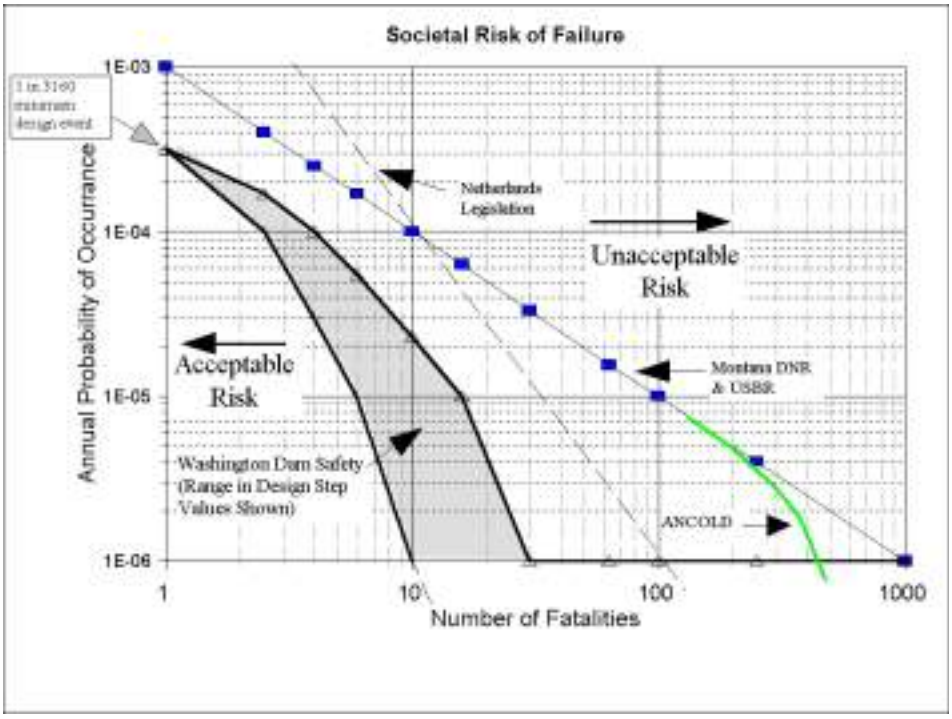

Figure 4 – Listing of Risks and Performance Levels

ACTIVITY/ITEM	TYPICAL NUMBER OF PERSONS AT RISK	RISK LEVEL	PERFORMANCE LEVEL
NATIONAL FLOOD INSURANCE PROGRAM • Risk from Natural Flooding	Varies Widely		1/100 AEP 100 Year Flood
FATAL DISEASE[3] • All Causes	1	1/120 AC	
ASCE STRUCTURAL CODE[4] • Performance of Individual Structural Members for Ordinary Buildings Subject to Natural Hazards due to Wind and Earthquake Loads	Typically 1-20		1/1000 AEP
EXISTING OFFSHORE DRILLING PLATFORMS[5] • Performance Subject to Wind, Wave and Earthquake Loads	Varies 0 – 25		1/1000 AEP
ACCIDENTAL DEATH[6] • All Causes	Few 1-3	1/2000 AC	
ACCIDENTAL DEATH[4] • Motor Vehicles	1-6	1/3000 AC	
ACCIDENTAL DEATH[4] • Non-Motor Vehicles	Few 1-3	1/6000 AC	
UNIFORM BUILDING CODE[7] • Performance of Essential Buildings such as Hospitals and Emergency Response Facilities to Maintain Building Functionality and Protect Occupants for Buildings Subjected to Wind and Earthquake Loads	Typically 50-200		1/5,000 AEP
BRITISH SPILLWAY DESIGN[8]	Small Community More than 30		1/10,000 AEP 10,000 Year Flood
DEPT. OF ENERGY BUILDINGS[9] • Performance of Building to Contain Radioactive or Toxic Materials and Protect Occupants for Buildings Subjected to Wind, Flood or Earthquake Loads	Varies - Often Large Numbers of People at Risk		1/10,000 AEP
DEPT. OF ENERGY BUILDINGS[7] • Very High Confidence of Containment of Radioactive and Toxic Materials and Protection to Occupants for Buildings Subjected to Wind, Flood or Earthquake Loads	Varies - Often Large Numbers of People at Risk Both Onsite and Offsite		1/100,000 AEP
NUCLEAR POWERPLANTS[10] • Damage to Core of Nuclear Powerplant from Earthquakes	Varies Potentially Very Large Numbers of People		1/100,000 AEP
AIR TRANSPORTATION[4] • Fatalities - All Aircraft	Varies 1-300	1/150,000 AC**	
AIR TRANSPORTATION[4] • Fatalities - Commercial Airlines	Varies 50-350	1/700,000 AC**	
NUCLEAR POWERPLANTS[8] • Performance Goal for Radioactive Releases Greater than 25 REM	Varies Potentially Very Large Numbers of People at Risk		1/1,000,000 AEP

Note: AC - Annual Chance of Occurrence AEP - Annual Exceedance Probability ** - Based on an "Average Traveler"

A review of both these tables shows a basic trend. In those activities where few lives are at risk, the public accepts nominal values of protection. Conversely, as the number of persons at risk and the consequences of a failure increase, the level of protection expected by society and the engineering profession increases significantly. This viewpoint is termed "risk-averse" with regard to loss of life. This is illustrated in Figure 6, which shows DSO criteria compared to other risk criteria such as Montana and the USBR[11], which are risk neutral (i.e., a constant value of risk of 1 in 1000 loss of life/year).

Figure 5 – Comparison of Societal Risk Criteria

Additive Point Rating Scheme

The next step in developing the risk-based standards was the development of an additive weighting scheme to determine numerical ratings of the consequences of dam failure. This scheme reflects the relative importance and range of severity of the impacts posed by each consequence. Cumulative rating points with values between 200 and 800 points were used to define the working range for the eight-step format. Factors were selected within the 3 general categories shown in Figure 6, which described the nature of the consequences of dam failure.

Utility curves or consequence rating tables were developed for each of the indicator parameters in Figure 6 to implement the additive weighting scheme. A worksheet (Appendix B, Ref 14) was then developed for compiling the rating points and selecting an appropriate design step. The point rating scheme was calibrated using a wide cross-section of project types and downstream settings to yield results (design steps) consistent with the 5 benchmarks shown in Figure 3.

Figure 6 – Numerical Rating Format for Assessing Consequences of Dam Failure

CONSEQUENCE CATEGORIES	CONSEQUENCE RATING POINTS	INDICATOR PARAMETER	CONSIDERATIONS
CAPITAL VALUE OF PROJECT	0 - 150	DAM HEIGHT	Capital Value of Dam
	0 - 75	PROJECT BENEFITS	Revenue Generation or Value of Reservoir Contents
POTENTIAL FOR LOSS OF LIFE	0 - 75	CATASTROPHIC INDEX	Ratio of Dam Breach Peak Discharge to 100 Year Flood
	0 - 300	POPULATION AT RISK	Population at Risk Potential for Future Development
	0 - 100	ADEQUACY OF WARNING	Likely Adequacy of Warning in Event of Dam Failure
POTENTIAL FOR PROPERTY DAMAGE	0 - 250	ITEMS DAMAGED OR SERVICES DISRUPTED	Residential and Commercial Property Roads, Bridges, Transportation Facilities Lifeline Facilities Community Services Environmental Degradation from Reservoir Contents (Tailings, Wastes.)

Probabilistic Design Data

Before we could implement the risk-based standards described above, magnitude-frequency relationships were needed for extreme events such as floods and earthquakes. Unfortunately, this type of information is not readily available to most states, and much work is still needed around the United States to develop probabilistic precipitation and seismic data for extreme events. In Washington State, we benefited from Dr. Mel Schaefer's detailed studies of extreme storms in the Northwest[12,13], and his development of probabilistic based procedures[14] for generating precipitation magnitude-frequency relationships for any location in the state. Thus, Washington State has the necessary hydrologic data to employ them in a logical and consistent manner in our risk based design/performance practice. This data is used in determining a design storm event with an appropriate AEP to match the design/performance step for the dam in question. This storm is then used to compute the inflow design flood to size the spillway(s) for a new project, or to determine the adequacy of the spillway for an existing dam.

In the seismic arena, we are encountering difficulties on design Step 1 and above in Western Washington and Step 3 and above in Eastern Washington in dealing with the population of existing dams. Our difficulties stem from the severity of the earthquake loadings projected for the Pacific Northwest. Seven interface earthquakes of Moment Magnitude (M_w) 8 or larger are believed to have struck the coast in the last 3500 years[15]. The last event in 1700 was estimated from Japanese tidal records to have been a M_w 9. Thus, all projects in the western half of the state must consider a seismogenic source capable of generating minutes of strong ground motion at a mean recurrence interval of 500 years. With the exception of California, Oregon and Alaska, few other states have to deal with such intense ground motion on so short a mean recurrence interval. In addition, the intensity and duration of shaking yields a high probability of liquefaction. Thus, a significant fraction of the analyses must predict the post-liquefied, deformation response of soils. This is an area of active research in the geotechnical profession. While data is being generated at considerable expense on high profile projects, little guidance is available for extrapolating to the small dams that comprise the majority of the projects under our purview.

Here, any rigorous assessment scheme would face the same difficulties confronting us. In much of the rest of the country the appreciably less intense seismic setting would minimize the difficulties of implementing our design step scheme.

Design Standards for Other Critical Elements

For critical elements at new dam projects where a design loading is not readily applicable (e.g. conduits, seepage), a qualitative approach is used, where redundancy and survivability concepts are employed to achieve adequate reliability against failure. For these critical elements on existing dams, a qualitative approach is used, rather than a quantitative assessment. This is achieved through review of the design and identification of deficiencies for the critical element, coupled with a qualitative assessment of the likelihood of failure based on past experience and engineering judgement. However, we are considering the utilization of some of the more formal risk assessment procedures for these elements currently employed by the Bureau of Reclamation.

Risk Prioritization Scheme

At the close of the 1980's, the Dam Safety Office had over 60 dams listed as having safety deficiencies. Many of these dams were projects inspected under the National Dam Safety Program from 1977-81, and had no action toward making repairs in 10 years. With such a large number of unsafe dams, and limited staffing, it became clear to the DSO that some way of prioritizing these projects was in order. Thus, in conjunction with the development of the risk-based standards described previously, in 1990 the DSO developed a prioritization ranking scheme for dams with safety deficiencies.

The scoring and ranking algorithm developed by the DSO is simple in concept and application, but was been found to be more than adequate for producing an initial ranking of projects. The algorithm is contained within our Microsoft Access database, and a report showing the ranking of projects can be generated by the touch of a key. This ranking is then used as a starting point where other project specific intangibles can be considered by management. The number of projects targeted for enforcement action at any time are chosen to maximize compliance, while not jeopardizing other critical functions of the dam safety program. Typically, this represents an active enforcement workload of about 10 projects.

The underlying logic in the development of this algorithm is fairly simple, and includes the following key ideas:

- For dams with similar deficiencies, those dams with the greatest consequences should be given higher priority.
- For dams with similar consequences, those dams with the more serious deficiencies should be given higher priority.
- For dams with similar deficiencies and similar consequences, those dams with a poorer chance for warning to the public should be given higher priority.
- Dams with only minor deficiencies should be ranked lower than dams with significant deficiencies, regardless of the consequences.
- The risk associated with three minor deficiencies is ranked just below that of one moderate deficiency.
- The risk associated with two moderate deficiencies is ranked just below that of one major deficiency.

- All things being equal, older dams should be given a higher priority.

These concepts were then incorporated into developing the equations for computing the number of priority points. Two different equations were developed for computing the priority points. The first equation is for dams where one or more of the safety deficiencies are rated moderate major or emergency. The second equation is for a project where all deficiencies are rated minor. These equations are shown in Figure 7. Rating points were then developed for the consequences, adequacy of warning, and seriousness of deficiencies, as shown if Figure 8. The points were selected and calibrated to meet the underlying logic goals discussed previously.

Figure 7: Equations for Prioritization Ranking

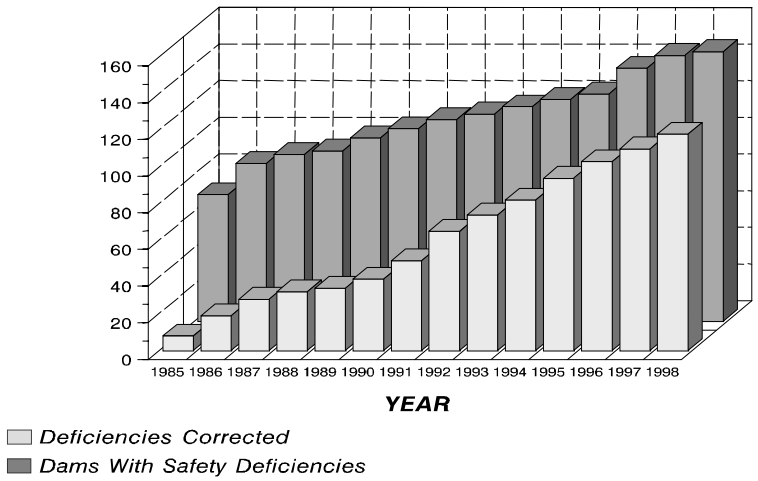
One or More Safety Deficiencies Rated Moderate, Major or Emergency	**Priority = [*Hazard Class*] + [*Warning*] + [∑(*Seriousness of Deficiencies*)] + [*Agel2*]**
All Safety Deficiencies Rated Minor	**Priority = 0.5 ∗[[*Hazard Class*] + [*Warning*] + [∑(*Seriousness of Deficiencies*)] + [*Agel2*]]**

Figure 8: Rating Points for Prioritization

RATING POINTS FOR CONSEQUENCES – BY HAZARD CLASS	
High Hazard	
Hazard Classification 1A - (100+ homes at risk)	500 points
Hazard Classification 1B – (11-99 homes at risk)	400 points
Hazard Classification 1C – (3-10 homes at risk)	300 points
Significant Hazard	
Hazard Classification 2 – (1 or 2 homes at risk)	200 points
Low Hazard	
Hazard Classification 3 – (0 homes at risk)	100 points
RATING POINTS FOR ADEQUACY OF WARNING	
Inadequate Warning – (< 10 minutes advanced warning)	100 points
Marginal Warning – (between 10 and 30 minutes)	50 points
Adequate Warning – (greater than 30 minutes)	0 points
RATING POINTS FOR SERIOUSNESS OF EACH DEFICIENCY (Primary focus on deficiencies that could lead to a dam failure or uncontrolled release of reservoir)	
Emergency Condition	250 points
Major Deficiency	145 points
Moderate Deficiency	65 points
Uncertain Seriousness	65 points
Minor Deficiency	20 points

The seriousness of safety deficiencies are evaluated based on the matrix in Figure 9. This matrix is intended for guidance only, and ultimately, the final rating of seriousness of deficiencies is based on knowledge of the project and on engineering judgement.

Figure 9 – Matrix for Evaluating Seriousness of Deficiencies



CONDITION	HYDRAULIC ADEQUACY	EMBANKMENT STABILITY	SEEPAGE ON EMBANKMENTS, FOUNDATION, ABUTMENTS	OUTLET CONDUIT(S)
SATISFACTORY	Can accommodate IDF	Meets criteria for static & seismic stability	Minimal seepage consistent with past behavior	KSU Conduit Rating > 8
MINOR DEFICIENCIES	Can only accommodate flood 1 step below Design Step	Meets criteria for static stability, marginal seismic stability under design earthquake	Minor seepage quantity, inconsistent with past behavior No evidence of internal erosion	KSU Conduit Rating 6-8
MODERATE DEFICIENCIES	Can only accommodate flood 2 steps below Design Step	Marginal static stability 1.3 < FS < 1.5 inadequate seismic stability or liquefaction under design earthquake	Moderate seepage quantity Or Anomalous increase in quantity Minor concerns of piping	KSU Conduit Rating 4-6
MAJOR DEFICIENCIES	Can only accommodate flood 3 steps below Design Step	Inadequate static stability 1.0 < FS < 1.3 inadequate seismic stability or liquefaction under design earthquake	Relative Large Seepage Quantity Multiple Points of Seepage And/or Significant concern of piping	KSU Conduit Rating 2-4
EMERGENCY	Cannot Accommodate 25-year Flood	Significant slope failures that intercept dam crest or involve major portion of the embankment	Large or rapidly changing seepage quantity Multiple points of seepage and ongoing piping	KSU Conduit Rating 0-2

CONCLUSIONS

Since its implementation in 1990, the use of the risk-based standards approach has been quite successful in Washington State. It has provided a consistent level of protection against failure between projects located across the state, despite significant differences in seismicity and rainfall. For new dams, we have been able to apply risk concepts in a standards-based approach that is fairly straightforward and easy to use.

For the evaluation of existing dams, we have been able to utilize a combination of probabilistic methods, risk concepts and risk-based standards to determine if the dam has an adequate level of protection against failure. If dams do not meet state standards, we are able to estimate the relative level of risk they currently pose, and prioritize our compliance efforts on those projects with the greatest risk. It has also allowed us to inform dam owners not only that their dams are “unsafe”, but also educate them as to what level of risk their unsafe project poses to the downstream public. In addition, we have utilized a prioritization scheme for compliance efforts on unsafe dams, based on the relative risk of each project. These combined approaches have resulted in great progress in repairing the backlog of dams with identified safety deficiencies in the State of Washington. For example, of the 46 dams inspected under the National Dam Inspection Program still listed as unsafe in 1990, 40 had been repaired by 1999. In addition, 78 of the 101 additional dams identified by the state dam safety program since 1985 have been repaired. Figure 10 shows the cumulative summary of corrective action since 1981.

Figure 10 – Cumulative Number Of Dams Repaired in Washington Since 1981

ASPECTS OF RISK ASSESSMENT THAT MAY BE VALUABLE TO STATE PROGRAMS

Based on our experience, we feel that several aspects of risk assessment and risk management can be of benefit to other dam safety organizations. No matter what standards are used, all dam safety professionals are in the business of managing risk, and the more knowledgeable we are about risk, the better we can make decisions that protect public safety. Using probability and risk concepts allows a dam safety professional to understand the risks and manage them better.

At the 1999 ASDSO/FEMA Specialty Workshop on Risk Assessment for Dams in Logan, Utah, several areas were identified as being potentially of use to state dam safety programs. The areas showing the most promise for the states included qualitative risk assessments such as Failure Mode Evaluation and Analysis (FMEA), prioritization and portfolio approaches, and developing risk-based standards for spillway and/or seismic design, as in Washington and Montana. These areas are highlighted as follows:

- FMEA can be a useful tool, even for those regulators that exclusively use deterministic standards. FMEA allows the regulator a better understanding of the potential site-specific failure modes, the possible failure scenarios and potential consequences, and effective risk reduction measures and dam safety related actions.
- Risk prioritization and portfolio approaches, such as Washington's, can be valuable tool for states to manage their limited resources toward fixing unsafe dams. Using a prioritization scheme, unsafe projects can be ranked for compliance and enforcement activity, based on the risk that they pose to downstream population. The most critical projects can then be targeted for enforcement action.
- Washington's risk-based standards approach may be of interest to some states, especially in spillway design. In fact, Montana's dam safety program has used our example to develop risk based spillway standards of their own. The drawback to implementing these standards on a broader scale is the current lack of probabilistic precipitation data in the U.S. beyond the 500-year event. It can be quite expensive for states to undertake this effort on their own. The Logan workshop identified the need for large-scale regional studies to be performed for probabilities of extreme rainfall events across the U.S. If these studies are completed, then it may be more attractive for some states to implement risk-based spillway standards.

- States using %PMP as a design level for analysis of spillways are already using a non-deterministic standard and by default are accepting risk, but the probability of the %PMP event, and corresponding risk to public safety is unknown. These states may benefit from the aforementioned regional precipitation studies, which would allow them to learn the probability of their %PMP standards. Depending on the results, the states may elect to go to risk-based standards, or may decide to adjust the percentage of PMP to increase or decrease the risk level.

- Quantitative risk assessment is not likely to be a useful tool for most state dam safety programs, due to the lack of probabilistic data, inadequate staffing levels, and amount of effort required to perform an assessment for each dam. Most states regulate a large number of small to medium sized dams, and would not have adequate staffing or resources to complete comprehensive studies on each dam.

ACKNOWLEDGEMENTS

The revisions and updates to Technical Note 3 were accomplished under the authorship of Melvin Schaefer, Ph.D., P.E., and Bruce Barker, P.E., of MGS Engineering Consultants, Olympia, Washington.

The original Technical Note 3 was compiled in 1993 under the leadership and principal authorship of Dr. Schaefer, supervisor of the Department of Ecology's Dam Safety Section at that time.

OVERVIEW

This Technical Note provides engineering guidance for developing design storms for use in computing Inflow Design Floods (IDFs) using rainfall-runoff computer models. It is a companion document to Technical Note 2, *Selection of Design/Performance Goals for Critical Project Elements*[24], and to Chapter 2.4 of *Part IV* of the *Dam Safety Guidelines* on the computation of Inflow Design Floods.

Originally published in April 1993, the procedures in the original Technical Note 3 were based on the findings of two studies that had been completed in the early 1990s. Site-specific precipitation-frequency estimates were based on the findings of a regional precipitation-frequency analysis that was published in *Regional Analyses of Precipitation Annual Maxima in Washington State*[18]. The temporal patterns of design storms were based on the findings of an analysis of 252 storms, which were published in Ecology Report 89-51, *Characteristics of Extreme Precipitation Events in Washington State*[19].

The original Technical Note 3 was based on storm data collected from 1940-1986. Nearly 20-years have now passed, and in that time, many noteworthy storms have occurred and new technologies have become available. These changes warranted an update of Technical Note 3 to incorporate the additional information and improved techniques.

Of particular note, regional precipitation-frequency analyses were completed in 2006 for Washington State (Schaefer[20, 21]) using more than 700 precipitation gages and high-resolution spatial mapping techniques within a GIS framework. This has resulted in increased reliability for developing site-specific precipitation-frequency estimates.

A study of short-duration precipitation in the Seattle area was completed in 2003 (Schaefer[22]) that provided the first comprehensive examination of the magnitude of 5-minute, 10-minute, and 15-minute precipitation maxima within short, intermediate, and long-duration storms in Western Washington. This has increased the reliability of specifying the high-intensity portions of design storms for Western Washington.

Lastly, analyses have been conducted for the temporal characteristics of 142 noteworthy storms that occurred in the period from 1986 to 2007. Thus, this update of Technical Note 3 is now based on a database of 394 storms for the short, intermediate, and long-duration storms for the various climatic regions across Washington State.

1. INTRODUCTION

Developing candidate design storms is a key step in creating a rainfall-runoff model for computing an Inflow Design Flood (IDF). In particular, the amount and timing of precipitation of a storm are usually dominant factors in determining the size of the resultant flood.

If a project under design/evaluation has a small reservoir relative to the potential runoff of the contributing watershed, then flood peak discharge is normally the controlling consideration. Precipitation intensity is usually the primary consideration in developing the design storm for this case.

In contrast, if the reservoir is very large relative to the potential runoff of the contributing watershed, then runoff volume will be the controlling factor. The total volume of precipitation is then the primary consideration.

For most real world situations, projects are sensitive to various combinations of flood peak discharge and runoff volume. Therefore, both precipitation intensity and volume must be considered in developing design storms.

In the Northwest, considerations of precipitation volume and intensity are further complicated by seasonal effects, which must be accounted for in rainfall-runoff modeling. Short duration thunderstorms, which can contain very high precipitation intensities, typically occur in the warm season. Conversely, the long duration general storm events occur primarily in the winter months. These are characterized by large precipitation volumes but relatively moderate and uniform intensities. To accommodate these meteorological characteristics, it is normally necessary to develop several candidate design storms, representing various storm durations, intensities, and volumes. This allows a determination of the controlling event for design/evaluation of spillway size and hydraulic adequacy.

This technical note is intended to provide engineering guidance in developing candidate design storms that reflect the diversity of storm duration, intensity and volume found in the Northwest.

1.1 TERMINOLOGY

A variety of terms are needed to describe the characteristics of design storms. The following selected terms are defined to clarify their meaning in this technical note and *Part IV of the Dam Safety Guidelines* regarding *Dam Design and Construction.*

At-Site - Refers to site-specific characteristics as distinguished from regional characteristics. When used in the context of regional analyses, it refers to precipitation characteristics at a specific measurement recording station or geographic location of interest.

Annual Exceedance Probability (AEP) - The chance that a specified magnitude of some phenomenon of interest is equaled or exceeded during a given year. Herein, AEP refers to the chance that a specified magnitude of precipitation will be equaled or exceeded during a given year. For example, in Olympia, Washington, a 24-hour precipitation depth of 5.3 inches has an AEP of 0.01. Stated another way, there is one chance in one-hundred that 5.3 inches of precipitation or more will fall in Olympia in some 24-hour period in any given year.

Candidate Design Storm - A hyetograph that is used in rainfall-runoff modeling to examine the flood response of a watershed and the response of a project's reservoir and spillways. The candidate design storm that produces the most stringent loading condition for a project's reservoir and spillway(s) is deemed the Design Storm.

Depth-Duration Curve - A precipitation mass curve constructed in a manner whereby the largest incremental precipitation amounts are located at the start of the mass curve and progressively smaller amounts are accumulated to produce the remainder of the curve (see also reference 24).

Design Step - An integer value from one through eight that is used as an index for increasingly stringent design/performance goals. The design step is used to set design events and loading conditions for critical project elements such as spillways.

Design Storm - The hyetograph, depicting the precipitation volume, intensities, and duration, used in rainfall-runoff modeling to generate the Inflow Design Flood for determining the hydraulic adequacy of a project.

General Storm - A generic term for precipitation produced over large areas by synoptic scale weather features such as cyclones and associated fronts.

Hyetograph - A graphical representation of precipitation as it occurs with time. It may be for a specific location or represent an average over a specified area. It may be

discretized or continuous over time, displaying either precipitation intensities, incremental precipitation or accumulated precipitation.

Interduration - A generic term used for specifying some period of time within a storm. For example, there may be interest in the greatest precipitation amount (precipitation maxima) within any given 1-hour period (the 1-hour interduration) within a long-duration storm.

Intensity Index - A dimensionless measure of the precipitation intensity used in dimensionless design hyetographs to graphically characterize the precipitation intensity. Actual intensities are obtained by multiplying the intensity index values by the applicable value of the 2-hour, 6-hour, or 24-hour *Precipitation Scaling Depth* for the short, intermediate, and long-duration design storms respectively.

Intermediate-Duration Precipitation Event - A precipitation event where the duration of precipitation typically persists from 6 to 18 hours. When used in the context of a design storm, this term refers to 18-hour events which are characterized by moderate to high rainfall intensities, contain a large total precipitation volume.

Large Watershed - For purposes of this technical note, a large watershed is large enough that a storm's spatial distribution may vary significantly over the watershed and must be accounted for explicitly. Generally, these watersheds exceed 10 mi^2 for a long-duration or intermediate-duration storm design event, and larger than 1 mi^2 for a short-duration thunderstorm design event.

Local Storm - A storm comprised of an isolated convective cell or group of cells, commonly referred to as a *Thunderstorm*. These storms can produce very high precipitation intensities over localized areas. Its occurrence is unrelated to any synoptic weather feature such as a cyclone or associated front.

Long-Duration Precipitation Event - A precipitation event that typically persists from 24 to 72 hours. When used in the context of a design storm, this term refers to 72-hour events characterized by relatively moderate and uniform intensities, containing a very large total volume.

Orographic Precipitation - Precipitation that occurs from lifting of atmospheric moisture over mountain barriers.

Precipitation Magnitude-Frequency Curve - A graphical description of the relationship between precipitation magnitude (depth or volume) and annual exceedance probability. Also called a precipitation-frequency curve.

Precipitation Depth - The amount of precipitation, expressed in inches or millimeters, that would collect in a standard measuring device. It is synonymous with point rainfall. When used in connection with a geographic area, such as a watershed, it represents the average precipitation depth over the entire area.

Precipitation Intensity - The rate of precipitation expressed in inches/hour or millimeters/hour.

Precipitation Scaling Depth - The watershed-specific precipitation depth used to scale a dimensionless design hyetograph to the magnitude of interest for the specified Design Step. Precipitation scaling depths for the 2-hour, 6-hour, and 24-hour duration are used for scaling the short-duration, intermediate-duration and long-duration dimensionless design hyetographs, respectively.

Probable Maximum Precipitation (PMP) - Theoretically, the greatest depth of precipitation for a given duration that is physically possible over a given size storm area at a particular geographical location at a certain time of the year (National Weather Service[14] definition).

Short-Duration Precipitation Event - A precipitation event lasting from 30 minutes to 6 hours. When used in the context of a design storm, this term commonly refers to thunderstorm events characterized by short bursts of very high rainfall intensities, often with limited total volume occurring over isolated areas.

Small Watershed - For purposes of this technical note, a small watershed is small enough that the spatial variability of precipitation over the watershed is not significant. This corresponds to watersheds smaller than 10 mi^2 when a long-duration or intermediate-duration storm is the design event, and watersheds smaller than 1 mi^2 when a short-duration thunderstorm is the design event.

Storm Characteristics – A generic term that encompasses a variety of statistical measures of features of interest about a storm. This would include such measures as: the elapsed time from onset of precipitation to the occurrence of the maximum intensity; the sequencing of precipitation amounts for 5-minute increments during the 15-minute period of maximum precipitation in the storm; the greatest 1-hour precipitation amount as a proportion of the maximum 24-hour amount; and for

long-duration intermittent storms, the length of the dry period between successive major blocks of precipitation.[1]

Thunderstorm - A generic term for precipitation produced by a convective storm event where thunder is heard. Thunderstorms in the Pacific Northwest are characterized by high precipitation intensities occurring over relatively small areas for short periods of time. They may be accompanied by hail and lightning. (Also see local storm.)

Total Precipitation Depth - The total precipitation amount within a design storm. The total precipitation depth is larger than the precipitation scaling depth for a design storm.

1.2 GENERAL GUIDANCE IN APPLYING CANDIDATE DESIGN STORMS

For most investigations, it is necessary to develop several candidate design storms to analyze the response of the reservoir and spillway(s) to various flood characteristics. The principal storm characteristics that affect the flood peak discharge, runoff volume, and flood hydrograph shape are the intensity, volume, and duration of precipitation. The diversity of these characteristics for storms in Washington can be suitably described using three candidate storms, one for each of three durations. The terms Short-Duration, Intermediate-Duration, and Long-Duration are used to differentiate between the durations of the candidate design storms.

It will be seen later that the precipitation amounts for the 2-hour, 6-hour, and 24-hour durations are used to scale the dimensionless hyetographs for the short, intermediate and long-duration candidate design storms, respectively.

The following general guidance is provided for applying candidate design storms to the design/evaluation of spillway size, hydraulic adequacy, and/or reservoir floodwater storage capacity. This guidance is based on past experience in rainfall-runoff modeling using the design storm procedures described here. However, this does not preclude the user from investigating the flood response from other candidate design storms or historical storms as deemed necessary to determine the controlling event.

[1] See *Characteristics of Extreme Precipitation Events in Washington State*[19] for a detailed discussion of storm characteristics.

1.2.1 Western Washington

Long-duration storms are commonly the controlling design events in Western Washington. This is particularly the case when the reservoir has a relatively large storage volume relative to the runoff potential of the tributary watershed. It is always the design event for off-channel storage reservoirs with minimal tributary watershed area.

Projects with small storage capacity relative to the runoff potential of the tributary watershed are sensitive to flood peak discharge. In these situations, the higher intensities in intermediate-duration storms may become the controlling consideration.

Short-duration thunderstorm events usually do not produce sufficient runoff volume to be the controlling event for project spillways. Stormwater detention facilities in urban areas are the possible exception. In this situation, there may be a high percentage of impervious area, which could make the peak discharge from a short-duration event the controlling consideration.

1.2.2 Eastern Washington

The short duration thunderstorm is commonly the controlling design event in Eastern Washington when the tributary watershed is less than about 20 mi^2. The very high intensities in these storms can produce very large flood peak discharges, which often becomes the dominant consideration in sizing the spillway(s).

The long-duration storm is usually the controlling design event when the tributary watershed is very large or when the reservoir storage capacity is large relative to the runoff potential of the tributary watershed. The long-duration storm is always the design event for off-channel storage reservoirs where there is minimal area tributary to the reservoir. Intermediate-duration storms in Eastern Washington are occasionally found to be the controlling event for design of project hydraulic works.

1.2.3 Design Storm Spatial Distribution

There are two basic approaches used in rainfall-runoff modeling to describe the spatial (areal) distribution of precipitation over the watershed. The most commonly used approach is a "lumped" method where a single temporal distribution of precipitation is used and is expressed in terms of basin-average values. This approach is well-suited to situations where the variability of precipitation depth and temporal distribution does not vary greatly over the watershed. The second approach is a "distributed" method where precipitation depth and the temporal distribution of precipitation vary over the watershed. The variation in precipitation depth and temporal distribution may be allocated on a grid-

cell or polygon basis or may vary by sub-basin depending on the computational structure of the watershed model.

The vast majority of impoundments in Washington reside in small watersheds. As used here, the term *small watershed* refers to the size of the watershed relative to the areal coverage of the storm. In these cases, it is often reasonable to use a lumped method where a single hyetograph describes the temporal distribution of precipitation over the watershed. Since most state regulated dams are on small watersheds, the procedures described here are intended for application of a lumped approach.

The areal reduction factors listed in Table 1[13, 19] may be used for computing basin-average values from point precipitation values. The range of watershed sizes shown in Table 1 may be used as general guidance for the limit of using a lumped method. Specifically, areal adjustments are needed when the watershed under investigation exceeds 10 mi^2 and a long-duration or intermediate-duration storm is the design event. Areal adjustments are also needed when the watershed under investigation is larger than 1 mi^2 and a short-duration thunderstorm is the design event. Additional information on storm attenuation and areal adjustments can be found in *Characteristics of Extreme Precipitation Events in Washington State*[19], HMR-57[14], and NOAA Atlas 2[13].

For large watersheds, there will be cases where it is reasonable to explicitly depict the spatial distribution of precipitation over the watershed. For those cases, GIS-based isopluvial maps have been provided as part of this Technical Note, which are available from Ecology's Dam Safety Office.

Table 1 – Areal Adjustment Factors to Account for Storm Spatial Distribution as a Percentage of At-Site Precipitation Amount

WATERSHED SIZE	STORM INTERDURATION									
	¼-HR	1-HR	2-HR	3-HR	6-HR	12-HR	18-HR	24-HR	48-HR	72-HR

2. SELECTING THE DESIGN STEP

Technical Note 2, *Selection of Design/Performance Goals for Critical Project Elements*[24] discusses the procedures for selecting the Design Step. Technical Note 2 also explains the relationship between the design steps and the design/performance goals. The Design Step format as applied to design storms is reproduced here for convenience (Figure 1).

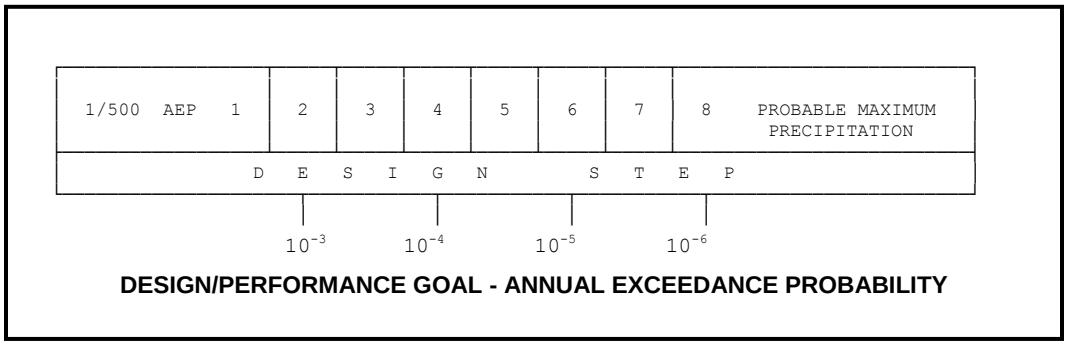

Figure 1 – Design Step Format as Applied to Design Storms

2.1 RELATION OF DESIGN STEP TO PROBABLE MAXIMUM PRECIPITATION

When Design Step 8 is indicated as the appropriate design level, Probable Maximum Precipitation (PMP) is used as the precipitation scaling depth. PMP values are obtained from HMR-57[14] and the design storm may be assembled using HMR-57 procedures or dimensionless design storms may be used from this Technical Note. However, use of PMP values from HMR-57 does not necessarily provide a level of protection equal to a design/performance goal of 10^{-6} AEP.

Since PMP is a deterministic procedure that does not employ probabilistic methods, there is not a fixed relationship between PMP and annual exceedance probability. A comparison of the findings of the recent regional precipitation analysis for Washington (Schaefer et al[20, 21]) with PMP estimates (HMR-57[14]) indicates that the AEP of PMP varies widely across Washington. The AEP of PMP varies with both geographic location and duration, from a minimum of about 10^{-5} AEP to perhaps 10^{-8} AEP.

2.1.1 Constraints on Applying PMP and Design Step

PMP values are estimates. Those estimates, like probabilistic estimates, are subject to uncertainties. Recognizing these uncertainties and the very large variability across Washington in the level of protection afforded by PMP, it was determined that PMP applications must also meet a minimum design/performance goal. This requirement improves consistency of application and avoids the potential for under-design. Therefore, when Design Step 8 is indicated and PMP is selected, the actual precipitation value used in design must be at least as large as that associated with an event with a computed AEP of 10^{-5} (Design Step 6).

Situations may also arise when the precipitation magnitude for the chosen Design Step exceeds the PMP estimate. In these cases, the PMP value is used as the precipitation scaling depth for developing the design storm.

3. COMPUTING PRECIPITATION FOR SCALING CANDIDATE DESIGN STORMS

Studies over past decades have shown that regionalization techniques (Hosking and Wallis[10], National Research Council[25], Potter[16], and Stedinger et al[23]) are vastly superior for estimating magnitude-frequency characteristics than past practices of single station analyses. The procedures used here to provide site-specific precipitation magnitude-frequency estimates are based on regional analysis procedures contained in *Regional Precipitation-Frequency Analysis and Spatial Mapping of Precipitation for 24-Hour and 2-Hour Durations in Western and Eastern Washington* (Schaefer et al[20, 21]). This was a statewide study completed in 2006 for the Washington State Department of Transportation.

3.1 COMPUTING PRECIPITATION-FREQUENCY RELATIONSHIPS

The first step in developing a candidate storm is to determine the precipitation depth, for the selected location and storm duration, to use for scaling the candidate design storm. Gridded GIS datasets for a grid-cell resolution of approximately 0.23 mi^2 were developed as part of the statewide regional precipitation-frequency analysis. A separate gridded dataset was developed for 2-hour, 6-hour, and 24-hour precipitation maxima for the 10-yr, 25-yr, 100-yr, and all 8 Design Steps. These gridded datasets are available as part of this Technical Note. Figure 2 depicts a color-shaded isopluvial[2] map for 24-hour precipitation maxima for the 100-year recurrence interval, created from a gridded dataset.

These datasets can be queried to produce a precipitation-frequency relationship for the site of interest and obtain the precipitation scaling depths for construction of candidate storms. Queries of the gridded datasets can be made using standard GIS software or software that is available through the Dam Safety Office. Figure 3 depicts a precipitation-frequency relationship for 24-hour precipitation maxima for a site near Olympia, Washington. Precipitation-frequency relationships can be developed for 2-hour and 6-hour precipitation maxima in a similar manner for scaling short-duration and intermediate-duration candidate storms, respectively.

[2] A line on a map drawn through geographical points having the same rainfall or precipitation index.

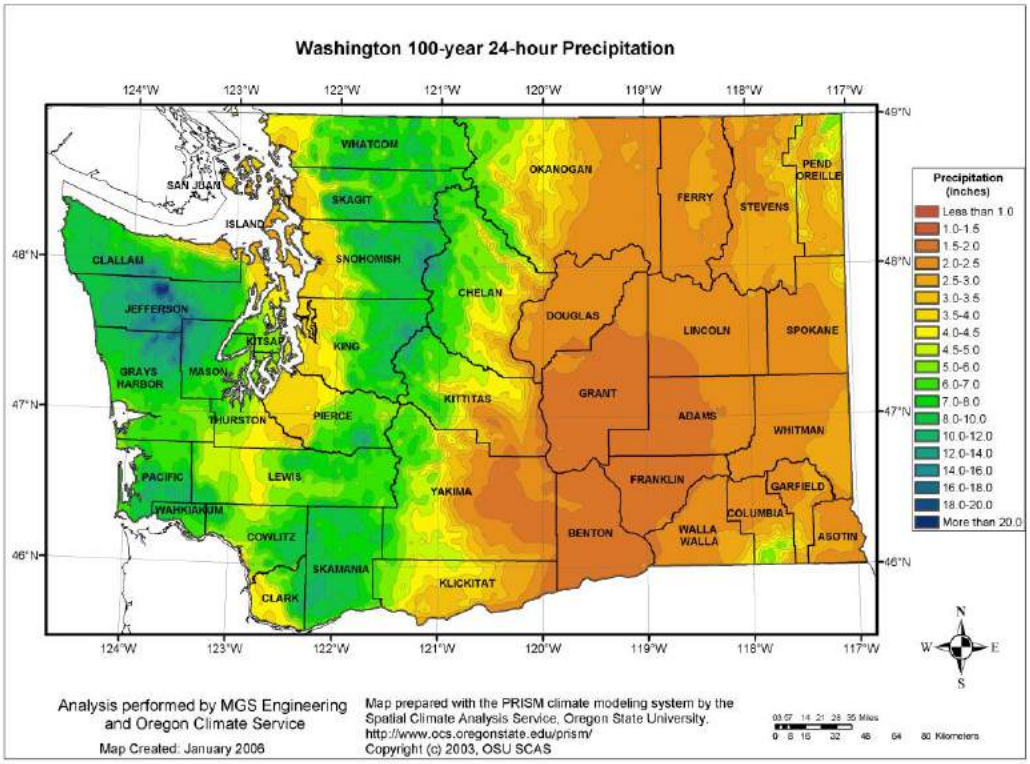

Figure 2 – Color-Shaded Isopluvial Map of 24-Hour Precipitation Maxima for Washington State, 100-Year Recurrence Interval

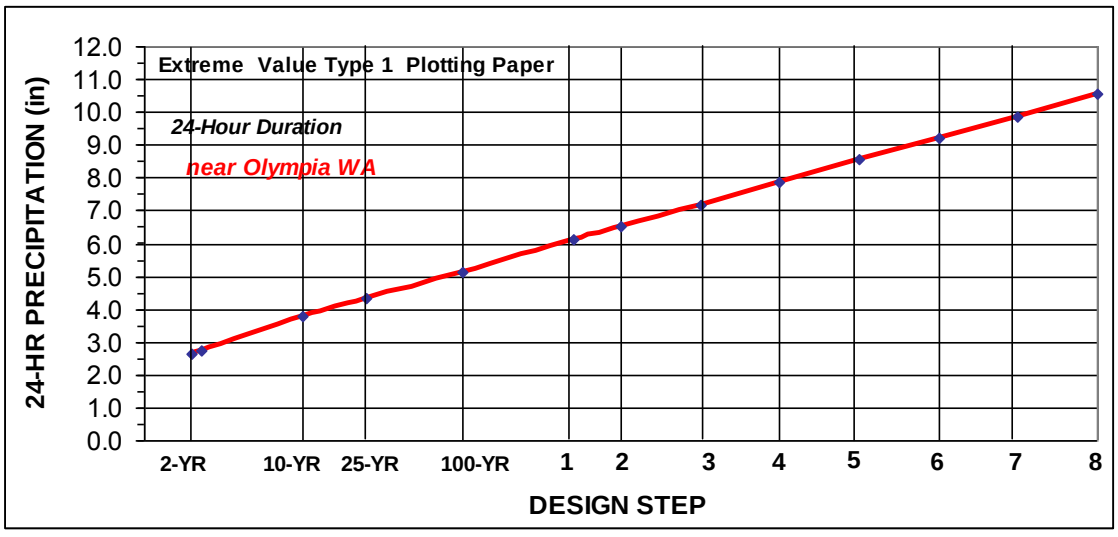

Figure 3 – Precipitation-Frequency Relationship for 24-hour Precipitation Maxima for a Site near Olympia, Washington

3.1.1 Large Watersheds

For large watersheds, a basin-average precipitation value is used for scaling in developing a candidate design storm. A basin-average precipitation value is obtained using GIS software and intersecting the polygon for the watershed boundary with the appropriate gridded precipitation dataset for the selected Design Step. A basin-average value is computed from an areal weighting of the precipitation values for the grid-cells within the watershed. To develop a spatial distribution of precipitation for use with a distributed watershed model, the spatial distribution from the gridded dataset provides a logical starting point.

3.1.2 Design Usage

The gridded precipitation datasets provide expected values (best-estimates) based on the regional solutions for each grid-cell location. In engineering design applications, it is common practice to incorporate some design conservatisms to account for uncertainties and to provide protection from under-design. For probabilistic methods, accounting for uncertainties usually employs some type of confidence interval. Monte Carlo analyses have been conducted to investigate the uncertainties associated with precipitation estimates based on the at-site and regional statistics used to make quantile estimates.

Based on these findings, it was determined that an overage of 15 percent would provide about an 80 percent level of protection from under-design. Thus, all precipitation values obtained from the gridded precipitation datasets which are to be used in a design application are to be increased by 15 percent as shown in Equation (1).

$$P_{sd} = 1.15\, P_{gds} \qquad \text{Equation (1)}$$

where:
- P_{sd} = Precipitation amount to be used for scaling in developing a candidate storm for design application (*precipitation scaling depth*)
- P_{gds} = Precipitation value obtained from gridded dataset for the chosen Design Step

4. DEVELOPING CANDIDATE DESIGN STORMS

A hyetograph describes the time history of precipitation depth or intensity at a given location or over a specific area. The hyetograph is the standard form to input precipitation into rainfall-runoff computer models. The temporal and spatial distribution of precipitation, as described by a hyetograph, are inherently stochastic (random) and vary widely from storm to storm. Therefore, it is important that hyetographs used in design or evaluation of a project be developed using probabilistic procedures. This allows incorporation of storm characteristics that reflect the manner in which extreme storms have historically occurred (Schaefer[19]).

The procedures used here for constructing hyetographs are based on probabilistic analyses of 394 extreme storms in Washington from the period 1940-2006. A thorough discussion of those procedures is contained in *Characteristics of Extreme Precipitation Events in Washington State*[19]. Information and procedures from that document have been used to develop dimensionless hyetographs for small watersheds.

The simplified methods presented in Section 4.2.2 will allow the user to easily assemble candidate design storms using the library of dimensionless design hyetographs available through Ecology's Dam Safety Office.

4.1 DIMENSIONLESS DESIGN HYETOGRAPHS

As discussed previously, it is usually necessary to develop several candidate design storms to analyze the response of the reservoir and spillway(s) to various flood characteristics. The principal storm characteristics which affect the flood peak discharge, runoff volume, and hydrograph shape are the precipitation intensity, volume and duration. The diversity of these storm characteristics can be suitably described using several candidate storms, reflecting a range of storm durations. The following sections present information and procedures for scaling dimensionless design hyetographs to create short, intermediate, and long-duration candidate design storms. Applying the design storms in rainfall-runoff models is discussed in Chapter 2.4 of *Part IV* of the *Dam Safety Guidelines*, titled *Inflow Design Flood*.

4.1.1 Dimensionless Design Hyetographs Organized by Climatic Region

Climatic regions are geographic areas with similar climatic and topographic characteristics that result in storms having similar storm characteristics. One of the major changes that affected this Technical Note was a refinement of the climatic region delineation contained in the 2006 regional precipitation-frequency analysis (Schaefer

et al[20, 21]). This required regrouping of the 252 historical storms that were analyzed in Ecology Report 89-51 (Schaefer[19]). Similarly, the 142 historical storms observed in the period from 1986-2006 were grouped according to the new climatic regions, and analyzed according to procedures described in the report 89-51. Separate analyses were then conducted for each climatic region for each of the three storm durations.

The dimensionless design hyetographs used to develop candidate design storms are organized according to climatic region and duration (short, intermediate, and long). Thus, the user must first identify the climatic region where the project watershed is located in order to select the appropriate dimensionless design hyetograph. Climatic regions (shown in Figure 4) and boundaries are described below.

Climatic Regions for Western Washington

Region 5 **- Coastal Lowlands** – The lowlands along the west coast of Washington, Oregon, and Vancouver Island open to the Pacific Ocean. The eastern boundary is either a generalized contour line of 1,000 feet elevation, or the ridgeline of mean annual precipitation that separates the coastal lowlands from the interior lowlands, such as within the Aberdeen-Montesano gap.

Region 151 **- Coastal Mountains West** – The windward faces of the Olympic Mountains, Willapa Hills, Black Hills, Coastal Mountains in Oregon, and Vancouver Island Mountains in British Columbia above a generalized contour line of 1,000 feet elevation. These areas are bounded to the west by the 1,000 feet contour line, and bounded to the east by the ridgeline of mean annual precipitation near the crestline of the mountain barrier.

Region 142 **- Coastal Mountains East** – The leeward faces of the Olympic Mountains, Willapa Hills, Coastal Mountains in Oregon, and Vancouver Island Mountains in British Columbia above a generalized contour line of 1,000 feet elevation. These areas are bounded to the west by the ridgeline of mean annual precipitation near the crestline of the mountain barrier, and bounded to the east by the 1,000 feet contour line. This also includes isolated mountain features such as the Black Hills.

Region 32 **- Interior Lowlands West** – The interior lowlands below a generalized contour line of 1,000 feet elevation bounded to the east by the trough-line of mean annual precipitation through the Strait of Juan De Fuca, Puget Sound Lowlands and Willamette Valley. This is a zone of low orography where mean annual precipitation generally decreases from west to east.

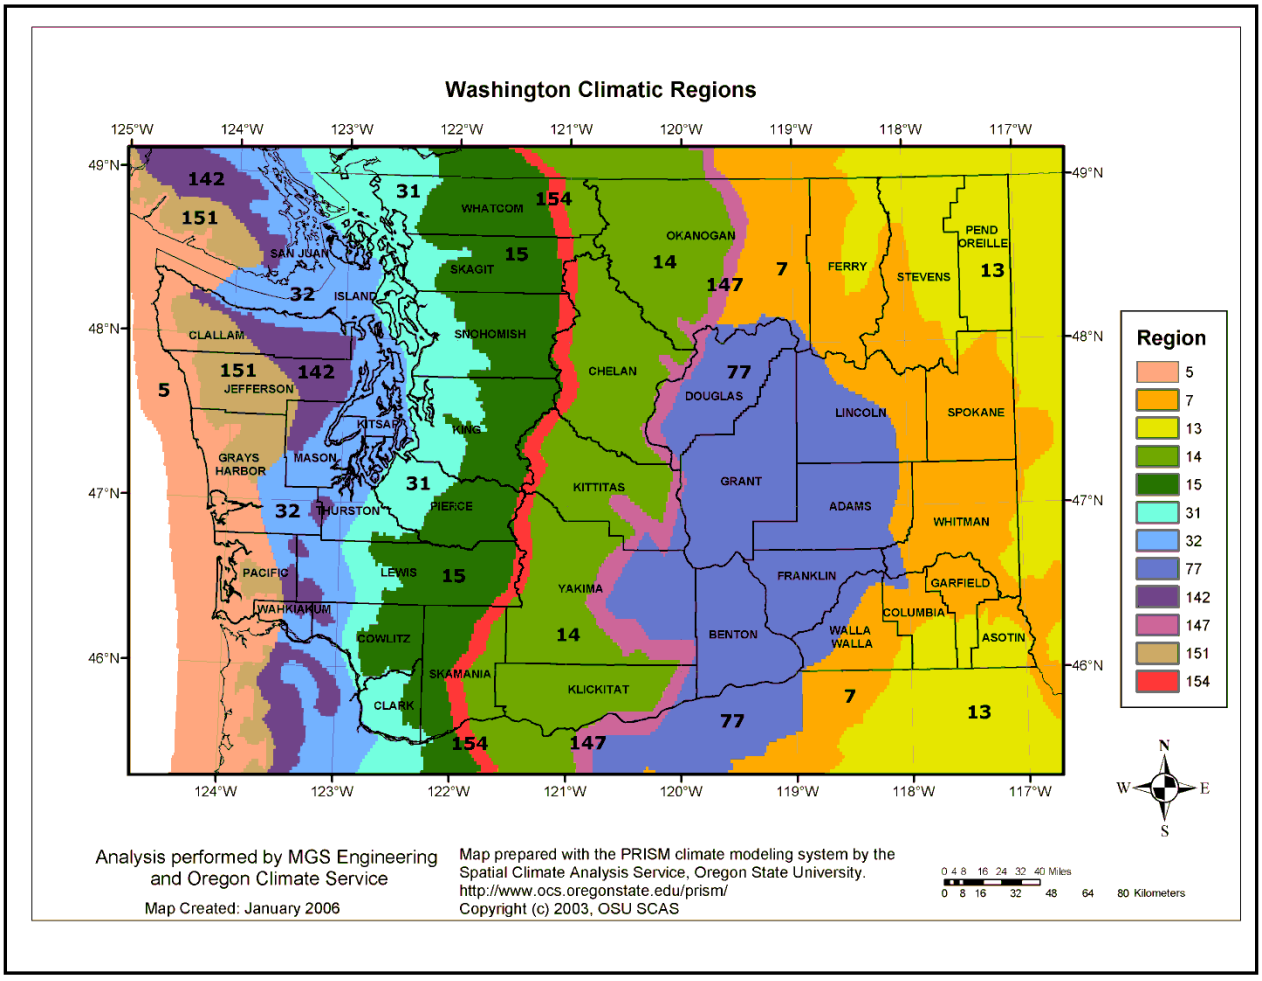

Figure 4 – Delineation of Climatic Regions and Transition Zones for Washington State and Surrounding Areas

Region 31 **- Interior Lowlands East** – The interior lowlands below a generalized contour line of 1,000 feet elevation bounded to the west by the trough-line of mean annual precipitation through the Strait of Juan De Fuca, Puget Sound Lowlands, and Willamette Valley. This is a zone of low orography where mean annual precipitation generally increases from west to east.

Region 15 **- West Slopes of Cascade Mountains** – This region is comprised of the windward face of the Cascade Mountains in Washington, Oregon, and British Columbia above a generalized contour line of 1,000 feet elevation. This region is bounded to the east by the ridgeline of mean annual precipitation near the Cascade crest that forms the boundary with Region 14 located on the east slopes of the Cascade Mountains.

Climatic Regions[3] for Eastern Washington

Zone 154 **- Cascade Crest Transition Zone –** This is a transition zone near the crest of the Cascade Mountains between the west and east slopes of the Cascade Mountains (Regions 15 and 14). The transition zone has a nominal width of about 6 miles.

Region 14 **- East Slopes of Cascade Mountains** – This region is comprised of mountain areas on the east slopes of the Cascade Mountains where precipitation annual maxima are produced predominately by winter storm events. This region is bounded to the west by the ridgeline of mean annual precipitation that generally parallels the crest line of the Cascade Mountains. Region 14 is bounded to the east by the contour of 14 inches mean annual precipitation for locations north of the Methow River Valley and by the contour line of 12 inches mean annual precipitation for areas to the south of the Methow River Valley.

Zone 147 **- Cascade Foothills Transition Zone** – This is a transition zone between the east slopes of the Cascade Mountains (Region 14) and arid and semi-arid areas to the east. The transition zone has a nominal width of about 6 miles.

Region 77 **- Central Basin –** The Central Basin region is comprised of the Columbia Basin and adjacent low elevation (non-orographic) areas in central eastern Washington. It is bounded to the west by Region 14. The region is bounded to the north and east by the generalized (smoothed) contour line of 12 inches mean annual precipitation.

Region 7 **- Okanogan , Spokane, Palouse –** This region is comprised of a mixture of lowland areas of low to moderate relief and extensive valley areas between mountain barriers. This includes areas near Spokane, the Palouse, and areas along the Okanogan River. The region is bounded to the northwest by Region 14. It is bounded to the south and west by Region 77, which generally conforms to the contour line of 12 inches mean annual precipitation at the eastern edge of the Central Basin. It is bounded to the northeast by the Kettle River Range and Selkirk Mountains at approximately the contour line of 22 inches mean annual precipitation. It is bounded to the southeast by the Blue Mountains also at the contour line of 22 inches mean annual precipitation.

Region 13 **- Northeastern Mountains and Blue Mountains –** This region is comprised of mountain areas in the easternmost part of Washington State where there is a significant orographic effect on precipitation depths. It includes portions of the Kettle River Range, Selkirk Mountains, and Cabinet Mountains in the northeast, the Bitterroot Range to the East, and the Blue Mountains in the southeast corner of Eastern Washington. Mean annual precipitation ranges from a minimum of 22 inches

[3] The list of regions in Eastern Washington includes two transition zones.

to over 70 inches in the mountain areas. The western boundary of this region generally conforms to the contour line of 22 inches mean annual precipitation.

4.1.2 Changes Made in Updating Dimensionless Design Hyetographs

As compared to the original release of Technical Note 3, changes to the dimensionless design hyetographs were made in response to four separate sources of new information. First, the new climatic region delineation (Figure 4) resulted in new groupings of historical storms and greater homogeneity of storm characteristics within the new regions. Second, 142 additional storms were analyzed for the short, intermediate and long-durations for the period from 1986-2006. This large number of storm events added greatly to the total database of storms and altered the sample statistics slightly. Third, analyses of short 5-minute, 10-minute and 15-minute precipitation maxima in the Seattle area improved resolution of high-intensity portions of storms for western Washington. Fourth, experience gained since 1990 about the temporal behavior of extreme storms allowed improvements and simplification in the approach to assembly of the dimensionless hyetographs.

The following sections provide brief summaries of the differences in the updated dimensionless design hyetographs relative to those contained in the original Technical Note 3.

4.1.3 Short-Duration Design Storms

Figures 5, 6, and 7 depict short-duration dimensionless design hyetographs for the selected climatic regions. Significant increases were made to the high-intensity portion of the short-duration storm for Western Washington based on data from the Seattle precipitation gaging network and NOAA automated gages (Schaefer[22]). The storm characteristics for Eastern Washington are very similar to those in the original Technical Note 3.

4.1.4 Intermediate-Duration Design Storms

Figures 8 through 13 depict intermediate-duration dimensionless design hyetographs for selected groupings of climatic regions. In general, the high-intensity portions of the new design storms nearly match those for design storms in the original Technical Note 3. Minor changes were made to precipitation maxima for the 15-minute and 30-minute durations for Climatic Regions 14 and 13 for Eastern Washington. Minor increases were also made to the total precipitation for all design hyetographs. The greatest increases in the total precipitation occurred for Climatic Regions 15 and 14 in the Cascade Mountains.

4.1.5 Long-Duration Design Storms

Figures 14 through 19 depict long-duration synthetic design hyetographs for selected climatic regions. In general, the high-intensity portions of the new design hyetographs are similar to the high-intensity sections for design storms in the original Technical Note 3. The largest changes came from regrouping the storms according to the new climatic regions in Eastern Washington. In addition, the time resolution was improved by using a 15-minute time-step to replace the 30-minute time-step used in the original design hyetographs. Lastly, additional data and experience allowed use of one long-duration design storm per climatic region instead of two design storms per region as done in the original Technical Note 3.

4.1.6 Intensity Index Format for Dimensionless Design Hyetographs

The dimensionless design hyetographs displayed in Figures 5 through 20 are constructed using an Intensity Index. This format allows direct conversion to a precipitation intensity hyetograph with units of inches/hour by scaling (multiplying) by the chosen *Precipitation Scaling Depth* for the selected Design Step (2-hour, 6-hour, or 24-hour precipitation for the short, intermediate or long-duration dimensionless design hyetograph, respectively). For example, a precipitation scaling depth of 2.0 inches for the 2-hour duration would yield a maximum intensity of 5.2 inches/hour if applied to Figure 5. Multiply all ordinate values in Figure 5 by 2.0 to yield a precipitation intensity hyetograph.

4.1.7 Dimensionless Depth-Duration Curves for Large Watersheds

Assembly of a candidate design storm for a large watershed represents a watershed-specific application. Generic dimensionless design hyetographs cannot be developed in advance because the scaling of the storm is dependent on areal adjustments for watershed size as well as scaling by precipitation depth. Appendix B contains dimensionless depth-duration curves for all of the dimensionless design hyetographs for use on large watersheds.

4.2 ASSEMBLING CANDIDATE DESIGN STORMS FOR SMALL WATERSHEDS

In the majority of impoundment projects constructed in Washington, the size of the tributary watershed is very small relative to the areal coverage of the design storm. For these situations, no adjustments to the at-site precipitation estimates are needed to account for the storm's areal distribution over the watershed. For small watersheds, where no adjustments are required to account for the spatial distribution of the storm, dimensionless design hyetographs are available in electronic format on Compact Disc (CD) or on the Department of Ecology website.

The standard steps to construct candidate design storms, when no areal adjustments are required, are shown in the flow chart in Figure 20. The same procedure is used for short, intermediate, and long-duration candidate design storms that are scaled by separate precipitation scaling depths for the 2-hour, 6-hour and 24-hour durations, respectively.

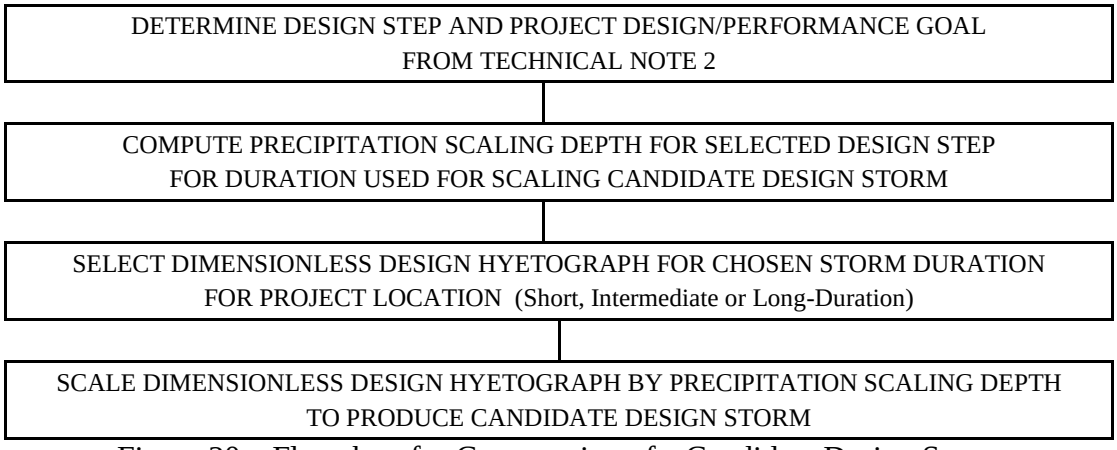

Figure 20 – Flowchart for Construction of a Candidate Design Storm for Small Watersheds

4.2.1 Example Assembly of Short-Duration Candidate Design Storm

Construct a short-duration candidate design storm for a site near Wenatchee, WA.

Given: Climatic Region – Transition Zone 147; 2-hour precipitation scaling depth for Design Step 3 is 3.14-inches, obtained from querying the gridded precipitation dataset for 2-hour precipitation maxima for Design Step 3, and applying the 15 percent design factor per Equation 1 as appropriate.

1. Multiply the ordinates of the short-duration dimensionless design hyetograph for Transition Zone 147 (Figures 6 and 21) by the precipitation scaling depth of

3.14-inches. (The dimensionless design hyetographs are available in electronic format through Ecology's Dam Safety Office.) The resultant candidate design storm is shown in Figure 22.

2. Many watershed models use precipitation depth as input. For these applications, convert precipitation intensities to precipitation depths by multiplying the intensities from Step 1 by 12 for a 5-minute time-step.

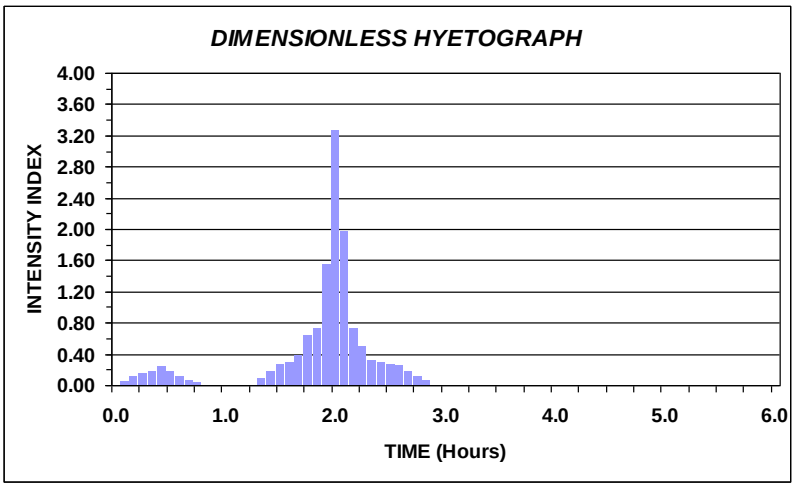

Figure 21 – Short-Duration Dimensionless Design Hyetograph for Transition Zone 147

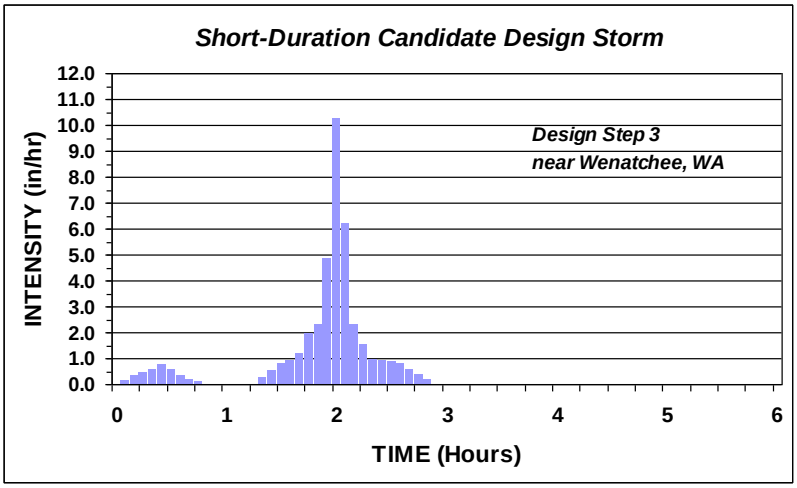

Figure 22 – Scaled Short-Duration Candidate Design Storm for Site near Wenatchee, Washington

4.2.1 Example Assembly of Long-Duration Candidate Design Storm

Construct a long-duration candidate design storm for a site near Olympia, Washington. Given: Climatic Region 32; 24-hr precipitation scaling depth for Design Step 5 is 8.54 inches, obtained from querying gridded precipitation dataset for 24-hour precipitation maxima for Design Step 5, and applying the 15 percent design factor as appropriate.

1. Multiply the ordinates of the long-duration dimensionless design hyetograph for Climatic Region 32 (Figures 16 and 23) by the precipitation scaling depth of 8.54 inches. The resultant candidate design storm is shown in Figure 24.
2. For those watershed models that use precipitation depth as input, convert precipitation intensities to precipitation depths by multiplying the intensities from Step 1 by 4 for a 15-minute time-step.

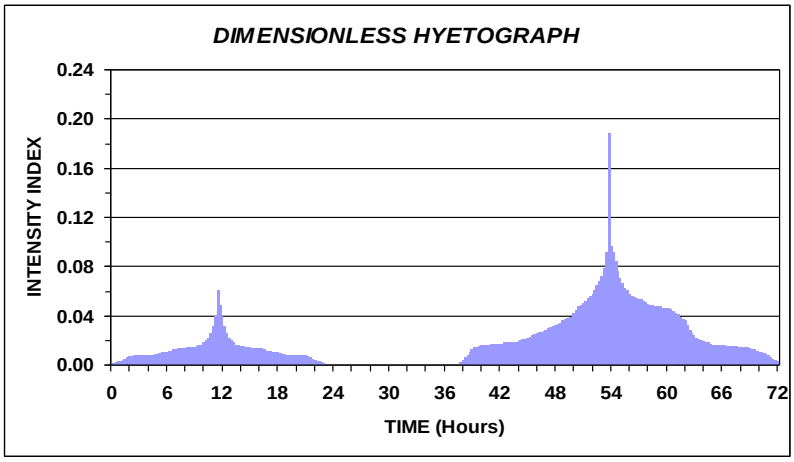

Figure 23 – Long-Duration Dimensionless Design Hyetograph for Climatic Region 32

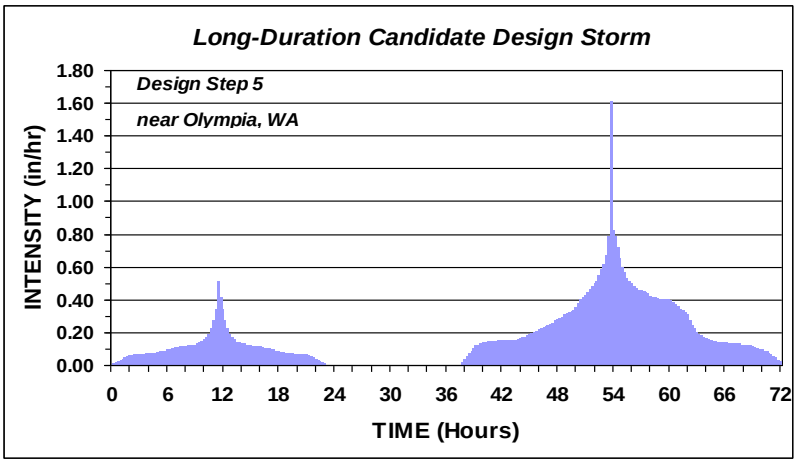

Figure 24 – Scaled Long-Duration Candidate Design Storm for Site near Olympia, Washington

4.3 ASSEMBLING CANDIDATE DESIGN STORMS FOR LARGE WATERSHEDS

As discussed previously, a large watershed is one where the basin-average precipitation varies sufficiently from the maximum point precipitation depth that the spatial distribution of the storm is an important consideration. This corresponds to watersheds that exceed 10 mi^2 for long or intermediate-duration storms as the design event, and watersheds larger than 1 mi^2 for a short-duration thunderstorm as the design event.

Constructing a design storm hyetograph for a large watershed is a watershed-specific application. Thus, generic hyetographs for large watersheds cannot be developed in advance. The areal adjustment values in Table 1 may be used in determining if the dimensionless design hyetographs for small watersheds may be acceptable. Alternatively, if areal adjustments will be important in assembling the candidate design storms for the large watershed, then watershed-specific hyetographs must be developed.

The flow chart in Figure 25 illustrates the standard steps for constructing candidate design storms when areal adjustments are required. Appendix B contains dimensionless depth-duration curves used for assembling the candidate design storms.

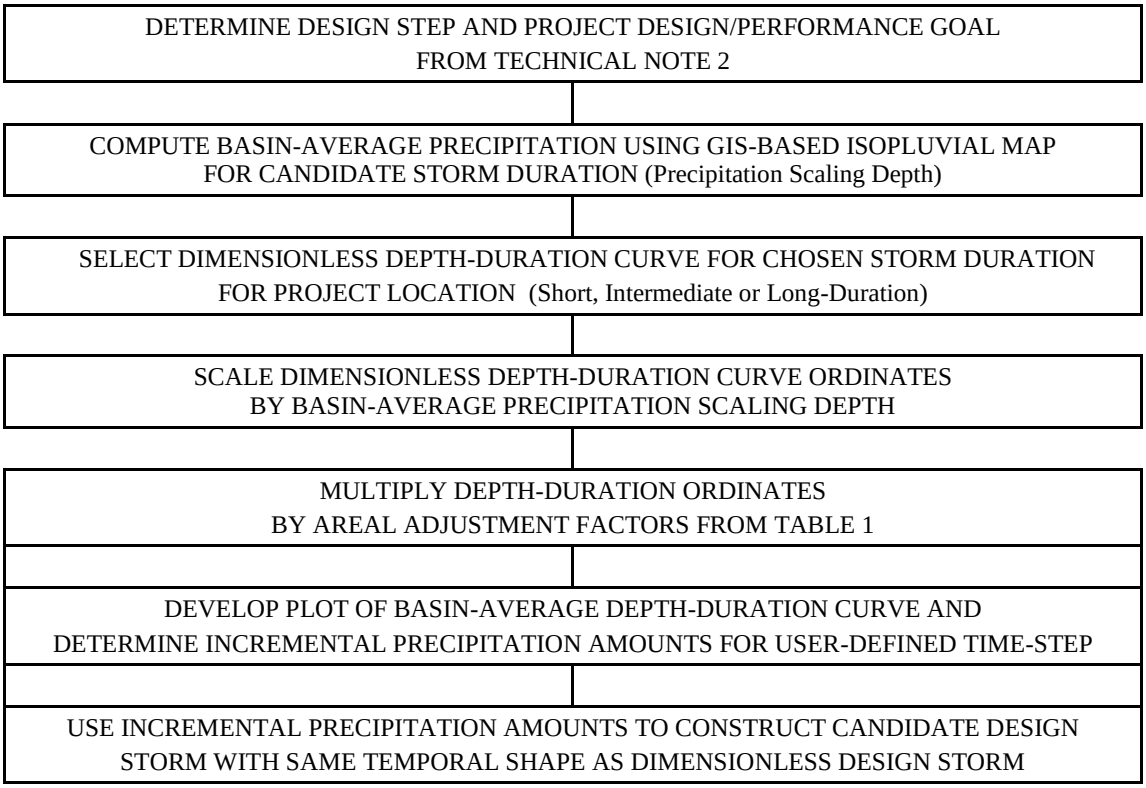

Figure 25 – Flowchart for Construction of a Candidate Design Storm for Large Watersheds

4.3.1 Example Assembly of Intermediate-Duration Candidate Design Storm

Construct an intermediate-duration candidate design storm for a site near Seattle, WA.

Given: Watershed area is 50-mi^2; Climatic Region 31; 6-hour precipitation scaling depth for Design Step 4 is 3.02-inches, obtained from querying the gridded precipitation dataset for 6-hour precipitation maxima for Design Step 4 and computing basin-average precipitation for the watershed, and applying the 15 percent design factor per Equation 1 as appropriate.

1. Multiply the ordinates of the intermediate-duration dimensionless depth-duration curve Figure 26) for Climatic Region 31 (Appendix B) by the precipitation scaling depth of 3.02-inches. This produces a depth-duration curve for watersheds up to 10 mi^2 (Figure 27).
2. Multiply the scaled depth-duration curve ordinate values by the areal reduction factors for the intermediate-duration listed in Table 1 for a 50-mi^2 watershed. Use linear interpolation to obtain areal reduction factors for interdurations residing between listed values. This produces the scaled depth-duration curve for a 50-mi^2 watershed (Figure 27).
3. Obtain incremental precipitation amounts by successively subtracting values from the scaled depth-duration curve (Step 2) on a 15-minute time-step.
4. Multiply the incremental precipitation amounts from Step 3 by a factor of 4 to convert to precipitation intensities (in/hr).
5. Rearrange the incremental intensities in the same pattern as shown for the dimensionless design hyetograph (Figures 10 and 28). This produces the intermediate-duration candidate design storm for the 50-mi^2 watershed (Figure 29).
6. For those watershed models that use precipitation depth as input, convert precipitation intensities to precipitation depths by multiplying the intensities from Step 5 by 4 for a 15-minute time-step.

Note the higher intensity portion of the candidate design storm (Figure 29) is muted relative to the shape of the dimensionless design hyetograph (Figure 28). This is a result of applying the areal reduction factors.

APPENDIX A
CATALOG OF HISTORICAL STORMS

OVERVIEW

Storm dates and locations listed in this catalog are associated with precipitation amounts that have exceeded a 20-year recurrence interval at a given location at one or more durations. Categorization of a storm as being a short-duration, intermediate duration or long-duration extreme storm is based on comparison of the precipitation maxima for the storm being most rare at the 2-hour, 6-hour or 24-hour duration, respectively. This is the same approach that was used in the original study of extreme storms entitled *Characteristics of Extreme Precipitation Events in Washington State* and completed in October 1989 (Ecology Publication 89-51). Data collection for that study ended in early 1986 and included storms recorded at automated precipitation gages that operated in the period from 1940-1986. Storms identified in the earlier study are listed in black in this catalog.

Records from precipitation gages in Washington State and border areas have been scanned to identify storms that have occurred since 1986 that have exceeded the 20-year recurrence interval criterion as discussed above. As in the original study, storms have been categorized as either short, intermediate or long-duration based on the precipitation maxima at the 2-hour, 6-hour and 24-hour durations respectively. These recent storms are listed in blue in this catalog.

Storms in the original study were grouped into orographic and non-orographic regions in both western and eastern Washington. These regions were defined based on NWS climatic zones in use at that time. Since the original study, regional precipitation-frequency analyses have been conducted for Washington State which included delineation of climatic regions. The complete collection of noteworthy storms from 1940-2007 have been regrouped in this catalog using the new climatic region delineations for Washington State (Figure 4).

Many of the most extreme storms listed in the catalog have been placed in Excel spreadsheets and configured to allow scaling of the storms into larger or smaller storm events. These storms are termed *scalable historical storms* and are particularly useful for examining the flood response of a reservoir and spillway system to the type of storm event that has occurred in the climatic region where a given project is located. Scaling of these storms is done in a manner similar to that for the dimensionless design hyetographs. Use of scalable historical storms provides another avenue to confirm the hydrologic adequacy of a spillway system using a suite of diverse storm characteristics.

Scalable historical storms are available through the Dam Safety Office.

Table 2 - Catalog of Short-Duration Extreme Storms for Region 5 - Coastal Lowlands

APPENDIX B
DIMENSIONLESS DEPTH-DURATION CURVES

OVERVIEW

This appendix contains listing of the ordinates of dimensionless depth-duration curves for use in developing short, intermediate and long-duration candidate design storms for large watersheds. See Section 4.3 for a discussion of the procedures for developing candidate design storms for large watersheds.

REGIONAL PRECIPITATION-FREQUENCY ANALYSIS AND SPATIAL MAPPING OF PRECIPITATION FOR 24-HOUR AND 2-HOUR DURATIONS IN WESTERN WASHINGTON

EXECUTIVE SUMMARY

Regional frequency analyses were conducted for precipitation annual maxima in western Washington for durations of 24-hours and 2-hours. A total of 430 precipitation gages in Washington, southern British Columbia and northern Oregon were included in the study representing 15,124 and 4,797 station-years of record for the 24-hour and 2-hour durations, respectively. A regional analysis methodology was utilized that pools data from climatologically similar areas to increase the dataset and improve the reliability of precipitation-frequency estimates. The regional analysis methodology included L-moment statistics, and an index-flood type approach for scaling the annual maxima data. L-moment statistics were used to: characterize the variability, skewness and kurtosis of the data; measure heterogeneity in proposed homogeneous sub-regions; and assist in identification of an appropriate regional probability distribution.

It was found that the study area could be described by seven climatic regions. These seven climatic regions were geographic areas that had similar topographic and climatological characteristics and were subjected to similar meteorological conditions during storm events. This included three coastal regions, two interior lowland regions and two Cascade Mountain regions. In particular, the need was recognized to distinguish between windward and leeward areas in both mountain and lowland areas. Separate regional analyses were conducted for each of the seven climatic regions for each of the two durations. Within each climatic region, precipitation gages were assigned to groups where the gage sites had similar magnitudes of mean annual precipitation. A total of 32 sub-regions were formed by this process and were found to be acceptably homogeneous. Predictor equations were then developed to describe the variability of the L-moment ratios, L-Cv and L-Skewness, between the sub-regions and within and/or across climatic region boundaries. The sub-region L-moment ratio plots for L-Skewness and L-Kurtosis revealed the data to be near or slightly more kurtotic than the Generalized Extreme Value distribution. The four-parameter Kappa distribution was chosen to describe the regional magnitude-frequency relationship for both the 24-hour and 2-hour durations.

Spatial mapping techniques were employed for mapping of the precipitation-frequency information. This included spatial mapping of at-site means, L-moment ratio values of L-Cv and L-Skewness, and mapping of precipitation for selected recurrence intervals at both the 24-hour and 2-hour durations. Procedures were employed to minimize differences between mapped values and observed station values in a manner that was consistent with the regional behavior of the data and also recognized uncertainties due to natural sampling variability.

Color-shaded isopluvial maps were developed for the 2-year, 10-year, 25-year, 50-year, and 100-year precipitation at both the 24-hour and 2-hour durations. An isopluvial map was also developed for 6-month, 24-hour precipitation, which is useful for water-quality treatment design applications. Electronic gridded datasets were provided for WSDOT use in creation of GIS applications that utilize precipitation-frequency information.

A catalog of extreme storms was assembled that lists precipitation events in western Washington that exceeded a 20-year return period. The information from the storm catalog was used to conduct seasonality analyses. The seasonality analyses were used to identify the frequency of occurrence of extreme storms by month. In particular, the seasonality analyses identified those months that were the most likely and least likely for an extreme event to occur. This information is useful in rainfall-runoff modeling and can be used by WSDOT staff in conducting hydrologic analyses throughout western Washington.

REGIONAL PRECIPITATION-FREQUENCY ANALYSIS AND SPATIAL MAPPING OF PRECIPITATION FOR 24-HOUR AND 2-HOUR DURATIONS IN WESTERN WASHINGTON

March 2002

OVERVIEW

This report documents the findings of regional precipitation-frequency analyses of 24-hour and 2-hour precipitation annual maxima for western Washington. It also describes the procedures used for spatial mapping of the precipitation-frequency estimates for selected recurrence intervals.

This study is an update of the information contained in the precipitation-frequency atlas published by the National Weather Service in 1973 (NOAA Atlas 2[16]). Data collection for the NWS study ended in 1966, and this study includes the 34-years of record collected since 1966. These additional data provide a precipitation database with more than double the record length than was available in the original NWS study.

Since the original study, major advances have been made in the methods for statistical analysis of precipitation annual maxima, and for spatial mapping of precipitation in complex terrain. Specifically, L-Moment statistical analysis techniques[7,9] conducted within a regional framework have greatly improved the reliability of precipitation magnitude-frequency estimates, particularly for rare storm events. Development of the PRISM model[3] incorporating digital terrain data has also improved the spatial mapping of precipitation and increased the reliability of estimating precipitation in the broad areas between precipitation measurement stations. These methodologies are particularly effective in areas with high topographic and climatic variability such as in western Washington, where mean annual precipitation varies from less than 20-inches to over 200-inches. Both of these methodologies have been utilized in conducting the precipitation-frequency analyses and in developing the isopluvial maps for selected recurrence intervals.

STUDY AREA

While western Washington is the area of interest, the study area was expanded to provide additional data in border areas. Accordingly, the study area included areas in southwestern British Columbia, northwestern Oregon, and areas in the Cascade Mountains in eastern Washington (Figure 1). Specifically, the study area is bounded on the North at latitude 49° 30′ N, bounded to the south by latitude 45° 00′ N, and bounded to the east by the contour line of 20-inches mean annual precipitation, approximately longitude 120°00′ W. Addition of precipitation stations in the boundary areas also provided data from areas climatologically similar to data-sparse areas in Washington such as the windward and leeward faces of the Olympic Mountains, Willapa Hills, and the Cascade Mountains.

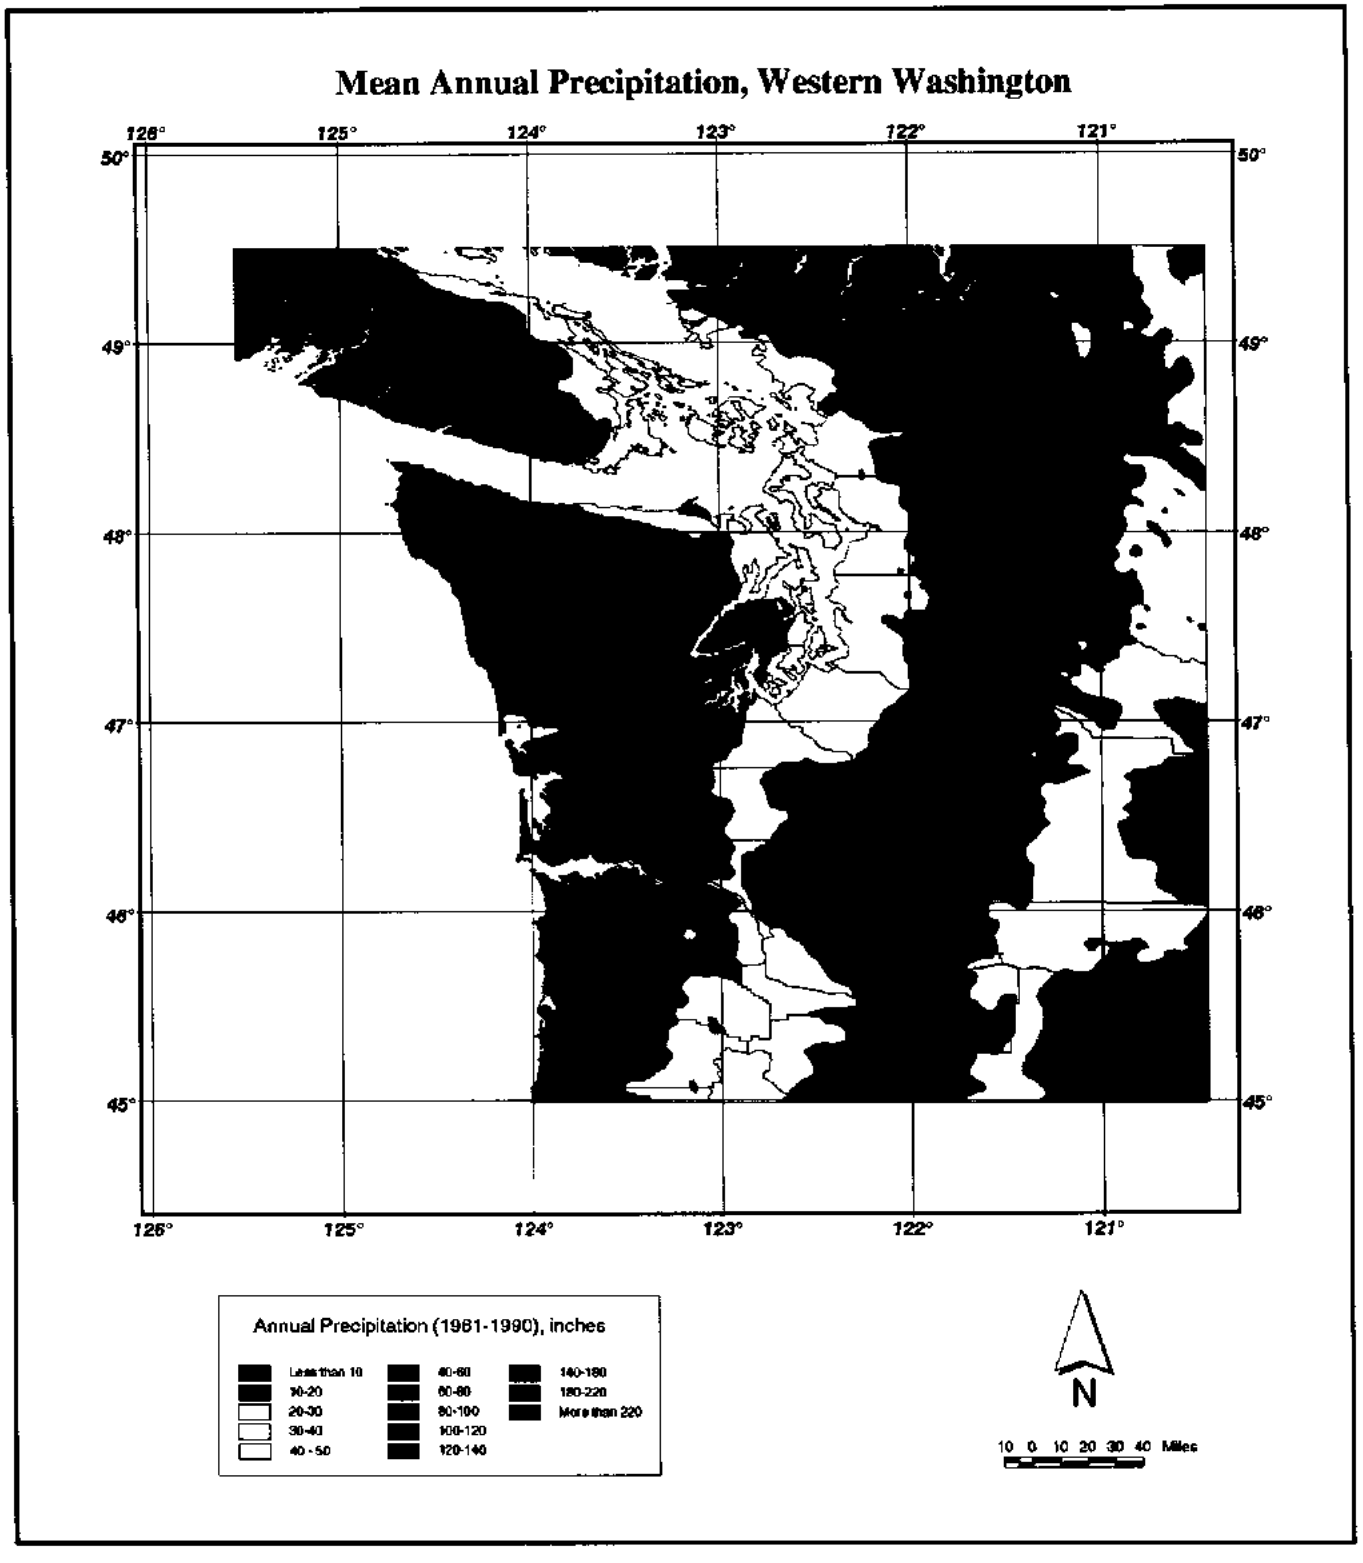

Figure 1 – Mean Annual Precipitation[20,21] for Western Washington Study Area

CLIMATIC AND METEOROLOGIC CHARACTERISTICS OF STUDY AREA

Annual Precipitation

Mean annual precipitation within the study area varies dramatically from the coast to the eastern slopes of the Cascade Mountains (Figure 1). Mean Annual Precipitation[20] (MAP) ranges from a high of over 240-inches in the Olympic Mountains, to a low near 18-inches in the Olympic rain shadow area near Sequim, and to 20-inches in the foothills of the Cascades in eastern Washington.

Weather Systems and Sources of Atmospheric Moisture

In general, two ingredients are needed for precipitation to occur, a source of atmospheric moisture and a meteorological mechanism to release that moisture. There is also a greater potential for extreme precipitation events when the source of moisture originates in areas with warmer temperatures and higher dewpoints. There are three generalized geographic areas that are sources of atmospheric moisture to the study area and have differing characteristic temperatures and dewpoints. These source areas include: the Gulf of Alaska; the Pacific Ocean north of the Canadian border; and the Pacific Ocean from as far south as latitude 20°N near the Hawaiian Islands.

Storm systems[16,18,19] moving in a southeasterly direction out of the Gulf of Alaska primarily affect northern portions of the study area and generally contain cooler temperatures and dewpoints. Storm systems originating over the Pacific Ocean are the most common and those that originate from southerly latitudes near the Hawaiian Islands have been responsible for many of the largest long-duration precipitation events experienced in the winter months. Synoptic-scale cyclonic weather systems and associated fronts generally provide the mechanism for producing precipitation annual maxima at the 24-hour and longer durations. Precipitation is enhanced in mountain areas as atmospheric moisture is lifted over the Olympic, Coastal and Cascade Mountains. This orographic component of precipitation has the greatest effect at 24-hour and longer time scales, and can significantly enhance the total accumulation of precipitation over several days. Precipitation annual maxima at the 24-hour duration occur predominately in the fall and winter seasons in western Washington.

Precipitation annual maxima at the 2-hour duration may occur as a result of several different storm mechanisms. They may occur due to low-to-moderate convective activity associated with a large-scale synoptic weather system in the fall or winter season. In this case, the 2-hour annual maxima are embedded within a much longer duration storm event. They may also occur due to more intense convective activity that may, or may not, be associated with an organized weather system. In this latter case, the 2-hour annual maxima are often associated with "thunderstorms" in the spring and summer, which are short-duration localized storm events with limited areal coverage.

DATA SOURCES

A precipitation annual maximum is the greatest precipitation amount in a 12-month period for a specified duration at a given measurement site. The water-year, October 1st to September 30th is the 12-month period used for determining precipitation annual maxima for the 24-hour and 2-hour durations for these analyses.

Precipitation annual maxima and associated storm dates were obtained from precipitation records from a variety of sources. The majority of the data were obtained from the electronic files of the National Climatic Data Center (NCDC). Data for southwestern British Columbia were obtained from the Canadian Atmospheric Environment Services Agency (AES). Data from Snotel gages in mountains areas were obtained from electronic files from the Natural Resources Conservation Service (NRCS). Several counties in Washington also provided data for urban areas, including: King, Kitsap, Snohomish, Thurston and Clark Counties.

Precipitation Gage Types, Methods of Measurement and Reporting

Precipitation is measured by a variety of devices and reported by a number of different agencies in the United States and Canada. Descriptions of the gage types and reporting methods are summarized below.

Daily Gages – Daily gages in US and Canada are standardized devices comprised of simple vertical cylinders open to the atmosphere. A variety of shields for protection from the wind are used in both countries, with shields being more common now than in the past. Precipitation is measured once each day at a specified time and represents the precipitation for the previous 24-hours.

Automated Gages – Automated gages such as weighing buckets, Fisher-Porter tipping buckets, and other types of tipping buckets can provide information about precipitation intensity on various time scales. The standards in both the US and Canada are for reporting on either hourly or 15-minute intervals. Weighing bucket gages with paper strip charts came on-line around 1940-1945 in the US and many were installed in Canada in the 1950's and 1960's. Tipping bucket gages and automated reporting systems were installed at many sites beginning in the 1970's. These gages are often given the generic term hourly gages to distinguish them from daily gages.

Snotel Gages – Snotel gages are a type of automated gage commonly used in mountain areas. They have external heating systems and are designed for cold weather operation. Precipitation that falls as snow is converted to liquid water for measurement. Snotel gages typically report precipitation on a daily basis on a midnight-to-midnight reporting schedule.

Number of Gages and Gage Types

The number of gages and gage types used in the regional analyses are summarized in Tables 1a,b. Both daily and hourly precipitation gages are co-located at many NCDC sites in the US. This occurred at 61 stations in Washington and Oregon. To avoid duplication, the record from the gage with the longest record was utilized in the analyses for the 24-hour duration. When both the daily and hourly records were of similar length, the record from the hourly gage was selected. The precipitation station networks are shown in Figures 2a,b for the 24-hour and 2-hour durations, respectively.

Table 1a – Number and Type of Gages Utilized for Analyses of 24-Hour Annual Maxima

STATION LOCATION	DAILY GAGE	HOURLY GAGE	SNOTEL GAGE
British Columbia	56	6	0
Washington	146	78	44
Oregon	44	31	11
Municipal Gages	14	0	0
TOTAL	**260**	**115**	**55**

61 NCDC stations have co-located daily and hourly gages

DATA SCREENING AND QUALITY CHECKING

Extensive efforts were made in screening and quality checking the annual maxima data. Quality checking was needed to eliminate false annual maxima associated with a variety of data measurement, reporting, and transcription errors, particularly incomplete reporting during some years. The record for all sites and climatic-years was checked for completeness. In addition, all records were scanned for anomalously small or large precipitation amounts and the Hosking and Wallis[9,10] measure of discordancy [9,10] was also used to identify gages whose sample statistics were markedly different from the majority of gages in a given region. Suspicious gages and data were checked to verify the validity of records. Nearby sites were also checked to corroborate the magnitude and date of occurrence of any anomalously small or large precipitation annual maxima. Data that were clearly erroneous were removed from the datasets.

Stationarity and Serial Independence

Two underlying assumptions inherent in frequency analyses are the data are stationary over the period of observation and prediction, and the data at a given site (gage) are serially independent. As part of the data screening process, standard statistical tests for stationarity and serial independence were conducted. Inter-station correlation analyses were also conducted to assess the relative amount of correlation between annual maxima data at nearby gages.

To meet the stationarity criterion, the data must be free from trends during the period of observation. For each duration, this was confirmed by standard linear regression techniques where the station data were first rescaled by division by the at-site mean and then regressed against the year of occurrence minus 1900. This approach allowed comparisons to be made among all gages and to interpret the relative magnitude of any trend over the past century. The average values of the slope parameter were +0.20%, and +0.15% for the 24-hour, and 2-hour durations, respectively. The regression results for the collective group of gages were tested against a null hypothesis of zero slope (stationarity). The null hypothesis could not be rejected at the 5% level and the data at both durations were accepted as stationary.

To confirm independence of the annual maxima data, serial correlation coefficients were computed for the data at each gage for each duration. The regression results for the collective group of gages at each duration were tested against a null hypothesis of zero serial correlation (independence). The null hypothesis could not be rejected at the 5% level. As expected, the annual maxima data were found to be serially independent.

REGIONAL FREQUENCY ANALYSIS METHODOLOGY

The cornerstone of a regional frequency analysis is that data from sites within a homogeneous region can be pooled to improve the reliability of the magnitude-frequency estimates for all sites. A homogeneous region may be a geographic area delineated on a map or it may be a collection of sites having similar characteristics pertinent to the phenomenon being investigated.

Early in the study it was recognized that the climatic and topographic diversity in the study area would likely preclude the use of large geographic areas that would meet statistical criteria for homogeneity. It was decided to employ climatic/geographic regions that had basic similarities in the climatic and topographic setting. It was anticipated that these regions might require further sub-division to meet homogeneity criteria for use in regional frequency analysis.

Description of Climatic/Geographic Regions

Identification of climatologically similar regions meant delineating geographic areas that had similar climatological and topographical characteristics. To assist in this effort, a literature review was conducted to examine region designations utilized in prior studies. This included a review of NOAA Atlas 2[16], studies of extreme precipitation in the Pacific Northwest (NWS[18,19]), and prior regional frequency analyses conducted in coastal mountain areas (Schaefer[23,25,26]).

Based on information in those studies and the spatial characteristics of mean annual precipitation, seven climatic/geographic regions were identified (Figure 3). In particular, the map of mean annual precipitation (Figure 1) developed by Daly using the PRISM[3] model provided the basic mapping information for delineating the boundaries of the climatic regions. This map is based on the 1961-1990 time period, which is the most recent NOAA 30-year decadal-based climate tracking period. The magnitude and gradient of mean annual precipitation were the primary measures used to define the boundaries between the regions. Those regions include:

Coastal Lowlands (Region 5) – The lowlands along the west coast of Washington, Oregon and Vancouver Island that are open to the Pacific Ocean. The eastern boundary is either a generalized contour line of 1,000 feet elevation, or the ridgeline of mean annual precipitation that separates the coastal lowlands from the interior lowlands, such as within the Aberdeen-Montesano gap.

Coastal Mountains West (Region 151) – The windward faces of the Olympic Mountains, Willapa Hills, Black Hills, Coastal Mountains in Oregon, and Vancouver Island Mountains in British Columbia above a generalized contour line of 1,000 feet elevation. These areas are bounded to the west by the 1,000 feet contour line, and bounded to the east by the ridgeline of mean annual precipitation near the crestline of the mountain barrier.

Coastal Mountains East (Region 142) – The leeward faces of the Olympic Mountains, Willapa Hills, Black Hills, Coastal Mountains in Oregon, and Vancouver Island Mountains in British Columbia above a generalized contour line of 1,000 feet elevation. These areas are bounded to the west by the ridgeline of mean annual precipitation near the crestline of the mountain barrier, and bounded to the east by the 1,000 feet contour line.

Interior Lowlands West (Region 32) – The interior lowlands below a generalized contour line of 1,000 feet elevation bounded to the east by the trough-line of mean annual precipitation through the Strait of Juan De Fuca, Puget Sound Lowlands and Willamette Valley. This is a zone of low orography where mean annual precipitation generally decreases from west to east.

Interior Lowlands East (Region 31) – The interior lowlands below a generalized contour line of 1,000 feet elevation bounded to the west by the trough-line of mean annual precipitation through the Strait of Juan De Fuca, Puget Sound Lowlands and Willamette Valley. This is a zone of low orography where mean annual precipitation generally increases from west to east.

Cascade Mountains West (Region 15) – The windward face of the Cascade Mountains in Washington, Oregon, and British Columbia above a generalized contour line of 1,000 feet elevation. This region is bounded to the east by the ridgeline of mean annual precipitation near the Cascade crest.

Cascade Mountains East (Region 14) – The leeward face of the Cascade Mountains in Washington, Oregon, and British Columbia above the 20-inch isopluvial of mean annual precipitation. This region is bounded to the west by the ridgeline of mean annual precipitation near the Cascade crest.

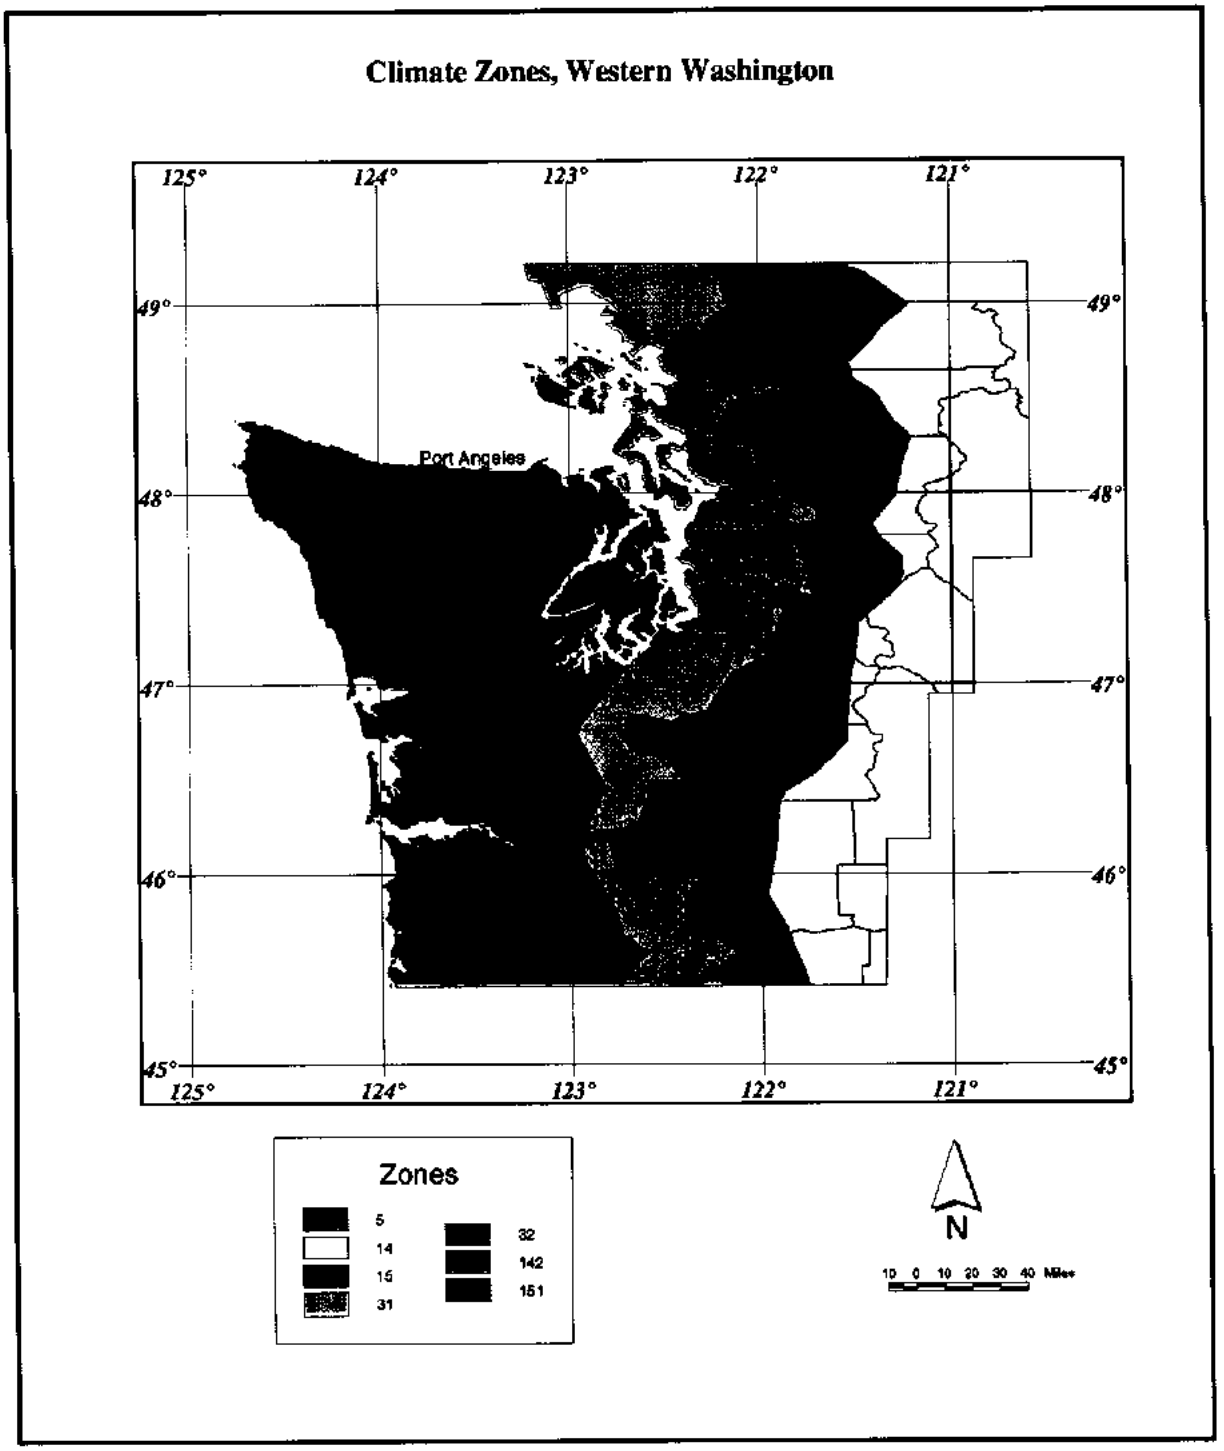

Figure 3 – Delineation of Climatic Regions for Western Washington Study Area

REGIONAL GROWTH CURVE

Implicit in the definition of a homogeneous region is the condition that all sites can be described by one probability distribution having common distribution parameters after the site data are rescaled by their at-site mean. Thus, all sites have a common regional magnitude-frequency curve (regional growth curve, Figure 4) that becomes site-specific after scaling by the at-site mean of the data from the specific site of interest. Thus,

$$Q_i(F) = \hat{\mu}_i \; q(F) \qquad (1)$$

where $Q_i(F)$ is the at-site inverse Cumulative Distribution Function (CDF), $\hat{\mu}_i$ is the estimate of the population at-site mean, and $q(F)$ is the regional growth curve, regional inverse CDF. This is often called an index-flood approach to regional frequency analyses and was first proposed by Dalrymple[2] and expanded by Wallis[30,31].

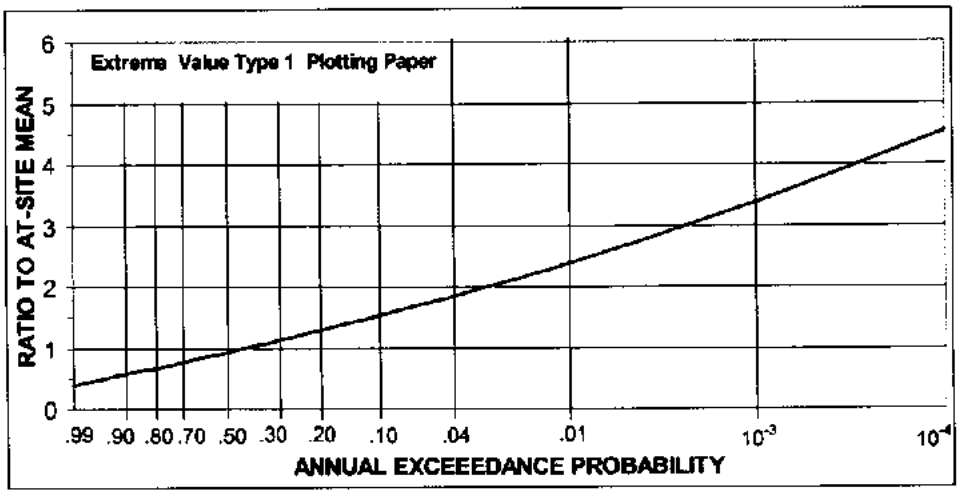

Figure 4 – Example of Regional Growth Curve

FORMING HOMOGENEOUS SUB-REGIONS

It was anticipated that the climatic regions defined here would require sub-division to meet homogeneity criteria. The methodology used herein for forming and testing proposed homogeneous sub-regions follows the procedures recommended by Hosking and Wallis[9,10].

The basic approach is to propose homogeneous sub-regions (grouping of sites/gages) based on the similarity of the physical/meteorological characteristics of the sites. L-moments (Hosking[7,9], Appendix E) are then used to estimate the variability and skewness of the pooled regional data and to test for heterogeneity as a basis for accepting or rejecting the proposed sub-region formulation.

In general, proposed homogeneous sub-regions can be formed by utilizing some measure(s) of physical and/or climatological characteristics for assigning sites/gages to sub-regions. Candidates for physical features[16,18,19] include such measures as: site elevation; elevation averaged over some grid size; localized topographic slope; macro topographic slope averaged over some grid size; distance from the coast or source of moisture; distance to sheltering mountains or ridgelines; and latitude or longitude. Candidate climatological characteristics include such measures as: mean annual precipitation; precipitation during a given season; seasonality of extreme storms; and seasonal temperature/dewpoint indices.

A review of the topographic and climatological characteristics in each region shows that the seven climatic regions already had similarities regarding several of the physical and climatological measures listed above. As such, only one additional measure, mean annual precipitation (MAP) was needed for grouping of sites/gages into homogeneous sub-regions within a given climatic region. Homogeneous sub-regions were therefore formed with gages/sites within a small range of MAP.

Heterogeneity Measures of Proposed Homogeneous Sub-Regions

Heterogeneity measures have been developed by Hosking and Wallis[9,10] as indicators of the amount of heterogeneity in the L-moment ratios for a collection of sites/gages. The statistics H1 and H2 measure the relative variability of observed L-Cv and L-Skewness sample statistics, respectively, for gages/sites in a sub-region. Specifically, these measures compare the observed variability to that expected from a large sample drawn from a homogeneous region from the Kappa distribution[12] having weighted average L-moment ratios that were observed in the sub-region. Initial recommendations from Hosking and Wallis[9,10] were that regions with H1 and H2 values less than 1.00 were acceptably homogeneous. Values of H1 and H2 between 1.00 and 2.00 were possibly heterogeneous. Values greater than 2.00 indicated definite heterogeneity and that redefinition of the region and/or reassignment of sites/gages should be considered.

These heterogeneity criteria measure statistical heterogeneity from known distributions and do not account for variability that arises from other sources. Most cooperative precipitation measurement networks include gages operated by various organizations and individuals that provide a varied level of quality control. Therefore, precipitation measurements often contain additional variability due to: gages being moved during the many years of operation; frequent change of operators and level of diligence in timely measurement; missing data arising from inconsistent reporting; lack of attention to measurement precision; and localized site and wind condition changes over time due to building construction or growth of trees in the vicinity of the gage. Recognizing this additional variability, Wallis[29] has suggested that for precipitation annual maxima, H1 values less than 2.00 may be considered acceptably homogeneous and H1 values greater than 3.00 would be indicative of heterogeneity. Both the H1 and H2 measures will be used later to assess the relative heterogeneity in proposed sub-regions.

Acceptance of Proposed Homogeneous Sub-Regions

When a proposed sub-region is found to satisfy homogeneity criteria, the regional L-moment ratios are then used to conduct goodness-of-fit tests (Hosking and Wallis[9,10]) to assist in selecting a suitable probability distribution, and to estimate the parameters of the regional distribution. Examples of this type of approach are described by Schaefer in his study of Washington State[23], southern British Columbia[25], and the Sierra Mountains in California[26]. The basic approach adapted to this study is summarized below:

Adopted Methodology

1) Form proposed homogeneous sub-regions by assigning gages within a climatic region to groups within a small range of mean annual precipitation;
2) Compute L-moment sample statistics for gages within the proposed homogeneous sub-regions;
3) Use L-moment heterogeneity criteria to test proposed homogeneous sub-regions;
4) Develop a mathematical predictor for describing the behavior of regional L-Cv and L-skewness values with mean annual precipitation across the climatic region;
5) Conduct goodness-of-fit tests to identify a suitable probability distribution for regional growth curve;
6) Solve for the distribution parameters of the selected probability distribution for each sub-region using the regional values of L-Cv and L-skewness (from Step 4).

Systematic Variation of L-Cv and L-Skewness with Mean Annual Precipitation

As described previously, climatic regions were comprised of numerous homogeneous sub-regions. A mathematical relationship was therefore needed to link the sub-regions and provide estimation of L-moment ratios L-Cv and L-Skewness across a climatic region. The relationships were developed in a manner to provide continuity with adjacent climatic regions. This approach had the additional benefit of eliminating or minimizing discontinuities at the boundaries between the climatic regions. Recognizing that the sub-regions were formed as groupings of gages within a small range of mean annual precipitation (MAP), it was found that MAP was a suitable explanatory variable. The predictor equations took the general forms:

$$L\text{-}Moment\ Ratios = \alpha\, e^{-\beta(MAP)} + \delta \qquad (2a)$$

$$L\text{-}Moment\ Ratios = \alpha + \beta(LN[MAP]) \qquad (2b)$$

where: alpha (α), beta (β), and delta (δ) are parameters specific to a given climatic region or group of climatic regions, and delta is a limiting value at large values of mean annual precipitation.

ANALYSES OF 24-HOUR DURATION ANNUAL MAXIMA

Homogeneous sub-regions were formed as collections of gages within small ranges of mean annual precipitation (MAP) within each of the climatic regions. The range of MAP was chosen so that about 8 to 12 gages, 400 to 500 station-years of record, were included in each sub-region with each gage having at least 15 years of record. This resulted in a total of 32 sub-regions for the 24-hour duration (Table 2). Record lengths at precipitation measurement stations varied from a minimum of 15-years to over 100-years, with nearly 50% of the stations having record lengths in excess of 50-years. Figure 5 depicts the number of stations within various ranges of record length.

Table 2 – Number of Sub-Regions, Gages and Station-Years of Record for 24-Hour Duration Annual Maxima

CLIMATIC REGION	NUMBER OF SUB-REGIONS	DAILY GAGES	HOURLY GAGES	SNOTEL GAGES	STATION-YEARS OF RECORD

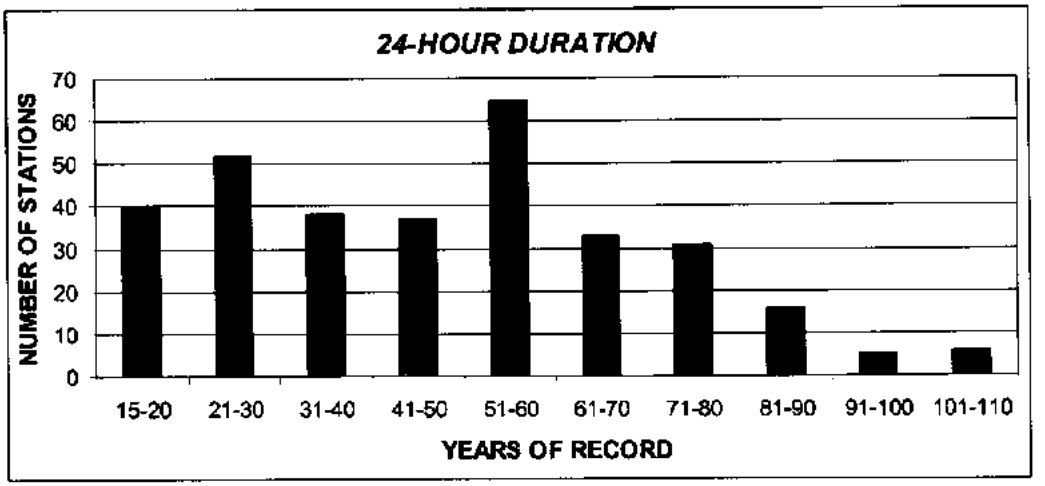

Figure 5 – Histogram of Record Lengths at Stations for 24-Hour Annual Maxima

Regional Solutions for L-Moment Ratios, L-Cv and L-Skewness

Regional predictor equations for L-moment ratios were developed for groupings of sub-regions in the climatic regions using forms of the regression equations shown in Equations 2a and 2b. It was found that a single predictor equation could often be developed applicable to adjacent climatic regions (Tables 3a,b). For those climatic regions where an exponential decay predictor equation was appropriate (Equation 2a), delta values were first estimated based on regional L-moment ratio values computed from those sub-regions with the largest sub-region values of mean annual precipitation.

For the case of climatic regions 15 and 14, where the boundary is near the crest of the Cascade Mountains, sub-region L-moment ratio values were also computed for gages near the Cascade crest. The sub-region and boundary L-moment ratio values were used to assist in estimation of the delta parameter, which provided continuity between mountain regions 15 and 14.

A least squares solution was used to determine the alpha and beta parameters. Standardized root mean square error (RMSE) was also computed for the predictor equation for each region(s) to provide a measure of the goodness-of-fit of the predictor equation. The resultant predictor equations for L-Cv are listed in Tables 3a,b and graphically depicted in Figures 6a,b,c,d.

Few precipitation gages exist at high elevations in the Olympic Mountains. Extrapolation is required in this area to provide L-moment ratio values applicable to locations with mean annual precipitation exceeding about 140-inches. The regression parameters for high mountain areas in region 142, on the leeward face of the Olympic Mountains, were based on the behavior of L-moment ratio values for gages with the greatest mean annual precipitation on the windward face of the Olympics. This approach provided continuity across the crest of the Olympics for very high values of mean annual precipitation as seen in Figures 5a,b and 6a,b.

Skewness measures are highly variable for the record lengths commonly available for precipitation-frequency analysis. This greater sampling variability is exhibited in larger RMSE values for the predictor equations for L-Skewness (Tables 4a,b). Regional predictor equations for L-Skewness were developed in the same manner as that described above for L-Cv. The predictor equations for L-Skewness are listed in Tables 4a,b and graphically depicted in Figures 7a,b,c,d.

Heterogeneity Measures, 24-Hour Duration

Heterogeneity measures H1 and H2 (Hosking and Wallis[9,10]) were used to judge the relative heterogeneity in the proposed sub-regions for L-Cv and L-Skewness, respectively. Computation of H1 and H2 values for the various sub-regions indicated the majority of sub-regions were acceptably homogeneous (Table 5). In those cases where computed heterogeneity measures exceeded acceptance criteria, the excursions were generally of a minor amount. Only one sub-region on the windward face of the Olympics had large excursions beyond the acceptance criteria. In summary, mean annual precipitation was an excellent explanatory variable for describing the variability of L-Cv and L-Skewness across the study area.

Table 5 – Results of Heterogeneity and Goodness-of-Fit Tests for 24-Hour Duration

CLIMATIC REGIONS	NUMBER OF SUB-REGIONS	HOMOGENEOUS SUB-REGIONS H1 ≤ 2.00	HOMOGENEOUS SUB-REGIONS H2 ≤ 1.00	SUB-REGIONS ACCEPTING GEV DISTRIBUTION
5 - 151	5	3	4	5
142 - 32	9	6	7	8
31 -15	13	13	11	13
14	5	4	4	3
TOTAL	**32**	**26**	**26**	**29**

Identification of Regional Probability Distribution, 24-Hour Duration

One of the primary tasks in the regional analyses was to identify the best probability distribution for describing the behavior of the annual maxima data. Accordingly, a goodness-of-fit test statistic (Hosking and Wallis[9,10]) was computed for each sub-region for use in identifying the best three-parameter distribution. Using the L-moment based test statistic, the Generalized Extreme Value (GEV) distribution[9,27] was identified most frequently as the best three-parameter probability model (Table 5).

A plot of regional L-Skewness and L-Kurtosis values for the 32 sub-regions at the 24-hour duration in shown in Figure 8. Nearness to the GEV distribution is clearly evident and consistent with the goodness-of-fit test results listed in Table 5.

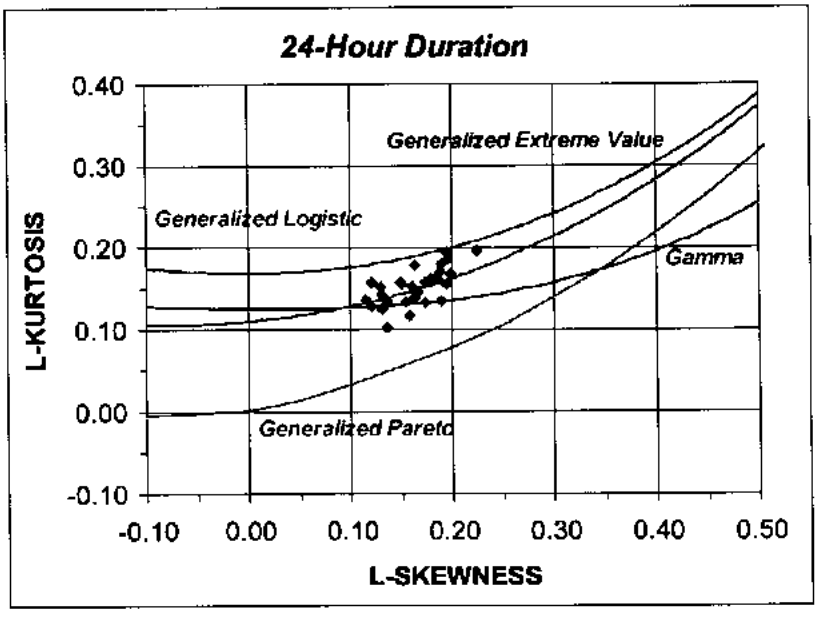

Figure 8 – L-Moment Ratio Plot for Sub-Regions for 24-Hour Duration

The GEV is a very suitable distribution for estimation of precipitation quantiles out to the 500-year recurrence interval. If quantile estimates are desired for events more extreme than the 500-year recurrence interval, it would be worthwhile to refine the selection of the regional probability distribution. Given this consideration, it was decided to utilize the four-parameter Kappa[9,12] distribution, which can mimic the GEV and produce a variety of regional growth curves immediately around the GEV. The inverse form of the Kappa distribution is:

$$q(F) = \xi + \frac{\alpha}{\kappa}\left\{1 - \left(\frac{1 - F^{h}}{h}\right)^{\kappa}\right\} \qquad (3)$$

where: ξ, α, κ, and h are location, scale and shape parameters respectively.

An h value of zero leads to the GEV distribution, an h value of 1 produces the Generalized Pareto (GP) and an h value of -1 produces the Generalized Logistic (GL) distribution. Thus, positive values of h produce regional growth curves that are flatter than the GEV, and negative values of h produce steeper regional growth curves. Minor adjustments of h near a zero value (GEV) allow fine-tuning of the regional growth curves. This minor adjustment of the h value only becomes important for the estimation of very rare quantiles.

To solve for an appropriate h value, a hierarchical approach (Fiorentino[4]) was taken wherein the shape parameter h was computed as the average value from the group of sub-region solutions. An average value of -0.057 was computed with a standard error of estimation of approximately $\pm$ 0.045. Based on this information, a nominal h value of -0.05 was adopted. This produces a regional growth curve slightly steeper than the GEV for very rare events and essentially matches the GEV out to the 100-year recurrence interval.

ANALYSES OF 2-HOUR DURATION ANNUAL MAXIMA

As in the analysis of 24-hour annual maxima, homogeneous sub-regions at the 2-hour duration were formed as collections of gages within small ranges of mean annual precipitation (MAP) within each of the climatic regions. The range of MAP was chosen so that about 6 to 10 gages, 200 to 350 station-years of record, were included in each sub-region with each gage having at least 15-years of record. This resulted in a total of 15 sub-regions for the 2-hour duration (Table 6). Record lengths at precipitation measurement stations varied from a minimum of 15-years to near 60-years, with nearly 50% of the stations having record lengths in excess of 40-years. Figure 9 depicts the number of stations within various ranges of record length.

Table 6 – Number of Sub-Regions, Gages and Station-Years of Record for 2-Hour Duration Annual Maxima

Regional Solutions for L-Moment Ratios, L-Cv and L-Skewness

Regional predictor equations for L-moment ratios at the 2-hour duration were developed in the same manner as that for the 24-hour duration. The resultant predictor equations for L-Cv are listed in Table 7 and graphically depicted in Figures 10a,b,c. The predictor equation for L-Skewness is listed in Table 8 and graphically depicted in Figure 11.

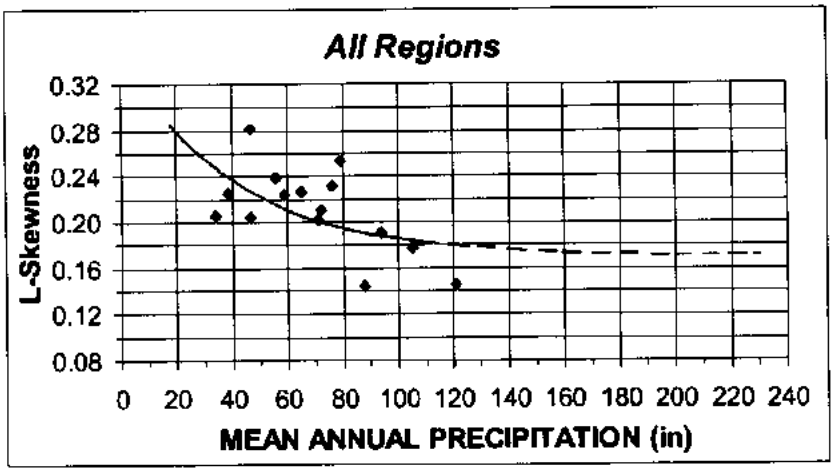

Figure 11 – Predictor Equation Solutions of Observed L-Skewness for All Climatic Regions for 2-Hour Duration

The suitability of the general form of the L-moment predictor equation (Equation 2a) is not as apparent in Figure 11 as was the case for other climatic regions. The naturally high variability of sample L-skewness values makes it more difficult to discern the underlying behavior of the data. However, the general form of the solution curve is consistent with behavior seen at the 24-hour duration and the behavior seen in other regional precipitation studies where the L-skewness values converge to some limiting value for sites with very high mean annual precipitation.

Heterogeneity Measures, 2-Hour Duration

Heterogeneity measures H1 and H2 (Hosking and Wallis[9,10]) were used to judge the relative heterogeneity in the proposed sub-regions for L-Cv and L-Skewness, respectively. Computation of H1 and H2 values for the various sub-regions indicated the majority of sub-regions were acceptably homogeneous (Table 9). In those cases where computed heterogeneity measures exceeded acceptance criteria, the excursions were generally of a minor amount. Only one sub-region on the windward face of the Olympics had large excursions beyond the acceptance criteria. In summary, mean annual precipitation was an excellent explanatory variable for describing the variability of L-Cv and L-Skewness across the study area.

Table 9 – Results of Heterogeneity and Goodness-of-Fit Tests for 2-Hour Duration

CLIMATIC REGIONS	NUMBER OF SUB-REGIONS	HOMOGENEOUS SUB-REGIONS H1 ≤ 2.00	HOMOGENEOUS SUB-REGIONS H2 ≤ 1.00	SUB-REGIONS ACCEPTING GEV DISTRIBUTION
5 - 151	2	1	1	2
142 - 32	4	4	2	4
31 -15	7	5	7	6
14	2	2	2	1
TOTAL	**15**	**12**	**12**	**13**

Identification of Regional Probability Distribution, 2-Hour Duration

The Generalized Extreme Value (GEV) distribution was identified most frequently as the best three-parameter probability model (Table 9) using the L-moment based test statistic for goodness-of-fit. A plot of regional L-Skewness and L-Kurtosis values for the 15 sub-regions at the 2-hour duration in shown in Figure 12. It is seen that the majority of data pairs plot nearest the GEV distribution, with the centroid being slightly above, slightly more kurtotic, than the GEV distribution.

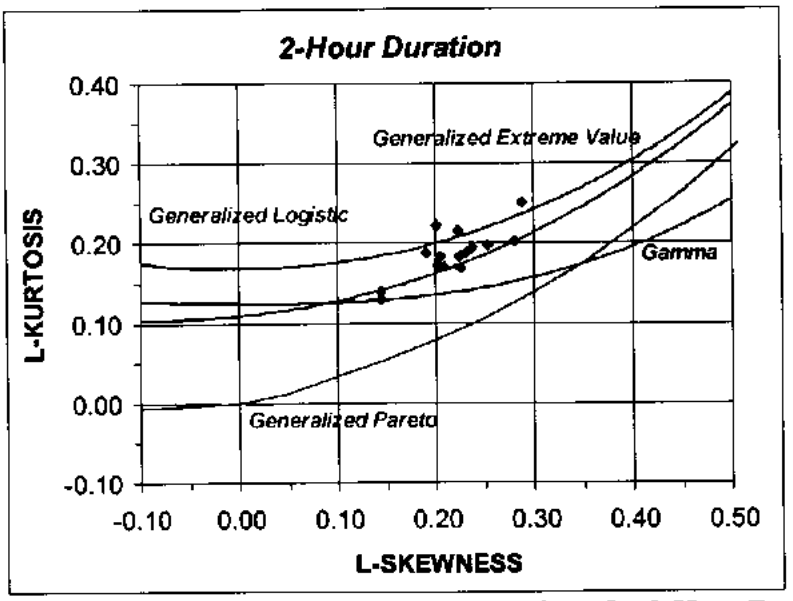

Figure 12 – L-Moment Ratio Plot for Sub-Regions for 2-Hour Duration

As was the case for the 24-hour duration, the GEV is a suitable distribution for estimation of precipitation quantiles out to the 500-year recurrence interval. If quantile estimates are desired for events more extreme than the 500-year recurrence interval, it would be worthwhile to utilize the four-parameter Kappa distribution and to refine the selection of the *h* parameter. To solve for an appropriate *h* value, a hierarchical approach (Fiorentino[4]) was taken wherein the shape parameter *h* was computed as the median value from the group of sub-region solutions. A median value of -0.150 was computed with a standard error of estimation of approximately $\pm$ 0.093. Based on this information, a nominal *h* value of -0.15 was adopted. This produces a regional growth curve slightly steeper than the GEV for very rare events and essentially matches the GEV distribution up to the 100-year recurrence interval.

PRECIPITATION MAGNITUDE-FREQUENCY ESTIMATES FOR GAGED SITES

The first step in developing a site-specific precipitation magnitude-frequency curve is to compute the regional growth curve. The findings described in the previous sections provide the information necessary for developing the regional growth curve for the 24-hour and 2-hour durations. Specifically, the first three parameters of the Kappa distribution (ξ, α, and κ) are solved (Hosking and Wallis[9,12]) using a mean of unity and the applicable regional values of L-Cv and L-Skewness as indicated in Tables 3a,b and 4a,b. The fourth parameter (*h*) of the Kappa distribution is set to the regional average value applicable to the selected duration. Equation 3 is then used to describe the regional growth curve. The site-specific precipitation-frequency curve is obtained by scaling the regional growth curve by the at-site mean.

For gaged sites, the at-site mean ($\hat{\mu}$) can be computed from the gage mean ($\bar{x}$) based on the correction factors (C_{nop}) in Table 10. A correction factor (Weiss[32]) is needed to adjust the gage sample mean to account for precipitation measurement and reporting on a fixed time interval rather than on the desired continuous basis. The at-site mean is computed from the gage mean as:

$$\hat{\mu} = C_{nop}(\bar{x}) \tag{4}$$

Table 10 – Correction Factors (C_{nop}) to Adjust Gage Sample Statistics

GAGE TYPE	DURATION	
	2-Hour	24-Hour
Daily Gage Snotel Gage	n/a	1.13
Automated Gage Hourly Reporting	1.04	1.00
Automated Gage 15-Minute Reporting	1.00	1.00

This procedure can be explained by an example using an existing gaged site. The Seattle-Tacoma Airport gage is located in the Interior Lowlands West, climatic Region 31. The mean annual precipitation for the site is 37.9-inches. For the 24-hour duration, the regional value of L-Cv is 0.159, which is obtained from Equation 2a and parameter values from Table 3b. The regional value of L-Skewness is 0.187, which is obtained from Equation 2a and parameter values from Table 4b. The regional value of the h parameter is -0.05 for the 24-hour duration. Using a mean value of unity, the solution for the four parameters of the Kappa distribution[12,15], yields:

$$\xi = 0.8716,\ \alpha = 0.2166,\ \kappa = -0.0394,\ \text{and}\ h = -0.05.$$

Use of Equation 3 yields the regional growth curve depicted in Figure 13a. Seattle-Tacoma Airport has an hourly gage with a gage mean of 2.10-inches for the 24-hour duration for 60-years of record. Use of Equation 4 with a correction factor of 1.00 yields an at-site mean value of 2.10-inches for the 24-hour duration. The at-site precipitation magnitude-frequency curve is obtained by scaling the regional growth curve by the at-site mean and is depicted in Figure 13b. The observed 24-hour annual maxima for the Seattle-Tacoma Airport site for the period from 1940-2000 are also depicted in Figure 12b for a comparison of the regional solution and the sample data.

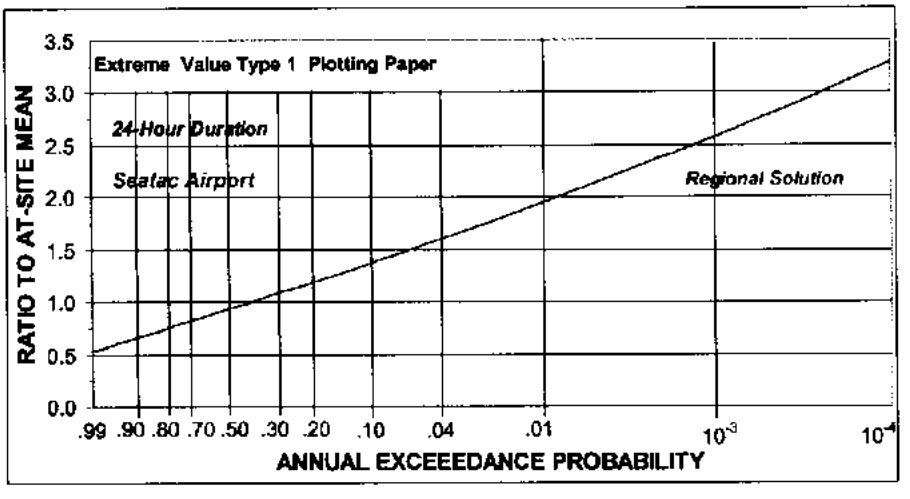

Figure 13a – Regional Growth Curve for Seattle-Tacoma Airport for 24-Hour Duration

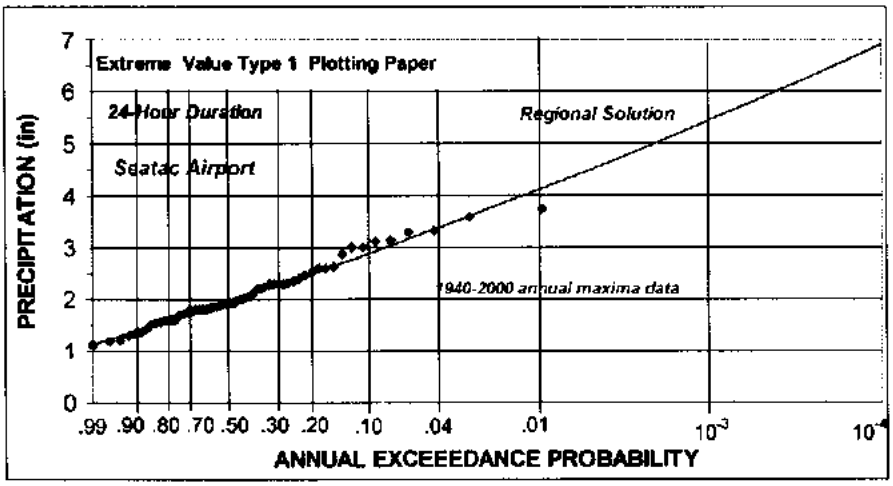

Figure 13b – Precipitation Magnitude-Frequency Curve for Seattle-Tacoma Airport for 24-Hour Duration

SPATIAL MAPPING OF PRECIPITATION-FREQUENCY INFORMATION

Products from the PRISM model[3] operated by Oregon Climate Service were used in conducting spatial mapping of precipitation for selected recurrence intervals. Gridded datasets and isopluvial maps were prepared for the 2-year, 10-year, 25-year, 50-year and 100-year recurrence intervals for the 24-hour and 2-hour durations. A gridded dataset and isopluvial map was also prepared for the 6-month (twice/year) recurrence interval for the 24-hour duration, which is needed for some water quality applications. Precipitation estimates for the 6-month and 2-year recurrence intervals were converted from annual maxima to partial duration series equivalents using the conversion developed by Langbein[15,27]. This was done to improve the frequency estimates for common events and to be consistent with past mapping products produced by the National Weather Service[16].

The spatial mapping of precipitation for selected recurrence intervals is dependent upon the production of two key components in addition to the regional precipitation-frequency information. The first component required is the spatial mapping of at-site means (station mean values, also called mean annual maxima). Grid-cell values of at-site means are used to scale dimensionless magnitude-frequency relationships to obtain precipitation estimates for the recurrence interval of interest. The second component required is the spatial mapping of regional statistical parameters. This provides L-moment ratio statistics applicable to each grid-cell in the study area domain, which are used to determine the probability distribution parameters for describing the magnitude-frequency relationship applicable to each grid-cell. Thus, the spatial mapping of at-site means and the spatial mapping of regional statistical parameters are the primary work products needed for isopluvial mapping.

Mean Annual Precipitation

The gridded dataset of mean annual precipitation provides a basis for spatial mapping of both at-site means and L-moment statistics and is therefore an important element of this project. An analysis of mean annual precipitation for the period from 1961 to 1990 has been completed for the study area by Oregon Climate Service using the PRISM model[3,20]. The resultant map has been utilized in this study and provides digital values of mean annual precipitation on a gridded latitude-longitude system with a nominal resolution of 1.25 minutes per grid-cell for the study area (about 1.4 mi^2). This resolution yields a study area domain that is a matrix of 216 rows by 336 columns, 72,576 grid-cells.

SPATIAL MAPPING OF AT-SITE MEANS

Spatial mapping of at-site means encompasses a number of separate tasks that address the spatial behavior of at-site means and seeks to minimize differences between mapped values and sample values computed at precipitation measurement stations. This typically involves first developing relationships between at-site means computed at precipitation measurement stations and climatic/physiographic factors. These relationships are then used to populate the grid-cells in the study area domain with the values predicted from the regression equation based on the climatic/physiographic factors representative of each grid-cell. Residuals are then computed for each of the station at-site means that quantify the magnitude of difference between mapped values and station values. This allows analyses to be conducted of the residuals to identify if there is a coherent spatial pattern to the magnitude and sign of the residuals. When coherent residual patterns are encountered, they are used to adjust the original estimates. Lastly, standard bias and root mean square error measures are computed to quantify the overall goodness-of-fit of the mapped values relative to the observations at the gages. The completed maps of the at-site means for the 24-hour and 2-hour durations are shown in Figures 14a,b, respectively.

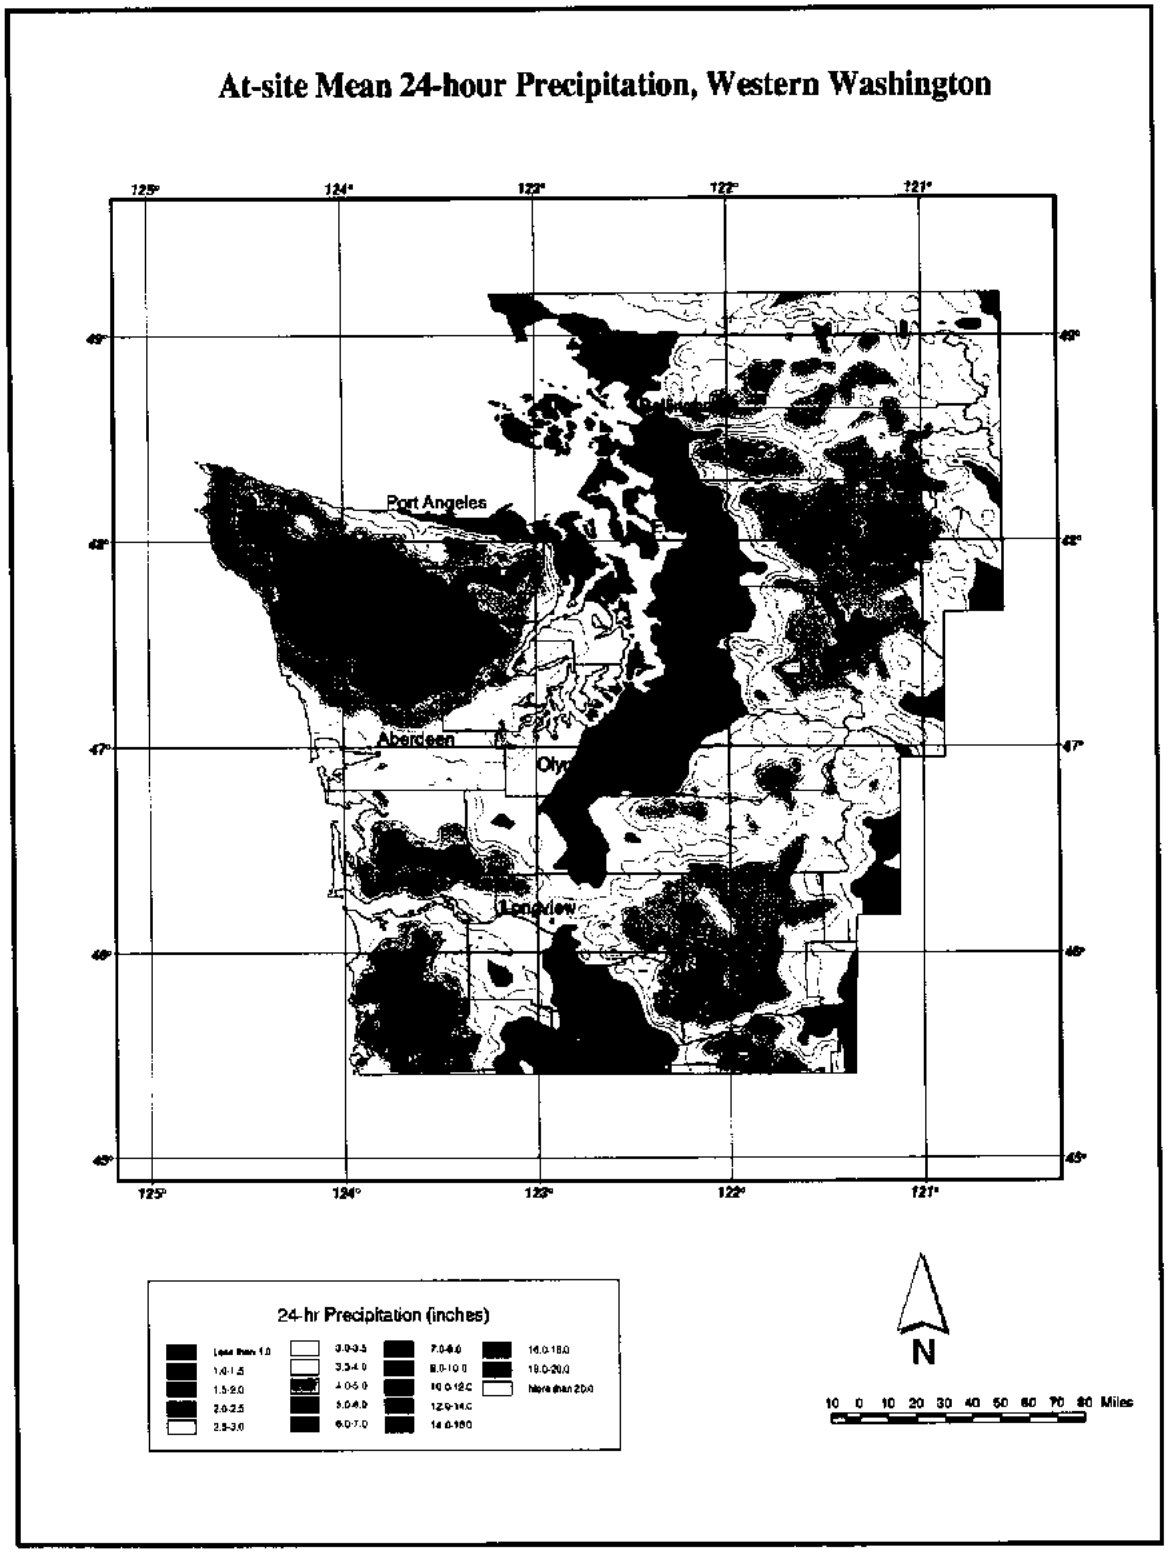

Figure 14a – Map of At-Site Means for 24-Hour Duration for Western Washington

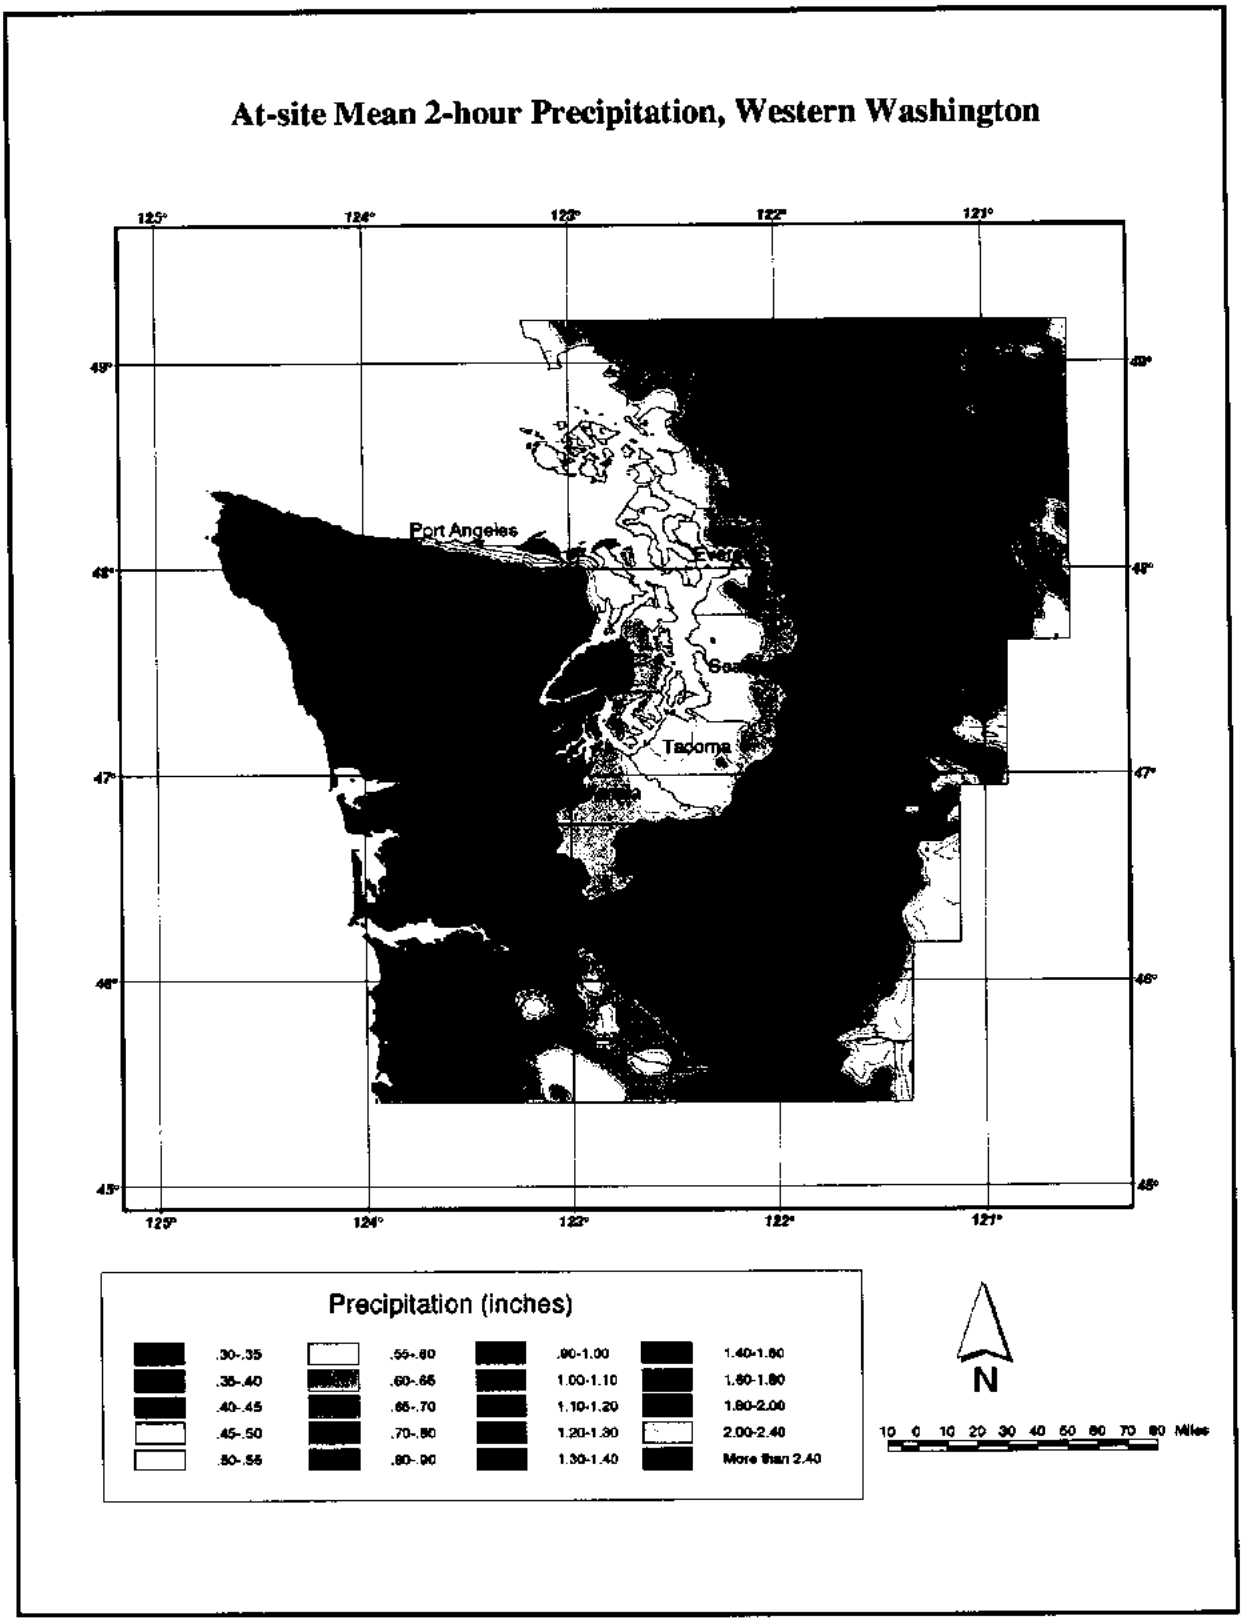

Figure 14b – Map of At-Site Means for 2-Hour Duration for Western Washington

Quantitative Assessment of Success Achieved in Spatial Mapping of At-Site Means
A quantitative measure was needed to assess the relative success of the spatial mapping procedures in capturing the spatial behavior of the at-site means. This is a difficult task in all studies of this type because the true values of the at-site means are unknown. The logical standard for comparison is the station sample value of at-site mean. However, sample values of the station at-site mean will differ from the true population values due to sampling variability, and other natural and man-related variability associated with precipitation measurement and recording.

We chose to approach this problem by framing the question as - how do the observed station values compare with the final mapped values? Given this question, the bias and root mean square error (RMSE) computations can be expressed in standardized units using the mapped values as the predicted value. This equates to computing bias and RMSE for the standardized residuals (SR_2) as:

$$SR_2 = (S - P_2) / P_2 \qquad (5)$$

where: S is the observed station value of the at-site mean (in); and P_2 is the mapped value of the station at-site-mean (in).

The computed standardized residuals are listed in Tables 11a,b. It is seen that the final mapped values of the at-site means are nearly unbiased. If the RMSE values for the stations are representative of the at-site mean maps taken as a whole, then the final maps of at-site means have a standard error of estimate that is near 5%. The RMSE of the final mapped values are generally similar in magnitude to that expected from natural sampling variability and, thus, are as low as can reasonably be expected.

Table 11a –Bias and Root Mean Square Error of Standardized Residuals for Final Mapped Values of At-Site Means for 24-Hour Duration

REGION	FINAL MAPPED VALUES	
	Bias	*RMSE*
COASTAL AREAS		
Region 5	+1.04%	5.26%
Region 151	-0. 68%	2.92%
Region 142	-1.47%	5.07%

Region 15	+0.55%	4.12%
Region 14	-0.85%	4.70%
ALL REGIONS	+0.21%	3.96%

SPATIAL MAPPING OF REGIONAL L-MOMENT STATISTICAL PARAMETERS

In order to compute precipitation estimates for the selected recurrence intervals, the appropriate value of L-Cv and L-skewness must be obtained for each grid-cell. This was accomplished by populating the grid-cells in the study area domain utilizing the functional relationships for L-Cv and L-skewness (Tables 3a,b and 4a,b) developed in the regional precipitation-frequency analysis.

A smoothing filter was then employed along regional boundaries to provide a smooth transition of L-moment ratio values across boundaries. In general, these were minor adjustments with changes of only a few percent, as particular care had previously been taken in the precipitation-frequency study to minimize differences at regional boundaries.

Separate gridded data files were prepared for L-Cv and L-skewness for each of the two durations, and are included as electronic files with this report (Appendix A).

PRODUCTION OF ISOPLUVIAL MAPS

Production of the isopluvial maps was accomplished by incorporation of the information described in the prior sections. For each grid-cell, the applicable value of the at-site mean and L-moment ratios L-Cv and L-skewness were used to solve the distribution parameters for the four-parameter Kappa distribution[9,12]. The distribution parameters were then used with Equation 3 to compute the expected value of the precipitation for the desired recurrence interval. This procedure was repeated for each grid-cell until the domain for the study area was populated. The resultant precipitation field was then contoured to yield isopluvials for selected values of precipitation.

An example of an isopluvial map produced by this process is depicted in Figure 15, which shows a color-shaded map of 24-hour 100-year precipitation. Isopluvial maps for the other selected recurrence intervals for the 24-hour and 2-hour durations are contained in Appendix B.

Precipitation Magnitude-Frequency Estimates for Moderate to Large Size Watersheds
The precipitation magnitude-frequency information contained in the gridded datasets and depicted on the isopluvial maps corresponds to 10-mi^2 and 1-mi^2 precipitation for the 24-hour and 2-hour durations, respectively. Estimation of precipitation volumes for larger watersheds for a selected recurrence interval requires the application of areal reduction factors[16,18,19]. Areal reduction factors would be obtained from analyses of historical storms. The topic of areal reduction factors, depth-area-duration analyses, and estimation of precipitation for moderate to large size watersheds is beyond the scope of this report. It is mentioned here to alert the reader that precipitation values from the gridded datasets and isopluvial maps need to be scaled by areal reduction factors to obtain estimates of precipitation volumes for moderate to large watersheds.

Uncertainty Bounds for 100-Year Values
The accuracy of estimation of 100-year precipitation annual maxima at a given location is dependent upon the success obtained in estimating the at-site mean, and L-moment ratios L-Cv and L-skewness, and the similarity between the chosen probability model (Kappa distribution) and the actual model mother-nature is using, which is unknown.

In general, uncertainties associated with the estimation of L-moment ratios L-Cv and L-skewness result in standard errors of estimation of about 5% at the 100-year recurrence interval. These relatively low levels of uncertainty are attributable to the very large datasets that were used to estimate the L-moment ratios and identify a suitable probability model. Interaction of these standard errors of estimation with that due to estimation of the at-site mean (Tables 11a,b) yield the standard errors of estimation shown in Table 12. The range in standard errors of estimation for a given duration is primarily due to the region-to-region variation of the standard errors for estimation of the at-site mean for the recurrence intervals cited in Table 12.

The values in Table 12 should be considered approximate as detailed studies for computation of uncertainty bounds have not been conducted. Further, these values represent regional averages. Values applicable to a given location may be somewhat smaller or larger than that indicated in Table 12.

Table 12 – Range of Standard Errors of Estimation for Selected Recurrence Intervals

DURATION	STANDARD ERROR OF ESTIMATION FOR PRECIPITATION	
	10-YEAR	100-YEAR
2-HOUR	4% - 7%	6% - 9%
24-HOUR	5% - 8%	7% - 10%

ELECTRONIC FILES
LISTING AT-SITE AND REGIONAL PARAMETERS FOR ALL GAGED SITES

Appendix A includes station catalogs for the stations/gages used in the study. It also references a compact disc (CD) containing ASCII text files and Excel spreadsheets listing the precipitation estimates for selected recurrence intervals. Specifically, the files contain the station identification number, station name, type of gage, climatic region number, latitude, longitude, elevation, mean annual precipitation, sample value of at-site mean, mapped value of at-site mean, regional values of L-Cv, L-skewness, *h* parameter for the Kappa distribution, and estimated 6-month, 2-year, 10-year, 25-year, 50-year, 100-year, and 500-year precipitation.

SEASONALITY OF EXTREME STORMS

The seasonality of extreme storms can be a valuable tool for application of the precipitation-frequency information in rainfall-runoff modeling. Specifically, information on the seasonality of storms is helpful in decision-making for setting watershed conditions antecedent to the storm. The seasonality of extreme storms was investigated by constructing frequency histograms of the storm dates for rare 24-hour and 2-hour precipitation amounts for each of the seven climatic regions. Extreme storms were taken to be precipitation amounts with annual exceedance probabilities less than 0.05 (rarer than a 20-year event). Precipitation amounts/gages with duplicate storm dates (generally dates within 7 calendar days) were removed before constructing the frequency histograms for each climatic region. The results of the seasonality analyses are discussed briefly below and additional frequency histograms are presented in Appendix C.

Well-defined seasonal patterns are apparent for the 24-hour and 2-hour durations. In western Washington, storms which are extreme at the 24-hour duration occur predominantly in the fall and winter months (Figure 16). These storms are the result of synoptic scale cyclonic weather systems and associated fronts. These storms remain organized and penetrate a considerable distance inland from the coast, as the eastern slopes of the Cascade Mountains also exhibit a distinctive fall-winter seasonal pattern.

Storms which are extreme at the 2-hour duration exhibit greater seasonal variability. In lowland areas, storms that are extreme at the 2-hour duration occur both in the warm season and in the fall and winter period (Figure 17a). Some of these events are localized events having limited areal coverage with precipitation occurring over a relatively short period of time. Other events are embedded in longer duration cool season storm events and are associated with large-scale weather systems having more widespread areal coverage. As the precipitation amounts become more rare and increase in magnitude, there is a greater likelihood that they are associated with a localized event and have temporal characteristics of a thunderstorm. These more rare events are more likely to occur in the warm season as a result of convective storm activity. (Figure 17b).

In coastal and mountain areas, the seasonality of extreme 2-hour storms covers the period from late-spring through winter. Moderately large 2-hour precipitation amounts are often embedded within longer duration storms associated with large-scale weather systems. For these sites, there is a greater percentage of storms at the 2-hour duration that occur in the fall and winter period (Figure 18).

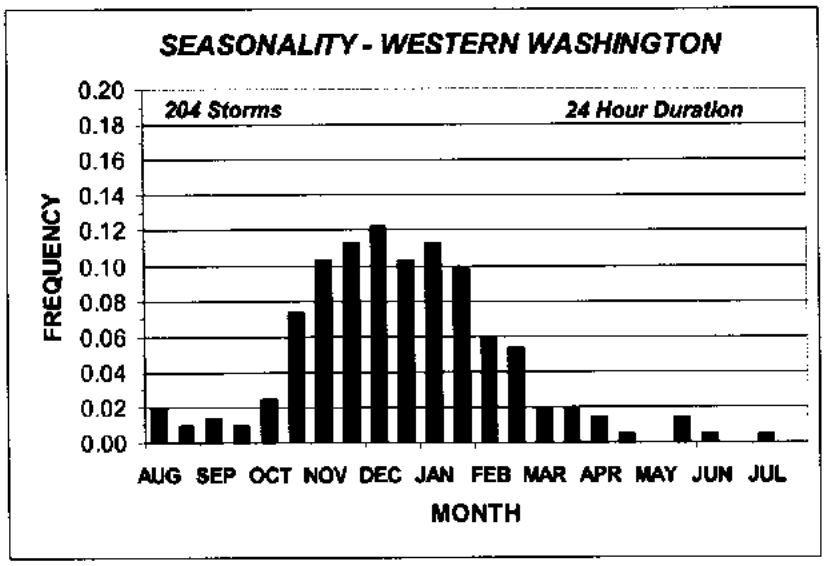

Figure 16 – Seasonality of Extreme Storms for All Climatic Regions for 24-Hour Duration

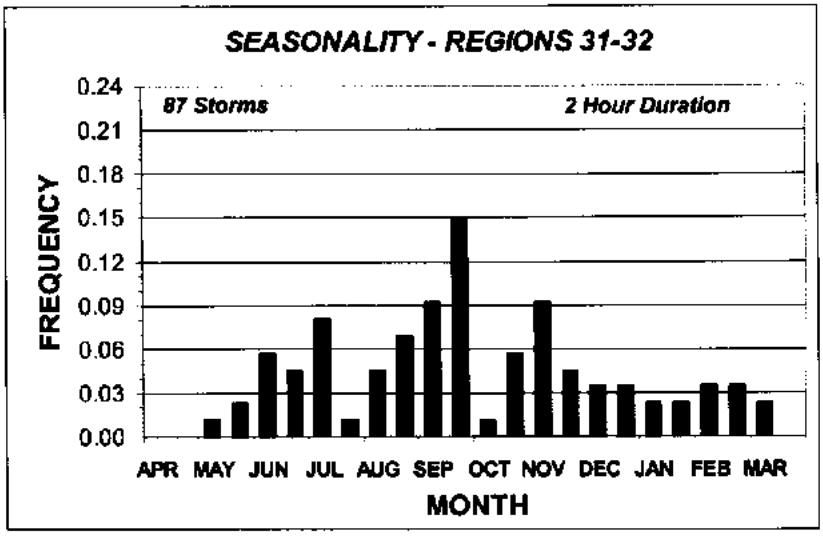

Figure 17a – Seasonality of Extreme Storms in Lowland Climatic Regions 31 and 32 for 2-Hour Duration

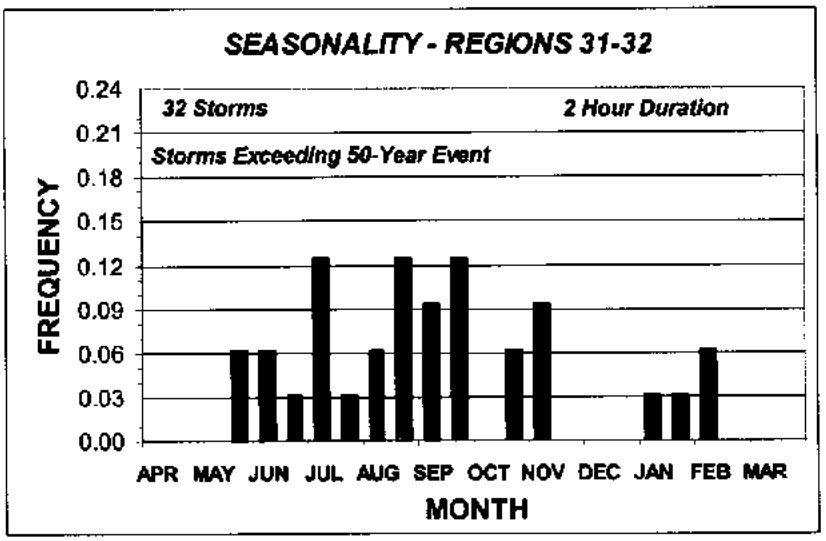

Figure 17b – Seasonality of Extreme Storms that Exceed 50-Year Event in Lowland Climatic Regions 31 and 32 for 2-Hour Duration

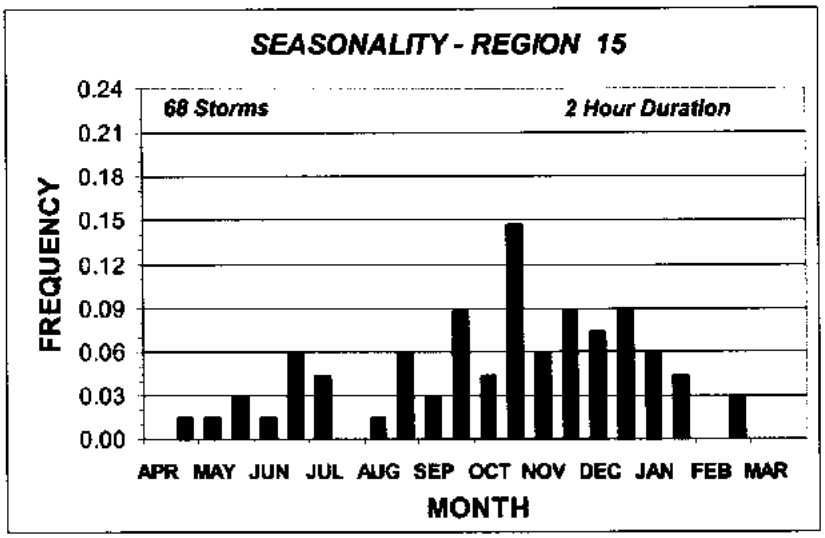

Figure 18 – Seasonality of Extreme Storms for Climatic Region 15 Windward Face of Cascade Mountains for 2-Hour Duration

CATALOG OF EXTREME STORMS

A catalog of extreme storms is contained in Appendix D. The catalog lists those storm events at the 24-hour and 2-hour durations where the annual exceedance probabilities were less than 0.05 (rarer than a 20-year event). These are the same storm events/storm dates as used in the seasonality analysis. The temporal patterns from these storms would be logical candidates for single event rainfall-runoff modeling of extreme storms.

Appendix A

STATION CATALOGS

AND

ELECTRONIC FILES OF PROJECT DELIVERABLES

OVERVIEW

This appendix includes station catalogs for the stations/gages used in the study for analysis of precipitation annual maxima at the 24-hour and 2-hour durations. These listings include the station identification number, station name, type of gage, climatic region number, latitude, longitude, elevation, and mean annual precipitation. A compact disc (CD) is also included as part of this appendix that contains electronic files for all of the project deliverables. Two items of particular interest are: a listing of precipitation magnitude-frequency estimates for each of the stations for the 6-month, 2-year, 10-year, 25-year, 50-year, 100-year, and 500-year recurrence intervals; and gridded datasets of precipitation-frequency values for the recurrence intervals listed above, that can be imported into GIS software .

The CD contains files with the following contents:

- catalog of stations
- precipitation annual maxima for all gages
- catalog of extreme storms
- gridded datasets for 24-hour and 2-hour mean annual maxima (at-site means)
- gridded datasets of L-moment ratios L-Cv and L-Skewness for 24-hour and 2-hour durations
- gridded datasets of precipitation estimates for selected recurrence intervals
- precipitation magnitude-frequency estimates for selected recurrence intervals for each station
- final report and supporting graphics

OVERVIEW

This appendix contains isopluvial maps of the 2-year, 10-year, 25-year, 50-year, and 100-year precipitation for the 24-hour and 2-hour durations. An isopluvial map for the 6-month recurrence interval (twice-year) is also depicted for the 24-hour duration. Estimates of precipitation for 6-month and 2-year recurrence intervals were made using standard conversions developed by Langbein[15,27] for conversion from annual maxima to partial duration series equivalents. Gridded datasets used to create these maps are contained on the Compact Disc (CD) described in Appendix A. Electronic files of the graphic images (jpeg files) contained in this appendix are also included on the CD.

6-month 24-hour Precipitation, Western Washington

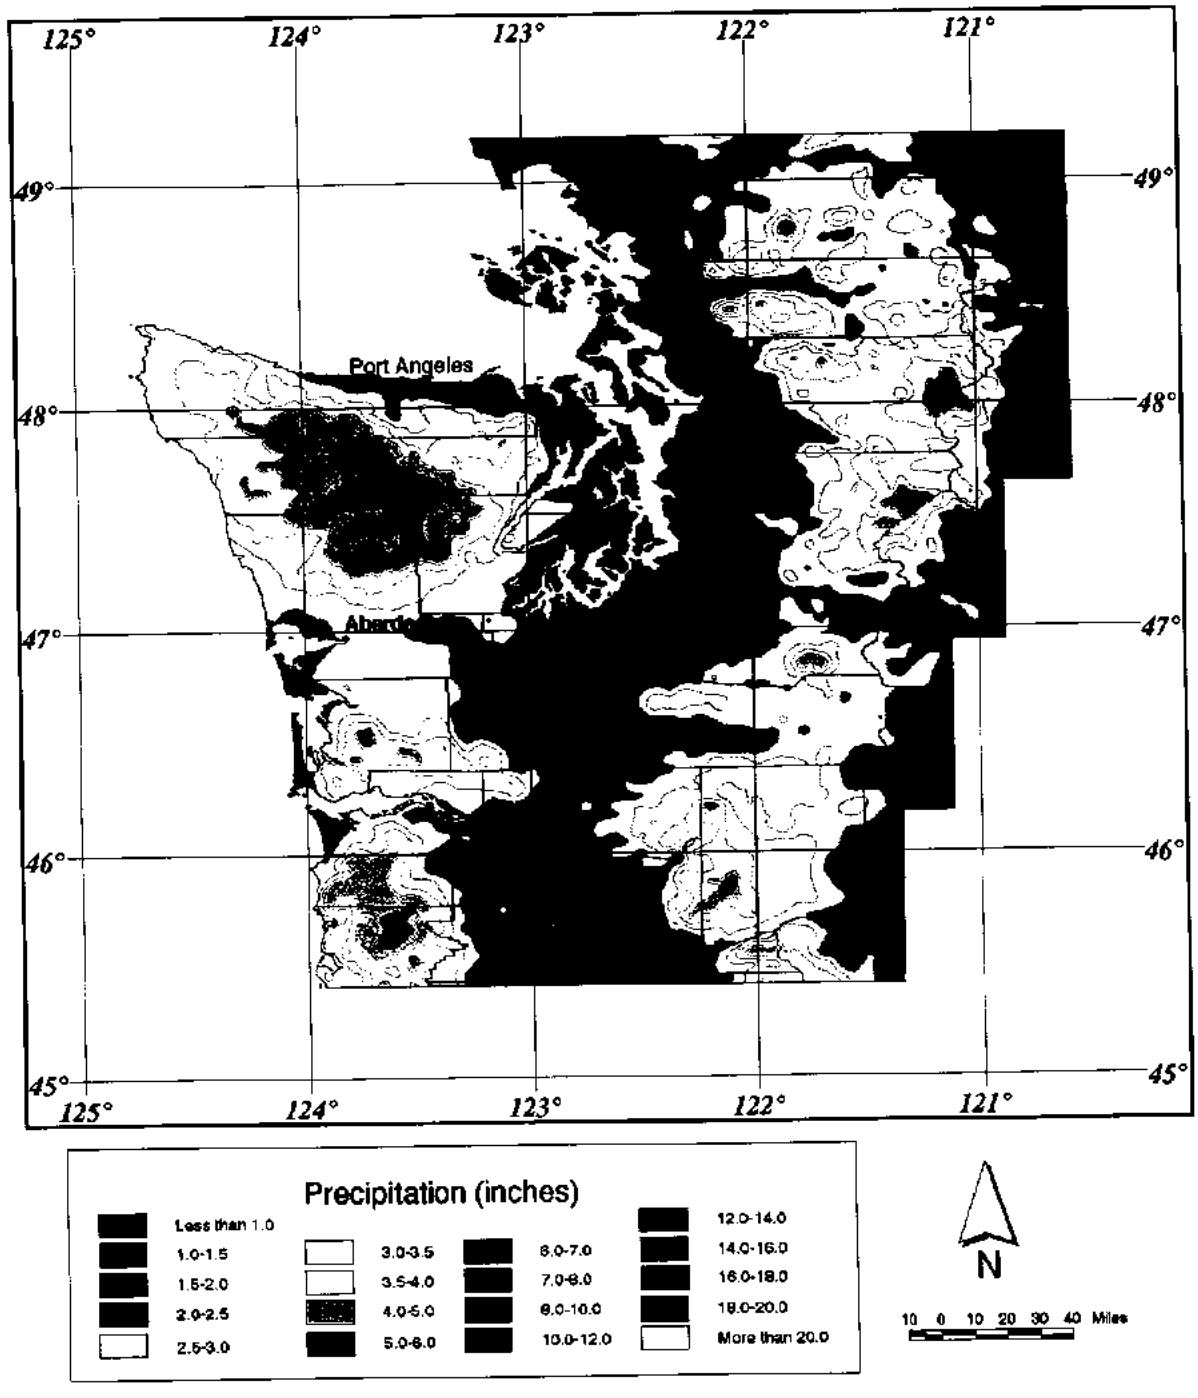

Figure B1 – Isopluvial Map of 24-Hour Precipitation for 6-Month Recurrence Interval for Western Washington

2-year 24-hour Precipitation, Western Washington

OVERVIEW

The seasonality of extreme storms was investigated by constructing frequency histograms of the storm dates for rare 24-hour and 2-hour precipitation amounts for each of the seven climatic regions. Extreme storms were taken to be precipitation amounts with annual exceedance probabilities less than 0.05 (rarer than a 20-year event). Precipitation amounts/gages with duplicate storm dates (generally dates within 7 calendar days) were removed before constructing the frequency histograms for each climatic region.

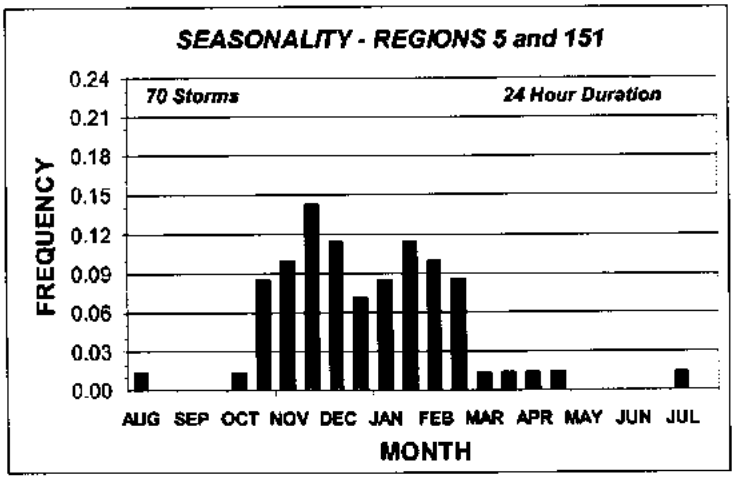

Figure C1 – Seasonality of Extreme Storms at 24-Hour Duration
for Coastal Lowlands and Coastal Mountains West, Climatic Regions 5 and 151

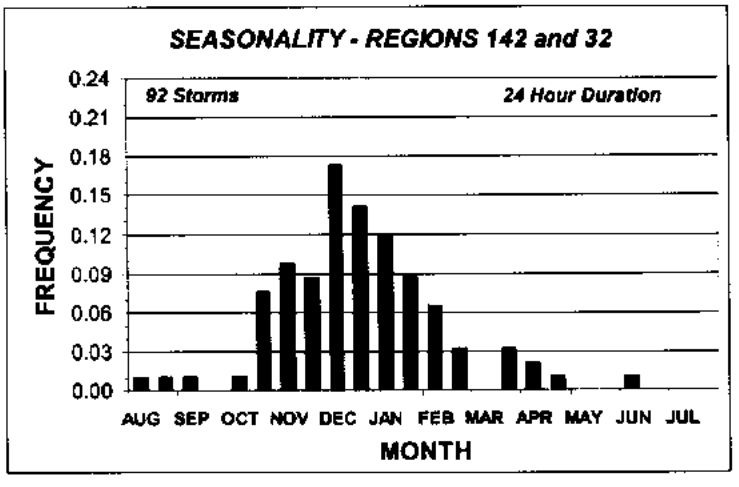

Figure C2 – Seasonality of Extreme Storms at 24-Hour Duration
for Coastal Mountains East and Interior Lowlands West, Climatic Regions 142 and 32

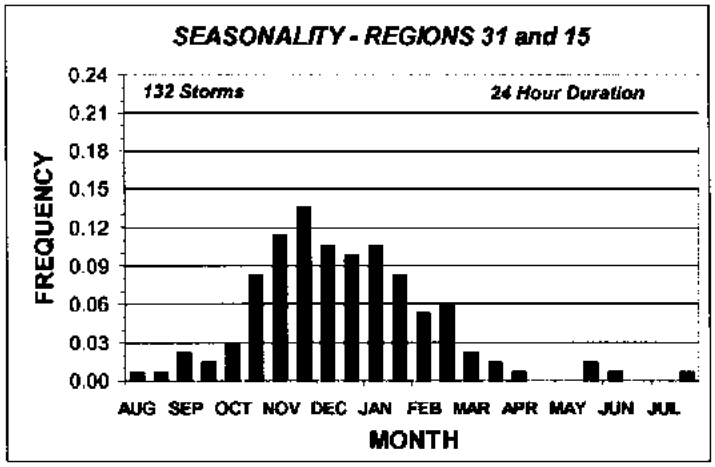

Figure C3 – Seasonality of Extreme Storms at 24-Hour Duration
for Interior Lowlands East and Cascade Mountains West, Climatic Regions 31 and 15

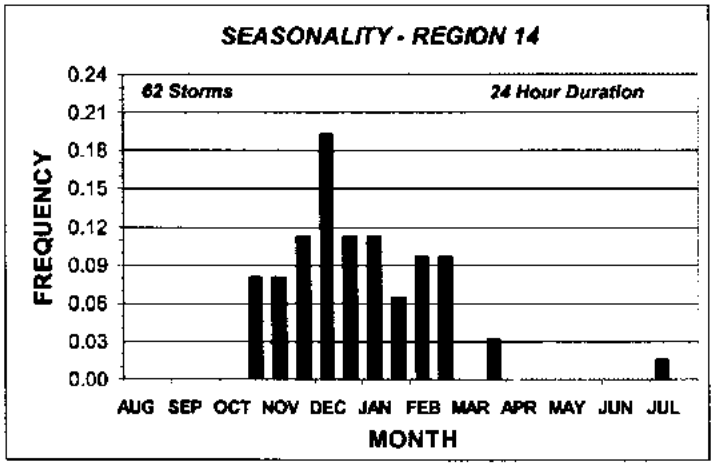

Figure C4 – Seasonality of Extreme Storms at 24-Hour Duration
for Cascade Mountains East, Climatic Region 14

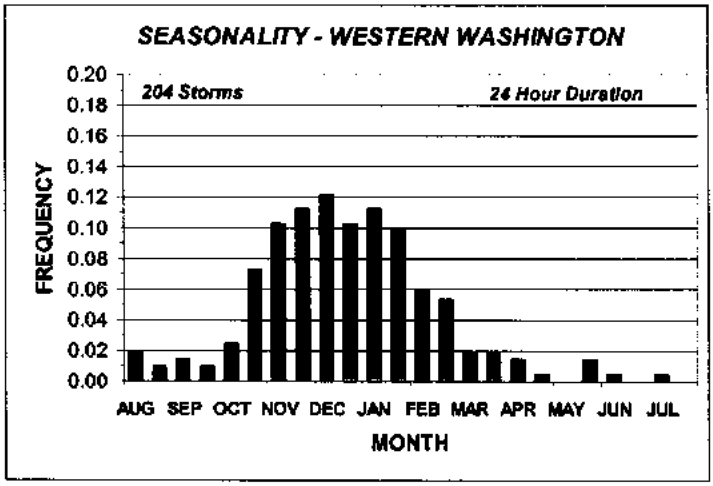

Figure C5 – Seasonality of Extreme Storms at 24-Hour Duration
for All Western Washington Climatic Regions

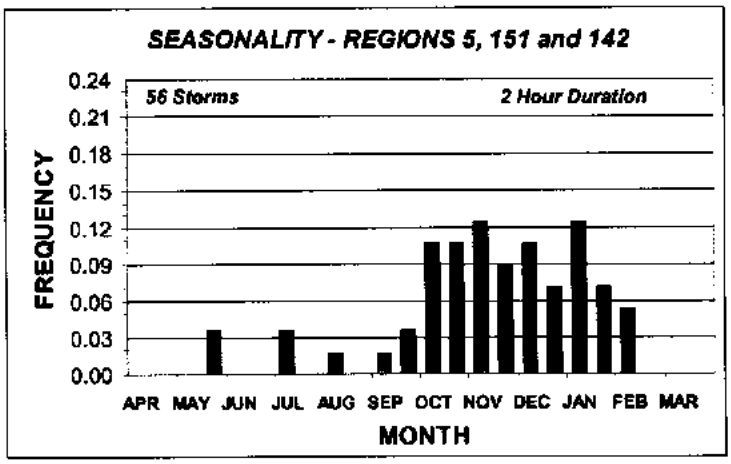

Figure C6 – Seasonality of Extreme Storms at 2-Hour Duration
for Coastal Lowlands and Coastal Mountains, Climatic Regions 5, 151 and 142

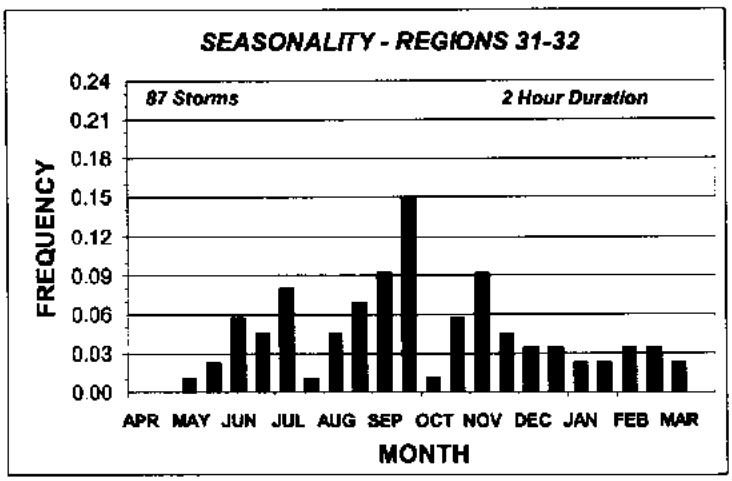

Figure C7 – Seasonality of Extreme Storms at 2-Hour Duration
for Interior Lowlands East and West, Climatic Regions 31 and 32

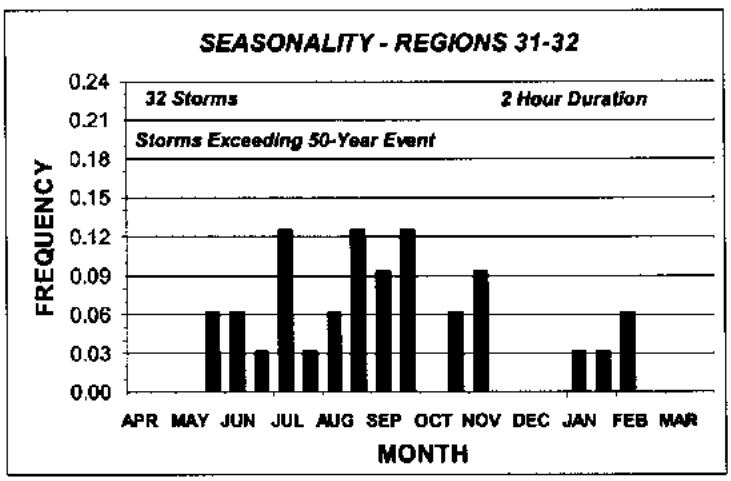

Figure C8 – Seasonality of Extreme Storms that Exceed 50-Year Event at 2-Hour Duration
for Interior Lowlands East and West, Climatic Regions 31 and 32

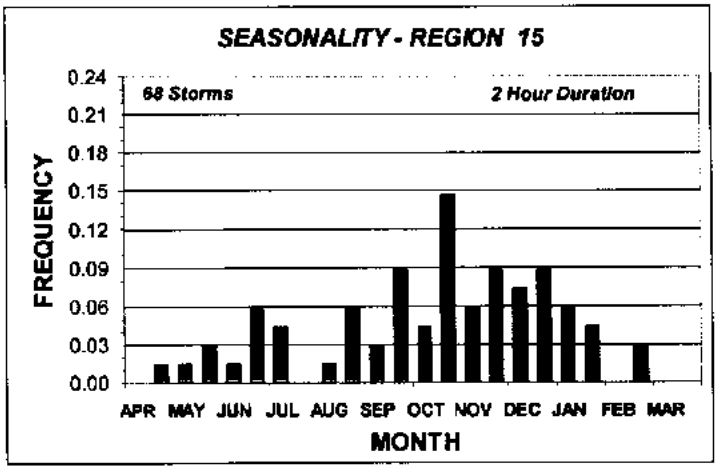

Figure C9 – Seasonality of Extreme Storms at 2-Hour Duration for Cascade Mountains West, Climatic Region 15

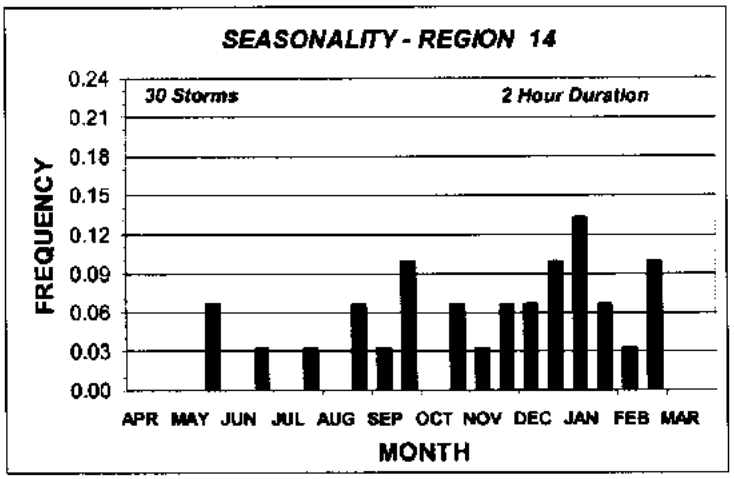

Figure C10 – Seasonality of Extreme Storms at 2-Hour Duration for Cascade Mountains East, Climatic Region 14

Appendix D

CATALOGS OF EXTREME STORMS
FOR 24-HOUR AND 2-HOUR DURATIONS

OVERVIEW

This appendix contains catalogs of the dates and locations of the occurrence of extreme storms. An extreme storm is deemed to occur when a recorded precipitation amount has exceeded a 20-year recurrence interval for that site. When numerous gages record precipitation amounts that exceed the 20-year threshold for a given storm date, the hourly gage with the rarest precipitation measurement is listed in the catalog. Hourly gages are listed because the primary application of the storm catalog is for identification of temporal storm patterns that would be useful in rainfall-runoff modeling of extreme events. Separate tables have been prepared, where the location, date and precipitation amount are listed for the various climatic regions.

Appendix E

L-MOMENT STATISTICS

L-MOMENT STATISTICS

L-moments are a dramatic improvement over conventional statistics for characterizing the variance and skewness of data, for describing the shape of a probability distribution, and for estimating the distribution parameters (Hosking[7,9,13]). They are particularly useful for describing environmental data that are often highly skewed. The at-site L-moment measure of location, and L-moment ratio measures of scale, skewness and kurtosis are:

Location, mean:

$$\text{Mean} = L_1 \quad \text{(E1)}$$

Scale, L-Cv (t_2):

$$t_2 = L_2/L_1 \quad \text{(E2)}$$

L-Skewness (t_3):

$$t_3 = L_3/L_2 \quad \text{(E3)}$$

L-Kurtosis (t_4):

$$t_4 = L_4/L_2 \quad \text{(E4)}$$

where:

$$L_1 = \beta_0 \quad \text{(E5)}$$

$$L_2 = 2\beta_1 - \beta_0 \quad \text{(E6)}$$

$$L_3 = 6\beta_2 - 6\beta_1 + \beta_0 \quad \text{(E7)}$$

$$L_4 = 20\beta_3 - 30\beta_2 + 12\beta_1 - \beta_0 \quad \text{(E8)}$$

and where the at-site data are first ranked in ascending order from 1 to n ($x_{1:n}$) and:

$$\beta_0 = n^{-1} \sum_{j=1}^{n} x_j \quad \text{(E9)}$$

$$\beta_1 = n^{-1} \sum_{j=2}^{n} x_j \, [(j-1)/(n-1)] \quad \text{(E10)}$$

$$\beta_2 = n^{-1} \sum_{j=3}^{n} x_j \, [(j-1)(j-2)]/[(n-1)(n-2)] \quad \text{(E11)}$$

$$\beta_3 = n^{-1} \sum_{j=4}^{n} x_j \, [(j-1)(j-2)(j-3)]/[(n-1)(n-2)(n-3)] \quad \text{(E12)}$$

Regional L-moments ratios are obtained as weighted averages of the at-site L-moments ratios where the at-site values are weighted by record length. Specifically: n_i is the record length at site i of N sites: n_R is the total record length for the N sites in the region; t_2^i, t_3^i, t_4^i are L-moment ratios at site i ; and:

$$n_R = \sum_{i=1}^{N} n_i \tag{E13}$$

Regional Mean (L_1^R) is unity using the index-flood procedure:

$$L_1^R = 1 \tag{E14}$$

Regional L-Cv (t_2^R):

$$t_2^R = n_R^{-1} \sum_{i=1}^{N} n_i \, t_2^i \tag{E15}$$

Regional L-Skewness (t_3^R):

$$t_3^R = n_R^{-1} \sum_{i=1}^{N} n_i \, t_3^i \tag{E16}$$

Regional L-Kurtosis (t_4^R):

$$t_4^R = n_R^{-1} \sum_{i=1}^{N} n_i \, t_4^i \tag{E17}$$

The regional L-moment ratios for L-Skewness (t_3^R) and L-Kurtosis (t_4^R) were corrected for bias based on bias correction equations provided by Hosking and Wallis[8,9]. These equations are valid for the range of regional L-moment ratios observed in the study area, where:

$$\text{bias } t_3^R = 4N(.10 - t_4^R) / n_R \tag{E18}$$

$$\text{bias } t_4^R = 4N(.15 - t_4^R) / n_R \tag{E19}$$

Appendix F

SELECTED DEFINITIONS

At-Site - the term at-site is used in various ways. It may be used to distinguish analyses/data at a specific site from regional analyses/data. It may be used in reference to a given gage/station or a specific geographic location. Observed at-site precipitation is synonymous with observed point rainfall.

At-Site Mean - the mean value of precipitation for a specified duration at a specific location. For a gaged site, it is based on the gaged record for the specified duration. At an ungaged site, it is based on a statistical relationship. Also see mean annual maxima.

Climatic Region - a geographic area that has similar physical and climatological characteristics.

Convective Precipitation - precipitation that results from lifting of atmospheric moisture due to vertical instability in the air column. The thunderstorm is one type of convective precipitation producing mechanism.

Convergence Precipitation - convergence is intended to encompass all precipitation producing mechanisms associated with the circulation of a cyclonic weather system.

Extreme Storm - a precipitation amount for a specified duration that has an annual exceedance probability less than 0.05; rarer than a 20-year event.

Gage Mean - the mean value computed from the annual maxima data at a precipitation gage for some specified duration. At-site mean values are determined from gage mean values using minor correction factors to adjust from fixed measurement intervals to true intervals. See Weiss[32].

Gaged Site - a geographic location where a precipitation gage is used to measure and record precipitation data. See also ungaged site.

Homogeneous sub-region - a collection of sites/gages with similar physical and/or climatic characteristics that can be described by a common regional growth curve.

Mean Annual Maxima (MAM) - the mean value of precipitation annual maxima for a specified duration at a specific location. It is the terminology commonly used in Canada as an alternate to at-site-mean.

Mean Annual Precipitation (MAP) - the average precipitation for a calendar year. (An example of an at-site-mean).

Orographic Precipitation - precipitation that occurs due to the lifting of atmospheric moisture over mountain barriers.

Precipitation Annual Maxima - the greatest precipitation amount in a 12-month period for a specified duration. The annual period may be a calendar year, or any other 12-month period. The water-year, October 1st to September 30th is the 12-month period used in these analyses.

Regional - the term regional is used in a generic manner to distinguish data/analyses for a group of sites/gages as opposed to individual at-site data/analyses. The term regional may be used in reference to homogeneous sub-regions or climatic regions.

Regional Growth Curve - a magnitude-frequency curve with a mean value of unity that is applicable to all sites within a homogeneous region.

Seasonality - frequency characteristics for the time of year (month) during which certain characteristics of precipitation have been observed to occur.

Station - refers to the weather station/collection site for precipitation. A particular station/location may contain any combination of daily, synoptic and automated gages. The term station and site are often used interchangeably.

Ungaged Site - a geographic location where no precipitation measurements are available.

E.48. West Virginia

TITLE 47
LEGISLATIVE RULE
DEPARTMENT OF ENVIRONMENTAL PROTECTION
WATER RESOURCES

SERIES 34
DAM SAFETY RULE

§47-34-1. General.

1.1. Scope and Purpose. -- This legislative rule establishes requirements relating to the design, placement, construction, enlargement, alteration, removal, abandonment, and repair of dams in this State that fall within the definition set forth in 2.12. This legislative rule also establishes requirements to govern the disbursement and use of moneys held in the State Dam Safety Rehabilitation Revolving Fund. The scope does not extend to those dams that are related to coal activities.

1.2. Authority. -- W. Va. Code §22-14-4 and §22-14-19(c).

1.3. Filing Date. -- May 20, 2009.

1.4. Effective Date. -- June 1, 2009.

1.5. Amendment of Existing Rule. -- This legislative rule amends the Dam Safety Rule, 47 C.S.R. 34, filed and made effective May 10, 1995.

§47-34-2. Definitions.

2.1. "Abandonment" means to render a dam non-impounding by filling the reservoir created by that dam with solid materials and by diverting the natural drainway around the site.

2.2. "Act" means the West Virginia Dam Control and Safety Act, W. Va. Code §22-14-1, et seq.

2.3. "Applicant" means a person who applies for a certificate of approval or a loan pursuant to the provisions of this rule.

2.4. "Appurtenances" means any ancillary part of a dam or reservoir system which contributes to the operation or construction of the dam.

2.5. "Assessment Officer" means a person appointed by the Secretary to carry out the review and hearing procedures outlined in this rule.

2.6. “Authority” means the West Virginia Water Development Authority provided in W. Va. Code §22C-1-1 et seq.

2.7. "Average Time Headway" means the number of seconds in one day divided by the average daily traffic.

2.8. "Breach" means partial removal of a dam, creating a channel through the dam at the original stream bottom elevation.

2.9. "Bridge" means a structure, including any abutments or supports appurtenant to that structure, which:

2.9.a. Meets the definition of "dam" set forth in subsection 2.12.;

2.9.b. Is constructed across a natural drainway for the purpose of maintaining a pathway, railway, roadway, support structure, or other passageway for transporting persons, traffic, or other static or moving loads; and

2.9.c. Has an opening under the structure to provide for the passage of normal stream flow.

2.10. "Certificate of Approval" means the written approval issued by the Secretary to a person who has applied to the Secretary for a certificate of approval that authorizes the person to place, construct, enlarge, alter, remove, abandon, or repair a dam and which specifies the conditions or limitations under which the work is to be performed by the applicant.

2.11. "Cost" means the total of all reasonable and necessary costs incurred by a person or the Secretary to finance the engineering, design, alteration, improvement, repair, breaching or removal of a deficient dam for carrying out all works and undertakings necessary or incidental to the accomplishment of any project receiving a loan under this rule, including:

2.11.a. The costs of developmental, planning, and feasibility studies, surveys, plans, and specifications;

2.11.b. The costs of architectural, engineering, financial, legal, or other special services;

2.11.c. The costs of acquisition of land and any buildings and improvements thereon, including the discharge of any obligations of the sellers of such land, buildings, or improvements;

2.11.d. The costs of site preparation and development, including demolition or removal of existing structures, construction and reconstruction, labor, materials, machinery, and equipment;

2.11.e. The reasonable costs of financing incurred by the person applying for a loan from the Fund in the course of the development of the project, carrying charges incurred before placing the project in service, interest on funds borrowed to finance the project to a date subsequent to the estimated date the project is to be placed in service, necessary expenses incurred in connection with placing the project in service, and the funding of accounts and reserves as required by the Secretary;

2.11.f. Other items as are deemed reasonable and necessary by the Secretary.

2.12. "Dam" means an artificial barrier or obstruction --including any works appurtenant to it and any reservoir created by it -- which is or will be placed, constructed, enlarged, altered, or repaired so that it does or will impound or divert water and is or will be twenty-five (25) feet or more in height from the natural bed of a stream or watercourse measured at the downstream toe of the barrier and which does or can impound fifteen (15) acre-feet or more of water or is or will be six (6) feet or more in height from the natural bed of such stream or watercourse measured at the downstream toe of the barrier and which does or can impound fifty (50) acre-feet or more of water. “Dam” does not mean:

2.12.a. Any dam owned by the federal government;

2.12.b. Any dam for which the operation and maintenance thereof is the responsibility of the federal government;

2.12.c. Any farm pond constructed and used primarily for agricultural purposes -- including, but not limited, to livestock watering, irrigation, retention of animal wastes, and fish culture -- that has no potential to cause a loss of human life in the event of embankment failure; or

2.12.d. Roadfill or other transportation structures that do not or will not impound water under normal conditions and that have a designed culvert or similar conveyance or capacity that would be used under a highway at the same location: Provided, That the Secretary may apply the provisions of W. Va. Code §22-14-10 for hazardous, non-impounding structures that become a hazard to human life or property through the frequent or continuous impoundment of water.

2.13. “Deficient dam” means a noncoal-related dam that exhibits one or more design, maintenance, or operational problems that may adversely affect the performance of the dam over a period of time or during a major storm or other inclement weather that may cause loss of life or property; or a noncoal-related dam that otherwise fails to meet the requirements of the Act or this rule.

2.14. "Dam Safety Section" means the Dam Safety Section of the Department of Environmental Protection.

2.15. "Dangerous Condition" means any structural or hydraulic condition of a dam or its appurtenances which may lead to:

2.15.a. Failure of the dam and possible loss of human life or substantial loss of property;

2.15.b. Harm to the public health or welfare; or

2.15.c. Significant harm to the environment.

2.16. "Design Storm" means predicted precipitation of given intensity, frequency, and duration based upon National Weather Service data that is required to be considered in the design of a dam.

2.17. "Disbursement" means the transfer of cash from the Fund to an applicant.

2.18. "Diversion Ditch" means a designed channel constructed for the purpose of collecting and transmitting surface runoff resulting from a given design storm.

2.19. "Embankment" means a constructed deposit of earth or waste materials, usually exhibiting at least one sloping face.

2.20. "Emergency Condition" means an imminently dangerous condition where failure of the dam is possible at any time.

2.21. "Emergency Spillway" means a hydraulic structure designed to discharge water in excess of that which an impoundment is designed to store or which cannot be passed through a principal spillway.

2.22. "Enforcement Action" means a written notification provided to an alleged violator by the Secretary within thirty (30) calendar days of an inspection, or in accordance with the provisions of the Act.

2.23. "Engineer" or "Registered Professional Engineer" means a person who by reason of his or her knowledge of mathematics, the physical sciences, and the principles of engineering, acquired by professional education and practical experience, is qualified to engage in the practice of professional engineering, and holds a current certificate of registration issued by the State granting its licensee the privilege of practicing professional engineering in accordance with the provisions of W. Va. Code §30-13-1 et seq.

2.24. "Freeboard" means the vertical distance between the lowest point of the crest of the embankment of a dam and the reservoir water surface.

2.25. "Fund" means the State Dam Safety Rehabilitation Revolving Fund.

2.26. "Geotechnical Engineering" means the application of soil mechanics, rock mechanics, and geology to the solution of problems involving engineering structures and their interaction with surrounding earth materials.

2.27. "Hazard Classification" means a classification rating assigned to a structure based upon engineering evaluations and judgments for predicting the danger to human life, property, and environment should a failure of the structure occur.

2.28. "High Risk Highway" means a roadway, roadfill, bridge, support structure, or other passageway for transporting persons, traffic, or other static or moving loads where the average time headway between vehicles in traffic is less than the duration of overtopping caused by the dam break flood wave.

2.29. "Hydraulics" means the study of the physical behavior of liquids, especially water, in natural or man-made systems or processes.

2.30. "Hydrologic Analysis" means a determination, using accepted engineering methods, to establish surface water runoff for a given design storm.

2.31. "Hydrology" means the science that deals with the occurrence and behavior of water in the atmosphere, on the ground, and underground.

2.32. "Impoundment" means a basin for the retention of water, sediment, or waste.

2.33. "Incised Reservoir" means an impoundment, or that portion of an impoundment, which has been excavated below the natural stream level into natural ground.

2.34. "Loan" means a loan made by the Authority to an applicant pursuant to section 20.

2.35. "Loan Agreement" means an agreement entered into between the Authority and the applicant pertaining to a loan.

2.36. "Low Risk Highway" means a roadway, roadfill, bridge, support structure, or other passageway for transporting persons, traffic, or other static or moving loads where the average time headway between vehicles in traffic is greater than the duration of overtopping caused by the dam break flood wave.

2.37. "Major Damage" means destruction, ruin, collapse, or displacement of dwellings, commercial or industrial buildings, public highways or bridges, or important public utilities. Dwellings, buildings, public highways or bridges, or important public utilities will sustain major damage when:

2.37.a. The dwelling, commercial or industrial building, public highway or bridge, or important public utility is in the direct path of the dam break flood wave, or;

2.37.b. Important public utilities equipment or public highways or bridges will be harmed sufficiently to cause disruption of service, or to require repair or replacement of the important public utility equipment, or public highway or bridge, or;

2.37.c. The dwelling, commercial or industrial building or important public utility will experience more than 1.5 feet of flood rise due to the dam break flood wave above the lowest ground elevation adjacent to the outside foundation walls; or more than 1.5 feet of flood rise due to the dam break

flood wave above the lowest floor elevation of the dwelling, commercial or industrial building or important public utility. The lower of the elevations shall govern.

2.38. "Minor Damage" means insignificant harm to dwellings, commercial or industrial buildings, public highways or bridges, or public utilities that does not qualify as major damage.

2.39. "Natural Bed" means the lowest elevation of a stream, intermittent stream, or channel created by nature which has not been altered or changed by the actions of man.

2.40. "Natural Drainway" means any natural watercourse which may carry water to the tributaries and rivers of the watershed.

2.41. "Notice of Civil Administrative Penalty" means a written notification provided to a violator by the Secretary, by means of certified mail or personal service, assessing a civil administrative penalty. A notice of civil administrative penalty shall include:

2.41.a. A reference to the section of the statute, rule, notice, order, or certificate of approval term allegedly violated;

2.41.b. A concise statement of the facts alleged to constitute the violation;

2.41.c. A statement of the amount of the initial civil administrative penalty to be imposed; and

2.41.d. A statement of the alleged violator's right to an informal hearing.

2.42. "Notice of Dismissal" means a written notification provided to a violator by the assessment officer or the Secretary dismissing and vacating the civil administrative penalty. A notice of dismissal may be issued at any time during the proceedings.

2.43. “No Hazard” means a situation that is not associated with the structural or hydraulic condition of a dam.

2.44. "P100" means the rainfall amount based upon a one hundred (100) year frequency, six (6) hour duration rainfall event (i.e, a 100-year, 6-hour storm).

2.45. "Person" means any public or private corporation, institution, association, society, firm, organization or company organized or existing under the laws of this or any other state or country; the state of West Virginia; any state governmental agency; any political subdivision of the state or of its counties or municipalities; a sanitary district; a public service district; a drainage district; a conservation district; a watershed improvement district; a partnership; trust, or estate; a person or individual; a group of persons or individuals acting individually or as a group; or any other legal entity. The term "person", when used in this article, includes and refers to any authorized agent, lessee or trustee of any of the foregoing or receiver or trustee appointed by any court for any of the foregoing.

2.46. "Piping" means progressive internal erosion of earth material or adjacent unaltered material caused by water movement through embankment material with sufficient force to move soil particles, leading to the development of a channel or a hole.

2.47. "Principal Spillway" means the hydraulic structure designed to discharge water stored between the normal pool and the emergency spillway invert elevations.

2.48. "Probable Maximum Precipitation" or "PMP" means the depth-duration-area rainfall event for a particular area that represents the maximization of the most critical meteorological conditions that are considered possible to occur.

2.49. “Project” means planning, design, or construction activity necessary to obtain a certificate of approval or to obtain a loan for repair or removal of a dam.

2.50. "Project Area" means all areas physically affected by the construction of a dam including, but not limited to, the dam and its appurtenances, the reservoir area, construction zones, permanent or temporary access roads, borrow areas, materials storage areas, staging areas, and waste disposal areas.

2.51. "Removal" means complete elimination of the dam embankment or structure to restore the approximate original topographic contours of the valley.

2.52. "Roadfill" means a barrier or obstruction which:

2.52.a. Meets the definition of "dam" set forth in subsection 2.12.;

2.52.b. Is constructed across a natural drainway for the purpose of maintaining a roadway or similar crossing across that drainway; and

2.52.c. Has a culvert located in the drainway that is of sufficient size to prevent the normal impoundment of water.

2.53. "Safety Factor" or "Factor of Safety" means the ratio of the sum of the forces or moments resisting mass movement to the sum of the forces or moments tending to produce mass movement.

2.54. "Secretary" means the Secretary of the West Virginia Department of Environmental Protection or his or her authorized representative.

2.55. "Sediment" means solid material, either mineral or organic, resulting from the works of man that has been moved from its site of origin by water.

2.56. "Serious Problem" means a structural or hydraulic condition that if left uncorrected may lead to a dangerous condition.

2.57. "Significant Harm to the Environment" means the degradation of a public or private surface water supply, the alteration of habitat that adversely affects wildlife, or the reduction of the productivity of agricultural land.

2.58. "Site" means the permanent location of a dam, including the dam and its appurtenances, the reservoir area, diversion ditches, and sediment control facilities.

2.59. "Subsidence" means a sinking, collapsing, or cracking of a portion of the earth's surface resulting from the presence of a void or voids beneath the surface.

2.60. "Violator" means the person who is alleged to have violated the Act, or any rule, notice to comply, order, or certificate of approval term imposed pursuant to the Act.

2.61. "Written Decision" means a written decision furnished to the violator concerning the Secretary's final decision regarding the assessment of a civil administrative penalty and the reasons therefor.

§47-34-3. Classification of Dams.

3.1. Types of Dams - For the purpose of this rule, dams are divided into four general types:

3.1.a. Embankment Dams - Embankment dams are usually constructed of materials which exhibit rock-like or soil-like properties.

3.1.b. Gravity Dams - Gravity dams are usually constructed of concrete or masonry materials which form a rigid body.

3.1.c. Waste Disposal Dams - Waste disposal dams are usually constructed of waste materials such as fly ash or coal refuse. The reservoir is utilized to dispose of waste material, thereby creating a continuously decreasing freeboard condition.

3.1.d. Dams of Multiple Type - In cases where a dam exhibits properties of more than one type, such as gabion structures or roller-compacted concrete, the person or his or her agent must apply design techniques which are reasonably applicable to the particular structure involved.

3.2. Dam-Related Measurements.

3.2.a. Measuring Dam Height - The height of a dam is measured from the crest or uppermost point on the dam to the lowest point in the natural bed of the stream or watercourse at the downstream toe of the dam. Gravity overflow dams must be measured to the highest level which is greater than ten percent (10%) of the total crest length of the dam. The height of dams with sloping crests shall be determined by a weighted-average height above the natural bed of the stream or watercourse, excluding spillways.

3.2.b. Measuring Reservoir Volume - For purposes of determining whether a dam meets the criteria set forth in subsection 2.12. as applied to reservoir volume calculations, the volume must be calculated at the crest elevation of the dam that is equivalent to the elevation used in determining the dam height.

3.2.c. Incised Reservoirs - The height of the embankment of an incised reservoir must be measured using the method set forth in paragraph 3.2.a. Reservoir volume must be calculated from the crest of the embankment to the elevation of the lowest point in the natural bed of the stream or watercourse at the downstream toe. That portion of the water stored below stream grade shall not be included in determining whether a dam meets the criteria set forth in subsection 2.12.; however, it must be reported in the application as part of the total reservoir volume.

3.3. Dams in Series - If the Secretary determines that a series or combination of water-impounding structures within the same watercourse, or within the tributaries of the watercourse, which cumulatively meet the definition of "dam" set forth in subsection 2.12. constitute a hazard to human life, and failure of one or more of the impounding structures may induce failure of any or all of the remaining impounding structures, he or she may require the owner or owners of each impounding structure to comply with the requirements of this rule.

3.4. Incidental Dams.

3.4.a. Roadfills.

3.4.a.1. If the Secretary finds that a roadfill has become a hazard to human life or property through the frequent or continuous impoundment of water, he or she may order the owner of that roadfill

to take all steps that are necessary to protect life or property in accordance with the emergency powers provided under W. Va. Code §22-14-10.

3.4.a.2. A certificate of approval will not be required for roadfills.

3.4.b. Bridges.

3.4.b.1. If the Secretary finds that a bridge has become a hazard to human life or property through the frequent or continuous impoundment of water, he or she may order the owner of that bridge to take all steps that are necessary to protect life or property in accordance with the emergency powers provided under W. Va. Code §22-14-10.

3.4.b.2. A certificate of approval will not be required for bridges.

3.4.c. Diversions - A certificate of approval will be required for dikes or other structures used to divert water and otherwise meeting the definition of "dam" set forth in subsection 2.12.

3.4.d. Stream Encroachments - If the Secretary finds that a natural drainway has been restricted by filling or other artificial means so that the restriction can or does impound water, and the fill and resulting reservoir meets the height and storage requirements of a "Dam" as defined in this rule, he or she may order the fill removed or require a certificate of approval or both.

3.5. Classification of Dams - The applicant for a certificate of approval must propose the hazard classification for his or her dam based upon the classification guidelines listed in paragraph 3.5.b. and the hazard evaluation performed pursuant to paragraph 3.5.c. The classification proposed by an applicant is subject to approval by the Secretary.

3.5.a. Changes in Dam Classification - The Secretary will periodically review the hazard classification of each dam subject to this rule and may reclassify a dam if he or she determines that the hazard potential has changed. The owner shall be notified by the Secretary of any hazard classification change.

3.5.b. Hazard Classifications.

3.5.b.1. Class 1 (High Hazard) Dams - Class 1 dams are those dams located where failure may cause loss of human life or major damage to dwellings, commercial or industrial buildings, main railroads, important public utilities, or where a high risk highway may be affected or damaged. This classification must be used if failure may result in the loss of human life.

3.5.b.2. Class 2 (Significant Hazard) Dams - Class 2 dams are those dams located where failure may cause minor damage to dwellings, commercial or industrial buildings, important public utilities, main railroads, or cause major damage to unoccupied buildings, or where a low risk highway may be affected or damaged. The potential for loss of human life resulting from failure of a Class 2 dam must be unlikely.

3.5.b.3. Class 3 (Low Hazard) Dams - Class 3 dams are those dams located in rural or agricultural areas where failure may cause minor damage to nonresidential and normally unoccupied buildings, or rural or agricultural land. Failure of a Class 3 dam would cause only a loss of the dam itself and a loss of property use, such as use of related roads, with little additional damage to adjacent property. The potential for loss of human life resulting from failure of a Class 3 dam must be unlikely.

3.5.b.3.A. An impoundment exceeding forty (40) feet in height or four hundred (400) acre-feet storage volume shall not be classified as a Class 3 dam.

3.5.b.3.B. A waste disposal dam, the failure of which may cause significant harm to the environment, shall not be classified as a Class 3 dam.

3.5.b.4. Class 4 (Negligible Hazard) Dams - Class 4 dams are dams where failure is expected to have no potential for loss of human life, no potential for property damage and no potential for significant harm to the environment. Examples of Class 4 dams include: dams across rivers, failure of which under any conditions will not flood areas above normal stream bank elevations; dams located in the reservoir of another dam which, under any conditions, can contain water released by failure of the Class 4 dam; and dams in series where the toe of the Class 4 dam(s) is in close proximity to the reservoir of a dam which can contain failure of the Class 4 dam(s) under any condition. In considering a request for a Class 4 designation, the Secretary may require written concurrence from the owner(s) of downstream dams that may be affected by failure of the Class 4 dam. Approval for use of this classification is vested in the Secretary, and will be based on engineering evaluation of the dam(s) and downstream areas in question.

3.5.c. Hazard Evaluation.

3.5.c.1. Downstream Hazards - In evaluating the hazard potential of a dam in order to determine its hazard classification, a complete evaluation of the downstream area which will be affected in the event of dam failure must be performed. A sudden flooding of inhabited land accompanied by a water flow with damaging velocity, a wall of water, or the flooding of inhabited structures will all be deemed to have the potential to result in a loss of human life. The planned or potential future development of downstream areas must also be considered when evaluating hazard classification.

3.5.c.2. Dam Break Analysis - An applicant must perform a downstream breach analysis to evaluate and map the downstream inundation area under assumed normal conditions and overtopping failure conditions.

3.5.c.2.A. The Secretary may waive the downstream breach analysis required under subparagraph 3.5.c.2. for a Class 2 or Class 3 or Class 4 dam where downstream conditions prevent any future introduction of new facilities or residences that thereby change the hazard classification of the dam.

3.5.c.3. Upstream Hazards - No dam shall be constructed which, during maximum pool conditions, will flood upstream dwellings, public utilities, primary highways, or main railroads unless otherwise approved by the Secretary based upon site-specific conditions.

3.5.d. Risk Assessment - The applicant may propose a risk assessment according to the following provisions to determine the effect upon dwellings or other buildings downstream (paragraph 3.5.d.1.), to reduce the hazard classification (subdivision 3.5.b.) or to reduce the design storm requirements (paragraph 7.1.a.2.) based upon failure of the dam by overtopping. The applicant must include appropriate calculations to support the request for hazard classification or design storm requirement reduction. The Secretary will not consider risk assessment based upon planned evacuation, probability of inhabitation, or monetary recovery of property damage. If both paragraph 3.5.d.1. (Dwellings or other Buildings Affected Downstream) and paragraph 3.5.d.2. (Highways Affected Downstream) pertain to the downstream area, then the hazard classification representing the greatest risk category and the largest of the design storm requirements resulting from the above calculations shall apply. Approval of hazard classification reduction or reduction of design storm requirements based upon risk assessment is vested in the Secretary, and will be based on engineering evaluation of the dam(s) and downstream areas in question.

3.5.d.1. Dwellings or Other Buildings Affected Downstream - The Secretary may consider reduced design storm requirements (subparagraph 7.1.1.b.) within the approved hazard classification, if the applicant can demonstrate that all affected dwellings, commercial and industrial buildings or important public utilities will be inundated and evacuated prior to the dam failure. The applicant must

also demonstrate that the potential for loss of human life resulting from the dam failure is not significantly increased from that which occurs immediately prior to the dam failure.

3.5.d.2. Highways Affected Downstream - The Secretary may consider reduced hazard classification (paragraph 3.5.b.) and reduced design storm requirements (subparagraph 7.1.a.2.), if the applicant can demonstrate that affected highway(s) will be impassable and traffic will be stopped in the dam failure inundation area due to the highway(s) being flooded by high water prior to the dam failure. The applicant must also demonstrate that the potential for loss of human life resulting from the dam failure is not significantly increased from that which occurs immediately prior to the dam failure.

§47-34-4. Certificates of Approval.

4.1. Certificate Required - A person must obtain a certificate of approval from the Secretary in order to place, construct, enlarge, alter, breach, remove, abandon, or perform major repairs upon any dam in this State that falls within the definition set forth in subsection 2.12.

4.2. Certificate Issuance.

4.2.a. Certificates of approval may constitute full and final approval of a dam or be issued for alterations or repairs, in which case the certificate may or may not constitute final approval of the dam.

4.2.b. The Secretary will issue or refuse to issue a certificate of approval based upon the following:

4.2.b.1. The receipt of a complete application, including all applicable fees, in accordance with the provisions of subsection 5.1;

4.2.b.2. The review of the application form and plan package for sufficiency; and

4.2.b.3. The results of any hearings held in accordance with the provisions of W. Va. Code §22-14-7.

4.2.c. The Secretary will return defective applications to the applicant by certified or registered mail, return receipt requested, in order that the applicant may correct any defect. The applicant must send a corrected application to the Secretary within thirty (30) days of the date of the applicant's receipt of the returned application. The Secretary may extend the thirty-day period upon the receipt of a written request from the applicant.

4.2.d. Upon the receipt of written approval from the Secretary of the sufficiency of the application, the applicant shall immediately publish a Class I legal advertisement in a qualified newspaper, as defined in W. Va. Code §59-3-1, serving the county in which the proposed dam is to be located or in which the existing dam is located. The notice shall include the name and address of the applicant, the location of the dam for which the application was filed, and such other information as may be specified by the Secretary in his or her written approval.

4.3. Hearings Prior to Certificate Issuance - Any person who may be adversely affected by the issuance of a certificate of approval shall have a right to a hearing before the Secretary. A written request for a public hearing, detailing the specific objections to the issuance of the certificate of approval, must be sent to the Secretary within fifteen (15) days of the publication of the Class I legal advertisement required under subdivision 4.2.d. Hearings that concern specific objections to the issuance of a certificate of approval will be conducted in accordance with the provisions of W. Va. Code §22-14-7 at a location and time set by the Secretary.

4.4. Certificate Revocation or Suspension - The Secretary may revoke or suspend a certificate of approval in accordance with the provisions of W. Va. Code §22-14-8 if he or she determines that a dam for which the certificate was issued constitutes a danger to life and property.

4.5. Certificate Terms and Conditions - A certificate of approval may include such terms and conditions as the Secretary may find necessary for the construction or operation of the dam. These terms and conditions may be amended by the Secretary in accordance with the provisions of W. Va. Code §22-14-8.

4.6. Approval to Impound Water - No person may cause a reservoir to initially fill with water, or refill a drained reservoir, without written approval from the Secretary.

4.6.a. Upon the receipt of a written petition from a dam owner, the Secretary may waive or modify the refilling approval requirement of subsection 4.6 in a case where frequent draining and refilling of a reservoir is the intended purpose and normal operation of the owner's dam.

4.7. Other Approvals - The Secretary may refuse to issue a certificate of approval or may delay issuing a certificate of approval if the applicant fails to obtain necessary approvals from State or federal agencies.

4.7.a. Waterways Under State or Federal Jurisdiction - Construction of a dam across a waterway which is under the jurisdiction of the State or federal government may require State or federal agency approval prior to issuance of a certificate of approval by the Secretary.

4.7.b. Wetlands - Construction of a dam which may inundate, drain, or otherwise adversely affect wetlands (i.e., swamps, marshes, bogs, and similar areas) may require State and federal agency approval.

§47-34-5. Application Procedures.

5.1. Application Preparation and Submission.

5.1.a. Applications for a certificate of approval shall be prepared by or under the direct supervision of an engineer.

5.1.b. Applications shall be submitted on the forms provided by the Secretary. Application forms must be completed in their entirety without unauthorized omissions, alterations, or additions. Applications shall be signed by the applicant and an engineer.

5.1.c. A complete application will consist of a completed and signed application form, all applicable fees, and a plan package containing the information required under subsection 6.4.

5.1.d. Plans, reports, specifications, and design drawings shall be signed and sealed by an engineer in accordance with the provisions of subsection 6.2.

5.2. Application Review.

5.2.a. Applications will be reviewed for sufficiency by the Dam Safety Section. The review will consider the completeness and technical accuracy of the information submitted and will evaluate all engineering plans and assumptions to determine the safety of the dam.

5.2.b. Applications which are incomplete or otherwise not in compliance with the requirements of this rule will be returned to the applicant for correction in accordance with the provisions of W. Va. Code §22-14-7.

§47-34-6. Plans and Specifications.

6.1. Plans and Specifications - Plans and specifications relating to the design, placement, construction, enlargement, alteration, removal, abandonment, or repair of a dam must be prepared in accordance with the requirements of sections 7 through 12.

6.2. Engineer's Signature and Seal Required - All plans and specifications shall be signed and sealed by an engineer. The engineer's signature and seal are required on each full-size plan sheet, even if the sheets are bound together, and are further required on the front page of any engineering report book and each unbound sheet of drawings or specifications included in appendices or pockets.

6.3. Engineering Practices - All plans and specifications for the placement, construction, enlargement, alteration, breaching, removal, abandonment, or repair of a dam shall be in the charge of an engineer.

6.3.a. Standard Practices - All engineering designs, procedures, processes, and analyses shall be based upon standard, accepted, and sound engineering practices. Practices which are questionable or difficult to prove analytically may be rejected by the Secretary or returned for additional information.

6.3.b. Experimental Practices - Experimental design will not be approved by the Secretary unless the experiment meets the following conditions:

6.3.b.1. Engineering analysis indicates the design is realistic and success is likely;

6.3.b.2. Failure of the experiment to perform properly will not endanger life and property or cause the failure of the dam; and

6.3.b.3. The engineer and dam owner agree to redesign and modify the experimental design if it does not perform properly.

6.4. Plan Package Organization - Each plan package submitted for approval shall contain the following information, arranged in the following order, unless an alternative submission format is approved by the Secretary:

6.4.a. Project Narrative - A general narrative discussion of the project shall be included in the plan package to detail the following:

6.4.a.1. Existing site conditions;

6.4.a.2. Local geology and geotechnical considerations;

6.4.a.3. Design life of the dam and its appurtenances;

6.4.a.4. Subsidence potential;

6.4.a.5. Design techniques with associated design computations and data;

6.4.a.6. Environmental protection measures for the control of erosion and sedimentation and for the disposal of construction wastes;

6.4.a.7. Method of construction, including clearing and grubbing, topsoil stockpiles, and surface and subsurface drainage structures;

6.4.a.8. Phases or sequence of construction; and

6.4.a.9. Routine inspection and maintenance procedures and schedules.

6.4.b. Construction Sequence and Schedule - A proposed or recommended sequence of construction, with a schedule listing the anticipated number of working days necessary to accomplish each item in the sequence, shall be included in the plan package. The construction sequence and schedule must be specific to the dam and must cover the following general categories:

6.4.b.1. Sediment control measures;

6.4.b.2. Clearing and grubbing;

6.4.b.3. Road or utility relocations;

6.4.b.4. Development of borrow areas;

6.4.b.5. Placement of coffer dams or diversions;

6.4.b.6. Excavation of foundation areas;

6.4.b.7. Excavation of spillways;

6.4.b.8. Placement of embankment or structural materials;

6.4.b.9. Placement of spillways and appurtenances to spillways;

6.4.b.10. Seeding and mulching of the project area;

6.4.b.11. General cleanup of the project area; and

6.4.b.12. Other information as requested by the Secretary.

6.4.c. Project Specifications - Specifications submitted with the plan package must be specific to construction of the dam or must contain a specific section concerning construction of the dam. Inclusion of specifications for the dam throughout other general construction specifications is not acceptable. Specifications shall be included in the plan package to detail the following:

6.4.c.1. Clearing and grubbing;

6.4.c.2. Soil stockpiles;

6.4.c.3. Subdrain construction;

6.4.c.4. Slopes;

6.4.c.5. Grades;

6.4.c.6. Surface drainage structures such as embankment diversion ditches;

6.4.c.7. Spreading and compaction requirements, including lift thicknesses, moisture content, and degree of compaction;

6.4.c.8. Material and gradation requirements for subsurface drainage structures;

6.4.c.9. Pipes;

6.4.c.10. Concrete, including testing and curing;

6.4.c.11. Anti-seep mechanisms;

6.4.c.12. Cutoff trenches including specific treatment of joints, bedding planes, fractures, weak zones, overhangs or faults;

6.4.c.13. Channel and slope protection (e.g., riprap);

6.4.c.14. Project quality control and testing;

6.4.c.15. Blasting;

6.4.c.16. Construction erosion and sediment control;

6.4.c.17. Construction waste disposal;

6.4.c.18. Dust abatement;

6.4.c.19. Revegetation;

6.4.c.20. Installation and reading of monitoring devices;

6.4.c.21. Inspection and maintenance; and

6.4.c.22. Other information as requested by the Secretary.

6.4.d. Maps and Drawings.

6.4.d.1. Maps shall be included in the plan package showing the project area in relation to primary highways, county seats, and major drainages. County highway maps may be used for this purpose.

6.4.d.2. A map showing the limits of the watershed with respect to the project area shall be included in the plan package. The minimum map scale meeting this requirement is a 7-1/2 minute United States Geological Survey topographic map with the project area plotted on it.

6.4.d.3. A plan view map of the project area that shows all disturbed and reservoir areas shall be included in the plan package showing detailed contour intervals (i.e., a five-foot maximum interval).

6.4.d.3.A. The location of the following items, if present, shall be plotted on the plan view map:

6.4.d.3.A.1. Caves;

6.4.d.3.A.2. Cemeteries and graves;

6.4.d.3.A.3. Seeps;

6.4.d.3.A.4. Springs;

6.4.d.3.A.5. Mine drainage;

6.4.d.3.A.6. Underground mine openings;

6.4.d.3.A.7. Underground mine workings;

6.4.d.3.A.8. Borings and test pits;

6.4.d.3.A.9. Cross-sections;

6.4.d.3.A.10. Project stationing;

6.4.d.3.A.11. Reference points;

6.4.d.3.A.12. Instrumentation;

6.4.d.3.A.13. The subdrain system;

6.4.d.3.A.14. Diversion channels;

6.4.d.3.A.15. Surface water drainage channels;

6.4.d.3.A.16. Spillway channels;

6.4.d.3.A.17. Borrow source areas; and

6.4.d.3.A.18. Proposed waste disposal areas.

6.4.d.3.B. Additional detailed plan views of the dam or its spillways and appurtenances may be required by the Secretary.

6.4.d.4. Transverse and longitudinal cross-sections and profiles of the dam shall be included in the plan package showing original ground, subdrain locations, elevations, benches, spillways, and other pertinent features of the project area. A cross-section shall be provided for stability computations showing the dam at critical areas, with subsurface data plotted in accordance with the provisions of part 7.4.b.1.D.4.

6.4.d.5. Cross-sections and profiles of major drainage facilities shall be included in the plan package.

6.4.d.6. Construction drawings shall be included in the plan package showing subdrains, spillways, anti-seep mechanisms, and other pertinent structures.

6.4.e. Inventory of Protected Sites.

6.4.e.1. An inventory of sites protected under State or federal law must be conducted by each applicant seeking a certificate of approval to:

6.4.e.1.A. Construct a new dam; or

6.4.e.1.B. Alter or enlarge an existing dam whereby new areas will be disturbed or flooded.

6.4.e.2. The minimum acceptable protected sites inventory shall include the following components:

6.4.e.2.A. A field survey shall be conducted by the applicant or his or her agents to ascertain the presence of any cave (i.e., a naturally occurring underground subterranean cavity such as a cavern or grotto) within the area to be disturbed or flooded by the project. The location of all caves must then be plotted on the plan view map required under paragraph 6.4.d.3. If no caves are present in the area to be disturbed or flooded, that fact must be noted in a statement attached to the plan view map submitted to the Secretary.

6.4.e.2.B. A field survey shall be conducted by the applicant or his or her agents to ascertain the presence of any cemetery or grave within the area to be disturbed or flooded by the project. The location of all cemeteries and graves must then be plotted on the plan view map required under paragraph 6.4.d.3. If no cemeteries or graves are present in the area to be disturbed or flooded, that fact must be noted in a statement attached to the plan view map submitted to the Secretary.

6.4.e.2.C. A copy of the plan view map required under subparagraph 6.4.d.3. shall be sent by the applicant to the West Virginia Division of Natural Resources, Nongame Wildlife Program, P.O. Box 67, Elkins, West Virginia 26241. A letter of transmittal that briefly explains the nature of the applicant's project must accompany the map so that State officials may have the opportunity to assess whether the applicant's project will adversely impact any animal or plant species that is listed by the federal government as endangered or threatened in Endangered Species Act. [1987 Stat. 884, as amended: 16 U.S.C. 1531 et seq.]. A copy of the applicant's letter of transmittal must be included in the plan package submitted to the Secretary; and

6.4.e.2.D. A copy of the plan view map required under subparagraph 6.4.d.3. shall be sent by the applicant to the West Virginia Division of Culture and History, Historic Preservation Unit, Cultural Center, State Capitol Complex, 1900 Kanawha Boulevard East, Charleston, West Virginia 25305. A letter of transmittal that briefly explains the nature of the applicant's project must accompany the map so that State officials may have the opportunity to assess whether the applicant's project will adversely impact any historic site that is listed by the West Virginia Division of Culture and History on the State Register of Historic Places. A copy of the applicant's letter of transmittal must be included in the plan package submitted to the Secretary.

6.4.e.3. If either artifacts of historical significance or human remains are uncovered by construction or related activities, the Dam Safety Section must be contacted immediately. The Secretary may suspend activities in the vicinity of such artifacts or remains until appropriate investigations have been conducted.

6.4.f. Erosion and Sediment Control - The plan package must include either:

6.4.f.1. A copy of the applicant's letter transmitting a permit application for the WV/NPDES Storm Water Construction General Permit to the Secretary, if the disturbed area within the site will exceed limits necessary for a NPDES permit, or;

6.4.f.2. An erosion and sediment control plan as required in subdivision 7.5.a., if the disturbed area within the site is less than the limits necessary for a NPDES permit.

§47-34-7. Design Requirements.

7.1. Hydrologic Considerations.

7.1.a. General Hydrologic Requirements.

7.1.a.1. Hydrologic Investigation.

7.1.a.1.A. A survey shall be conducted to evaluate soil types, land use, land slope, watershed area, runoff curve number, and any other factors needed to establish watershed characteristics. A summary of all hydrologic and hydraulic data compiled in the initial site investigation and used in the analysis shall be included in table or figure form in the plan package.

7.1.a.1.B. A stream flow analysis shall be conducted to evaluate stream flow quantity and quality as it affects the dam and its appurtenances.

7.1.a.2. Design Storm Requirements - The design storm and any incremental reduction of the design storm proposed by the applicant is subject to approval by the Secretary. All dams shall be designed to meet the following minimum hydrologic criteria based upon hazard classification:

7.1.a.2.A. Class 1 Dams - Class 1 dams shall be designed for the probable maximum precipitation of six (6) hours in duration. The design precipitation for a Class 1 dam may be reduced based on Risk Assessment (subdivision 3.5.d.), but in no case to less than seventy percent (70%) of the probable maximum precipitation.

7.1.a.2.B. Class 2 Dams - Class 2 dams shall be designed for fifty percent (50%) of a probable maximum precipitation of six (6) hours duration. The design precipitation for a Class 2 dam may be reduced based on Risk Assessment (subdivision 3.5.d.), but in no case to less than twenty-five percent (25%) of the probable maximum precipitation.

7.1.a.2.C. Class 3 Dams - Class 3 dams shall be designed for twenty-five percent (25%) of a probable maximum precipitation of six (6) hours in duration. The design precipitation for a Class 3 dam may be reduced based on Risk Assessment (subdivision 3.5.d.), but in no case to less than a P100 rainfall of six (6) hours in duration.

7.1.a.2.D. Class 4 Dams - Class 4 dams shall be designed for a P100 rainfall of six (6) hours in duration.

7.1.a.3. Antecedent Moisture Conditions - Where applicable to the development of a hydrograph, Antecedent Moisture Condition II (AMC II) may be used unless a different condition class is required by the Secretary.

7.1.a.4. Flood Routings - An analysis shall be performed for the reservoir and spillways which includes inflow hydrographs, stage storage curves, stage discharge curves, and routings. The spillways must be able to safely discharge that portion of the design storm that is not stored in the reservoir. If a computer analysis is used, the input data and output results must be clearly labeled and identified. Trial calculations or intermediate results not relevant to the final results may be omitted from the plan package.

7.1.b. Specific Hydrologic Requirements.

7.1.b.1. Embankment Dams.

7.1.b.1.A. Storage and Discharge.

7.1.b.1.A.1. Class 1 dams designed with either an open channel spillway only or with an emergency spillway and a principal spillway together must be capable of discharging that portion of the design storm that cannot be safely stored in the impoundment. Class 1 dams designed with a decant or principal spillway only must be capable of storing the volume of water generated by a PMP rainfall event of six (6) hours in duration. The design of a Class 1 dam must assure that ninety percent (90%) of the stored volume of the design storm will be discharged within ten (10) days after the storm event.

7.1.b.1.A.2. Class 2 dams must be designed with either an open channel spillway only or a combination of principal and emergency spillways. A Class 2 dam shall be capable of passing that portion of the design storm that cannot be safely stored in the impoundment. The design of a Class 2 dam must assure that ninety percent (90%) of the stored volume of the design storm will be discharged within ten (10) days after the storm event.

7.1.b.1.A.3. Class 3 dams must be designed with either an open channel spillway only or a combination of principal and emergency spillways. A Class 3 dam shall be capable of passing that portion of the design storm that cannot be safely stored in the impoundment. The design of a Class 3 dam must assure that ninety percent (90%) of the stored volume of the design storm will be discharged within ten (10) days after the storm event.

7.1.b.1.B. Surface Drainage Control - Surface drainage control devices (e.g., vegetated slopes, benches, groin ditches, and collection channels) shall be provided as necessary to protect the dam and its appurtenances from the effects of erosion. Riprap or other erosion protection measures shall be included where excessive velocity is anticipated or experienced. All surface drainage control devices must be designed to exit safely beyond the downstream toe of an embankment in a natural drainway capable of carrying the design flow without excessive erosion. The 50-year, 6-hour rainfall event shall be used as the design storm for surface drainage systems.

7.1.b.1.C. Spillway Frequency of Operation - Outlet works that incorporate vegetated earth or unlined earth emergency spillways shall be designed so that the average frequency of operation is no greater than the following recurrence schedule, based upon a 6-hour rainfall event:

7.1.b.1.C.1. Class 1 Dams - Once in one hundred (100) years.

7.1.b.1.C.2. Class 2 Dams - Once in fifty (50) years.

7.1.b.1.C.3. Class 3 and Class 4 Dams - Once in twenty-five (25) years.

7.1.b.1.D. Overtopping Embankments - Regardless of their hazard classification, dams designed to overtop in accordance with the provisions of subparagraph 7.4.b.1.E. shall not overtop more frequently than once in one hundred (100) years, based upon a 6-hour rainfall event.

7.1.b.2. Gravity Dams - Gravity dams may be designed in the same manner as the corresponding hazard classes of embankment type dams in subparagraph 7.1.b.1.A. except that designed overtopping of the dam may be substituted for the emergency spillway requirements.

7.1.b.3. Waste Disposal Dams.

7.1.b.3.A. Storage and Discharge - The following storage and discharge systems may be used in design of waste disposal dams:

7.1.b.3.A.1. Open Channel Only or Emergency Spillway with Principal Spillway - A dam designed with either an open channel spillway only or with an emergency spillway and a principal spillway together shall be capable of discharging that portion of the design storm that cannot be safely

stored in the impoundment. This type of design must assure that ninety percent (90%) of the stored volume of the design storm will be discharged within ten (10) days after the storm event. Slurry impoundments shall be provided with a means of removing water to maintain the lowest practical water level.

7.1.b.3.A.2. Principal Spillway or Decant Only - A dam designed with a decant or principal spillway only shall be capable of storing the volume equivalent to a minimum of one (1) design storm. Risk assessment shall not be applied to dams with principal spillway or decant only. This type of design must assure that ninety percent (90%) of the stored volume of the design storm will be discharged within ten (10) days after the storm event. Slurry impoundments shall be provided with a means of removing water to maintain the lowest practical water level.

7.1.b.3.A.3. No Outlet Works - A dam designed without discharge structures shall be capable of storing the volume equal to a minimum of two (2) design storms. Risk assessment shall not be applied to dams with no outlet works. Water shall be removed from the impoundment to its lowest practical level by pumping or other means if storm water reduces the storage capacity to one (1) design storm or less.

7.2. Hydraulic Considerations.

7.2.a. General Hydraulic Requirements.

7.2.a.1. Hydraulic Analysis - Using standard engineering practices, a hydraulic analysis shall be performed for the spillways and surface drainage system. Typical cross-section design techniques may be used where constant slopes are encountered. All hydraulic structures shall be designed to safely control the velocity of water in order to prevent excessive erosion. Accepted engineering practices shall be used to design riprap, non-flexible channel linings, bedding, and energy dissipators.

7.2.b. Specific Hydraulic Requirements.

7.2.b.1. Open Channels - Open channels, including open channel spillways, shall be analyzed for flow depth, velocity, nonuniform flow conditions, super-elevation, and hydraulic jumps.

7.2.b.1.A. Stage Discharge - Where an open channel is used as a spillway, a stage discharge rating shall be developed using standard engineering practices for the type and shape of the spillway. In developing the rating, increase in upstream water depth due to change in velocity head must be considered.

7.2.b.1.B. Water Surface Profiles - Where channel slopes or cross-sections vary and nonuniform flow conditions result, a water surface profile may be necessary in order to analyze the channel flow depths and the location of hydraulic jumps.

7.2.b.1.C. Hydraulic Jumps - Where hydraulic jumps will occur, channel sidewall height shall be sufficient to contain the jump. The channel lining shall be designed to withstand the hydraulic jump without damage.

7.2.b.1.D. Critical Flows - Channels shall be designed so that water will not flow at critical depth for extended distances. In channels of varying slope or cross-section where nonuniform flow occurs, the transition through critical flow shall be as rapid as possible.

7.2.b.1.E. Super-elevation - Channel walls shall be designed to contain super-elevated flows in curves. Where curves occur in spillway channels, the Secretary may approve super-elevation

wall height based upon one-half of the design flow, but not less than the P100 design flow, provided the excess overflow will impinge on natural ground and will not endanger the dam, human life, or property.

7.2.b.2. Closed Conduit Systems - Closed conduit systems including principal spillways, risers, and pipes shall be analyzed to determine the controlling limits of weir, orifice, and pipe flows.

7.2.b.2.A. Risers and Drop Inlets - Risers shall be protected with a designed trash rack and anti-vortex device. The drop inlet shall be sized to provide a rapid transition from partial to full pipe flow conditions.

7.2.b.2.B. Stage Discharge - When a closed conduit system is used as a principal system, a stage discharge rating shall be developed using standard engineering practices for weir, orifice, and pipe flow calculations.

7.2.b.2.C. Slug Flow - Conduit systems shall be designed to avoid formation of alternating partial and full pipe flow conditions through proper selection of pipe slope and headwater or tailwater conditions.

7.3. Geotechnical Considerations.

7.3.a. Geotechnical Investigation - A geotechnical investigation shall be performed. The quantity, location, and depth of borings, test pits, or trenches must be adequate for the evaluation of the bearing capacity and subsurface conditions for the proposed structure and may vary based upon the height, impoundment volume, and hazard classification of the dam. Factors to be considered include depth of soil, characteristics of bedrock, and determination of groundwater location. Results of in-situ testing and soil sampling shall be reported in the plan package. Soil profiles shall be utilized for critical foundation locations of the structure, spillways, and other pertinent locations which affect the safety of the structure. A geological study shall also be conducted to evaluate stratigraphy, landslides, bedrock discontinuities such as soft seams, joints, joint systems, bedding planes, and fault zones which may adversely affect the structure's performance. Past and future mining including thickness of coal seams, depth and type of rock above the coal seam, and previous or expected subsidence problems shall be considered where subsidence may affect the safety of the structure.

7.3.a.1. Project Area Survey - A project area survey shall be conducted to establish baselines and elevations of the dam embankments, reservoir and borrow areas, and appurtenant structures. The survey shall locate all test pits, borings, gas wells, oil wells, water wells, mine openings, landslides, and areas of natural seepage.

7.3.a.2. Borrow Areas - Borrow areas shall be evaluated for appropriate construction materials and required volume. Borrow areas and excavation materials shall be tested to determine the suitability of material for use in embankments or drains.

7.3.b. Laboratory Testing - Laboratory tests shall be conducted on a sufficient number of samples of foundation and embankment materials to provide an accurate representation of soil conditions. Tests shall include, but not be limited to, a complete soil classification including grain size, sieve, hydrometer analysis, Atterberg limits, density, water content, compaction tests, shear strength, consolidation, and permeability where applicable. Compaction and proctor curves shall be developed for all fill materials as appropriate.

7.3.c. Geotechnical Evaluation - A summary of all geotechnical data determined in the initial site geotechnical investigation and used in the analysis shall be included in table or figure form in the plan package.

7.3.c.1. Seepage Analysis - An analysis of seepage and its detrimental effects on structural integrity shall be made. The analysis shall include consideration of potential piping in the embankment, foundations, and abutments. Seepage control measures shall be specified as necessary in order to enhance the stability of the embankment and adjacent area. Drainage systems shall be designed and constructed using a material approved by the Secretary and shall be protected by a properly designed filter zone using standard geotechnical engineering design practices. The design shall specify methods for sealing or controlling seepage encountered in foundation zones during construction.

7.3.c.1.A. Foundation Treatment - If analysis indicates a highly fractured foundation, the engineer shall specify necessary treatment of the foundation zone including, but not limited to, foundation grout curtains, dental concrete treatment of fractures or overhangs, and detailed methods of foundation zone cleaning. Material used in grouts shall be specified in accordance with the provisions of subparagraph 7.4.a.1.B.

7.3.c.2. Foundation Stability - The foundation must be designed to have adequate bearing capacity to support the embankment and any appurtenant works. Potential subsidence and settlement and their consequences shall be considered using standard engineering practices. Special attention shall be given to differential settlement which would lead to cracking of the dam. Spillway pipes on compressible foundations shall be protected from damage due to settlement.

7.3.c.3. Landslides - The potential for landslides, as determined in the initial project area investigation, shall be evaluated by the engineer. If landslides noted in the project area could cause instability of the dam or appurtenant structures, blockage of spillways and other critical drainage structures, or overtopping of the dam by displacement of water in the reservoir area, such conditions shall be corrected to a minimum static safety factor of 1.5.

7.4. Structural Considerations.

7.4.a. General Structural Requirements - All structures shall be designed to perform as intended for the design life of the dam with proper maintenance or replacement.

7.4.a.1. Structural Materials - Materials selected for use in the dam shall be of adequate quality and durability for the intended purpose of the structure. All structures shall be designed to have sufficient strength plus an adequate safety factor against failure during maximum anticipated loading conditions.

7.4.a.1.A. Earth Materials - Earth materials selected for use in dam construction shall be free from roots, brush, organic materials, construction waste, and other debris. Where rock or rock fill is specified, the rock shall be durable and not subject to slaking or breakdown. Size gradations of the earth materials shall be specified to perform as planned. Compaction requirements for earth materials shall be specified in the plan package.

7.4.a.1.B. Concrete Design - Concrete shall be designed in accordance with standard engineering practices. Concrete design specifications shall include materials, proportioning, form-work, reinforcement, joints and embedded items, production, placing, repair of surface defects, finishing, curing and protection, testing, evaluation and acceptance, and allowable tolerances for acceptance.

7.4.a.1.B.1. Concrete Specifications - The engineer shall specify the nature of concrete to be used with sufficient detail for on-site quality control. The concrete may be specified by specific mix, aggregate, water content, additives, compressive strength, slump, and air entrainment or by reference to specific standards of concrete quality. If published standard specifications are referenced, a copy of the standard or pertinent sections of the standard shall be included in the plan package.

7.4.a.1.B.2. Concrete Placement - The engineer shall specify methods and limits of placement of the concrete including foundation preparation, maximum lift height, maximum time allowed between mixing and placement, methods of working into forms and corners, methods of consolidation and use of vibrating devices, and allowable ambient air temperatures and concrete temperatures.

7.4.a.1.B.3. Concrete Curing - The engineer shall specify the method of curing the concrete including moist curing or membrane curing, wetting, types of covering, acceptable curing temperature range of the concrete, any anticipated cold weather curing specifications or methods such as protection from freezing and insulation methods, hot weather placement methods and limitations, and curing time.

7.4.a.1.B.4. Concrete Finishing - The engineer shall specify the type of finishing to be applied to the concrete and the acceptable temperature range.

7.4.b. Specific Structural Requirements.

7.4.b.1. Embankment Dams.

7.4.b.1.A. Selection of Materials - Material selected for construction of embankments shall be select earth material that is free from roots, brush, organic matter, construction waste, and other debris. The material must not be subject to breakdown or chemical reaction. Unless otherwise approved by the Secretary, the selected material must be thoroughly tested for density, shear strength, liquid and plastic limits, and optimum moisture content. The source of the material and available quantities shall be identified and adequate sampling performed in order to attain consistent quality and soil characteristics.

7.4.b.1.B. Seepage and Piping Control - The Secretary may require installation of a properly designed filter drain system to prevent embankment failure due to seepage and/or internal erosion of any dam which can cause loss of human life or major damage to dwellings, or commercial or industrial buildings, important public utilities, or where a high risk highway may be affected.

7.4.b.1.C. Zoned Embankments.

7.4.b.1.C.1. Filter Drains - Filter drains shall be used in embankment zones where necessary to intercept seepage, reduce phreatic level, and reduce potential for internal erosion. Drain outlets shall be visible, not submerged under normal conditions, unobstructed, and protected with an animal guard where conduits are utilized.

7.4.b.1.C.1(a) Gradations - The gradations of the filter material shall be sized to prevent or resist the migration of embankment material into the voids of the filter. The filter shall be permeable relative to the surrounding embankment material.

7.4.b.1.C.1(b) Size - The filter drain shall be capable of passing the maximum anticipated seepage flows without excessive pore pressure. The combination of filter permeability and area shall be considered in sizing the drain.

7.4.b.1.C.1(c) Durability - The material used in the filter shall be hard, durable material that is not subject to slaking, breakdown, or chemical reaction.

7.4.b.1.C.1(d) Conduits - Perforated pipes may be used in the filter drain to increase capacity. Perforations shall be compatible with the filter gradations so that filter material will not enter the pipe. The pipe shall be capable of supporting the fill load and shall be of a material which will last for the design life of the structure. Corrugated metal pipe shall not be used in critical areas of the embankment or in any areas where the pipe is not reasonably accessible for replacement.

7.4.b.1.C.1(e) Filter Cloth - Filter cloth shall not be used in critical areas of the embankment or in any areas where the cloth is not reasonably accessible for replacement.

7.4.b.1.C.2. Diaphragm Cutoff Walls - When concrete cutoff walls are used as an impermeable barrier, the concrete wall shall be placed upon an adequate foundation and be constructed of reinforced concrete. Where pipes pass through the concrete wall, adequate support for the pipe shall be provided to prevent differential settlement and pipe shearing.

7.4.b.1.D. Embankment Stability -The following stability requirements apply to Class 1 through Class 3 dams. The Secretary may approve lower safety factors for Class 4 dams, based on engineering recommendations.

7.4.b.1.D.1. Embankment Safety Factors - Slope stability shall be analyzed to show that the embankment design achieves the following factors of safety under the conditions listed. Unless otherwise indicated, factors of safety requirements apply to both upstream and downstream slopes of the embankment:

7.4.b.1.D.1(a) A safety factor of 1.5 for the embankment loading conditions specified in part 7.4.b.1.D.3.;

7.4.b.1.D.1(b) An end of construction safety factor of 1.3;

7.4.b.1.D.1(c) An upstream slope rapid drawdown safety factor of 1.2; and

7.4.b.1.D.1(d) An earthquake safety factor under steady-state seepage conditions of 1.2 using seismic loading appropriate to the geological site conditions.

7.4.b.1.D.2. Appurtenance Structural Stability - Embankments constructed as part of an appurtenant structure where failure will lead to a dangerous condition in the dam shall achieve a static safety factor of 1.5.

7.4.b.1.D.3. Embankment Loading Conditions - Loading conditions shall assume a long-term steady-state condition with the phreatic surface originating at the elevation of the emergency spillway crest for embankment dams with emergency spillways or at a maximum design pool elevation for embankment dams without spillways.

7.4.b.1.D.4. Stability Analyses - All slope stability analyses shall be performed using standard engineering practices. Exceptions to this requirement will be allowed by the Secretary only where there is sufficient evidence to indicate that slope failures will not occur.

7.4.b.1.D.4(a) Critical cross-sections of the dam using equal X and Y axes scales shall be provided in the plan package. The cross-sections shall show the embankment limits, foundation zones, soil zones, phreatic line, assumed reservoir elevation, stability arcs or failure planes through the dam, and resulting safety factors for each critical arc or failure plane shown.

7.4.b.1.D.4(b) A listing of soil zone unit weights, angles of internal friction, and cohesion values for each soil shown on the cross-section shall be provided in the plan package. If an alternative analysis is utilized, assumed soil values of the analysis shall be shown.

7.4.b.1.E. Overtopping Embankments.

7.4.b.1.E.1. Rock-Covered Embankments - Rock-covered embankments shall be designed so that the rocks selected will be sized to withstand the maximum depth and velocity of the overtopping flow and be individually placed to maximize the interlocking effect. A minimum of two (2) layers of boulders is required. Boulders shall cover the crest, downstream face, and necessary areas of the upstream face of the dam and extend beyond the dam abutments to the extent necessary to contain the overtopping flow depth. Graded smaller rock shall fill the voids where the boulders contact the embankment to prevent erosion due to flow through the voids. The rock cover may be covered with soil and vegetated, provided that the equipment used to place the soil will not break the rock.

7.4.b.1.E.2. Roller-Compacted Concrete Embankments. Roller-compacted concrete lift thickness and width shall be sized to withstand the maximum anticipated loading and uplift forces. Filter drains and weep holes shall be provided to relieve hydrostatic pressure behind roller-compacted concrete facings. The roller-compacted concrete may be covered with soil and vegetated.

7.4.b.2. Gravity Dams. The following stability requirements apply to Class 1 through Class 3 dams. The Secretary may approve lower safety factors for Class 4 dams, based on engineering recommendations.

7.4.b.2.A. Stability Loading Conditions - Loading conditions for the stability analysis shall assume maximum overflow head from the design storm.

7.4.b.2.B. Gravity Dam Stability.

7.4.b.2.B.1. Overturning - The reaction of all forces must act within the middle one-third of the base. This requirement may be modified by the Secretary if detailed computations prove that overturning will not occur.

7.4.b.2.B.2. Sliding - The dam shall have a factor of safety against sliding of at least 3.0 for normal loading conditions and 1.5 for maximum loading conditions. The sliding factor of safety may be reduced to no less than 2.0 for normal loading conditions where intimate knowledge of subsurface conditions has resulted from a state-of-the-art subsurface investigation, testing program and design analysis. The subsurface investigation and testing necessary to reduce the factor of safety should include, but not be limited to: sampling and testing of weak zones such as discontinuities, joints, joint fill material, fracture zones, bedding planes, and faults and; determination of peak, ultimate and residual strengths of foundation materials. Design analyses should include, but not be limited to: three dimensional analyses of foundation strength resulting from the subsurface investigation. The adequacy of subsurface investigations, testing, and design analyses necessary to reduce the factor of safety is subject to approval by the Secretary.

7.4.b.2.B.3. Bearing - The factor of safety against bearing failure shall be at least 1.5 for maximum stress at the downstream toe.

7.4.b.3. Waste Disposal Dams - The potential for liquefaction must be considered and the design shall include safeguards against the development of this condition.

7.4.b.4. Spillways - All spillways shall be designed to discharge an adequate distance beyond the downstream toe of the dam in a natural drainway to prevent erosion of the downstream toe or other detrimental effects to the dam structure.

7.4.b.4.A. Conduit Spillways - Inlets shall be protected by a designed trash rack and riser type spillways shall be designed to prevent detrimental vortexing. Risers shall have adequate weight to be non-buoyant and shall be of sufficient strength to withstand maximum dynamic water and ice forces. Foundations for risers shall be designed to support the riser without serious movement or deformation.

7.4.b.4.A.1. Conduits - Pipe conduits shall be placed on a designed foundation and bedding of sufficient strength to minimize settlement and other detrimental effects to the conduit. Anti-seep or anti-piping mechanisms shall be provided for all conduits passing through the dam, foundation, or abutments to control seepage along the pipe. Design allowances shall be made to compensate for differential settlement, elongation, and movement of the pipe conduit if the cradle is placed on a yielding foundation. Pipe conduits shall be of sufficient strength to support the maximum external loads and the maximum internal hydraulic pressure without leaking, and shall resist uplift pressures. The pipe conduit shall be constructed of material which will not deteriorate during the design life of the structure.

7.4.b.4.A.1(a) Use of Corrugated Metal Pipes - Corrugated metal pipes, whether coated or uncoated, shall not be used in new Class 2 or new Class 1 dams. Corrugated metal pipes in existing dams must be either replaced with new pipe or retrofitted with an appropriate liner if the Secretary determines that the existing pipe constitutes a hazard to the proper operation of the dam because the pipe has developed leaks, has deteriorated, or has otherwise ceased to function properly.

7.4.b.4.A.2. Outlets - Pipe conduits shall be designed to outlet in a natural drainway or a designed channel leading to a natural drainway. An energy dissipator shall be provided to eliminate erosion at the pipe outlet and be designed for maximum pipe flow. If pipe blockage by animals may occur, the pipe outlet shall be protected by an animal guard.

7.4.b.4.A.3. Gated Drain Pipe Required for New Freshwater Dams - All new freshwater dams shall have a gated drainpipe for draining the impoundment. The gate or valve shall be located in the reservoir or in the saturated zone upstream of the cutoff wall or impermeable barrier. If the gate is located within the embankment or structure, a service well shall be provided. The elevation of the gate system shall be such that the reservoir will be drained completely to original stream level. The drain system shall be designed to drain ninety percent (90%) of the volume of stored water at normal pool in ten (10) days including normal base flow and have a minimum capacity of three (3) times the normal base flow for the watershed with a headwater-to-diameter (HW/D) ratio of 1.5, unless otherwise approved by the Secretary. The drain conduit shall meet the requirements for conduits set forth in part 7.4.b.4.A.1. A designed trash rack shall be provided at the inlet of the drain. The controls to operate the drain gate shall be accessible without the use of specialized equipment or of divers. The drawdown rate for reservoir storage volumes in excess of two thousand (2000) acre-feet may be established by the Secretary.

7.4.b.4.A.4. Existing Dams with Gated Drain Pipes - All existing dams currently equipped with a gated drain pipe must meet the design requirements of part 7.4.b.4.A.3. and continue to be operated and maintained with the gated drain pipe. If such a gate or valve was not previously installed, a gate or valve shall be installed in the reservoir or in the saturated zone upstream of the cutoff wall or impermeable barrier. The Secretary may approve reduced drawdown time and flow quantity requirements for existing drains. Drain systems not meeting the design requirements of part 7.4.b.4.A.3. or dams with leaking or inoperative drain systems must be repaired or modified to maintain the greatest practical capacity of the drain system. If installation of the upstream gate or valve is impractical without draining of the reservoir and reservoir drainage will cause major economic loss to the owner, the Secretary may approve delay of the upstream gate or valve installation until the next necessary draining of the reservoir, provided that the existing drain system is functioning properly and is not leaking in a manner that would create a serious problem. If the existing drain system develops a serious problem, the Secretary may order immediate remedial action. The Secretary may grant an exemption to this subpart when investigation of the existing drain system determines to the Secretary's satisfaction that installation of an upstream drain gate or valve is not feasible.

7.4.b.4.A.5. The term "gate" or "valve" as used in this rule is a general term referring to a device used for controlling water flow.

7.4.b.4.B. Open Spillways - Unless specifically excluded, spillways of this type include the various designs of open type spillways including open channel, side channel, chute, labyrinth, and ogee.

7.4.b.4.B.1. Earth Spillways - Spillways that are constructed of or in earth material shall be designed to pass the maximum design flow without excessive erosion. Earth spillways shall not be constructed over dam embankment fill material.

7.4.b.4.B.1(a) Flexible Linings - Vegetation, rock riprap, soil reinforcement, or other flexible linings may be used to increase flow quantities and velocities in earth spillways within design limits.

7.4.b.4.B.2. Concrete Spillways.

7.4.b.4.B.2(a) Concrete - The engineer shall specify the grade and strength of concrete to be used in the spillway construction. The concrete structure shall be of sufficient strength to withstand the maximum design applied load.

7.4.b.4.B.2(b) Foundation - Concrete shall be placed on a prepared foundation and bedding capable of sustaining the applied loads without excessive deformation.

7.4.b.4.B.2(c) Drains - Designed filter drains and water pressure relief devices shall be provided under concrete slabs and walls to collect and safely convey water from seepage or leakage of construction joints and to relieve uplift pressure from seepage conditions.

7.4.b.4.B.2(d) Joints - Construction joints shall be made watertight by use of a sealant material. Sliding joints shall be supported by a slab to maintain alignment.

7.4.b.4.B.2(e) Cutoff Barriers - Cutoff barriers keyed into the foundation shall be provided to prevent or reduce seepage flow under the spillway.

7.4.b.4.B.2(f) Energy Dissipators - An energy dissipator shall be provided to reduce the hydraulic energy at the end of the spillway. The dissipator shall be designed to function properly for flows of at least one-half of the design spillway flow. Flows in excess of the design capacity of the energy dissipator shall not endanger the dam or its appurtenances and may result only in erosion.

7.4.b.4.B.3. Nonstandard Spillway Design - The Secretary may reject any spillway design if such design is of a nonstandard or untested nature and it is not possible to analytically predict the performance of the spillway or the detrimental effects of cross-waves, eddies, vortices, super-elevation, or hydraulic jumps within the spillway system.

7.4.b.5. Water Supply Pipes - Water supply pipes through a dam shall be constructed of a long-life, high-strength material. Welded joints or mechanical joints with sealing rings, or an alternative sealing method approved by the Secretary, shall be utilized. Pipes shall be properly bedded to reduce differential settling or elongation. Anti-seep mechanisms or filter drains shall be provided to prevent piping along the exterior of the pipe. If the pipe is enclosed in or passes through concrete, the relative coefficients of expansion shall be considered. Anti-corrosive measures shall be employed if soil tests indicate corrosion may be a problem. An upstream shutoff valve shall be installed on all new dams or when upgrading existing dams where reservoirs are to be drained as part of the upgrading. The section of the pipe through the dam shall be capable of withstanding a minimum pressure of twice the maximum reservoir head. The pipe shall be pressure-tested for leaks at maximum reservoir head pressure prior to the final covering of the pipe installation.

7.5. Miscellaneous Considerations.

7.5.a. Erosion and Sediment Control - Erosion and sediment control measures sufficient to comply with the provisions of paragraph 8.1.m. shall be included in the project design where the disturbed area within the site is less than NPDES limits. If the disturbed area within the site exceeds NPDES limits, a letter documenting submission of a NPDES permit application must be submitted in accordance with subparagraph 6.4.f.1.

7.5.b. Waste Disposal Areas - The engineer shall delineate locations in the project area which are to be used as waste disposal areas.

7.5.c. Instrumentation - The engineer shall recommend instrumentation as necessary to monitor and measure performance of new dams or modifications to existing dams. The engineer shall specify the types and purpose of the recommended instrumentation.

7.5.c.1. Piezometers or Observation Wells - Piezometers or observation wells may be required by the Secretary on embankment type dams to monitor phreatic level and water pressures in critical areas of the embankment and, if necessary, the foundation or abutments. All piezometer or well heads shall be anchored in concrete and protected from vandalism with a locking metal cylinder surrounding the piezometer or well pipe.

7.5.c.2. Survey Monuments - Survey monuments may be required by the Secretary on embankment and gravity dams to monitor displacement, settlement, rotation, and deformation. Survey monuments on earth dams shall be sufficiently embedded into the structure to prevent localized movement of the monument. Protective casings shall be installed if necessary to prevent damage or forced movement of the survey point.

7.5.d. Staged Construction - Waste disposal dams designed in stages of construction shall be capable of storing or passing the design storm specified in paragraph 7.1.a.2. and subparagraph 7.1.b.1.A. during all stages of construction except during the initial start-up period, unless otherwise approved by the Secretary. During the initial start-up period, the dam shall be capable of storing or passing the P100 rainfall event as soon as possible. Construction shall increase storm capacity, reaching the full design storm capacity within two (2) years.

§47-34-8. Construction or Modification of a Dam.

8.1. Construction Requirements.

8.1.a. Notification of the Commencement of Construction - Prior to the commencement of construction activities in the project area, the person who has been issued a certificate of approval, or his or her representative, shall notify the Secretary of the following:

8.1.a.1. The intent of the contractor to start construction in the project area and the date of such start-up.

8.1.a.2. The name, address, and telephone number of the owner's authorized contact person at the project area who is responsible for communicating with the Dam Safety Section and for receiving inspections reports and legal notifications.

8.1.b. Conformance with Plans - All work undertaken in the construction or modification of a dam shall be in strict conformance with the plans and specifications contained in the plan package submitted under subsection 5.1 and approved by the Secretary. Any changes to the approved plans and specifications shall be submitted to and approved by the Secretary prior to implementation.

8.1.c. On-Site Documents - A copy of the certificate of approval, the approved plans and specifications, all outstanding notices to comply or orders to comply that have been issued by the Secretary, and the monitoring and emergency action plans prepared in accordance with the provisions of subsection 15.6 and subsection 15.7 shall be available at the project area office for reference by construction personnel and the Secretary.

8.1.d. Adverse Weather Conditions - Construction work shall be suspended on all or part of the project when adverse weather conditions (e.g., prolonged precipitation, extreme temperatures) jeopardize the performance of work in conformance with the approved plan package.

8.1.e. Clearing and Grubbing - Clearing and grubbing shall be performed in the foundation, borrow, and soil stockpile areas. Clearing is required in the maximum permanent pool area unless otherwise approved by the Secretary.

8.1.f. Foundation Preparation - Foundation preparation shall include installation of keyways and subdrains, removal of soft areas, and similar project area preparation operations dictated by the approved plans and specifications and by project area conditions. The foundation shall be inspected by the Secretary prior to placement of embankment materials. If foundation problems are discovered during this inspection, additional foundation preparation may be required by the Secretary.

8.1.g. Placement of Materials.

8.1.g.1. All fill shall be placed in accordance with the approved plans and specifications.

8.1.g.2. Compaction testing shall be completed as specified in the approved specifications; the results of such testing shall be reported in accordance with the provisions of subdivision 8.4.a.

8.1.g.3. Filter drains shall be constructed in accordance with the approved plans and specifications. Filter material shall be tested for compliance with design gradations; the results of such testing shall be reported in accordance with the provisions of subdivision 8.4.a. Filter materials shall be placed to prevent segregation and contamination and shall be concurrently covered to prevent contamination or damage.

8.1.h. Grading.

8.1.h.1. All fill shall be graded in accordance with the approved plans and specifications.

8.1.h.2. The working surface and outslopes of the fill shall be concurrently graded through all phases of embankment construction.

8.1.h.3. The top of the fill shall be crowned to provide positive drainage during construction.

8.1.h.4. Final grading shall be conducted in order to facilitate revegetation.

8.1.i. Spillways and Appurtenances.

8.1.i.1. Spillways and appurtenances shall be constructed in accordance with the approved plans and specifications.

8.1.i.2. When downslope placement of fill material is used in the construction of spillways, the fill material shall be compacted in horizontal layers to achieve the design configuration.

8.1.i.3. All riprap material shall be of hard, durable rock which is not acid-forming or toxic. Riprap shall be placed to prevent size segregation.

8.1.i.4. When bedding is used under riprap, the rock material shall be placed in a manner so as not to damage or contaminate the bedding.

8.1.i.5. When protective channel linings are specified, the linings shall be installed as soon as the channel is constructed to grade in accordance with the approved plans and specifications.

8.1.i.6. When concrete is used in construction of spillways and appurtenances, the concrete shall be placed, cured, and finished in accordance with the provisions of part 7.4.a.1.B.2. through part 7.4.a.1.B.4. Standard engineering tests shall be performed in accordance with the provisions of paragraph 8.2.b.1. and reported in accordance with the provisions of subdivision 8.4.a.

8.1.i.7. All pipes, risers, and appurtenances shall be installed in accordance with the approved plans and specifications. Compaction testing shall be completed to ascertain that fill material around pipes, risers, and appurtenances has been placed in accordance with the approved plans and specifications; the results of such testing shall be reported in accordance with the provisions of subdivision 8.4.a. Sufficient fill shall be placed over pipes so as to prevent damage by heavy equipment.

8.1.j. Minimum Stream Flow - An adequate flow of water may be required by the Secretary in the stream below the dam during construction and reservoir filling to maintain water quality in the stream and to support fish and other aquatic life. The Secretary may require stream flow augmentation in accordance with the provisions of subdivision 15.3.b.

8.1.k. Blasting - Blasting may only be utilized in accordance with and as specified in the approved plans and specifications. Blasting based upon unforeseen project area conditions not covered in the approved plan package shall not be performed prior to approval by the engineer with the concurrence of the Secretary.

8.1.l. Storm Water Discharge - The sequence of construction work shall be planned to maximize the safe discharge of storm water while minimizing the amount of water retained in the impoundment. Either the principal spillway structures, including inlets and outlets, shall be operable prior to placement of construction material above the original valley elevation or diversion channels approved by the Secretary shall be in place.

8.1.m. Erosion and Sediment Control.

8.1.m.1. General Requirements - Erosion and sedimentation must be controlled to prevent a degradation of land and streams below the dam or project area, including visible deposits of sediment, and to prevent any violation of State water quality standards. Erosion and sediment control measures shall, at the minimum, conform with current erosion and sediment control reference manuals and apply to the entire project area.

8.1.m.2. Specific Requirements - Cleared areas, borrow areas, disturbed areas along stream channels and waterways, and fills, whether complete or in progress, must be equipped with erosion and sediment control devices (i.e., diversions, waterways, sediment basins, straw bale dikes, or silt fences).

8.1.m.2.A. Location of Sediment Control Devices - Erosion and sediment control devices must be located as close to the disturbed area as practical. Effort must be made to contain the sediment load within the disturbed area in order to prevent the entry of sediments into the natural drainway or stream.

8.1.m.2.B. Removal of Sediment Control Devices - Erosion and sediment control devices must remain in place until permanent vegetation is established or the area is otherwise stabilized. Prior to the removal of the devices, trapped sediment must be removed and placed in a location approved by the Secretary. Straw bale dikes and silt fences must be removed when no longer needed; sediment basins or ponds must be abandoned in a manner approved by the Secretary. Barren and denuded areas remaining after the removal of a control device must be revegetated.

8.1.m.2.B.1. The Secretary may modify or waive the requirements of subparagraph 8.1.m.2.B. for erosion and sediment control devices that are located within the impoundment area of the dam.

8.1.m.2.C. Cleaning Frequency - Sediment control diversions, silt fences, straw bale dikes, and waterways must be inspected once each week, and after each rainfall, and accumulated sediment must be removed in order to maintain design capacity. Sediment ponds, basins, and traps must be restored to design capacity when sediment accumulation approaches sixty percent (60%) of design capacity, or more frequently if so specified by the Secretary in writing.

8.1.m.2.D. Temporary Seeding and Mulching - Temporary seeding and mulching shall be utilized on bare areas where no construction activity is anticipated for a period of three (3) or more weeks. Areas that shall receive seeding and mulching include the reservoir area, borrow areas, soil stock piles, and steep fill slopes where no further work is planned prior to final grading. Where seeding is not feasible due to severe slope or time of year, the Secretary may approve mulching alone at a rate of three (3) tons of straw or hay per acre, or equivalent.

8.1.m.2.E. Water Routing - Water that is pumped or drained from work areas (e.g., excavations, foundations, and below grade fills) must be routed to properly-sized sediment control devices so that any sediment contained in the water is removed prior to discharge of the water from the project area. Pump discharges may not cause erosion or suspension of additional solids. No untreated water may be pumped or drained to the natural stream or stream diversion channel.

8.1.m.2.F. In-Stream Treatment - Barriers, such as silt fences or straw bales, located in the natural drainway or stream will not be considered acceptable as the primary means of sediment control for the project area. Properly designed sediment basins or ponds may be used for sediment control in the natural drainway or stream if the location of the basin or pond does not cause significant additional disturbance in undisturbed downstream areas. Use of a starter dike or the dam under construction may be considered appropriate for sediment control of the reservoir area provided the necessary detention time is achieved.

8.1.m.2.G. Sediment Control During Construction - Erosion and sediment control measures must be in place prior to the beginning of dam construction activities. Clearing and grubbing or sediment control measures not specified for the beginning of construction must be implemented in a timely manner as needed.

8.1.m.2.H. Permanent Erosion Measures - Permanent measures (e.g., vegetation, grading, diversions, waterways, and outlet structures) shall be included on all completed or existing dams, where applicable, to prevent the erosion of embankments, abutments, stream channels, and waterways during the life and operation of the dam.

8.1.n. Disposal of Construction Wastes.

8.1.n.1. General Disposal Requirements - All waste materials that result from construction activities shall be disposed of in a manner approved by the Secretary.

8.1.n.2. Specific Disposal Requirements.

8.1.n.2.A. Surplus Waste Materials - Surplus soil and rock materials shall be deposited in waste disposal areas delineated in the approved plans.

8.1.n.2.B. Organic Waste Materials - Trees, brush, root masses, and construction-related wood materials may be either buried in waste disposal areas delineated in the approved plan package or burned in accordance with local and State burning ordinances

8.1.n.2.C. Concrete Waste Materials - New or old waste concrete materials may be disposed of in areas approved by the Secretary for surplus soil and rock materials. New, unset waste concrete shall not be deposited in a location where it will enter watercourses, either directly or indirectly as a result of runoff. After it has set, the new waste concrete may be moved to waste disposal areas delineated in the approved plans.

8.1.n.2.D. Other Waste Materials - Chemicals, petroleum products, plastics, garbage, sewage, and any associated containers shall be disposed of in a manner approved by the Secretary.

8.1.n.2.E. Off-Site Waste Materials - No waste materials or soil waste may be transported to the project area for disposal.

8.1.o. Dust Abatement - The contractor shall fully suppress dust on haul and access roads and as necessary within the project area. Water, or an alternative dust palliative approved by the Secretary, shall be used for dust suppression; the use of oil or waste oil is prohibited.

8.1.p. Access Roads - A permanent access road shall be provided to each dam site. The road must be adequate for emergency vehicular traffic. Single lane unpaved roads are acceptable provided the roads are properly maintained. The access road must be designed and located as to not be unduly affected by stream or spillway flows during heavy rainfall events. The road may be secured with a locked gate provided that the key is available to dam monitors and State and local emergency personnel for emergency response.

8.2. Quality Control.

8.2.a. Construction Monitoring.

8.2.a.1. All construction activities shall be monitored by an engineer or his or her designated representative. Construction monitoring shall not be the responsibility of the construction contractor unless specifically approved by the Secretary in writing.

8.2.a.2. Responsibility for assessing the quality of the workmanship and ascertaining compliance with the approved plans and specifications shall be vested primarily in the owner's engineer. The Dam Safety Section shall also monitor construction activities and workmanship in order to ascertain compliance with the approved plans and specifications, in accordance with the provisions of W. Va. Code §22-14-9.

8.2.a.3. Critical phases of construction shall be monitored by the engineer or his or her designated representative constantly during active construction; noncritical phases of construction shall be checked at least once per day during active construction.

8.2.a.4. Additional supervision or testing will be required by the Secretary if evidence of inadequate construction supervision exists.

8.2.b. Materials Testing - Construction materials shall be periodically tested on-site to ascertain compliance with design specifications in the approved plan package. Final quality control testing shall not be the responsibility of the construction contractor.

8.2.b.1. Concrete Testing - Routine tests of slump, air entrainment, and temperature shall be performed on each truck delivery. Cylinder samples for compression testing shall be taken each day or every twenty-five (25) cubic yards of delivered concrete, whichever is more frequent, unless otherwise required by the Secretary.

8.2.b.2. Earth Fill Testing - Earth fill materials shall be tested for compaction and moisture content every alternate layer or each one thousand (1,000) cubic yards, whichever is more frequent. Random fill shall be evaluated for compliance with approved gradation specifications. Critical fill areas shall have gradation tests performed to evaluate compliance with the approved specifications.

8.2.b.3. Filter Materials Testing - Gradation tests shall be performed on filter materials. Close visual observation for signs of material segregation shall be performed. Additional tests may be required by the Secretary to determine durability and soundness of the filter material.

8.3. Construction Inspections.

8.3.a. Inspections During Construction.

8.3.a.1. A visual inspection for construction progress, unstable conditions, quality control, and conformance with the approved plans and specifications shall be held at least once each working day (or more frequently as determined by the engineer). The inspection shall be performed by an engineer or a person under the direct supervision of the engineer. The frequency of inspection may be changed by the Secretary depending upon specific project area conditions.

8.3.a.2. Additional inspections shall be held after each heavy rainfall event in order to detect problems and propose remedial measures. These inspections shall be performed by an engineer or a person under the direct supervision of the engineer.

8.3.a.3. Instrumentation shall be monitored every seven (7) days unless otherwise specified by the engineer. Monitoring shall be performed by an engineer or a person under the direct supervision of the engineer. The frequency of monitoring may be changed by the Secretary depending upon specific project area conditions.

8.3.b. Final Construction Inspection - Upon the completion of the construction or modification of a dam, a joint inspection shall be conducted by the Secretary and the engineer. The purpose of the inspection is to verify that all work has been accomplished in accordance with the approved plan package.

8.3.c. Acceptance of Construction - When the dam owner is advised by the Secretary that the construction appears satisfactory, the owner shall submit to the Secretary a certification by an engineer that all construction was in substantial conformance with the approved plans and specifications, including any modifications that have been approved by the Secretary. This certification shall be submitted within ninety (90) days of the Secretary's advisement. As-built drawings, including all variations from the original specifications and changes in location of borrow or waste disposal areas, shall be submitted with the engineer's certification. If substantial modifications of the original specifications have been made during the construction period, the Secretary may require that a corrected application form be submitted. Upon the receipt of the engineer's certification with the as-built drawings (and a corrected application form, if necessary), a letter of acceptance will be issued by the Secretary.

8.3.d. Completed Dams - After acceptance of construction by the Secretary, the dam and its appurtenances shall be inspected annually for a period of three (3) years by an engineer experienced in such inspections. The Secretary reserves the right to attend any inspection and require prior notification of the inspection by the owner of the dam. A report of each inspection shall be prepared and filed with the Secretary in accordance with the provisions of subdivision 15.5.a.

8.4. Construction Reporting Requirements.

8.4.a. Monthly Progress Reports During Construction - A written report containing the results of each inspection of construction progress shall be submitted to the Secretary every month while the dam and its appurtenances are under construction. The report shall include, but not be limited to, specific instrumentation readings, test results, freeboard, crest elevation, and specific construction or quality control problems with documentation of implemented solutions. Upon the completion of the construction or modification of the dam, notice shall be given by the dam owner to the Secretary so that a final construction inspection can be made in accordance with the provisions of subdivision 8.3.b.

8.4.b. Post-Construction Inspection Reports - A report shall be submitted to the Secretary by the dam owner reporting the findings of the final construction inspection required under subdivision 8.3.b. Certification by an engineer shall be submitted to the Secretary with the inspection report to verify that the dam and its appurtenances were constructed in substantial conformance with the approved plans and specifications and that the dam and its appurtenances are functioning as designed.

§47-34-9. Breaching of a Dam.

9.1. Application to Breach a Dam - The owner of a dam must obtain a certificate of approval from the Secretary prior to the breaching of the dam. A complete application in accordance with the provisions of subsection 5.1. must be submitted to and approved by the Secretary prior to the commencement of breaching activities.

9.1.a. Plan Package Requirements - The plan package submitted in order to breach a dam shall be in accordance with the applicable requirements of section 6 and must also include the specific requirements delineated in subsection 9.2 through subsection 9.10. Narratives, plans, or specifications required under section 6 which are clearly not applicable to the proposed breaching activities may be omitted from the submittal; however, the Secretary reserves the right to specify those items which must be included in the breaching plan package.

9.2. Breach Dimensions - The breach opening in the dam shall be designed so that any water resulting from design storm inflows that is temporarily impounded behind the residual structure shall be less than the height and storage requirements of a "dam" set forth in subsection 2.12. The breach shall be to original stream bottom level, except that a small impoundment of less than one (1) acre-foot storage may be retained for sediment control purposes.

9.3. Breach Channel - The embankment shall be breached with a designed channel having the capacity to carry the peak runoff from the design storm corresponding to the dam's hazard classification. The channel created by the breach shall have an erosion-preventive lining adequate to withstand the depth and velocity of the peak flows from a P100 rainfall event. The channel side slopes shall achieve a minimum stability factor of safety of 1.5.

9.4. Safety - Reservoirs shall be completely drained before breaching operations begin. Breaching work shall be scheduled during dry weather using National Weather Service advice and proceed quickly to reduce the potential for impounding water.

9.5. Blasting - If blasting is to be used in the breaching of a dam, a blasting plan shall be submitted to the Secretary for approval. The plan shall include the distance to existing structures and the measures that will be taken to minimize air blast and flying materials. A pre-blast survey of existing nearby structures and water wells which may be affected by blasting may be required by the Secretary.

9.6. Erosion and Sediment Control - Erosion and sediment control measures sufficient to comply with the provisions of paragraph 8.1.m. shall be implemented during the breaching operation. The following measures shall also be implemented:

9.6.a. Reservoir areas, and the sediment deposits therein, shall be protected from erosion after the impounding capability has been eliminated by the breaching of the dam;

9.6.b. Silt deposits and barren areas in the reservoir shall be stabilized and revegetated;

9.6.c. Disturbed areas, including the faces on any remaining embankment, must be protected by vegetation or other means approved by the Secretary;

9.6.d. A channel in the reservoir sediment may be required by the Secretary in order to reestablish a stream channel; and

9.6.e. Permanent sediment basins, subject to ongoing maintenance, may be required by the Secretary if the dam owner cannot demonstrate the effectiveness of other structural and vegetative measures in stabilizing the reservoir area and dam site.

9.7. Placement of Earthen Material - Material removed from the dam shall be placed in waste disposal areas delineated in the approved plan package. The material shall be graded and compacted as necessary and stabilized from erosion by vegetation or other means approved by the Secretary.

9.8. Placement of Non-Earthen Material - Concrete rubble and other rock material shall be placed in waste disposal areas delineated in the approved plan package. The material shall be placed in a manner to reduce hazardous conditions; protruding metal, wire, or bars are prohibited. The requirements of subdivision 8.1.n. shall apply to the disposal of any other waste materials generated by the breaching operation.

9.9. Galleries and Drains - The effect of flows through the breach and backwater pressure on galleries and drains shall be evaluated. The galleries and drains shall be vented or sealed as necessary to prevent failure of the remaining structure.

9.10. Safety of Remaining Structure - The remaining structure shall have sufficient strength to support the maximum hydraulic loading without failure. The engineer shall attempt to reduce or eliminate hazards associated with an "attractive nuisance."

9.11. Construction Practices - The requirements of section 8 shall apply when breaching a dam unless clearly not applicable to the breaching operation; however, the Secretary reserves the right to specify which requirements are applicable.

§47-34-10. Removal of a Dam.

10.1. Application to Remove a Dam - The owner of a dam must obtain a certificate of approval from the Secretary prior to the removal of the dam. A complete application in accordance with the provisions of subsection 5.1. must be submitted to and approved by the Secretary prior to the commencement of removal activities.

10.1.a. Plan Package Requirements - The plan package submitted in order to remove a dam shall be in accordance with the applicable requirements of section 6 and must also include the specific requirements delineated in subsection 10.2 through subsection 10.8. Narratives, plans, or specifications required under section 6 which are clearly not applicable to the proposed removal activities may be omitted from the submittal; however, the Secretary reserves the right to specify those items which must be included in the removal plan package.

10.2. Removal Requirements - Removal of a dam shall consist of the complete removal of the structure to the original ground except in special cases where it may be necessary or advantageous to leave small sections of the structure. Unless otherwise approved by the Secretary, the removal of a dam shall consist of complete removal of the structure to approximate original contour. A total of no more than ten percent (10%) of the length of the structure may remain at the abutment areas.

10.3. Safety - Reservoirs shall be completely drained before removal operations begin. Removal work shall be scheduled during dry weather using National Weather Service advice and proceed quickly to reduce the potential for impounding water.

10.4. Blasting - If blasting is to be used in the removal of a dam, a blasting plan shall be submitted to the Secretary for approval. The plan shall include distance to existing structures and the measures that will be taken to minimize air blast and flying materials. A pre-blast survey of existing nearby structures and water wells which may be affected by blasting may be necessary.

10.5. Erosion and Sediment Control - Erosion and sediment control measures sufficient to comply with the provisions of subdivision 8.1.m. shall be implemented during the removal operation. The following measures shall also be implemented:

10.5.a. Reservoir areas, and the sediment deposits therein, shall be protected from erosion after the impounding capability has been eliminated by the removal of the dam;

10.5.b. Silt deposits and barren areas in the reservoir shall be stabilized and revegetated;

10.5.c. Disturbed areas, including the faces on any remaining embankment, must be protected by vegetation or other means approved by the Secretary;

10.5.d. A channel in the reservoir sediment may be required by the Secretary in order to reestablish a stream channel; and

10.5.e. Permanent sediment basins, subject to ongoing maintenance, may be required by the Secretary if the dam owner cannot demonstrate the effectiveness of other structural and vegetative measures in stabilizing the reservoir area and dam site.

10.6. Placement of Earthen Material - Material removed from the dam shall be placed in waste disposal areas delineated in the approved plan package. The material shall be graded and compacted as necessary and stabilized from erosion by vegetation or other means approved by the Secretary.

10.7. Placement of Non-Earthen Material - Concrete rubble and other rock material shall be placed in waste disposal areas delineated in the approved plan package. The material shall be placed in a manner to reduce hazardous conditions; protruding metal, wire, or bars are prohibited. The requirements of subdivision 8.1.n. shall apply to the disposal of any other waste materials generated by the removal operation.

10.8. Safety of Remaining Structure - If any portion of the structure remains, that portion shall have sufficient strength to support the maximum hydraulic loading without failure. The engineer shall attempt to reduce or eliminate hazards associated with an "attractive nuisance."

10.9. Construction Practices - The requirements of section 8 shall apply when removing a dam unless clearly not applicable to the removal operation; however, the Secretary reserves the right to specify which requirements are applicable.

§47-34-11. Abandonment of a Dam.

11.1. Application to Abandon a Dam - The owner of a dam must obtain a certificate of approval from the Secretary prior to the abandonment of the dam. A complete application in accordance with the provisions of subsection 5.1. must be submitted to and approved by the Secretary prior to the commencement of abandonment activities.

11.2. Reservoir Elimination - The reservoir area shall be completely filled to the crest elevation of the dam with approved material to eliminate the impoundment of water. The maximum impounding capacity upon completion of final grading shall not exceed one (1) acre-foot of impounding capacity. The final top elevation of the reservoir fill shall be higher than, and sloped into, the diversion system required under subsection 11.4.

11.3. Embankment Stability - The remaining embankment shall be shown to achieve a minimum factor of safety in accordance with the provisions of subparagraph 7.4.b.1.D.

11.4. Diversion System - A diversion system designed for a P100 rainfall event shall be provided to capture the stream at the upstream end of the reservoir and convey stream water and embankment runoff water around the site. The diversion system shall outlet safely beyond the downstream toe of the embankment in a natural drainway capable of carrying the design storm without excessive erosion. The Secretary may require the installation of an energy dissipator in accordance with the provisions of subpart 7.4.b.4.B.2.(f).

11.5. Sealing Conduits - All conduits through the embankment, with the exception of underdrain conduits, shall be sealed with concrete at the upstream end prior to elimination of the reservoir. The Secretary may require pressure testing of conduits to determine seal adequacy.

11.6. Erosion and Sediment Control - Erosion and sediment control measures sufficient to comply with the provisions of subdivision 8.1.m. shall be implemented during the abandonment operation.

11.7. Soil and Vegetative Cover - A sufficient layer of topsoil shall be provided to permit long-term growth of vegetation. A seeding and mulching mixture shall be proposed in the abandonment application to accomplish revegetation of the project area.

11.8. Retention of Jurisdiction - The Secretary shall retain jurisdiction over the site for a minimum period of five (5) years after abandonment, during which time the dam and its appurtenances shall be inspected annually by an engineer experienced in such inspections. The inspections shall include measurement readings of instrumentation to determine the level and volume of saturation within the reservoir fill material. The Secretary may also require more frequent reading and reporting of instrument readings to determine seasonal fluctuations of saturation. A report shall be filed with the Secretary detailing the findings of each inspection and describing intended maintenance work. Should a major storm occur, a similar report shall be filed to detail the resultant condition of the structure.

11.9. Final Approval of Abandonment - At the completion of the five-year period, a final joint inspection by the engineer and the Secretary shall be conducted to determine the effectiveness of the

abandonment design and the potential need for continued maintenance. Should the Secretary determine as a result of this inspection that an additional inspection time period or maintenance work is required, a letter detailing these requirements shall be sent to the owner. The Secretary will review instrument records and annual inspection reports to determine if the saturation level of material within the reservoir has decreased in volume to less than the legal definition of a "dam." Should the Secretary determine as a result of the inspection and review of instrumentation records that the volume of saturated material is less than the legal definition of a "dam" and the abandonment design has been effective, a letter of acceptance shall be issued stating that the dam has been properly abandoned.

§47-34-12. Reduction or Enlargement of a Dam.

12.1. Reduction of Dam Height To Less Than Jurisdiction.

12.1.a. A person planning to reduce the height of a dam so that the remaining structure will no longer meet the definition of "dam" set forth in subsection 2.12. must obtain a certificate of approval from the Secretary.

12.1.b. A complete application in accordance with the provisions of subsection 5.1. must be submitted to and approved by the Secretary prior to the commencement of reduction activities. The application must also contain information showing that the remaining impounding structure will not cause loss of life or appreciable property damage downstream should that structure fail.

12.1.b.1. Plan Package Requirements - The plan package submitted in order to reduce the height of a dam shall be in accordance with the applicable requirements of section 6 and must also include the specific requirements delineated in subdivision 12.1.c. and subdivision 12.1.d. Narratives, plans, or specifications required under section 6 which are clearly not applicable to the proposed reduction may be omitted from the submittal; however, the Secretary reserves the right to specify those items which must be included in the reduction plan package.

12.1.c. The remaining structure shall have a properly designed spillway system capable of passing a Class 3 design storm without overtopping.

12.1.d. The remaining structure shall achieve a factor of safety in accordance with the provisions of subparagraph 7.4.b.1.C. or subparagraph 7.4.b.2.B. as appropriate to the type of structure.

12.1.e. The requirements of section 8 apply when reducing the height of a dam unless clearly not applicable to the reduction operation; however, the Secretary reserves the right to specify which requirements are applicable.

12.1.f. The Secretary shall retain jurisdiction over the remaining structure until the reduction operation is completed and a letter of acceptance has been issued by the Secretary.

12.2. Enlargement of a Structure to Jurisdiction.

12.2.a. A person planning to enlarge an existing structure so that the completed structure will meet the definition of "dam" set forth in subsection 2.12. must obtain a certificate of approval from the Secretary.

12.2.b. A complete application in accordance with the provisions of subsection 5.1. must be submitted to and approved by the Secretary prior to the commencement of enlargement activities.

12.2.b.1. Plan Package Requirements - The plan package submitted in order to enlarge a structure to jurisdiction shall be in accordance with the applicable requirements of section 6. Narratives,

plans, or specifications required under section 6 which are clearly not applicable to the proposed enlargement may be omitted from the submittal; however, the Secretary reserves the right to specify those items which must be included in the enlargement plan package.

12.2.c. The Secretary will require adequate drilling and testing of the existing structure and foundation to ascertain in place conditions.

12.2.d. The requirements of section 8 shall apply when enlarging a structure to jurisdiction unless clearly not applicable to the enlargement operation; however, the Secretary reserves the right to specify which requirements are applicable.

§47-34-13. Dams Completed Before July 1, 1973.

13.1. Complete Application Required - An application for a certificate of approval shall be submitted to the Secretary for all dams completed before July 1, 1973 which meet the definition of "dam" set forth in subsection 2.12. If the engineer can demonstrate that the dam meets the design requirements specified in this rule, an application for approval of an existing dam shall be submitted. If the dam requires modification to meet the requirements, an application for modification of an existing dam shall be submitted. If the above options are not exercised by the dam owner, an application to breach, remove, or properly abandon the dam pursuant to this rule shall be submitted.

13.2. Performance Requirements - All dams completed before July 1, 1973 shall meet the applicable design requirements of section 7. Those dams which do not meet the applicable design requirement of section 7 shall be modified, breached, removed, or properly abandoned pursuant to the provisions of this rule. In developing the required plans, specifications, and documentation necessary to bring the structure into conformity with section 7, the design engineer may consider in his or her submitted analyses, peculiarities and local conditions for each impounding structure with recognition of the many factors involved, some of which may not be precisely known. Existing construction documentation and the historical performance of the structure including documented storms and spillway flows may be considered by the engineer as part of the evaluation of the structure. Upon approval by the Secretary of the plans, specifications, and documentation submitted by the engineer, the Secretary may issue a certificate of approval.

13.3. Plan Package Requirements - The plan package submitted for approval or modification of an existing dam shall be in accordance with applicable requirements of section 6, except that testing and analysis results may be substituted for design specifications. If as-built drawings are not available, the engineer may substitute drawings prepared by him or her which represent the existing conditions at the dam as determined through the testing and analysis program.

§47-34-14. Sale or Transfer of a Dam.

14.1. Notification and Documentation - Within thirty (30) days after the sale or transfer of a dam, the Secretary must be notified of that transaction by the person who was issued the certificate of approval for the dam.

14.1.a. The seller of a dam must provide the following documentation to the Secretary:

14.1.a.1. The name and address of new owner;

14.1.a.2. A copy of the signed agreement between the previous and new owner acknowledging certificate of approval responsibility and including any warranties, insurance coverage, or liability agreements between the parties;

14.1.a.3. The effective date of the ownership or responsibility transfer; and

14.1.a.4. Documentation that a copy of the certificate of approval or the most recent Dam Control Act notice to comply or order -- if a valid certificate of approval does not exist -- has been entered in the deed or land records of the county in which the dam is located.

14.1.b. The Secretary may reissue a corrected certificate of approval reflecting the sale or transfer of a dam upon the receipt of appropriate documentation and fees.

§47-34-15. Dam Operations and Safety.

15.1. Safe Operations - The owner of a dam shall ensure that his or her dam is operated in a safe and responsible manner so as not to endanger life or property.

15.2. Operations Plan - Owners of dams which require the operation of gates, penstocks, or other means of regulating the reservoir level or downstream flow shall develop and submit an operations plan to the Secretary for approval.

15.2.a. Plan Contents - The operations plan shall include, but not be limited to, normal and seasonal operational procedures for gates, penstocks, and other reservoir or downstream flow regulating devices. The name, address, and telephone number of each individual authorized to operate the dam shall also be included in the plan.

15.2.b. Plan Implementation - The operations plan shall be implemented immediately upon approval by the Secretary and shall be updated periodically as necessary to reflect any changes in personnel or operation procedures.

15.3. Releasing Water - The owner of a dam may release water or lower the reservoir elevation through the use of gates without prior approval of the Secretary provided that the release of water will not adversely affect the dam structure, property, or water quality or pose a hazard to human life.

15.3.a. Emergency Releases of Water - Under emergency conditions, the owner of a dam may release water at a rate which may violate the criteria established under subsection 15.3. provided that such emergency release will not pose an unjustifiable hazard to human life. Notification must be given of a pending emergency release of water in accordance with the provisions of subdivision 15.8.a. In accordance with the provisions of W. Va. Code §22-14-12, this regulatory provision shall not relieve the owner of the dam of any liabilities resulting from an emergency release of water.

15.3.b. Low Flow Augmentation - The Secretary may require the owner of a dam to maintain a specified stream flow below the dam or to augment the stream flow for appropriate in-stream uses.

15.4. Dam Safety Inspections - Periodic inspections of dams shall be performed to monitor and assess the condition of the dam. These scheduled safety inspections of completed dams shall be in the charge of an engineer.

15.4.a. Inspections by the Dam Owner - The owner of a dam or his or her agent shall perform safety inspections monthly or more frequently. Such inspections must survey the dam and its appurtenances to check for problems or changes since the last inspection. The owner or his or her agent shall inspect the dam more frequently than once per month during adverse weather conditions. The owner shall report any observed problems to the Secretary.

15.4.b. Inspections by the Secretary - The Secretary may inspect any dam at any time in accordance with the provisions of W. Va. Code §22-14-4(i).

15.4.c. Inspections by the Owner's Engineer - An engineering inspection shall be conducted annually for three (3) years after the completion of any dam, in accordance with the provisions of paragraph 8.3.d. Upon the conclusion of this three-year period, the dam shall be inspected by the owner's engineer at the frequency specified in subparagraph 15.4.c.1. through subparagraph 15.4.c.4. as appropriate to the hazard classification of the dam. The Secretary may require additional inspections based upon site conditions. The Secretary reserves the right to attend any inspection and require prior notification of the inspection from the owner of the dam.

15.4.c.1. Class 4 dams shall be inspected at least once every seven (7) years.

15.4.c.2. Class 3 dams shall be inspected at least once every five (5) years.

15.4.c.3. Class 2 dams shall be inspected at least once every three (3) years.

15.4.c.4. Class 1 dams shall be inspected at least once every two (2) years.

15.4.d. Inspection of Dams with Serious Problems - The Secretary may establish the frequency of inspection of dams with serious problems for both inspections by the dam owner under subdivision 15.4.a. and inspections by the owner's engineer under subdivision 15.4.c. The inspection of a dam with serious problems shall monitor slopes, seepage, bulges, scarps, vertical displacement, excessive erosion, piping, sudden changes in monitoring devices, and other visible factors which could indicate potential failure of the embankment, spillways, or other appurtenances. The Secretary reserves the right to attend any inspection and require prior notification of the inspection by the owner of the dam.

15.5. Dam Safety Inspection Reports.

15.5.a. Inspection Reports for Completed Dams - A written report containing the observations of each inspection that is required under subdivision 8.3.d. and subdivision 15.4.c. shall be submitted to the Secretary by the dam owner within thirty (30) days of the inspection. The report shall also describe maintenance work to be performed as a result of the inspection findings. Should a storm equal to or greater than a 50-year, 6-hour rainfall event occur, a similar report shall be filed to detail the resultant condition of the structure. Certification by an engineer shall be submitted to the Secretary with each inspection report to verify that the dam and its appurtenances are functioning as designed.

15.5.b. Inspection Reports for Dams with Serious Problems - A written report containing the observations of each inspection required under subdivision 15.4.d. shall be submitted to the Secretary by the dam owner within thirty (30) days of the inspection.

15.6. Monitoring Plans - Owners of Class 1 dams shall formulate and submit a monitoring plan to the Secretary for approval. Owners of Class 2 and 3 dams may be required by the Secretary to formulate and submit a monitoring plan for approval.

15.6.a. The monitoring plan developed by the dam owner must follow the format of the example plan provided by the Secretary and shall include, but not be limited to, the following:

15.6.a.1. A description of the dam, including appropriate drawings and location maps;

15.6.a.2. A listing of problems and deficiencies and any implemented repairs;

15.6.a.3. The inspection frequency under varying weather conditions;

15.6.a.4. A description of areas or items to be inspected;

15.6.a.5. Corrective actions to be taken;

15.6.a.6. The responsible persons' names, addresses, and telephone numbers;

15.6.a.7. The method of notification of the Secretary and county emergency services authorities; and

15.6.a.8. Other items required by the Secretary based upon site-specific conditions.

15.6.b. Monitoring plans shall be updated annually. More frequent updating of the plans may be required by the Secretary based upon rapidly changing personnel or site conditions. The monitoring plan shall be implemented immediately by the dam owner upon the approval of the plan by the Secretary.

15.7. Emergency Action Plans - Owners of Class 1 dams shall formulate and submit an emergency action plan to the Secretary for approval. Owners of Class 2 and 3 dams may be required by the Secretary to formulate and submit an emergency action plan for approval.

15.7.a. The emergency action plan developed by the dam owner must follow the format of the example plan provided by the Secretary.

15.7.b. The dam owner shall coordinate with county emergency service authorities in the development of the emergency action plan. The dam owner must provide copies of the inundation maps required under paragraph 3.5.c.2. to those authorities.

15.7.c. The dam owner shall provide county emergency services authorities with a copy of the monitoring plan, and all updates of that plan, approved by the Secretary pursuant to subsection 15.6.

15.8. Emergency Procedures.

15.8.a. Emergency Condition - If the owner of a dam determines that an emergency exists, he or she shall immediately notify any person who may be endangered if the dam should fail and then notify the appropriate county emergency services authorities and the Secretary. After providing notification of the emergency condition, the owner shall immediately take any remedial action, such as an emergency release of water, that is necessary to protect life and property. The Secretary may waive the requirement for a certificate of approval, as required under section 4, where it is necessary to accomplish repairs under emergency conditions.

15.8.b. Dangerous Condition - Should a dangerous condition develop, the Secretary shall be informed immediately. The owner of the dam shall immediately take any remedial action necessary to protect life and property. Emergency procedures developed in accordance with the provisions of subsection 15.6. and subsection 15.7. shall be implemented to protect life and property downstream. The site shall be inspected and monitored at least once every eight (8) hours until the emergency situation is alleviated. Continuous monitoring may be required by the Secretary when there is an imminent danger to the health, safety, or welfare of the public.

15.8.c. Evaluation of Dangerous Conditions - If a dangerous condition develops, an engineering evaluation shall be initiated as soon as possible to formulate a plan for permanent correction of the dangerous condition. The evaluation and corrective action plan shall be submitted to and approved by the Secretary prior to implementation.

15.9. Dam Owner Not Relieved of Responsibility - The Secretary's approval of a monitoring plan, or updates to such a plan, pursuant to subsection 15.6. or his or her approval of an emergency action plan

pursuant to subsection 15.7. shall not relieve the dam owner of his or her legal duties, obligations, or liabilities under W. Va. Code §§22-14-10 and 22-14-12.

§47-34-16. Dam Maintenance.

16.1. General Maintenance Requirements.

16.1.a. Required Maintenance - Each dam shall be maintained in accordance with the plans and specifications approved under the applicable certificate of approval. The Secretary may require maintenance to be performed on a dam, whether or not a certificate of approval has been issued for that dam.

16.1.b. Maintenance Plan - Owners of dams shall formulate and submit a written maintenance plan to the Secretary for approval. The maintenance plan shall include, but not be limited to, schedules for maintaining embankments, concrete structures, vegetative or rock covers, gates, gate mechanisms, penstocks, or other reservoir-regulating devices, spillways, and appurtenances. The maintenance plan shall be implemented immediately by the dam owner upon the approval of the plan by the Secretary. The maintenance plan shall be updated periodically as necessary to reflect changing site conditions.

16.2. Specific Maintenance Requirements.

16.2.a. All spillways and appurtenances shall be maintained to operate in accordance with the plans and specifications approved under the applicable certificate of approval.

16.2.b. All failures resulting from landslides or slope failures shall be corrected immediately if the failures significantly affect the safety or design capacity of the dam or its appurtenances. All failures shall be reported to the Secretary.

16.2.c. All pipes shall be repaired or replaced when damaged, or distorted, or if they otherwise fail to function properly in accordance with the plans and specifications approved under the applicable certificate of approval.

16.2.d. Leakage through joints, fissures, and cracks through or under the spillway channel shall be immediately investigated and repaired.

16.2.e. Any new gate which has been installed in a new dam or in the repair or modification of an existing dam, or any gate which has been opened within five (5) years prior to inspection by the Secretary, shall be opened to at least thirty-three percent (33%) of its maximum capacity at least once annually. Gates not meeting the above requirements may remain closed until operated for the purposes of the owner or to alleviate an emergency condition and shall thereafter be opened at least once annually. All gate mechanisms shall be lubricated annually regardless of the operational status of the gate.

16.3. Routine Maintenance.

16.3.a. Routine maintenance of spillways shall be performed. Such maintenance shall include the removal of sediment, brush, trees, obstructions, and rocks in stilling basins and the re-establishment of the structure to its original hydraulic design.

16.3.b. Routine inspections shall be made of all hydraulic structures in order to maintain proper operation. Special inspections shall be conducted whenever a significant flow through the structures has occurred.

16.3.c. If erosion on the embankment face or abutments occurs, the area shall be regraded and be provided with adequate drainage control or revegetation to prevent future occurrences.

16.3.d. All concrete structures and channel linings shall be maintained in accordance with the plans and specifications approved under the applicable certificate of approval. All cracks located in concrete channels shall be sealed immediately with a sealant approved by the Secretary.

16.3.e. Access roads shall be maintained in order to provide access for emergency inspections, vehicles, and equipment.

16.3.f. The embankment or concrete structure of a dam shall be kept clear of trees and shrubs. The downstream toe and abutments of the dam shall be cleared to natural ground for a lateral distance of at least twenty-five (25) feet. All dams with vegetative covers shall be mowed at least once annually. Grazing by farm animals shall be controlled to prevent animal trails or other damage to the vegetative cover.

16.3.g. The embankment shall be kept clear of burrowing animals.

16.3.h. All monitoring devices shall be routinely inspected and repaired or replaced as necessary so that the devices function properly.

§47-34-17. Dam Repairs.

17.1. General Repair Requirements - The Secretary may require repairs to be performed on a dam, whether or not the dam has a certificate of approval. Major repairs shall require a certificate of approval, issuance of which may or may not constitute final approval of the dam, as determined by the Secretary.

17.1.a. Routine Repairs (No Certificate Required) - Repairs conducted in accordance with the provisions of subsection 16.3. shall not normally require an application for a certificate of approval; however, the Secretary may require such an application based upon site-specific conditions.

17.1.b. Major Repairs (Certificate Required) - Any repairs to a dam other than routine repairs listed in subsection 16.3. shall require an application for a certificate of approval in accordance with the provisions of this rule.

17.2. Specific Repair Requirements.

17.2.a. Removal of Trees and Tree Roots - All trees shall be removed from the embankment and abutment areas, unless otherwise approved by the Secretary based upon site-specific conditions. Small trees with a base diameter of four (4) inches or less may be removed without removing the root system unless specific problems with the root system are evident. Larger trees may require special care in removal. The Secretary may require the removal of root systems of large trees if the potential for seepage along the root system exists. If removal of root systems requires extensive excavation of the embankment, the removal shall be considered a major repair requiring a complete application for a certificate of approval.

§47-34-18. Application and Annual Registration Fees.

18.1. Application Fees - Each application submitted to place, construct, enlarge, alter, repair, remove or abandon a dam shall include an application fee. No fee, however, shall be assessed for dams designed and constructed by the soil conservation service for soil conservation districts. The following application fees apply:

18.1.a. The application fee for placement, construction, alteration, enlargement, repair, or approval of a dam is three hundred dollars.

18.1.b. The application fee for breaching, or abandonment of a dam is two hundred dollars.

18.1.c. The application fee for removal of a dam is one hundred dollars.

18.2. Annual Registration Fees - Owners of existing dams holding certificates of approval shall be assessed an annual registration fee. In accordance with provisions of the Dam Control and Safety Act, West Virginia Code §22-14-7, existing certificates of approval will be extended for one year upon receipt of the annual registration fee, an inspection report in accordance with subsection 15.5., a monitoring and emergency action plan in accordance with subsection 15.6. and subsection 15.7., and a maintenance plan in accordance with subdivision 16.1.b.; Provided that where an approved, up-to-date: inspection report; monitoring and emergency action plan; and maintenance plan are on file in the Dam Safety Section, and where no outstanding violation(s) exist, then the certificate of approval will be extended without resubmission of the foregoing documents upon receipt of the annual registration fee. No fee shall be assessed, however, for dams designed and constructed by the soil conservation service for soil conservation districts. The following annual registration fees apply:

18.2.a. Class 4 dams shall be assessed twenty-five dollars.

18.2.b. Class 3 dams shall be assessed fifty dollars.

18.2.c. Class 2 dams shall be assessed seventy-five dollars

18.2.d. Class 1 dams shall be assessed one hundred dollars.

18.3. Any certificate of approval issued pursuant to W. Va. Code §22-14-7 and this rule is void without notification to the person holding the certificate of approval when the annual registration fee is more than one hundred eighty (180) days past due. Resubmission of an application in accordance with section 5 is required where a certificate has become void due to failure to pay the appropriate annual registration fee within one hundred eighty (180) days of the date due.

§47-34-19. Civil Administrative Penalties.

19.1. Enforcement Actions.

19.1.a. General - An authorized representative of the Secretary may commence an enforcement action for any observed violation.

19.1.b. Enforcement Action Procedures - An enforcement action shall be in writing, shall be signed by the Secretary or other authorized representative of the Secretary, and shall set forth with reasonable specificity:

19.1.b.1. The nature of the enforcement action with a reference to the section of the statute, rule, notice, order or certificate of approval term that was allegedly violated;

19.1.b.2. The time and date of the observance of the violation;

19.1.b.3. A reasonable description of the dam where the violation was observed, where within the operation or maintenance of the dam the observation was observed, and the condition or hazard determined by the Secretary;

19.1.b.4. The name, ownership and location of the dam and any identification number associated with it; and

19.1.b.5. In those instances where a notice or order has not been previously issued, the remedial action necessary to alleviate the violation and time limits for accomplishing the remedial action.

19.2. Penalty Assessment Procedures.

19.2.a. Review of Enforcement Action and Penalty Calculation - The Secretary shall review each enforcement action issued for civil administrative penalty assessment to determine:

19.2.a.1. The appropriateness of a civil administrative penalty;

19.2.a.2. The initial amount of penalty, if any, based upon the rates and methods given in subsection 19.5.;

19.2.a.3. The appropriateness of assessing a daily civil administrative penalty for continuing violations;

19.2.a.4. The total initial civil administrative penalty assessed; and

19.2.a.5. The appropriateness of assessing a separate civil administrative penalty against an individual person.

19.2.b. Notice of Civil Administrative Penalty - The Secretary shall provide the violator with a copy of the enforcement action and:

19.2.b.1. A notice of civil administrative penalty which shall include procedures for requesting an informal hearing and a notification of applicable time constraints; or

19.2.b.2. A notice of dismissal.

19.3. Hearings and Appeals.

19.3.a. Right to Informal Hearing - The violator has twenty (20) calendar days from his or her receipt of the notice of civil administrative penalty within which to request, in writing, an informal hearing before the assessment officer. If a hearing is requested, the assessment officer will hold the hearing within 60 days to deduce the actual facts and circumstances regarding the violation and, based thereon, will make a final recommendation of civil administrative penalty assessment to the Secretary. If no hearing is requested, the notice of civil administrative penalty becomes a final order after the expiration of the twenty-day period and the civil administrative penalty becomes due and payable.

19.3.b. Notice and Scheduling of Informal Hearing - If the violator requests an informal hearing within the twenty-day period, the assessment officer shall schedule a hearing in accordance with the following procedures:

19.3.b.1. The time and place the informal hearing is to be held is to be communicated to any authorized representative of the Secretary who filed an enforcement action bringing about the informal hearing, to the violator and to any person who has expressed an interest in writing concerning the enforcement action;

19.3.b.2. The communication shall be provided at least fifteen (15) calendar days prior to the time of the hearing; and

19.3.b.3. The assessment officer may continue the informal hearing only for good cause shown.

19.3.c. Informal Hearing Procedures - An informal hearing, as provided by this rule, is intended to be an informal discussion of the facts which gave rise to the issuance of an enforcement action and shall be conducted in the following manner:

19.3.c.1. The West Virginia Rules of Civil Procedure and West Virginia Rules of Evidence shall not apply;

19.3.c.2. A record of the informal hearing is not required but may be made by any party to the hearing at the party's expense; and

19.3.c.3. At formal review proceedings which may ensue, no evidence as to any statement made by one party at the informal hearing may be introduced as evidence by another party, nor may any statement be used to impeach a witness, unless the statement is or was available as competent evidence independent of its introduction during the informal hearing.

19.3.d. Written Decision - Within thirty (30) calendar days following the informal hearing, the Secretary shall issue and furnish to the violator a written decision affirming, increasing, decreasing, or dismissing the initial civil administrative penalty assessment and giving the reasons for the decision.

19.3.e. Request for Formal Hearing - Within thirty (30) calendar days after notification of the Secretary's informal hearing decision, the violator may request a formal hearing before the Environmental Quality Board. If no formal hearing is requested, the Secretary’s decision becomes a final order after the expiration of the thirty day period and the civil administrative penalty becomes due and payable.

19.4. Separate Civil Administrative Penalties.

19.4.a. The Secretary may assess a separate civil administrative penalty against any corporate director, officer, agent, or employee of a violator, or any other person, who authorizes, orders, or carries out a violation of the statute, rule, notice, order, or certificate of approval term or who fails or refuses to follow an order from the Secretary.

19.4.b. In determining the amount of a civil administrative penalty to be assessed against a person, consideration shall be given to the criteria specified in subsection 19.5.

19.4.c. The Secretary shall serve on each person to be assessed an administrative penalty a notice of separate civil administrative penalty assessment. For purposes of this subsection, service is considered sufficient if it satisfies Rule 4 of the West Virginia Rules of Civil Procedure for service of a summons and complaint. A notice of separate civil administrative penalty assessment shall include:

19.4.c.1. A reference to the section of the statute, rule, notice, order, or certificate of approval term allegedly violated;

19.4.c.2. A concise statement of the facts alleged to constitute the violation;

19.4.c.3. A statement of the amount of the separate civil administrative penalty to be imposed;

19.4.c.4. A copy of the underlying enforcement action; and

19.4.c.5. A statement of a person's right to an informal hearing.

19.4.d. A person shall have twenty (20) calendar days from receipt of the notice of separate civil administrative penalty assessment in which to request, in writing, an informal hearing before the assessment officer. If no hearing is requested, the notice of separate civil administrative penalty becomes a final order after expiration of the thirty-day period and the separate civil administrative penalty becomes due and payable.

19.4.e. The informal hearing, if requested, will be scheduled and conducted pursuant to this section.

19.5. Civil Administrative Penalty Calculation Procedures.

19.5.a. Calculation - The Secretary shall calculate a civil administrative penalty by taking into account the seriousness of the alleged violation, good faith efforts on the part of the violator (as provided for in paragraph 19.5.c. of this section) and any history of violations by the violator.

19.5.b. History of Violations (HOV) - The Secretary shall take into account the violator's history of violations by determining if any enforcement actions concerning Certificate terms, requirements of the Act, rule requirements, notices to comply or any orders have been taken against the violator during twenty-four (24) months prior to the violation. Those enforcement actions which were withdrawn, dismissed, or vacated shall not be included in the determination. Any outstanding violation within the time period shall constitute a history of violations.

19.5.c. Good Faith Effort - Good faith effort shall be determined in accordance with Table B.

19.5.d. Maximum Assessed Penalty - The maximum assessment for a single violation shall not exceed five thousand dollars ($5,000) per day with a maximum cumulative total of twenty thousand dollars ($20,000) for this same violation. Multiple violations shall not exceed a maximum cumulative total of twenty thousand dollars ($20,000) per day. The amounts applicable to a single violation must be adhered to when developing the cumulative total for multiple days.

19.5.e. Penalty - The civil administrative penalty shall be determined through the use of Table A.

19.5.f. Penalty With Good Faith Efforts by Violator - The civil administrative penalty determined by Table A shall be reduced, if applicable, through the use of Table B.

TABLE A

Seriousness of Violation
(dollars/day/violation)

Enforcement Action	**No Hazard**		**Serious Problem**		**Dangerous Condition**	
Failure to Comply With:	No HOV	With HOV	No HOV	With HOV	No HOV	With HOV
Certificate	250	625	750	1250	2500	5000
Act	625	1250	1500	1875	3125	5000
Rule	1250	1875	2125	2500	3750	5000
Notice	1875	2500	3125	3750	4375	5000
Order	2500	3125	3750	4375	4625	5000

TABLE B

Good Faith by Violator

Rating	0	1	2	3	4	5	6	7	8
Percent Reduction	0%	5%	10%	15%	20%	25%	30%	35%	40%

Good Faith Ratings:

0 Violator failed to take appropriate action
1-2 Violator took prompt, but insufficient action to fully comply with the violation within the required time period. Action was completed prior to end of extended time period.
3-4 Violator took prompt action and worked diligently to correct the violation. Conditions beyond the control of the violator prevented full compliance with the enforcement action and required that the compliance time period be extended for just cause.
5-6 Violator initiated compliance action immediately and expended all reasonable efforts to comply. Achieved compliance before the end of the original compliance time period.
7-8 Violator was already taking appropriate action at the time the violation was documented and expended exemplary effort in compliance action before the end of the compliance time period.

Determination of Penalty Assessment:

Enforcement Action Amount (Table A) _____

Less Good Faith Percent (Table B) _____

Total Assessment _____

§47-34-20. State Deficient Dams Rehabilitation Assistance Program.

20.1. The Secretary shall establish a State Deficient Dams Rehabilitation Assistance Program to direct the distribution of loans from the Dam Safety Rehabilitation Revolving Fund created under the Act.

20.2. Use of Moneys in the Fund. -- Moneys in the Fund shall be used to make loans to persons to finance costs for engineering, design, alteration, improvement, repair, breaching or removal of a deficient dam necessary to correct or remove the deficiencies and other activities as authorized by a federal grant or a legislative appropriation. The Fund may also be utilized by the Secretary to repair, remove or take other remedial action with respect to a deficient dam under the authority in section 22 of the Act. The Fund may also be used to defray administrative costs incurred by the Secretary or the Authority.

20.3. Each loan shall be in an amount that covers the reasonable and necessary cost of a project for which funds are sought by the applicant and which are not provided by other available sources. Dam owners may use multiple programs or sources to fund the rehabilitation costs for a deficient dam, up to 100 percent of rehabilitation costs. Dam owners cannot exceed 100 percent funding from multiple programs or sources and must provide the Secretary with any multiple source accounting to verify that the loan amount plus the additional sources of funding do not exceed 100 percent.

20.4. List of Deficient Dams. -- A State List of Deficient Dams shall be developed and updated periodically by the Secretary utilizing a priority ranking system, including, but not limited to, the following factors: size of dam and reservoir; condition of dam and its appurtenances; and hazard potential to life and property.

§47-34-21. Eligibility Criteria.

The Secretary shall consider eligibility for loans to include, but not be limited to, the following criteria:

21.1. Only those dams on the List of Deficient Dams are eligible for a loan from the Dam Safety Rehabilitation Revolving Fund in accordance with the priority specified in the List of Deficient Dams, provided that a person meets the criteria under subsection 21.3.;

21.2. A person has submitted a complete application for a project with eligible costs;

21.3. A person is in a state of readiness to proceed to planning, design or construction and expend loan payments in a timely manner;

21.4. A person has demonstrated his or her ability to pay is less than the estimated cost of repair or removal of the dam;

21.5. A person has demonstrated his or her ability to repay a loan. The Secretary shall evaluate the borrower’s financial stability, financial needs, and ability to repay based upon an appropriate examination of financial information, including, but not limited to, income and credit histories, income tax returns, financial statements and collateral offered to secure the loan;

21.6. Rehabilitation costs for any deficient dam are eligible, except for dams owned by the federal government;

21.7. Costs for State agency-required fish passage are eligible only if they are part of an overall rehabilitation project;

21.8. Costs for lake-enhancement projects such as lake dredging, sediment removal projects, or boat

ramps, which do not enhance the safety of a deficient dam are not eligible to be funded through the Fund;

21.9. A person has provided an acceptable schedule for project initiation and completion; and

21.10. A person has demonstrated he or she has the financial, legal, and managerial capabilities to ensure adequate design, construction, completion of the project, and subsequent operation and maintenance of the dam. As a part of this demonstration, the person shall complete and submit to the Secretary financial capability worksheets supplied by the Secretary.

§47-34-22. Applications for Loans.

22.1. A person who meets the eligibility criteria in section 21 may apply for a loan.

22.2. The applicant shall request a pre-application meeting with the Secretary to discuss the requirements of the program, including eligibility. A pre-application package, in a form prescribed by the Secretary, shall be completed and submitted to the Secretary prior to this meeting.

22.3. The review and approval by the Secretary of the pre-application package, including any project plans, design drawings and specifications, or other documents is for administrative purposes only and does not relieve the applicant or his agents and employees from properly planning, designing, constructing, operating, and maintaining the project as required under applicable federal and state statutes and rules.

22.4. If the project will involve two (2) or more persons, the applicant shall submit an agreement among the parties to the Secretary in a form prescribed by the Secretary.

22.5. After the pre-application meeting, a person desiring a loan from the Fund may make a separate application to the Secretary, on a form prescribed by the Secretary, for each project for which a loan is desired.

§47-34-23. Loan Agreements.

Upon approval of an application for a loan, the Secretary shall specify the provisions that are required to be contained in the loan agreement, including:

23.1. The specific purposes for which the proceeds of the loan shall be expended, the cost of the project, the amount of the loan, and the terms of repayment of the loan and the security therefor, which may include a deed of trust or other appropriate security instrument creating a lien on such project or any other collateral the Secretary may require;

23.2. The procedures as to the disbursement of loan proceeds including an estimated monthly draw schedule, and the duties and obligations imposed upon the applicant in regard to the acquisition or construction of the project;

23.3. The agreement of the applicant to repay the obligations of such applicant under the loan agreement. Revenue may be pledged for the repayment of the loan together with all interest, fees, and charges thereon and all other financial obligations of the applicant under the loan agreement;

23.4. If notes or other interim obligations are being issued by the applicant, the agreement of the applicant to take other repayment actions as are required of the applicant under the loan agreement;

23.5. Payments of the principal and any interest on a loan shall be made by the applicant in accordance with the following:

23.5.a. Computation of Interest on Loans. -- Each loan shall bear interest from the date of the delivery of the notes of the applicant evidencing the loan to the applicant (or such other date as is determined by the Secretary) at a rate or rates per annum, either fixed or variable, as determined by the Secretary.

23.5.b. Fees and Charges. -- In addition to payments of principal and interest on a loan, each applicant shall agree in the loan agreement to pay fees and charges equal to the applicant's share of the administrative expenses of the Secretary and the Authority relating to the loan program or any bond program established by the Secretary and the Authority.

23.6. The agreement of the applicant to accept the Authority's enforcement remedies under the Act in the event of any default under the loan; and

23.7. The agreement of the applicant to comply with all applicable federal and state statutes and rules and regulations and all applicable local ordinances pertinent to the financing, acquisition, design, construction, operation, maintenance and use of the project.

§47-34-24. Loans Conditioned Upon Availability of Moneys in the Fund.

The obligation of the Authority to enter into loan agreements shall be conditioned upon the availability of moneys in the Fund in amounts and on terms and conditions, as at the direction of the Secretary, will enable the Authority to make loans.

§47-34-25. Disbursement of Loan Moneys.

25.1. Following the Secretary's approval of a loan and conditions to be included in the loan agreement, the Authority shall provide the person with the loan agreement setting forth the specific terms of the loan. The loan agreement, following execution by the person, constitutes a binding commitment for moneys from the Fund.

25.2. Moneys shall be disbursed from the Fund only upon a written authorization from the Authority. On a monthly basis, there shall be disbursed to each recipient the amount certified as costs incurred for the project. Said certification shall be made on an approved form. Moneys will be dispensed from the Fund upon presentation of an executed payment request form.

25.3. Each person receiving a loan shall comply with all terms and conditions of the loan agreement or notes or other debt instruments evidencing the loan.

25.4. Prior to commencement of construction, the Secretary and recipient shall hold a pre-construction conference to review the activities that shall take place during construction of the project.

25.5. Interim inspections of the project shall be conducted by the Secretary periodically during construction. A final inspection shall be conducted by the Secretary after construction has been substantially completed and before the final construction loan payment is disbursed.

25.6. The Secretary may use moneys from the Fund in accordance with provisions of section 22 of the Act. Before seeking a requisition from the Fund, the Secretary shall provide the information required in Section 20 of the Act to the Authority. Costs recovered from an owner by civil action shall be promptly deposited in the Fund.

§47-34-26. Owner's Responsibilities.

Once a loan has been granted under this rule, the owner or owners of a dam shall cooperate with the Secretary by:

26.1. Facilitating access to the dam and its appurtenances;

26.2. Making available all records maintained pursuant to the provisions of this rule for inspection by the Secretary upon request and where appropriate by the Authority;

26.3. Furnishing the Secretary with all plans, specifications, operation and maintenance data, instrumentation data, and other information pertinent to the dam and its appurtenances, or the loan;

26.4. Providing the Secretary with an operation and maintenance plan;

26.5. Maintaining the dam and appurtenances in the state of repair and operating condition required by the exercise of prudence; due regard for life or property; the application of sound and accepted engineering principles; and provisions of this rule;

26.6. Developing a monitoring and emergency action plan for the approval of the Secretary and implementing the plan upon approval;

26.7. Providing the Secretary with written, regularly scheduled reports describing progress toward repair or removal of the dam; and

26.8. Demonstrating the ability to appropriately operate and maintain the dam after rehabilitation is complete.

§47-34-27. Procurement Standards.

27.1. Procurement Standards for Publicly-Owned Dams. -- Owners of publicly-owned dams shall comply with all applicable State laws and rules pertaining to competitive bid and prevailing wage requirements.

27.2. Procurement Standards for Privately-Owned Dams. -- Owners of privately-owned dams shall obtain a minimum of three bids prior to design, construction, or major procurement items as determined by the Secretary, provided that the Secretary may grant an exception in situations that may cause loss of life or property.

§47-34-28. Financial Management and Record Keeping.

28.1. Financial Management. -- A loan recipient shall establish and maintain a financial management system to account for all costs incurred related to a project. This system shall assure that generally accepted accounting principles and practices are consistently applied in all financial matters related to the project.

28.1.a. Financial management shall include the following elements:

28.1.a.1. The maintenance of ledgers containing accurate, current, and complete records of all financial actions related to the project;

28.1.a.2. The maintenance of records that identify the source and amount of all moneys used for the project and documentation of how such moneys were used; and

28.1.a.3. The maintenance of records that allow a comparison of actual project costs with

budgeted costs.

28.1.b. The recipient shall maintain an accounting system, which shall:

28.1.b.1. Establish a separate account for the project;

28.1.b.2. Record all transactions in a timely and verifiable manner;

28.1.b.3. Designate one (1) person who is not responsible for project operations to account for all project funds; and

28.1.b.4. Prepare and submit as directed, financial reports of the project.

28.2. Records. -- The recipient shall maintain official records for each loan received that include:

28.2.a. The loan application and loan approval documents;

28.2.b. All contracts and subagreements related to the project;

28.2.c. All documents related to financial management prescribed under subsection 28.1.;

28.2.d. A documentation of compliance with applicable federal and State statutes, rules, and regulations;

28.2.e. A documentation of the amount of moneys received and expended for the project;

28.2.f. A documentation of all property that was purchased for the project; and

28.2.g. Time records related to the project, if applicable.

E.49. Wisconsin

Chapter NR 333

DAM DESIGN AND CONSTRUCTION

NR 333.01 Purpose.
NR 333.02 Applicability.
NR 333.03 Definitions.
NR 333.04 Compliance schedules.
NR 333.05 Submission of plans, specifications and analyses.
NR 333.06 Dam hazard ratings.
NR 333.07 Hydraulic design and safety requirements.
NR 333.08 Construction.
NR 333.09 Financial assurance.

Note: Chapter NR 333 as it existed on May 31, 1985 was repealed and a new chapter NR 333 was created effective June 1, 1985.

NR 333.01 Purpose. The purpose of this chapter is to ensure that dams are designed, constructed and reconstructed so as to minimize the danger to life, health and property. This chapter is adopted pursuant to ss. 31.02 (2), 31.19 and 31.33, Stats.

History: Cr. Register, May, 1985, No. 353, eff. 6–1–85.

NR 333.02 Applicability. (1) The provisions of this chapter are applicable to dams not owned by the United States government that:

(a) Have a structural height of more than 6 feet and a maximum storage capacity of 50 acre–feet or more of water.

(b) Have a structural height of 25 feet or more and a maximum storage capacity of more than 15 acre–feet of water.

(c) Have a structural height of 6 feet or less or a maximum storage capacity of less than 50 acre–feet of water if the department determines that the dam is likely to endanger life, health or property if it is not designed, constructed or reconstructed in accordance with this chapter.

(2) All new and existing dams inspected, approved and licensed by a federal agency under 18 CFR Part 12, are exempt from the provisions of this chapter provided that the dam meets requirements which are at least as restrictive as the requirements of this chapter.

Note: Dams exempted from this chapter are still subject to the requirements of ch. 31, Stats., including, but not limited to, the requirements for permits and plan approvals.

History: Cr. Register, May, 1985, No. 353, eff. 6–1–85; CR 00–136: am. Register July 2001, No. 547 eff. 8–1–01.

NR 333.03 Definitions. (1) "Auxiliary spillway" means a secondary spillway designed to pass water only during flows exceeding the capacity of the principal spillway.

(2) "Base flow" means that part of the stream flow that is derived from groundwater and calculated as the 7–day low flow that occurs on an average of once in 2 years or has a 50% chance of occurring in any given year. The notation is $Q_{7,2.}$

(3) "Dam" means any artificial barrier in or across a watercourse which has the primary purpose of impounding or diverting water. A dam includes all appurtenant works, such as a dike, canal or powerhouse.

(4) "Department" means the department of natural resources.

(5) "Development" means any artificial change to improved or unimproved real estate not related to allowable open space use including, but not limited to, the construction of buildings, structures or accessory structures; the construction of additions or substantial improvements to buildings, structures or accessory structures; the placement of buildings or structures; and campgrounds.

(6) "Floodplain with the dam nonexistent" means that area of land downstream from a dam that would be inundated by water during the regional flood if the dam did not exist.

(7) "Floodway" means the channel of a river or stream and those portions of the floodplain adjoining the channel which are required to carry the regional flood discharge.

(8) "Hydraulic shadow" means that area of land downstream from a dam that would be inundated by water upon failure of the dam during the regional flood.

(9) "Land use controls in place" means future development within the hydraulic shadow is required to conform to the criteria specified in a zoning ordinance adopted and approved pursuant to s. 87.30, Stats., and also consistent with land use plans developed under s. 66.1001, Stats., or through restrictive covenants, easements, or other appropriate legal arrangements between the owner of the dam and the owners of all property within the hydraulic shadow.

(10) "Maximum headwater" means the maximum water surface elevation before overtopping would occur.

(11) "Maximum storage capacity" means the volume of water in acre–feet capable of being stored behind a dam at the maximum water surface elevation before overtopping would occur.

(12) "Minimum tailwater" means the water level downstream from a dam at base flow.

(13) "Open space use" means a use which has a relatively low flood damage potential, such as uses associated with agriculture, recreation, parking, storage yards, or certain sand and gravel operations.

(14) "Overtopping" means the flow of water over parts of a dam which are not part of its spillway system.

(15) "Owner" means any individual, partnership, public utility, company, cooperative, trust, corporation, association, state or interstate agency, city, village, town, county or special purpose district such as a drainage district or a public inland lake protection and rehabilitation district which has title to or recorded easement for operation, maintenance and access to a dam or to the specific parcel of land on which a dam exists.

(16) "Principal spillway" means the primary structure for the discharge of normal flow through a dam.

(17) "Q_{10}" means the flood flow having a recurrence interval of 10 years or a 10% chance of occurring or being exceeded in any given year.

(18) "Q_{50}" means the flood flow having a recurrence interval of 50 years or a 2% chance of occurring or being exceeded in any given year.

(19) "Q_{100}" means the flood flow having a recurrence interval of 100 years or a 1% chance of occurring or being exceeded in any given year.

(20) "Q_{500}" means the flood flow having a recurrence interval of 500 years or a 0.2% chance of occurring or being exceeded in any given year.

(21) "Q_{1000}" means the flood flow having a recurrence interval of 1000 years or a 0.1% chance of occurring or being exceeded in any given year.

(22) "Reconstruction" means alteration of an existing dam in a manner which affects its hydraulic capacity or structural integrity.

(23) "Regional flood" means a flood determined to be representative of large floods known to have occurred in Wisconsin and

Unofficial Text (See Printed Volume). Current through date and Register shown on Title Page.

which may be expected to occur on a particular stream once in every 100 years.

Note: The regional flood is based upon a statistical analysis of stream flow records available for the watershed or an analysis of rainfall or runoff characteristics in the watershed or both. The flood frequency of the regional flood is once in every 100 years. In any given year, there is a 1% chance that the regional flood may occur or be exceeded.

(24) "Structural height" means the difference in elevation in feet between the point of lowest elevation of the top of the dam before overtopping and the lowest elevation of the natural stream or lake bed at the downstream toe of the dam.

(25) "Submerged" means that the difference between the water surface elevations upstream and downstream from a dam is one foot or less.

(26) "Total spillway capacity" means the sum of the auxiliary spillway and principal spillway capacities of a dam.

History: Cr. Register, May, 1985, No. 353, eff. 6–1–85; am. (25), Register, April, 1987, No. 376, eff. 5–1–87; CR 00–136: renum. (1) to (4), (9), (13) to (16), (21) to (25), (27) and (28) to be (2) to (4), (1), (8), (14) to (17), (20) to (26), am. (1), (3), (15), (24) and (26), r. (5), (8), (17), (20) and (26), cr. (5), (9) and (13) Register July 2001, No. 547 eff. 8–1–01; **correction in (9) made under s. 13.93 (2m) (b) 7., Stats., Register January 2002 No. 553**.

NR 333.04 Compliance schedules. (1) DAM HAZARD RATING. The department shall assign a dam hazard rating according to the criteria in s. NR 333.06 for all dams subject to the provisions of this chapter. The assignment of a hazard rating shall be based on the findings of a dam failure analysis provided by the owner, pursuant to the standards of s. NR 333.05, according to the following schedule:

(a) For new dams, prior to granting permission or approval to construct.

(b) For existing dams which are to be reconstructed, prior to granting permission or approval to reconstruct.

(c) After a dam failure analysis has been approved by the department or is adopted in a floodplain zoning ordinance pursuant to s. 87.30, Stats., and approved by the department.

(d) Upon issuance of a department directive in a dam safety inspection report pursuant to s. 31.19, Stats.

(2) COMPLIANCE. (a) *New dams.* The design and construction of all new dams shall be in compliance with the requirements of this chapter.

(b) *Existing dams.* The owners of all existing dams shall bring their dams into compliance with the requirements of this chapter within 10 years after being notified of the dam's hazard rating pursuant to sub. (1), unless ordered to do so earlier under s. 31.19 (5), Stats.

(3) ENFORCEMENT. Administrative orders issued by the department under s. 31.19 (5), Stats., may be enforced under ss. 23.50, 23.79 (3), 30.03, 31.23 (2) and 31.25, Stats.

History: Cr. Register, May, 1985, No. 353, eff. 6–1–85; CR 00–136: r. and recr., Register July 2001, No. 547 eff. 8–1–01.

NR 333.05 Submission of plans, specifications and analyses. (1) PLANS AND SPECIFICATIONS. Plans and specifications prepared by a professional engineer registered in the state of Wisconsin shall be submitted to and approved by the department prior to the construction of a new dam or reconstruction of an existing dam.

(2) HYDRAULIC, HYDROLOGIC AND STABILITY ANALYSES. Hydraulic, hydrologic and stability analyses prepared by a professional engineer registered in the state of Wisconsin shall be submitted to and approved by the department prior to the construction of a new dam or the reconstruction of an existing dam. These analyses shall be conducted according to accepted engineering practice and unless the department determines otherwise shall be submitted in the form of a report which includes, at a minimum:

(a) Purpose of the report. Development of an emergency action plan, floodplain zoning or development of the hazard rating for the dam.

(b) Roles and participation of other agencies — DNR, DEG, community officials, other agencies.

(c) Data collection methods and sources of information — Development of cross sectional data, description of past flooding events, reference to previous studies, current floodplain zoning map.

(d) Methodologies and procedures — Operation of dam during high water, breach parameters, description of all spillway components, scenario for failure, failure conditions.

(e) Regional flood flows calculated in conformance with the standards in s. NR 116.07 (3).

(f) Hydraulic modeling — Determination and delineation of the following hydraulic conditions during the regional flood, using the standards in s. NR 116.07(4):

1. Hydraulic shadow — assuming that the dam is in existence and fails. Failure shall be considered to occur at the maximum upstream water elevation or at the point of overtopping, based upon the physical conditions at the dam.

2. Dam in place, no failure — assuming the dam operates in accordance with its department approved operation plan, if one is available, or not operated if there is no plan.

3. Dam nonexistent — assuming the dam has been removed and the natural stream cross–section is restored.

Note: For suggested dam breach parameters, see the National Weather Service "DAMBRK or FLDWAV" Users Manuals.

(g) Comparison table — Summary by cross section of the maximum flood elevation for the 3 hydraulic conditions.

(h) Determination of the dam hazard rating using the criteria in s. NR 333.06.

(i) Design flood flows, based on the hazard rating and the hydraulic design standards in s. NR 333.07.

(j) Calculations for routing of the design flood through the structure. Starting conditions for the routing shall be at the normal pool and normal flow tailwater elevations.

(k) Stability analysis of the dam, which considers sliding, overturning and foundation failure during base flow conditions and at maximum load conditions, including ice loading, during routing of the design flood through the dam.

(L) Appendices:

1. Plan view of the dam.

2. Elevation view of the dam from downstream including breach geometry.

3. Pertinent elevations of the dam.

4. Stage vs. storage curve or area vs. volume curve, or both.

5. Spillway capacity rating curves or calculations, where appropriate.

6. Downstream water surface profiles and floodway data tables, for the dam failure, and the with and without dam conditions, during the regional flood.

7. Maps for the 3 modeled conditions, with cross section locations and structure identification adequate to determine the hazard rating for the dam, for the dam failure condition map, showing the floodway, and to an appropriate scale consistent with the community floodplain zoning map.

8. Cross section plots of actual field cross sections and comparison with dam break input cross sectional data.

9. Hard copy and data disk with computer input and output for all modeled conditions, including hydrology and hydraulic runs.

10. Other supporting calculations as the department deems necessary.

Note: Mapping, profiles and floodway data tables must be suitable for zoning purposes, as required in s. NR 116.07 (4).

(3) ESTIMATED COSTS. The estimated cost of construction of the new dam or reconstruction of the existing dam, and the estimated cost of removing the dam and restoring the channel to its

natural condition, shall be submitted to the department prior to the construction of a new dam or reconstruction of an existing dam.

History: Cr. Register, May, 1985, No. 353, eff. 6–1–85; CR 00–136: am. (1) and (3), r. and recr. (2), Register July 2001, No. 547 eff. 8–1–01.

NR 333.06 Dam hazard ratings. (1) A hazard rating of low, significant or high for all existing and proposed dams shall be determined in accordance with the following criteria:

(a) *Low hazard.* A low hazard rating shall be assigned to those dams that have no development unrelated to allowable open space use in the hydraulic shadow where the failure or mis–operation of the dam would result in no probable loss of human life, low economic losses (losses are principally limited to the owners property), low environmental damage, no significant disruption of lifeline facilities, and have land use controls in place to restrict future development in the hydraulic shadow.

(b) *Significant hazard.* A significant hazard rating shall be assigned to those dams that have no existing development in the hydraulic shadow that would be inundated to a depth greater than 2 feet and have land use controls in place to restrict future development in the hydraulic shadow. Potential for loss of human life during failure must be unlikely. Failure or mis–operation of the dam would result in no probable loss of human life but can cause economic loss, environmental damage, or disruption of lifeline facilities.

(c) *High hazard.* A high hazard rating shall be assigned to those dams that have existing development in the hydraulic shadow that will be inundated to a depth greater than 2 feet or do not have land use controls in place to restrict future development in the hydraulic shadow. This rating must be assigned if loss of human life during failure or mis–operation of the dam is probable.

(2) The owner of a dam may request that the department change the hazard rating of an existing or proposed dam by submitting adequate information which demonstrates that the land use and land use controls downstream from the dam meet the requirements for a different hazard rating. The department shall advise the owner of its action on the requested change within 90 business days after receiving the request.

History: Cr. Register, May, 1995, No. 353, eff. 6–1–85; CR 00–136: r. and recr., Register July 2001, No. 547 eff. 8–1–01.

NR 333.07 Hydraulic design and safety requirements. (1) MINIMUM HYDRAULIC CAPACITY. Except as provided in sub. (2), all proposed and existing dams shall have the minimum hydraulic capacity shown in Table I:

Table I
Required Spillway Design Capacities

Dam Hazard Rating	Minimum Principal Spillway Capacity	Minimum Total Spillway Capacity
Low (L)	Q_{10}	Q_{100}
Significant (S)	Q_{50}	Q_{500}
High (H)	Q_{100}	Q_{1000}

(2) REDUCED REQUIREMENTS. (a) Unless the department determines that public safety requires full compliance with the substantive requirements of this rule, all dams which will be submerged by flows less than the minimum hydraulic capacity specified in Table I shall be designed to pass the flow of the river at submergence.

(b) Any owner may provide documentation to justify a different spillway capacity from that specified in Table I. The department shall review such documentation and may approve the spillway capacity proposed by the owner if it determines that such capacity will not result in an additional hazard to life, health or property when compared to the capacity specified in Table I.

(3) SAFETY MEASURES. The owners of all new and existing dams shall comply with the following safety measures:

(a) The owner shall have an adequate operation, inspection and maintenance plan for the dam.

(b) The dam shall be structurally stable for any flow condition up to and including the design flood flow.

(c) An adequate emergency action plan shall be prepared for the area downstream from the dam in consultation with the local unit of government and concurred in by the division of emergency government. An adequate emergency action plan shall include, but is not limited to, the following information:

1. A notification flow chart identifying involved agencies, other dam owners both upstream and downstream and their phone numbers.

2. Emergency operation procedures.

3. An inundation map of the hydraulic shadow on a scale of l" = 2000' or less that extends downstream to an elevation within one foot of the dam nonexistent profile.

4. Procedures for notification of all property owners affected by a dam failure and a list of their names, addresses and phone numbers.

Note: For additional information on emergency action plans refer to Chapter 6 of the Federal Energy Regulatory Commission's "Engineering Guidelines for the Evaluation of Hydropower Projects".

(d) Documentation showing that the requirements of pars. (a) to (c) have been met shall be submitted to the department for approval. The department shall review and approve or disapprove of the documented safety measures in writing within 90 business days after the department receives the documentation.

History: Cr. Register, May, 1985, No. 353, eff. 6–1–85; CR 00–136: r. (1), renum. (2) to (4) to be (1) to (3) and am. (1), (2), (3) (c) and (d) and Table I, Register July 2001, No. 547 eff. 8–1–01.

NR 333.08 Construction. (1) Construction of a new dam or reconstruction of an existing dam may not begin until the department approves the plans and specifications submitted under s. NR 333.05.

(2) Alterations to any plans or specifications that were approved by the department under s. NR 333.05 which will affect the flood flow capacity or structural integrity of a dam shall be approved by the department before construction or reconstruction of the dam.

(3) All dams shall be constructed or reconstructed under the supervision of a professional engineer registered in the state of Wisconsin. The supervising engineer shall, within 10 days after completing the construction or reconstruction of a dam, submit a statement indicating that the dam was constructed or reconstructed in accordance with the plans and specifications approved by the department under s. NR 333.05.

(4) As–built plans shall be submitted to the department within 30 business days after the completion of construction or reconstruction of a dam.

History: Cr. Register, May, 1985, No. 353, eff. 6–1–85; CR 00–136: am. (3), Register July 2001, No. 547 eff. 8–1–01.

NR 333.09 Financial assurance. (1) GENERAL REQUIREMENT. (a) Except as provided in par. (b), the owner of a dam shall file a bond, escrow account, lien or other financial assurance satisfactory to the department prior to the commencement of construction or reconstruction of the dam. The amount of such financial assurance shall equal the estimated cost of removing the dam and restoring the stream channel to its natural condition or the cost of constructing or reconstructing the dam, whichever is less, based on the cost estimate submitted by the owner under s. NR 333.05 (3).

(b) Where the owner is a state or interstate agency or a city, county, village, special purpose district or other unit of government, financial assurance is not required if the owner demon-

Unofficial Text (See Printed Volume). Current through date and Register shown on Title Page.

strates to the department's satisfaction that it has made or will make sufficient funds available to construct or reconstruct the dam or to ~~r~~emove the dam and restore the stream channel it its natural condition, whichever is less expensive.

(2) NOTIFICATION. As part of its approval of the plans and specifications submitted pursuant to s. NR 333.05, the department shall notify the applicant of the required level of financial assurance.

(3) FORFEITURE REQUIREMENTS. (a) The financial assurance filed with the department shall be conditioned upon faithful performance of all of the requirements of ch. 31, Stats., the provisions of this chapter, and the conditions of any permit or order issued to the applicant for the dam pursuant to ch. 31, Stats.

(4) RELEASE. The department shall release or authorize the release of the applicant's financial assurance within 60 business days after the receipt of a request for release if the department finds that the construction or reconstruction has been completed in accordance with the plans and specifications approved by the department, the provisions of this chapter and the conditions of any permit or order issued to the owner of the dam pursuant to ch. 3l, Stats.

History: Cr. Register, May, 1985, No. 353, eff. 6–1–85; CR 00–136: am. Register July 2001, No. 547 eff. 8–1–01.

Chapter NR 335

DAM MAINTENANCE, REPAIR, MODIFICATION, ABANDONMENT AND REMOVAL AID PROGRAM

NR 335.01 Purpose.
NR 335.02 Applicability.
NR 335.03 Definitions.
NR 335.04 Eligibility for a state grant.
NR 335.05 State share.
NR 335.06 Application and award procedures.
NR 335.07 Grant application.
NR 335.08 Eligible and ineligible costs.
NR 335.09 Criteria for priority ranking.
NR 335.10 Construction period.
NR 335.11 Final project approval.
NR 335.12 Grant payments.
NR 335.13 Adoption of land use controls in the hydraulic shadow.
NR 335.14 Grantee accountability.

Note: Chapter NR 335 was repealed and recreated by emergency rule effective 9–1–90. Chapter NR 335 as it existed on April 30, 1991, was repealed and a new chapter NR 335 was created effective May 1, 1991.

NR 335.01 Purpose. The purpose of this chapter is to establish procedures for implementation of the dam maintenance, repair, modification, or abandonment and removal aid program established under s. 31.385, Stats.

History: Cr. Register, April, 1991, No. 424, eff. 5–1–91.

NR 335.02 Applicability. (1) This chapter shall apply to all applications for state aid in the form of matching grants for dam maintenance, repair, modification, or abandonment and removal under s. 31.385, Stats.

(2) The provisions of this chapter are applicable to dams that:

(a) Are owned by a municipality or public inland lake protection and rehabilitation district; and

(b) Are not inspected, approved and licensed by a federal agency under 18 CFR Part 12.

History: Cr. Register, April, 1991, No. 424, eff. 5–1–91.

NR 335.03 Definitions. For the purpose of this chapter:

(1) "Abandonment" means the removal of a dam in compliance with ch. 31, Stats.

(2) "Approval" means the written approval of the department.

(3) "Authorized representative" means the official or employe designated by resolution of the governing body of a municipality or lake district to act on behalf of the owner under this chapter.

(4) "Dam" means any artificial barrier in or across a waterway which has the primary purpose of impounding or diverting water. A dam includes all appurtenant works, such as a dike, canal or powerhouse.

(5) "Department" means the department of natural resources.

(6) "Directives" means the requirements for repair, maintenance, modification or abandonment established by the department in the inspection report sent to the owner.

(7) "Grantee" means the municipality or lake district which receives a grant award from the state under this chapter.

(8) "Hydraulic shadow" means that area of land downstream from a dam that would be inundated by water upon failure of the dam during the regional flood.

(9) "Investigation" means an inspection performed by the department after the owner has received either directives in an inspection report or an order, to determine whether the owner may be eligible for a grant under this chapter for work that remains to be performed on the dam.

(10) "Lake district" means a public inland lake protection and rehabilitation district formed under ch. 33, Stats.

(11) "Land use controls" means a floodplain zoning ordinance adopted and approved pursuant to s. 87.30, Stats., or restrictive covenants, easements or other appropriate legal arrangements between the owner of the dam and the owners of all property within the dam's hydraulic shadow.

(12) "Large dam" means a dam that has either a structural height of more than 6 feet and a maximum storage capacity of more than 50 acre–feet or a structural height of 25 feet or more and a maximum storage capacity of more than 15 acre–feet.

(13) "Maximum headwater" means the maximum water surface elevation in an impoundment before overtopping would occur.

(14) "Maximum storage capacity" means the volume of water in acre–feet capable of being stored behind a dam at maximum headwater.

(15) "Modification" means any physical change to a dam, other than maintenance or repair of the existing components, that results in a change in the dam's hydraulic capacity or structural stability.

(16) "Municipality" means any town, village, city or county in this state.

(17) "Order" means an enforcement order issued by the department under s. 31.19 (5), Stats., to an owner to repair or abandon a dam.

(18) "Overtopping" means the flow of water over parts of a dam which are not part of its spillway system.

(19) "Owner" means any municipality or lake district which has title to a dam or to the specific piece of land on which a dam is physically located.

(20) "Principal spillway" means the primary structure for the discharge of normal flow through a dam.

(21) "Regional flood" means a flood determined to be representative of large floods known to have occurred in Wisconsin and which may be expected to occur on a particular stream once in every 100 years.

Note: The regional flood is based upon a statistical analysis of stream flow records available for the watershed or an analysis of rainfall or runoff characteristics in the watershed or both. The flood frequency of the regional flood is once in every 100 years. In any given year, there is a 1% chance that the regional flood may occur or be exceeded.

(22) "Repair" means work performed on a dam, including maintenance, which is required to provide proper operation or continued structural integrity of the dam and does not change the dam's hydraulic capacity.

(23) "Structural height" means the difference in elevation in feet between the point of lowest elevation of a dam before overtopping and the lowest elevation of the natural stream or lake bed at the downstream toe of the dam.

History: Cr. Register, April, 1991, No. 424, eff. 5–1–91.

NR 335.04 Eligibility for a state grant. (1) Any municipality or lake district that owns a dam in Wisconsin may apply for state aid for repair, modification or abandonment of the dam upon compliance with sub. (2).

(2) To be eligible to receive a grant under this chapter, the owner shall:

Unofficial Text (See Printed Volume). Current through date and Register shown on Title Page.

(a) Request, in writing, financial assistance under this chapter within 6 months after receiving directives or an order for repair, modification or abandonment of the dam resulting from a department investigation or inspection of the dam, or have received a directive from the department or have been under order by the department to repair, modify or abandon the dam, on or before August 9, 1989; and

(b) Comply with all applicable requirements of this chapter.

History: Cr. Register, April, 1991, No. 424, eff. 5–1–91.

NR 335.05 State share. The state share may not exceed 50% of the total eligible project costs nor exceed $200,000 for any one dam.

History: Cr. Register, April, 1991, No. 424, eff. 5–1–91.

NR 335.06 Application and award procedures. Aid available under this program shall be awarded to those projects with the highest points on a priority list, as determined by the criteria in s. NR 335.09, and in accordance with the procedures in this section. Projects on the priority list shall be funded within the limits of available funds. Applications with identical point totals shall be assigned priority based upon the date the complete application was received by the department with highest priority given to the earliest received complete application.

(1) All applications for a grant under this chapter shall be received by the department no later than April 1 of each year.

(2) The department shall establish a priority list by June 1 of each year which ranks all complete applications received by the April 1 deadline. Applicants shall be notified of their placement on the priority list and the probability of approval for funding. The ranking of applicants shall be made available upon written request.

(3) Applicants receiving a commitment for funding shall submit plans and specifications to the department, for approval, prior to October 1 of the same year the application is made.

(4) Applicants receiving a commitment for funding shall submit construction bids for the proposed work to the department within 60 days of department approval of plans and specifications. Following submission to the department, the owner may rebid the project without losing eligibility if the original bid is deemed too high or inappropriate. The applicant shall rebid the project within 60 days of receipt of the original bid. The department shall direct the owner to rebid the project if it deems the bid inappropriate. The applicant shall rebid the project within 60 days of receiving notification from the department that the department deems the bid inappropriate.

(5) The department shall issue, in writing, a notice of grant award within 30 days of receipt of an acceptable construction bid.

(6) All complete applications received after April 1 shall be considered for funding during the next year in which money becomes available. To be considered, any amendment to a late application shall be received by the department no later than the next April 1 application deadline.

(7) If there are insufficient funds to award aid to all eligible applicants on the priority list, the remaining projects shall be considered for funding during the next year in which money becomes available. To be considered, any amendments to unfunded applications shall be received by the department no later than the next April 1 application deadline.

History: Cr. Register, April, 1991, No. 424, eff. 5–1–91.

NR 335.07 Grant application. (1) PROCEDURE. (a) A separate grant application shall be submitted to the department for each individual dam for which financial assistance is requested under this chapter.

(b) The department shall review each application received for completeness and shall advise the applicant of any deficiencies, omissions or errors in the application in writing. Incomplete applications may not be considered if all information is not received by the department by April 1.

(2) CONTENTS OF APPLICATION. An application for a grant under this chapter shall be made on forms furnished by the department. In addition to the application form, the application shall include the following:

(a) Certified copies of the following resolutions of the governing body of the municipality or lake district:

1. A resolution designating an authorized representative, and authorizing the representative to apply for a grant under s. 31.385, Stats., and this chapter, on behalf of the owner.

2. A resolution stating that the owner agrees to pay a share of the eligible costs which is equal to the total project cost minus the state share.

3. Proof of receipt of a letter sent by certified mail, from the owner to the municipality responsible for the implementation of land use controls, informing the municipality that a change in the land use controls may be necessary to secure the hazard rating for the dam.

(b) All data and calculations to show that dams to be repaired or modified will meet all requirements of ch. NR 333 where applicable. All owners shall provide the following with the application:

1. A dam failure analysis including maps suitable for the purpose of implementing land use controls below the dam.

2. A conceptual design and cost estimate for the construction phase of the project defining the eligible project costs.

3. A cost estimate for the engineering work required to complete the project, including preparation of all documents required under this chapter.

(c) All data and calculations to show that dams to be abandoned will meet the requirements of ch. 31, Stats. All owners shall provide the following with the application:

1. An application, under ch. 31, Stats., for a permit or approval to abandon the dam.

2. All information necessary for the municipality responsible for implementation of land use controls to implement controls in the area flooded during the regional flood without the dam in place.

3. A project description and cost estimate for the construction portion of the project defining eligible project costs.

4. A cost estimate for the engineering work required to complete the project, including preparation of all documents required under this chapter.

Note: Application forms are available from the department by writing to the Wisconsin Department of Natural Resources, Bureau of Water Regulation and Zoning, P.O. Box 7921, Madison, WI 53707.

History: Cr. Register, April, 1991, No. 424, eff. 5–1–91.

NR 335.08 Eligible and ineligible costs. (1) ELIGIBLE COSTS. The following project costs, whether incurred under contract or in the form of salaries and benefits, may be reimbursed under this chapter, if the grant is awarded:

(a) Actual and reasonable engineering costs incurred in preparing the studies and application form required under s. NR 335.07 (2) (b) and (c);

(b) Actual and reasonable engineering costs incurred in preparing plans and specifications as required in s. NR 335.06 (3), the operation, inspection and maintenance plan, and the emergency action plan;

(c) Actual and reasonable construction costs incurred in the repair, modification or abandonment of the dam, including labor and materials; and

(d) Actual and reasonable engineering costs involved in the on–site inspection of the repair, modification or abandonment of the dam. On–site inspection by an engineer registered in the state of Wisconsin is required during critical stages of construction.

(2) INELIGIBLE COSTS. Ineligible costs include:

(a) Costs incurred prior to August 9, 1989;

(b) The cost of materials and labor for installation or repair of items directly associated with hydroelectric power facilities at the dam;

(c) Costs incurred prior to the date of the state grant award except engineering costs as provided in sub. (1);

(d) Costs of routine maintenance including, but not limited to, mowing grass, painting signs and debris removal;

(e) Costs of equipment necessary for routine maintenance of the dam;

(f) Costs for which payment has been or will be received under another state or federal cost sharing or grant program or from another municipality or any other outside funding source; and

(g) Costs attributable to the correction of errors or deficiencies in construction funded under this chapter due to failure to comply with department approved construction plans and specifications.

(3) ALLOCATION OF COSTS. Total project costs may be allocated between eligible and ineligible costs using one of the following methods:

(a) *Unit cost method.* When the unit cost method is used, costs for individual work items shall be prorated between eligible and ineligible portions of the project based on an equal cost per unit.

(b) *Project cost method.* When the project cost method is used, eligible project costs shall be based on engineering costs plus the cost of construction reflected in the contractor's billings to the owner. Owners using this method shall submit the contractor's itemized billings showing the breakdown of eligible work items.

History: Cr. Register, April, 1991, No. 424, eff. 5–1–91.

NR 335.09 Criteria for priority ranking. The following criteria shall be used by the department to rank proposed projects for the purpose of determining funding priority:

(1) Dam hazard rating based on current development in the hydraulic shadow:

(a) High hazard rating, 20 points;

(b) Significant hazard rating, 10 points; or

(c) Low hazard rating, 5 points.

(2) Adequate land use controls currently in effect or dam to be abandoned:

(a) Adequate land use controls in the hydraulic shadow, 20 points;

(b) Adequate land use controls in place within the 100 year floodplain, 10 points;

(c) No land use controls or inadequate land use controls in place, 0 points; or

(d) Dam to be abandoned, 20 points.

(3) Financial need (add the points for each column and divide by 2):

Points Applicable to Each Column	*Per Capita Income, Per cent of State Average	*Local Share of Project Cost Plus Current Long Term Non School Indebtedness as a Percent of Statutory Limitation Based on Equalized Valuation
1	135 and over	Less than 10%
2	100 to less than 135	10% to less than 20%
3	89 to less than 100	20% to less than 30%
4	80 to less than 89	30% to less than 40%
5	72 to less than 80	40% to less than 50%
6	65 to less than 72	50% to less than 60%
7	59 to less than 65	60% to less than 70%
8	54 to less than 59	70% to less than 80%
9	50 to less than 54	80% to less than 90%
10	less than 50	90% to less than 100%

* Based on the most recent department of revenue publication,Long Term Indebtedness of Wisconsin Political Subdivisions and Taxes, Aids and Shared Taxes and confirmation of its applicability by department investigation.

When determining financial need points for lake districts, the point totals are to equal the weighted average of the income and indebtedness figures for the individual municipalities making up the district, based on the percent of the district lying within each municipality.

(4) Total eligible project cost:

(a) Total estimated project cost greater than $50,000, 10 points; or

(b) Total estimated project cost of $50,000 or less, 0 points.

(5) Navigability:

(a) Dam on navigable stream, 10 points; or

(b) Dam on nonnavigable stream, 0 points.

(6) Large dam:

(a) Large dam, 10 points; or

(b) Small dam, 0 points.

History: Cr. Register, April, 1991, No. 424, eff. 5–1–91.

NR 335.10 Construction period. (1) All construction performed on an eligible project shall be completed in accordance with s. NR 335.12 within one year from the date of the grant award unless the department extends that period for good cause. If an extension is warranted by the circumstances and is requested in writing by the grantee before the end of the initial one–year construction period, the department may extend the construction period for up to 2 additional years.

(2) If the grantee fails to comply with sub. (1), the grantee may not receive any further state funds and shall reimburse the department for any state funds already received under this chapter. The uncompleted portion of the project shall be considered for funding in the next year in which money becomes available upon submission of a new application in compliance with this chapter.

History: Cr. Register, April, 1991, No. 424, eff. 5–1–91.

NR 335.11 Final project approval. After the project is complete and approved by the owner, the owner shall submit 3 copies of as–constructed plans and specifications, monthly inspection reports prepared by the inspecting engineer on the project, and written certification from the owner's engineer stating that the project was completed in compliance with s. 31.12 (4), Stats. The department shall conduct a final inspection of the project within 60 days after receiving the as–constructed plans and specifications, inspection reports, and certification. A project approval letter shall be sent to the owner within 30 days of final inspection by the department.

History: Cr. Register, April, 1991, No. 424, eff. 5–1–91.

NR 335.12 Grant payments. The grantee shall be paid the state share of those eligible project costs which have prior department approval in the following installments:

(1) If the dam is repaired or modified:

(a) 50% of the state share of total eligible costs, of the engineering contract and the construction bids, shall be paid to the grantee, following 50% completion of the project, within 90 days after the department has received a written request and supporting documentation by the owner's authorized representative. The department shall inspect the project, review the supporting documentation, and determine that the owner has expended at least 50% of the state share of total eligible costs and that the work meets the requirements of this chapter prior to making payment to the owner; and

(b) If the emergency action plan and inspection, operation and maintenance plan are approved by the department prior to the completion of the project, the state share of the remaining eligible costs, based on the final audited project cost, shall be paid to the grantee within 90 days after the department has conducted a final audit and has determined the final audited eligible costs. A final

Unofficial Text (See Printed Volume). Current through date and Register shown on Title Page.

audit shall be conducted within 90 days after the project has been completed and approved by the owner and the department pursuant to s. NR 335.11; or

(c) If the emergency action plan and inspection, operation and maintenance plan are not approved by the department prior to the completion of the project, the state share of the remaining eligible costs less 10%, based on the final audited project cost, shall be paid to the grantee within 90 days after the department has conducted a final audit and has determined the final audited eligible costs. A final audit shall be conducted within 90 days after the project has been completed and approved by the owner and the department pursuant to s. NR 335.11. The remaining state share of eligible costs shall be paid to the grantee within 60 days after the grantee has received approval, by the department, of an emergency action plan and an inspection, operation and maintenance plan.

(2) If the dam is abandoned:

(a) 50% of the state share of total eligible costs, based on the engineering contract and the construction bids, shall be paid to the grantee, following 50% completion of the project, within 90 days after the department has received a written request and supporting documentation by the owner's authorized representative. The department shall inspect the project, review the supporting documentation, and determine that the owner has expended at least 50% of the state share of total eligible costs and that the work meets the requirements of this chapter prior to making payment to the owner; and

(b) The state share of the remaining eligible costs, based on the final audited project cost, shall be paid to the grantee within 90 days after the department has conducted a final audit and has determined the final audited eligible costs. A final audit shall be conducted within 90 days after the project has been completed and approved by the owner and the department pursuant to s. NR 335.11.

History: Cr. Register, April, 1991, No. 424, eff. 5–1–91.

NR 335.13 Adoption of land use controls in the hydraulic shadow. If the grantee or the municipality responsible for the implementation of land use controls in the hydraulic shadow, or both, fail to adopt the land use controls necessary to secure the dam hazard rating in accordance with ch. NR 333, the grantee may not receive any further state funds under this chapter and shall reimburse the department for any state funds already received under this chapter. The necessary land use controls shall be adopted within one year after the department has approved the dam failure analysis submitted with the application. If adequate justification is received and approved by the department an extension of the one year deadline may be given.

History: Cr. Register, April, 1991, No. 424, eff. 5–1–91.

NR 335.14 Grantee accountability. (1) RECORDS MANAGEMENT. Each grantee shall maintain an accounting system that accurately reflects all fiscal transactions, incorporates appropriate controls and safeguards, and provides good audit trails, particularly to source or original documents.

(a) *Accounting procedures.* Financial schedules and statements filed with grant applications and payment requests shall be based on records maintained under generally accepted accounting principles which meet the following minimum requirements:

1. Accounts shall separate grant receipts and eligible project costs from those allocable to other programs and activities.

2. Payments received under another state or federal cost sharing or grant program or from another municipality or any other outside funding source and expenditures shall be listed in sufficient detail to provide a basis for accurate and complete reporting.

3. Supporting records for all expenditures shall be itemized in sufficient detail to reflect the nature and propriety of each. Proof of payment, such as cancelled checks or receipts from vendors, shall be maintained.

4. If the owner uses its own labor force, payroll records shall be maintained that reflect actual program hours worked by each employe as well as allocable gross wages and fringe benefits paid. Time and attendance records describing the work performed, specifying project hours worked by day, and both signed by the employe and bearing evidence of management approval, shall be maintained, along with computations showing hourly pay rates and allocation of fringe benefits.

(b) *Fiscal controls.* 1. Any consultant, construction or service contract totalling $10,000.00 or more annually shall be covered by a formal contract or agreement specifying financial terms, contract duration, and services to be rendered.

2. Allowable rates for use of an owner's own equipment shall be limited to the county–wide rates established annually by the department of transportation (DOT). Eligibility of the use of specialized equipment for which DOT rates are not available shall be based on the allocable portion of depreciation plus normal and reasonable operation expenses attributable to project activities.

(2) RECORDS RETENTION AND AUDITING. The grantee's records, and the records of contractors and engineers which are pertinent to a specific state grant award, shall be subject at all reasonable times to inspection, copying and audit by the department for a period of 7 years from the date of final payment.

CHAPTER 31

REGULATION OF DAMS AND BRIDGES AFFECTING NAVIGABLE WATERS

31.01 Definitions.
31.02 Powers and duties of department.
31.03 Permits for the Lower Wisconsin State Riverway.
31.04 Permits for dams.
31.045 Permits for dams that affect drained lands.
31.05 Applications for permits to construct.
31.06 Hearing.
31.07 Applications for permits to operate and maintain existing dams.
31.08 Hearing.
31.09 Proposals to accompany applications.
31.095 Water power permits, condition precedent.
31.10 Permit not to be valued.
31.11 Certificate of terms and forfeiture of permits.
31.12 Map, profile and plans.
31.13 Raising or enlarging existing dams.
31.14 Proof of ability to maintain dams required.
31.18 Obligations of owners of bridges and dams.
31.185 Permits to abandon dams.
31.187 Abandoned dams.
31.19 Inspection of dams; orders.
31.21 Transfer of permit.
31.23 Forfeitures; private bridges and dams.
31.25 Nuisances, abatement.
31.253 Dam removal; opportunity for hearing.
31.26 Civil liabilities.
31.29 May employ hydraulic engineer and assistants.
31.30 Dams on Brule River.
31.305 Dams in the Lower Wisconsin State Riverway.
31.307 Dam on Milwaukee River.
31.309 Portage levee system and canal.
31.31 Dams on nonnavigable streams.
31.32 Dams not to injure other dams or sites.
31.33 Jurisdiction of department.
31.34 Flow of water regulated.
31.35 Dams in areas leased by county; restrictions; control by circuit judge; when.
31.36 Levee commissioners.
31.38 Municipal authority to construct and maintain dams.
31.385 Dam safety; aid program.
31.387 Dam rehabilitation projects.
31.39 Fees for permits, approvals and hearings.
31.99 Parties to a violation.

31.01 Definitions. Terms used in this chapter are defined as follows:

(1) "Corporation" means a private corporation organized under the laws of this state.

(2) "Department" means the department of natural resources.

(3) "Grantee" means the person, firm, corporation or municipality to whom a permit is granted, and all subsequent owners of the grant.

(4) "Municipality" means any town, village, city or county in the state.

(5) "Navigable waters" means all waters declared navigable by ch. 30.

(6) "Permit", unless the context otherwise requires, means legislative permission granted under s. 31.06 to construct, operate and maintain a dam in or across navigable waters, or under s. 31.08 to continue the operation and maintenance of any dam so situated which was constructed before such legislative permits were required.

History: 1983 a. 189.

31.02 Powers and duties of department. (1) The department, in the interest of public rights in navigable waters or to promote safety and protect life, health and property may regulate and control the level and flow of water in all navigable waters and may erect, or may order and require bench marks to be erected, upon which shall be designated the maximum level of water that may be impounded and the lowest level of water that may be maintained by any dam heretofore or hereafter constructed and maintained and which will affect the level and flow of navigable waters; and may by order fix a level for any body of navigable water below which the same shall not be lowered except as provided in this chapter; and shall establish and maintain gauging stations upon the various navigable waters of the state and shall take other steps necessary to determine and record the characteristics of such waters.

(2) The department may investigate and determine all reasonable methods of construction, operation, maintenance, and equipment for any dam so as to conserve and protect all public rights in navigable waters and so as to protect life, health and property; and the construction, operation, maintenance and equipment, or any or all thereof, of dams in navigable waters shall be subject to the supervision of the department and to the orders and regulations of the department made or promulgated under this chapter.

(3) The department or any member or any agent or employee thereof shall at all times be accorded free access to any and all parts of any dam and appurtenances constructed or maintained in navigable waters and may enter upon any property to investigate a waterway or use of water from any lake or stream.

(4) The department may order and require any dam heretofore or hereafter constructed to be equipped and operated, in whole or part, as follows:

(a) With slides and chutes for the passage of logs and timber products.

(b) With a lock, boat hoist, marine railway or other device of a size and construction sufficient to accommodate navigation.

(c) With good and sufficient fishways or fish ladders, or in lieu thereof the owner may be permitted to enter into an agreement with the department to pay for or to supply to the state of Wisconsin annually such quantities of game fish for stocking purposes as may be agreed upon by the owner and the department.

(d) With spillways or flood gates capable of permitting the passage through or over the same of freshets and floods during all seasons of the year.

(e) With booms, piers or other protection works ample to safeguard flood gates from trash or other floating material.

(4g) The department may not impose the requirement under sub. (4) (c) on an owner of a dam unless all of the following apply:

(a) The rules promulgated under sub. (4r) are in effect.

(b) The federal government or the state implements a program to provide cost−sharing grants to owners of dams for equipping dams with fishways or fish ladders and a grant is available to the dam owner under the program.

(4r) The department shall promulgate rules specifying the rights held by the public in navigable waters that are dammed. The rules shall include provisions on the rights held by the public that affect the placement of fishways or fish ladders in navigable waters that are dammed.

(5) The department shall give written notice to the public service commission of any hearing under this chapter involving public utilities.

Text from the 2007−08 Wis. Stats. database updated by the Legislative Reference Bureau. Only printed statutes are certified under s. 35.18 (2), stats. Statutory changes effective prior to 11−2−10 are printed as if currently in effect. Statutory changes effective on or after 11−2−10 are designated by NOTES. Report errors at (608) 266−3561, FAX 264−6948, http://www.legis.state.wi.us/rsb/stats.html

Electronic reproduction of 2007−08 Wis. Stats. database, updated and current through 2009 Act 406 and October 31, 2010.

(6) Except as provided in sub. (7m), the department may operate, repair and maintain the dams and dikes constructed across drainage ditches and streams in drainage districts, in the interest of drainage control, water conservation, irrigation, conservation, pisciculture and to provide areas suitable for the nesting and breeding of aquatic wild bird life and the propagation of fur−bearing animals.

(7) The department shall confer with the drainage commissioners in each drainage district on the formation of policies for the operation and maintenance of the dams; in districts having no commissioners, the department shall confer in like manner with the committee appointed by the county board, if any, to represent either such drainage district, or in the event that the drainage district is dissolved, to represent the interests of the county in all matters whatsoever pertaining to water conservation and control within the area which theretofore constituted such drainage district. This subsection does not apply to the Duck Creek Drainage District.

(7m) The drainage board for the Duck Creek Drainage District shall operate, repair and maintain dams, dikes and other structures in district drains that the board operates in the Duck Creek Drainage District in compliance with ch. 88 and any rules promulgated by the department of agriculture, trade and consumer protection under ch. 88. If a county drainage board fails to perform its duties under this subsection, the department of natural resources may exercise its authority under subs. (6), (8) and (9).

(8) The department shall give careful consideration to the suggestions of the drainage commissioners or committee of the county board, but the final decision in all matters under consideration shall rest with the department.

(9) So far as seems practicable, the department may designate or employ the drainage commissioners of any drainage district, or the committee of the county board above referred to, to operate the dams in such district or area formerly comprising a drainage district or perform services in the repair and maintenance of the dams, dykes and other works.

History: 1999 a. 9; 2001 a. 105; 2007 a. 96.

Ordering a riparian owner to excavate and maintain a ditch to regulate lake levels was an unconstitutional taking of property. Otte v. DNR, 142 Wis. 2d 222, 418 N.W.2d 16 (Ct. App. 1987).

Artificial lakes and land subdivisions. Kusler, 1971 WLR 369.

31.03 Permits for the Lower Wisconsin State Riverway. For activities in the Lower Wisconsin State Riverway, as defined in s. 30.40 (15), no person obtaining a permit under this chapter may start or engage in the activity for which the permit was issued unless the person obtains any permit that is required for the activity under s. 30.44 or 30.445.

History: 1989 a. 31, 359.

31.04 Permits for dams. Permits to construct, operate and maintain dams may be granted to persons, corporations or municipalities under this chapter.

31.045 Permits for dams that affect drained lands. **(1)** For the construction, raising or enlarging of a dam that will affect the water level in a drainage district organized under ch. 88, no person who obtains a permit under this chapter may construct, raise or enlarge the dam unless the person obtains the approval of the drainage board with jurisdiction of the drainage district.

(2) For the construction, raising or enlarging of a dam that will affect the water level in a drain, for an individual landowner, that is constructed under an order issued under s. 88.94, no person who obtains a permit under this chapter may construct, raise or enlarge the dam unless the person obtains the approval of the landowner.

History: 1993 a. 456.

31.05 Applications for permits to construct. Any person, firm, corporation or municipality desiring a permit to construct, operate and maintain a dam shall file with the department a written application therefor, setting forth:

(1) The name of the navigable waters in or across which a dam is proposed to be constructed and a specific description of the site for the proposed dam.

(2) The purpose or purposes for which the proposed dam is to be constructed, operated and maintained.

(3) In case the application is for a permit to construct, operate and maintain a dam for a private purpose, proof satisfactory to the department that the applicant owns or has an enforceable option to purchase the described dam site and at least 65% of the land to be flowed, or the flowage rights on at least 65% of such land. This subsection shall not apply to a person who has the power of eminent domain.

(4) A general description of the proposed dam, of the material to be used in the construction thereof, and a general description of all booms, piers, and other protection works to be constructed in connection therewith.

(5) The approximate amount of hydraulic power that the proposed dam is capable of developing.

(6) The name of the city, village or town in which the site of the proposed dam will be located and the name of the nearest existing dam above and below the site of the proposed dam.

(7) A map on the scale of not less than one inch per 1,000 feet showing the lands that may be affected by the construction, operation or maintenance of the proposed dam, or by any flowage that may be caused thereby and approximately the outline of such flowage, which map shall indicate the ownership of each tract of land within the flowage.

(8) Such additional information of any nature that may be required by the department.

History: 1975 c. 349; 1993 a. 246.

31.06 Hearing. **(1)** Upon receipt of an application for a permit under s. 31.05 the department may order a hearing or it may mail a notice that it will proceed on the application without public hearing unless a request for a public hearing is filed as provided in this section. The notice shall be mailed to the clerk of each municipality directly affected by the proposed dam. The department may give further or other notice as it considers proper. The department shall mail a copy of the notice to the applicant who shall cause the notice to be published in each county in which affected riparian lands are located as a class 1 notice, under ch. 985. If a hearing is not requested in writing within 30 days after mailing of the notice, the department may waive the hearing.

(2) (a) If a hearing is ordered, the department shall, not less than 10 days before such hearing, mail written notice thereof to each person notified under sub. (1).

(b) The department shall require the applicant to publish a class 1 notice under ch. 985, of the hearing in each county in which affected riparian lands are located, and may require the applicant to mail such other notices as it deems necessary. Proof of publication and proof of mailing under this subsection and sub. (1) shall be filed with the department.

(3) (a) At a hearing under this section, or any adjournment of the hearing, the department shall consider the application and take evidence offered by the applicant and other persons supporting or opposing the proposed dam. The department may require the amendment of the application.

(b) If it appears that the construction, operation or maintenance of the proposed dam is in the public interest, considering ecological, aesthetic, economic and recreational values, the department shall so find and grant a permit to the applicant, provided the department also finds that the applicant has complied with s. 31.14 (2) or (3) and, where applicable, with s. 31.05 (3), based on the department's own estimate of the area of the flowage.

(c) 1. The enjoyment of natural scenic beauty and environmental quality are declared to be public rights to be considered along with other public rights and the economic need of electric power for the full development of agricultural and industrial activity and other useful purposes in the area to be served. In consider-

Text from the 2007−08 Wis. Stats. database updated by the Legislative Reference Bureau. Only printed statutes are certified under s. 35.18 (2), stats. Statutory changes effective prior to 11−2−10 are printed as if currently in effect. Statutory changes effective on or after 11−2−10 are designated by NOTES. Report errors at (608) 266−3561, FAX 264−6948, http://www.legis.state.wi.us/rsb/stats.html

ing public rights to the recreational use and natural scenic beauty of the river, the department shall investigate the potentialities of the lake and lakeshore created by the flowage and shall weigh the recreational use and scenic beauty of the lake and lakeshore against the known recreational use and scenic beauty of the river in its natural state. The department shall further weigh the known recreational use and scenic beauty of the particular section of river involved against the known recreational use and scenic beauty of other sections of the same river and other rivers in the area remaining in their natural state without regard to plans of other dams subsequently filed or to be filed.

2. The department shall deny the permit if it finds any of the following:

a. It appears that the river in its natural state offers greater recreational facilities and scenic value for a larger number of people than can by proper control of the flowage level be obtained from the use of the lake and lakeshore and that the remaining sections of the river and other rivers in the area in their natural state provide an insufficient amount of recreational facilities and scenic beauty, and it further appears that the economic need of electric power is less than the value of the recreational and scenic beauty advantages of the river in its natural state.

b. The permit will cause environmental pollution, as defined in s. 299.01 (4).

(4) Not more than 20 days after receiving notice as provided in sub. (1) each county clerk may and upon request of the chairperson of the county board shall give written notice as provided in s. 59.11 (2) of a special meeting of the county board to be held at a time and place set by the county clerk, not less than 2 weeks nor more than 3 weeks after mailing of such notice, for the purpose of making findings as hereinafter provided. The county clerk shall give notice of the time, place and purpose of such special meeting to the department and to the applicant, who shall cause the same to be published in the county, as a class 2 notice, under ch. 985, and the applicant shall cause a copy thereof to be mailed at least 7 days prior to such special meeting to every person interested in any lands that will be affected by the proposed dam and whose post−office address can by due diligence be ascertained. Proof of such publication and notice shall be filed with the county clerk. At such special meeting the county board shall hear evidence offered by the applicant and other persons and shall find and determine by a majority vote of the county board members−elect whether the lake and lake shore created by the flowage or the river in its natural state offers greater recreational facilities and scenic beauty value for the larger number of people. The county clerk shall forthwith certify such finding and determination to the department. The jurisdiction and findings of each county board shall apply to that part of the proposed dam and flowage which is within the county.

(5) If a hearing on the application for a permit is conducted as a part of a hearing under s. 293.43, the notice and hearing provisions in that section supersede the notice and hearing provisions of this section.

History: 1971 c. 273; 1973 c. 90; 1979 c. 34 s. 2102 (39) (g); 1979 c. 221; 1983 a. 192; 1995 a. 201, 227; 1999 a. 83.

Cross−reference: See also ch. NR 305, Wis. adm. code.

31.07 Applications for permits to operate and maintain existing dams. Any person, firm, corporation or municipality desiring a permit to operate and maintain a dam constructed in or across navigable waters without legislative permission prior to July 10, 1915, shall file with the department a written application therefor setting forth:

(1) The name of the navigable waters in or across which such dam was constructed and a specific description of the dam site.

(2) The year in which the construction of the dam was completed, and a detailed description of the dam and equipment, including the maximum height or head of water that may be maintained thereby and the kind and character of material of which the dam is constructed.

(3) The purpose for which the dam was theretofore operated and is operated at the time application hereunder is made, and the purpose for which it is proposed to operate and maintain the dam.

(4) The approximate amount of hydraulic power developed thereby.

(5) The name of the city, village or town in which the dam site is located and the name of the nearest existing dam above and below the dam site.

(6) Such additional information of any nature whatsoever as may be required by the department.

History: 1993 a. 246.

31.08 Hearing. Upon receipt of an application under s. 31.07 procedure shall be had substantially as required by s. 31.06, and if the department finds that such operation and maintenance does not materially obstruct existing navigation or violate other public rights and will not endanger life, health or property, a permit is hereby granted to the applicant, provided the department also finds that the applicant has complied with s. 31.14 (2) or (3).

Cross−reference: See also ch. NR 305, Wis. adm. code.

31.09 Proposals to accompany applications. Each applicant for a permit to construct, operate and maintain a dam for the purpose of developing power or for the purpose of aiding in the development of power by other dams through the creation of reservoirs or otherwise, and each applicant for a permit to construct, operate and maintain a dam for any other purpose whatsoever, which is capable of developing 50 theoretical horsepower or more available for 50% of the time throughout the year, shall file with an application for a permit, in addition to the requirements of s. 31.05 or s. 31.07, as the case may be, the following proposals:

(1) That the department prior to the time the permit is granted shall value the dam site and all flowage rights and other property necessary for the purposes set forth in the application for the permit, whether the same or any part thereof are owned by the applicant or not.

(2) That the department shall audit all outlays for property and for the construction of the dam, buildings, and other structures and works constructed, maintained, and operated and used and useful under the permit.

(3) That the permit, if granted, shall be granted and accepted subject to the express condition that the state of Wisconsin, if it shall have the constitutional power, or any municipality, on not less than one year's notice, at any time after the expiration of 30 years after the permit becomes effective, may acquire all of the property of the grantee, used and useful under the permit, by paying therefor, the cost of reproduction in their then existing condition of all dams, works, buildings, or other structures or equipment, used and useful under the permit, as determined by the department, and by paying in addition thereto the value of the dam site and all flowage rights and other property as determined by the department prior to the time the permit was granted, as provided in sub. (1), plus the amounts paid out for additional flowage rights, if any, acquired after the valuation made by the department as provided in sub. (1); and that the applicant waives all right to any further compensation.

History: 1991 a. 316.

31.095 Water power permits, condition precedent. **(1)** Except where the stream to be improved forms a boundary line between this and another state, no permit shall be granted or transferred in accordance with this chapter until the applicant has filed with both the department and the public service commission, in addition to all other things required by law to be filed, an agreement setting forth:

Text from the 2007−08 Wis. Stats. database updated by the Legislative Reference Bureau. Only printed statutes are certified under s. 35.18 (2), stats. Statutory changes effective prior to 11−2−10 are printed as if currently in effect. Statutory changes effective on or after 11−2−10 are designated by NOTES. Report errors at (608) 266−3561, FAX 264−6948, http://www.legis.state.wi.us/rsb/stats.html

Electronic reproduction of 2007−08 Wis. Stats. database, updated and current through 2009 Act 406 and October 31, 2010.

(a) That, in the event any electric energy generated under said permit shall be transmitted or conveyed beyond the confines of this state to be there sold, the applicant will furnish to any resident of this state or any corporation domiciled therein electric energy at reasonable rates to be determined by the commission, provided that the commission after public hearing shall find that public convenience and necessity require such service.

(b) That the rate as determined by the commission shall in no event exceed the rate charged by applicant for similar service supplied under like conditions for the energy so transmitted outside the state.

(2) The commission may hold hearings, fix rates and do all things necessary and convenient to carry out the purposes of sub. (1).

31.10 Permit not to be valued. Each and every permit is granted, and shall be conclusively deemed to be accepted, subject to the condition that no element of value whatever shall ever attach to or be allowed for such permit in and of itself in the sale or acquisition of the property used and useful under such permit or otherwise.

31.11 Certificate of terms and forfeiture of permits. The department shall issue to every grantee of a permit a certificate evidencing a grant of the permit allowed by law. Every permit, and every franchise heretofore granted by the legislature, to construct, maintain and operate a dam shall become null and void, unless the dam thereby authorized be completed within 5 years from the time when the permit or the franchise was granted; but the department, for good cause, may extend such time for a period not exceeding 2 years.

31.12 Map, profile and plans. (1) The grantee of a permit under s. 31.06, to construct, maintain and operate a dam, before commencing any work of construction authorized by the permit, shall submit to the department a complete map and profile on the scale of not less than one inch per 1,000 feet showing the land that may be affected by the construction and maintenance of the dam, or by any flowage that may be caused thereby, and the outline of the flowage, and such other hydrographic and topographic data as the department may prescribe, and shall also file complete detailed plans and specifications for the proposed dam, including all booms, piers, or other protection works.

(2) The department shall examine the map, profile, plans and specifications; shall hear the grantee thereon and may reject the same or any part thereof, if unsatisfactory or incomplete, or may suggest and require modifications thereof. If the map, profile and plans and specifications are satisfactory and complete, or, if the same shall be modified as suggested and required, the department shall so find and approve the same, and thereupon the grantee may construct the proposed dam in accordance therewith, but the department may, at any time during the construction of any dam and in the interest of the public safety, or of any public rights in navigable waters, authorize, order or require such changes in the plans and specifications and the construction of the dam as shall be necessary.

(3) If the department, in the case of an application for a permit to construct a dam with a capacity of less than 250 hydraulic horsepower at ordinary stage of water, shall find that the information and data furnished in the original or amended application is sufficient, the applicant shall not be required to furnish the additional or more detailed information or data specified in subs. (1) and (2). The department may, however, at any time during the construction of any such dam authorize, order or require changes in the construction or the method or plan of construction thereof, as provided in sub. (2).

(4) Within 10 days after the completion of any dam the grantee shall file with the department a verified statement that the same was constructed in accordance with the plans and specifications approved by the department; or in case no plans and specifications were required to be filed, then that the dam was constructed in accordance with the description contained in the application.

Cross−reference: See also ch. NR 353 and s. NR 335.11, Wis. adm. code.

31.13 Raising or enlarging existing dams. (1) If the owner of any existing dam wishes to raise or enlarge the same, the owner may apply to the department for permission so to do, but the permission granted under this section shall be in amendment of any existing franchise, license, or permit previously granted authorizing the construction or maintenance of such dam only to the extent of giving the right so to raise or enlarge such dam, and shall in no way enlarge, alter, abridge or nullify property rights, privileges or obligations as to such dam, or the maintenance or operation thereof theretofore acquired or incurred. In addition to the requirements of s. 31.05 (1), (6) and (7), the owner's application shall state:

(a) The year in which the dam was completed.

(b) If constructed by legislative permission, a statement of the act of the legislature authorizing the same.

(c) A detailed description of the dam, including the maximum height or head of water that may be maintained thereby and the kind and character of material of which the same is constructed.

(d) The purpose for which such dam has been and is now used and the purpose for which it is proposed to use the same.

(e) The approximate amount of hydraulic power developed thereby.

(f) Such additional information of any nature whatsoever as the department may require.

(2) Upon receipt of an application under this section procedure shall be had substantially as required by s. 31.06; and if the department finds that the dam, raised or enlarged or rebuilt, or rebuilt, enlarged and raised in accordance with the application, will not materially obstruct existing navigation or violate other public rights, and will not endanger life, health or property, and that the applicant has complied with s. 31.14 (2) or (3), permission is hereby granted to raise or enlarge or rebuild, or rebuild, enlarge and raise the same in accordance with the application.

History: 1991 a. 316.

Cross−reference: See also ch. NR 305, Wis. adm. code.

31.14 Proof of ability to maintain dams required. (1) It is the policy of this section to preserve public rights in navigable waters, including those created by dams, and to provide a means of maintaining dams and the developments which have been made adjacent to the flowage of such dams.

(2) Except as provided in sub. (3), a permit shall not be granted under s. 31.06, 31.08 or 31.13:

(a) Unless the applicant furnishes to the department proof of ability to operate and maintain the dam in good condition, either by the creation of a special assessment district under ss. 31.38 and 66.0703, or by any other means which in the department's judgment will give reasonable assurance that the dam will be maintained for a reasonable period of time not less than 10 years; or

(b) If a majority of the municipalities in which 51% or more of the dam or flowage is or will be located files with the department, prior to the granting of the permit, their objections to the granting of such permit in the form of resolutions duly adopted by the governing bodies of such municipalities.

(3) Subsection (2) does not apply if the applicant complies with each of the following requirements:

(a) Furnishes proof satisfactory to the department that the applicant owns or has an enforceable option to purchase all the land which is or will be flowed by the impoundment, together with the shoreline and an immediately adjacent strip of land at least 60 feet in width, but the department may in a particular case permit a narrower strip where the 60−foot minimum is impractical and may, in furtherance of the policy stated in sub. (1), require ownership of a wider strip.

(b) Files with the department a writing in such form as the department requires in which the applicant agrees that following

Text from the 2007−08 Wis. Stats. database updated by the Legislative Reference Bureau. Only printed statutes are certified under s. 35.18 (2), stats. Statutory changes effective prior to 11−2−10 are printed as if currently in effect. Statutory changes effective on or after 11−2−10 are designated by NOTES. Report errors at (608) 266−3561, FAX 264−6948, http://www.legis.state.wi.us/rsb/stats.html

the initial filling of the proposed pond the applicant will not convey the dam to another without first obtaining department approval. The department may require from an applicant who does not have the power of eminent domain a bond or other reasonable assurances that the applicant will adhere to such agreement.

(c) Furnishes proof satisfactory to the department that the applicant has dedicated or will dedicate a parcel of land for public access to the impounded waters.

(4) No person may assume ownership of a dam after October 21, 1961, or the ownership of that specific piece of land on which a dam is physically located after April 27, 1982, without first complying with sub. (2) or (3). The transfer of the ownership of a dam or the ownership of a specific piece of land on which a dam is physically located made without complying with sub. (2) or (3) is void unless a permit to abandon the dam was granted under s. 31.185 or unless the transfer occurred by operation of law. Every person who accepts ownership by operation of law is subject to this chapter.

(5) For the purpose of implementing the policy stated in sub. (1), the department may by rule require all or specified classes of persons operating a dam for profit to create a fund or reserve to be used for major repairs, reconstruction or removal of the dam when necessary. Such rules shall prescribe the manner in which such fund or reserve is to be created, maintained and expended. This subsection shall not apply to a person who has the power of eminent domain.

History: 1981 c. 246; 1991 a. 316; 1999 a. 150 s. 672.

This section does not apply to cranberry dams. Tenpas v. DNR, 148 Wis. 2d 579, 436 N.W.2d 297 (1989).

31.18 Obligations of owners of bridges and dams. (1) The grantee of any permit, the owner of any dam constructed before permits were required by law, and the owner of any bridge at the city of Portage or at any point above that city, over the Wisconsin River, shall maintain and operate all such dams, slides, chutes, piers, booms, guide booms, weirs, tunnels, races, flumes, sluices, pits, fishways, locks, boat hoists, marine railways and all other equipment required by the department for the protection of public rights in such waters, and for the preservation of life, health and property, in good repair and condition, and shall not willfully, or otherwise, injure, remove or destroy the same, or any part thereof, unless the department shall have approved such removal or destruction in writing. In the event of emergency the department shall have power, pending investigation and hearing, to order the repair of any dam without notice and hearing.

(2) The owner of any such dam shall open such slide or chute for the passage of any craft or material lawfully navigating the stream, whenever requested so to do by the person in charge of such navigation, without charge or toll therefor. But such owner shall be under no obligation to otherwise aid passage through the slide or chute.

(3) Except when emergency shall require the same for the protection of life, health or property, no substantial alteration or addition shall be made to any dam heretofore or hereafter constructed without obtaining an order therefor from the department, which order may be issued only after an investigation and upon a finding that the proposed alterations or additions will not impair the sufficiency of such dam or any existing public rights in such waters.

(4) The department shall in the interest of public rights in navigable waters, or to promote safety and protect life, health and property, require the grantee of any permit, under this chapter, or of any permit or authorization heretofore provided for by legislative enactment, prior to flowing any lands by the construction of a dam thereunder, to remove from such lands all or any portion of the standing and fallen timber and all or any portion of the brush. Provided that in cases where the application for permit proposes construction of a dam for water reservoir or water storage purposes, and not for the purpose of operating a hydroelectric generating plant, the nature, extent and time for such removal shall be determined prior to the granting of a permit, except that subsequent to the granting of a permit the department may make such modification in the removal requirements as may be in the public interest and which will not materially alter the economics of the project; and in making such original determination or any modification thereof the economic need for the project shall be considered.

Cross−reference: See also ch. NR 305, Wis. adm. code.

31.185 Permits to abandon dams. (1) No owner of any dam may abandon or remove or alter the dam without first obtaining a permit from the department. No person may transfer ownership of a dam or the ownership of the specific piece of land on which a dam is physically located without first obtaining a permit from the department.

(2) An application for a permit to abandon, remove or alter a dam or an application for a permit to transfer ownership of a dam or the ownership of a specific piece of land on which a dam is physically located shall be made to the department upon forms prescribed by it and shall contain the owner's name and address, a brief description of the dam and its location and other information as the department requires for the purpose of enabling it to act on the application.

(3) Section 31.06 governs procedure upon all applications hereunder.

(4) Prior to the hearing the department shall have its staff make its own investigation of the dam and, on the basis of such investigation, shall make recommendations as to the type of requirements, if any, which it would impose on the applicant under sub. (5) as a condition to granting the permit. Such recommendations shall be presented at the hearing. If no one registers opposition to the application at the hearing, the department shall grant the permit, subject to such conditions as it deems necessary under sub. (5). If someone registers opposition to the abandonment at the hearing and such opposition is not withdrawn, the department shall defer action on the application for a period of 120 days after the hearing. Within a reasonable time after the expiration of such period, the department shall deny the permit, or grant the permit, subject to such conditions as it imposes under sub. (5), unless, within such 120−day period, one or more municipalities or other persons or associations have agreed to acquire ownership of the dam and have furnished satisfactory proof of intent to comply with s. 31.14 (2) or (3).

(5) As a prerequisite to the granting of a permit under this section, the department may require the applicant to comply with such conditions as it deems reasonably necessary in the particular case to preserve public rights in navigable waters, to promote safety, and to protect life, health and property.

History: 1973 c. 90; 1981 c. 246.

Cross−reference: See also ch. NR 305, Wis. adm. code.

Sub. (5) is not directed to the removal of a dam by the DNR. It creates a different procedure for a private party who seeks to remove a dam. Froebel v. DNR, 217 Wis. 2d 652, 579 N.W.2d 774 (Ct. App. 1998), 97−0844.

31.187 Abandoned dams. (1) The department may remove or cause to be removed, in such manner as it deems fit, old and abandoned dams in streams in this state, upon giving 60 days' notice in writing to the owner thereof, if the owner can be found. If the owner of the dam is unknown or cannot, by due diligence, be found, the department shall publish a class 3 notice, under ch. 985, in the county in which the dam is situated.

(2) Whenever the department determines that the conservation of any species or variety of wild animals will be promoted thereby, the department may maintain and repair any dam located wholly upon lands the title to which is in the state either as proprietor or in trust for the people after giving due consideration to fixing the level and regulating the flow of the public waters.

Electronic reproduction of 2007−08 Wis. Stats. database, updated and current through 2009 Act 406 and October 31, 2010.

This section, and not s. 31.185 or 283.31, governs removal of a dam by the DNR. There is no statutory authority to grant injunctive relief against the DNR when it causes damages during a dam removal. Froebel v. DNR, 217 Wis. 2d 652, 579 N.W.2d 774 (Ct. App. 1998), 97−0844.

31.19 Inspection of dams; orders. (1g) DEFINITIONS. In this section:

(a) "High hazard dam" means a large dam the failure of which would probably cause loss of human life.

(b) "Low hazard dam" means a large dam the failure of which would probably not cause significant property damage or loss of human life.

(c) "Significant hazard dam" means a large dam the failure of which would probably cause significant property damage but would probably not cause loss of human life.

(1m) DETERMINATION OF DAM SIZE. For the purposes of this section, a dam is considered to be a large dam if either of the following applies:

(a) It has a structural height of 25 feet or more and impounds more than 15 acre−feet of water.

(b) It has a structural height of more than 6 feet and impounds 50 acre−feet or more of water.

(2) LARGE DAM INSPECTION. (a) *Inspection by the department.* At least once every 10 years the department shall conduct a detailed inspection of each high hazard dam and each significant hazard dam.

(ag) *Owner responsibility.* 1. Owners of each high hazard dam, each significant hazard dam, and each low hazard dam shall engage a professional engineer registered under s. 443.04 to inspect the dam as specified in this paragraph.

2. An owner of a high hazard dam shall cause the dam to be inspected at least 4 times between each inspection conducted by the department under par. (a). An owner of a significant hazard dam shall cause the dam to be inspected at least 2 times between each inspection conducted by the department under par. (a). An owner of a low hazard dam shall cause the dam to be inspected at least once every 10 years.

3. The owner of a dam required to be inspected under this paragraph shall submit to the department, no later than 90 days after the date of the inspection, a report of the results of the inspection. The report shall include information on any deficiencies in the dam, recommendations for addressing those deficiencies, and recommendations on improving the safety and structural integrity of the dam.

(ar) *Dam classification.* The department shall classify each dam in this state as a high hazard, significant hazard, or low hazard dam for the purpose of this section.

(b) *Exemption for federally inspected dams.* Notwithstanding the inspection requirements under pars. (a) and (ag), an inspection under par. (a) or (ag) is not required if the dam is inspected periodically by or under the supervision of a federal agency in a manner which is acceptable to the department and if the results of each inspection are made available to the department.

(3) INSPECTION UPON COMPLAINT. If the department receives a complaint in writing from the mayor of a city, supervisor of a town or the president or trustee of a village which alleges that a dam maintained or operated in or across any navigable or nonnavigable waters or a reservoir is in an unsafe condition or if the department receives a complaint in writing from a person which alleges that the person's property or any property under the person's control is endangered by a dam or reservoir, the department shall investigate or cause an investigation to be made of the complaint.

(4) DISCRETIONARY INSPECTION. The department may inspect or cause an inspection to be made of any dam or reservoir.

(5) ORDER; REDUCTION IN WATER LEVEL. If the department finds pursuant to an investigation that a dam or reservoir is not sufficiently strong or is unsafe and that the dam or reservoir is dangerous to life or property, it shall determine what alterations, additions or repairs are necessary and shall order the owner or person having control of the dam or reservoir to cause those alterations, additions or repairs to be made within a time specified in the order. If the department finds pursuant to an investigation that a dam or reservoir is not sufficiently strong or is unsafe and that the dam or reservoir is dangerous to life or property, it may cause to be drawn off, in whole or in part, the water in the reservoir or impounded by the dam if it determines that this action is necessary to prevent impending danger to persons or property.

History: 1975 c. 349, 421; 1983 a. 27; 1989 a. 31; 2009 a. 28.
Cross−reference: See also ch. NR 333, Wis. adm. code.

31.21 Transfer of permit. (1) No transfer or assignment of any permit granted under s. 31.06 or 31.08 shall be of any effect whatsoever unless it is in writing and a certified copy thereof within 10 days after the execution thereof, is filed with the department and unless such transfer or assignment is approved in writing by the department; and no such transfer or assignment shall be approved by the department except after an investigation and a finding that the transfer or assignment is not made or intended to be made for a purpose or to create a condition prohibited by s. 196.665 and that the transferee or assignee has complied with s. 31.14 (2) or (3). No permit shall be transferred or assigned to a foreign corporation, nor shall any permit granted to a municipality be assigned or transferred to any person, otherwise than as security for a loan made in good faith and concurrently with and as consideration for such transfer or assignment, and no foreign corporation shall have power to acquire title to any such permit, nor shall any person have power to acquire title to a permit granted to or acquired by a municipality, otherwise than in the enforcement of such security, and in no case shall any such foreign corporation hold title to or operate under any such permit for a period longer than 3 years.

(2) No municipality shall make or execute any lease or other contract with any person, firm, or corporation for the sale or use of hydraulic or hydroelectric power developed or generated by such municipality under a permit granted under s. 31.06 or 31.08 for a period longer than 10 years, unless the same shall be first approved by the department, after investigation and upon a finding that such lease or contract will not impair or interfere with the purpose or uses for which such dam was acquired or constructed by the municipality.

Cross−reference: See also ch. NR 305, Wis. adm. code.

31.23 Forfeitures; private bridges and dams. (1) Every person who constructs or maintains in navigable waters or aids in the construction or maintenance therein of any bridge or dam not authorized by law, shall forfeit for each such offense, and for each day that the free navigation of such waters are obstructed by such bridge or dam a sum not exceeding $50.

(2) Every person or corporation violating any of the provisions of this chapter, other than those mentioned in sub. (1), or violating any order made by the department pursuant to this chapter, shall forfeit for each such violation not more than $1,000.

(3) (a) There shall be no forfeiture under this section in any case where a bridge is built by a private citizen across any navigable waters having a width of 35 feet or more, providing such bridge does not impair the rights of the public for purposes of navigation or fishing.

(b) No such bridge shall be maintained unless its construction shall first be approved by the department after public hearing and on not less than 10 days' written notice to the applicant and to the county and town clerks of the county and town wherein all or a portion of the proposed bridge is to be located.

(c) Each applicant who shall apply to the department for a permit to construct any such bridge shall state in the application the proposed location of the bridge, the depth of the water to be spanned, the materials to be used in the construction of the bridge, the plans of the proposed bridge, together with such other facts as the department may require.

Text from the 2007−08 Wis. Stats. database updated by the Legislative Reference Bureau. Only printed statutes are certified under s. 35.18 (2), stats. Statutory changes effective prior to 11−2−10 are printed as if currently in effect. Statutory changes effective on or after 11−2−10 are designated by NOTES. Electronic reproduction of 2007−08 Wis. Stats. database, updated and current through 2009 Act 406 and October 31, 2010.

(d) Every such bridge used by the public shall at all times be maintained in a safe condition by the owners of the land abutting the approaches of the bridge, and the owners shall make such repairs as are reasonably necessary therefor. The town shall not become liable for any damages resulting from the insufficiency or want of repairs of such bridge. If the department upon inspection finds that such bridge is in need of repairs, it shall notify the owners responsible for the repairs thereof, and also send a copy of such notice to the town board, to make all repairs as are reasonably necessary therefor. If such repair work as ordered by the department is not commenced within 60 days after receipt of such notice, the department may close such bridge until it is so repaired. Whenever any owner responsible for such bridge shall fail to repair or maintain the bridge in a good and safe condition, after having been notified so to do by the department for 60 days after such notification, such town board upon its own initiative may make such required repairs on such bridge, and the cost thereof shall be paid by the owners responsible therefor, and the town clerk shall enter such amount of the cost of repairs upon the next tax roll of the town.

History: 1991 a. 316.

Cross−reference: See also chs. NR 301, 305, and 320, Wis. adm. code.

Sub. (1) provides no substantive rule for which a violation would initiate the abatement procedures under s. 31.25. The remedy provided is limited to the forfeiture provided under sub. (1). Capt. Soma Boat Line, Inc. v. Wisconsin Dells, 56 Wis. 2d 838, 203 N.W.2d 369 (1973).

31.25 Nuisances, abatement. Every dam, bridge or other obstruction constructed or maintained in or over any navigable waters of this state in violation of this chapter, and every dam not furnished with a slide, chute or other equipment prescribed by the department, is hereby declared to be a public nuisance, and the construction thereof may be enjoined and the maintenance thereof may be abated by action at the suit of the state or any citizen thereof.

Section 31.23 (1) provides no substantive rule for which a violation would initiate the abatement procedures under this section. Capt. Soma Boat Line, Inc. v. Wisconsin Dells, 56 Wis. 2d 838, 203 N.W.2d 369 (1973).

31.253 Dam removal; opportunity for hearing. **(1)** OPPORTUNITY FOR HEARING PRIOR TO DEPARTMENT ACTION. Except as provided under sub. (4), prior to seeking or causing the removal of a dam under this chapter, the department shall hold a public informational hearing on the proposed removal or publish a class 2 notice under ch. 985 stating that it will seek or cause the removal of the dam without holding a public informational hearing unless a hearing is requested in writing within 30 days after the last publication of the notice. The department may hold further hearings or give further notice as it deems appropriate.

(2) OPPORTUNITY FOR HEARING PRIOR TO COURT ACTION. Except as provided under sub. (4), a court may not order or authorize the removal of a dam in an enforcement action under this chapter unless a public informational hearing or an opportunity for a public informational hearing was provided.

(3) PUBLIC INFORMATIONAL HEARING. If the department conducts a public informational hearing under this section, the department shall explain the basis for its decision to seek or cause the removal of the dam, the procedures which will be followed and opportunities for citizen involvement in those procedures and the department shall provide an opportunity for citizens to present comments, testimony and evidence concerning the removal of the dam. Notwithstanding s. 227.42, this hearing may not be converted or treated as a contested case.

(4) EXCEPTIONS. (a) This section does not apply if the department or a court determines that a dam constitutes an immediate and significant hazard to persons or property.

(b) This section does not apply to an application under s. 31.185 or departmental action under s. 31.185.

History: 1983 a. 507; 1985 a. 182 s. 57.

31.26 Civil liabilities. **(1)** The owner of any dam or of any privately owned bridge across the Wisconsin River or the Black River or any of their tributaries shall be liable for all damages occasioned to property by a failure to provide such dam or bridge with slides, booms and chutes as required by s. 31.18 (1). The person or party suffering any such damage shall have a lien upon the dam and all mills, machinery and appurtenances of such owner erected thereon, or served with water thereby, and on the lands adjoining, not exceeding 40 acres; or, as the case may be, a lien upon such bridge and its approaches.

(2) The claimant of such lien shall file a notice thereof in writing in the office of the clerk of the circuit court of the county in which the dam or bridge is located within 60 days after sustaining such damages and shall commence an action to enforce the lien within 6 months after filing such notice. Such lien shall accrue upon the filing of such notice and failure to file the same or to commence such action within the times specified therefor respectively shall operate as a waiver of the lien. Judgment for the plaintiff for the recovery of damages and declaring such lien may be enforced by an execution sale of the property affected as in ordinary actions at law, and upon such sale all rights to maintain such dam or bridge shall pass to the purchaser.

(3) In case of any personal injury by reason of any such neglect or failure the damages sustained thereby may be recovered and a lien and judgment enforced in like manner; and if death results an action may be maintained by the representatives of the deceased in the manner provided in other cases of death resulting from negligence or wrong.

(4) No common law liability, and no statutory liability provided elsewhere in these statutes, for damage resulting from or growing out of the construction, maintenance or operation of any dam is released, superseded, or in any manner affected by the provisions of this chapter; and this chapter creates no liability on the part of the state for any such damages.

31.29 May employ hydraulic engineer and assistants. The department may employ and fix the salaries of a competent hydraulic engineer and other assistants necessary to carry out the provisions of this chapter.

31.30 Dams on Brule River. It is declared to be the policy of the state to prohibit forever the building or maintaining of any dam or dams across the Brule River or any of its tributaries in Douglas County, except that a dam with an adequate fishway may be constructed across said Brule River at each of the 3 sites hereinafter described, or at such other sites as are selected by the department in place of any or all of the sites hereinafter mentioned, the purpose of which shall be to provide a method whereby fish declared to be undesirable for said stream by the department may be eliminated or prevented from ascending the stream, and to permit said stream to be developed for trout in different stretches thereof: site No. 1 known as Clevedon site in the southeast quarter of the northwest quarter of section 10, township 49 north, range 10 west; site No. 2 known as the Old Mill site in the northwest quarter of the southeast quarter, section 11, township 47 north, range 10 west; and site No. 3, known as the Upper or Rock dam site in the northeast quarter of the southeast quarter of section 22, township 47 north, range 10 west; and all rights, privileges, and franchises granted prior to June 26, 1905, to any person or corporation to improve said Brule River or any of its tributaries in said county for any purpose whatever, are repealed and annulled. No domestic corporation organized subsequent to such date shall exercise any of the powers or privileges authorized or conferred by ss. 180.15 to 180.18, 1925 stats., in, across or along said river or any of its tributaries in Douglas County.

Cross−reference: See s. 30.25 for similar prohibition of dams on the Wolf River.

31.305 Dams in the Lower Wisconsin State Riverway. No dam may be constructed in the lower Wisconsin River as defined in s. 30.40 (14).

History: 1989 a. 31.

31.307 Dam on Milwaukee River. (1) The department shall conduct, or shall cause to be conducted, an environmental and engineering study concerning the removal of the North Avenue dam in the city of Milwaukee from the Milwaukee River.

(3) Upon completion of the study under sub. (1), the city of Milwaukee may apply for a permit to abandon the dam under s. 31.185 or the department may proceed under ss. 31.187 and 31.253 to cause the removal of the dam.

(4) For purposes of s. 30.92 (4) (b) 6., moneys expended from the appropriation under s. 20.370 (5) (cq) for the study under sub. (1) shall be considered as amounts expended for projects considered necessary without regard to location.

History: 1991 a. 39; 1995 a. 27.

31.309 Portage levee system and canal. (1) CITY OF PORTAGE LEVEE. (a) The department shall provide a grant in the 1995−97 fiscal biennium from the appropriation under s. 20.370 (5) (cq) to the city of Portage for the amount necessary for the renovation and repair of the city of Portage levee in the Portage levee system. The grant under this paragraph may not exceed $800,000 in fiscal year 1995−96 and $800,000 in fiscal year 1996−97.

(ag) The department shall provide a grant of $350,000 in fiscal year 2001−2002 and a grant of $350,000 in fiscal year 2002−2003 from the appropriation under s. 20.370 (5) (cq) to the city of Portage for the renovation and repair of the Portage canal.

(am) The city of Portage may use any amounts from the grant awarded under par. (a) for the renovation and repair of the Portage canal.

(b) When the department determines that the renovation and repair described under par. (a) are complete, the city of Portage shall assume the maintenance of the city of Portage levee in the Portage levee system in a manner that will best protect the surrounding area from the overflow of the Wisconsin River.

(2) LEWISTON AND CALEDONIA LEVEES. (a) The department shall maintain the Lewiston and Caledonia levees in the Portage levee system in a manner that will best protect the surrounding area from the overflow of the Wisconsin River.

(b) The department may expend in fiscal year 1995−96, from the appropriation under s. 20.370 (5) (cq), up to $400,000 for a study concerning the future of strengthening and maintaining the Lewiston and Caledonia levees in the Portage levee system. The study shall include a management plan for these 2 levees.

History: 1995 a. 27 ss. 1698, 1699, 1702 to 1706; Stats. 1995 s. 31.309; 1999 a. 9; 2001 a. 16.

31.31 Dams on nonnavigable streams. Any person may erect and maintain upon that person's land, and, with the consent of the owner, upon the land of another, a water mill and a dam to raise water for working it upon and across any stream that is not navigable in fact for any purpose whatsoever upon the terms and conditions and subject to the regulations hereinafter expressed; and every municipality may exercise the same rights upon and across such streams that they may exercise upon or across streams navigable for any purpose whatsoever.

History: 1991 a. 316.

31.32 Dams not to injure other dams or sites. No such dam shall be erected to the injury of any mill lawfully existing, either above or below it on the same stream; nor to the injury of any mill site on the same stream on which a mill or milldam shall have been lawfully erected and used or is in the process of erection, unless the right to maintain a mill on such last−mentioned site shall have been lost or defeated by abandonment or otherwise; nor to the injury of any such mill site which has been occupied as such by the owner thereof, if such owner, within a reasonable time after commencing such occupation, completes and puts in operation a mill for the working of which the water of such stream shall be applied.

31.33 Jurisdiction of department. (1) DAMS HERETOFORE OR HEREAFTER CONSTRUCTED; ACTION FOR DAMAGES. All mills and milldams lawfully erected or constructed, on streams not navigable at the time, under chapter 48, territorial laws of 1840, chapter 62, laws of 1857, ch. 56, R.S. 1858, ch. 146, R.S. 1878, ch. 146, R.S. 1898, ch. 146, 1911 stats., ch. 146, 1913 stats., or ch. 146, 1915 stats., or any special, private or local act, or under any other act whatsoever, that are not now abandoned but are still in existence and use, and all dams heretofore or hereafter erected or constructed on streams not navigable in fact for any purpose, shall be subject to and regulated and controlled, so far as applicable, by ss. 31.02, 31.12, 31.18, 31.19, 31.25, 31.26 and 196.665, except that those sections do not prevent the owner of any land flooded or otherwise injured by any milldam from recovering by action at law, full compensation for all damages resulting to him or her in times past and that will result to him or her in the future in consequence of that flooding and injury but no damages suffered more than 3 years before the commencement of the action shall be recovered. The amount recovered constitutes a first lien upon the milldam and upon the mill, if any, and the lien may be enforced by execution sale of the property affected. In every such action the amount paid or secured to be paid under prior laws as damages shall be considered and proper allowance made therefor. The authority granted under this subsection to bring the action does not preclude the owner from proceeding under ch. 32. The owner may not exercise his or her option to bring the action after condemnation proceedings have been commenced against his or her property under ch. 32.

(2) LICENSE. A license is granted to each owner of any such milldam now in existence and use, and to each owner of any such milldam hereafter constructed, to maintain and use the same to operate mills or machinery, or for any other lawful private or public purpose, but subject, however, to the supervision of the department acting under ss. 31.02, 31.12, 31.18, 31.19, 31.25, 31.26 and 196.665. The right created by the license shall follow the title to the milldam and a conveyance of the latter shall transfer the right to the grantee.

(3) INTERPRETATION. Whenever ss. 31.02, 31.12, 31.18, 31.19, 31.25, 31.26 and 196.665 are applied to mills or milldams specified in sub. (1) every reference in any of them to a "permit" or to a "grantee" of a permit shall be regarded as referring respectively to a license granted by this section and to the owner of such a mill or milldam.

(4) HEIGHT. The height to which water may be raised by any such milldam and the length or period of time for which it may be kept up each year, may be restricted and regulated by the orders of the department.

(5) VIOLATION OF ORDERS, PENALTIES. Every person, firm or corporation violating any of the orders respecting any such mill or milldam made by the department shall forfeit for each such violation a sum not exceeding $500 which may be recovered by civil action as provided by ch. 778.

History: 1979 c. 32 s. 92 (8); 1981 c. 390; 1989 a. 31.

Cross−reference: See also ch. NR 333, Wis. adm. code.

This section applies to nonnavigable artificial waterways insofar as is necessary to protect navigable waters and owners of flooded waters. 63 Atty. Gen. 493.

Wisconsin's Milldam Act: Drawing New Lesson's From Old Law. Martini. 1998 WLR 1305.

31.34 Flow of water regulated. Each person, firm or corporation maintaining a dam on any navigable stream shall pass at all times at least 25% of the natural low flow of water of such stream, except as otherwise provided by law. This section, however, shall not apply to a plant or dam where the water is discharged directly into a lake, mill pond, storage pond or cranberry marsh, nor shall it apply to cases where in the opinion of the department such minimum discharge is not necessary for the protection of fish life. Any person, firm or corporation violating this section shall be fined not less than $50 nor more than $1,000.

31.35 Dams in areas leased by county; restrictions; control by circuit judge; when. (1) Dams controlling the water elevations in areas covered by leases made under s. 59.01 shall be operated in such manner as not to divert waters or with-

Text from the 2007−08 Wis. Stats. database updated by the Legislative Reference Bureau. Only printed statutes are certified under s. 35.18 (2), stats. Statutory changes effective prior to 11−2−10 are printed as if currently in effect. Statutory changes effective on or after 11−2−10 are designated by NOTES. Report errors at (608) 266−3561, FAX 264−6948, http://www.legis.state.wi.us/rsb/stats.html

hold from any cranberry reservoir to the damage of any cranberry marsh now served or dependent upon such water supply or to any crops or works therein.

(2) The circuit court for the county where the leased lands are located shall, upon petition and proof that any cranberry marsh or crops or works thereon are endangered or likely to be damaged by the operation of any dam or water control, make a summary order for the release, impounding or control of the waters affected by the dam or dams, to be and remain in force until dissolved by due notice and hearing.

History: 1977 c. 449.

31.36 Levee commissioners. (1) The right−of−way for such levees, if any additional are found necessary, shall be furnished by the municipalities in which they are located, and no construction work shall be begun until such rights−of−way are provided.

(2) Whenever levee commissioners under either general or special act are charged with the expenditure of money appropriated by the state or by any municipality for the construction, extension, improvement or repair of any levee or breakwater along the shore or bank of a river, stream or lake, s. 31.38 shall apply for the purpose of acquisition and condemnation of lands for such purposes and such commissioners have all the powers conferred by s. 31.38 for these purposes. Condemnations shall comply with s. 66.0703, so far as applicable. Commissioners may procure by condemnation lands for right−of−way, earth material, borrow pits, quarry, timber and brush privileges as they may, in their judgment, deem necessary for such purposes.

(3) Whenever said levee commissioners are not vested with power to buy rights−of−way, earth material, borrow pits, quarry, timber and brush privileges from money appropriated by the state they may receive from any person or municipality donations of land and moneys to pay for lands and privileges condemned hereunder and for the expenses of such condemnation proceedings.

(14) This section does not modify or repeal s. 31.35.

History: 1993 a. 490; 1995 a. 27; 1999 a. 150 s. 672.

31.38 Municipal authority to construct and maintain dams. (1) Every municipality may, subject to this chapter, authorize the acquisition, construction, maintenance or repair of dams across any lake or stream adjoining or within the limits of such municipality, and may locate such dam within or without such limits.

(2) Whenever it is deemed necessary to acquire, construct, maintain or repair any such dam, a plan therefor, with specifications and cost estimates, shall be prepared and presented to the governing body of the municipality for adoption. Cost estimates may include the estimated cost of maintenance for a period of years. When adopted by the governing body, the plan shall, where required, be submitted to the department or proper officer of the United States for approval. No work shall be done in pursuance of such plan until it has been so approved.

(3) For the purpose of this section, a municipality may purchase or condemn lands within and, when necessary, without its limits in order to protect any property situated within such limits.

(4) The municipality shall proceed in accordance with s. 66.0703 to make special assessments to property on account of benefits resulting to the property from the improvement mentioned in sub. (2) or from the acquisition and maintenance of a dam. If the excess of benefits over damages accruing to property within the assessment district is not sufficient to pay the cost of the improvement, the municipality may pay the balance, either out of its general fund or out of any special fund created for that purpose. The municipality may issue its negotiable bonds, as provided in ch. 67, to pay for such improvement. The department upon request of a municipality shall assist in engineering, surveying and determination of charges necessary in establishing special assessment districts under this section, cost of which shall be advanced by the requesting municipality and later charged against the various parcels of the special assessment district in direct proportion to the assessed benefits of each parcel in the district.

(5) Whenever 2 or more municipalities propose to cooperate in acquiring, constructing, maintaining or repairing a dam, their governing bodies shall first meet and adopt a method of proceeding and a plan of apportioning to each its share of the entire cost. Such method of proceeding and plan of apportionment shall be embodied in a resolution adopted by the governing bodies of the cooperating municipalities acting jointly and later such resolution shall be adopted by each of the governing bodies acting separately.

(6) Whenever a county or town acts under this section, the references in s. 66.0703 to a city or village or clerk thereof mean the county or town or clerk thereof, as the case may be.

History: 1999 a. 150 s. 672.

31.385 Dam safety; aid program. (1b) In this section "dam safety project" means the maintenance, repair, modification, abandonment or removal of a dam to increase its safety or any other activity that will increase the safety of a dam.

(1m) The department shall promulgate the rules necessary to administer a financial assistance program for dam safety projects under which financial assistance shall be provided as follows:

(a) To municipalities and public inland lake protection and rehabilitation districts for any type of dam safety projects.

(b) To private owners for the removal of dams.

(c) To any persons for the removal of abandoned dams.

(2) The following standards shall apply to financial assistance under this section for dam safety projects:

(a) 1. Except as provided in subd. 2., financial assistance for a dam safety project is limited to the sum of the following:

a. No more than 50% of the first $400,000 of costs of the project.

b. No more than 25 percent of the costs of the project that exceed $400,000.

2. A project to remove a dam shall not be subject to the cost limits under subd. 1.

3. Financial assistance is limited to no more than $400,000 for each dam safety project.

(ag) Of the amounts appropriated under s. 20.866 (2) (tL) and (tx), at least $250,000 shall be used for projects to remove dams. A project to remove a dam may include restoring the stream or river that was dammed.

(ar) Of the amounts appropriated under s. 20.866 (2) (tL) and (tx), at least $100,000 shall be used for the removal of abandoned dams. The amounts required to be used under this paragraph are in addition to the amounts required to be used for the removal of dams under par. (ag).

(b) The department shall determine which projects shall receive funding priority.

(bm) The department may provide financial assistance for an activity other than the maintenance, repair, modification, abandonment or removal of the dam only if the cost of that activity will be less than the cost of the maintenance, repair, modification or removal of the dam.

(c) No financial assistance may be provided under this section for a dam safety project unless at least one of the following applies:

1. The department conducts an investigation or inspection of the dam under this chapter and the owner of the dam requests financial assistance under this section within 6 months after having received department directives, based on the department's investigation or inspection of the dam, for the repair, modification or abandonment and removal of the dam or for another activity to increase the safety of the dam.

2. The municipality, public inland lake protection and rehabilitation district or other person applying for state financial assis-

Electronic reproduction of 2007−08 Wis. Stats. database, updated and current through 2009 Act 406 and October 31, 2010.

tance under this section has received directives from the department or is under order by the department to maintain, repair, modify, abandon or remove a dam on August 9, 1989.

(d) The financial assistance shall be paid from the appropriations under s. 20.866 (2) (tL) and (tx), except as provided in 1991 Wisconsin Act 39, section 9142 (10d).

(3) The department shall provide municipalities, public inland lake protection and rehabilitation districts and other persons receiving state financial assistance under this section with technical assistance for dam safety projects under this section. The department shall coordinate the financial assistance program under this section with other related state and federal programs.

(4) (a) The department shall maintain an inventory of all dams in the state that require a dam safety project under this section. The inventory shall list the dam safety projects in the chronological order in which they are required to be undertaken. For each dam safety project on the inventory, the department shall include a statement of which parts of the dam safety project are required to protect the rights held by the public in the navigable waters contained by the dam.

(b) The department shall provide notice to the owner of a dam that is included in the inventory. The department shall by rule establish a notice and hearing process for a dam owner to object to the inclusion of the owner's dam on the list. The department shall use this notice and hearing each time a dam is included in the inventory. The process shall include a public hearing in the city, village or town in which the dam is located, a public comment period, and an appeals process.

(5) Notwithstanding the limitations under sub. (2) (a) and the funding allocation requirements under sub. (2) (ag) and (ar), the department shall provide financial assistance to the village of Cazenovia in the amount necessary for a dam safety project to repair a dam that is located in the portion of the village that is in Richland County. The amount of the financial assistance may not exceed $250,000. The village need not contribute to the repair costs, and sub. (2) (c) does not apply to this dam safety project. The repair of this dam need not be included as a dam safety project under the inventory maintained by the department under sub. (4) for the village to receive financial assistance under this section.

(6) (a) Notwithstanding the limitations under sub. (2) (a) and the funding allocation requirements under sub. (2) (ag) and (ar), the department shall provide financial assistance to all of the following:

1. Adams County for a dam safety project for Easton Dam in the amount necessary for the project, but not to exceed $150,000.

2. The city of Stanley for a dam safety project for Stanley Dam in the amount necessary for the project, but not to exceed $150,000.

3. The city of Montello for a dam safety project for Montello Dam, in the amount necessary for the project, but not to exceed $150,000.

4. Eau Claire County for dam safety projects for Lake Altoona Dam, for Lake Eau Claire Dam, and for a dam located in Coon Fork Lake County Park, in the amount necessary for the projects, but not to exceed $27,000.

(b) The counties and cities need not contribute to the costs of the dam safety projects under par. (a) 1. to 4., and sub. (2) (c) does not apply to these projects. The dam safety projects under par. (a) 1. to 4. need not be included as dam safety projects under the inventory maintained by the department under sub. (4) in order to receive financial assistance under this subsection.

History: 1989 a. 31, 336; 1991 a. 39; 1993 a. 16; 1997 a. 27; 1999 a. 9, 185; 2001 a. 16; 2007 a. 97; 2009 a. 28.

Cross−reference: See also chs. NR 335 and 336, Wis. adm. code.

31.387 Dam rehabilitation projects. The department shall establish and administer a grant program under which the department shall provide grants to counties to rehabilitate dams located in those counties. The department may only provide a grant for a project under this section to match federal funds provided for the project under the federal Watershed Protection and Flood Prevention Act of 1953 (Public Law 83−566).

History: 2001 a. 16.

31.39 Fees for permits, approvals and hearings. (1) FEES REQUIRED. The department shall charge a permit or approval fee for carrying out its duties and responsibilities under ss. 31.02 to 31.185 and 31.33 to 31.38. The permit or approval fee shall accompany the permit application or request for approval.

(2) AMOUNT OF FEES. (a) For fees charged for permits and approvals under ss. 31.02 to 31.185 and 31.33 to 31.38, the department shall classify the types of permits and approvals based on the estimated time spent by the department in reviewing, investigating and making determinations whether to grant the permits or approvals. The department shall then set the fees as follows:

1. For a permit or approval with an estimated time of less than 3 hours, the fee shall be $30.

2. For a permit or approval with an estimated time of more than 3 hours but less than 9 hours, the fee shall be $100.

3. For a permit or approval with an estimated time of more than 9 hours, the fee shall be $300.

(b) For conducting a hearing on an application for which notice is provided under s. 31.06 (1), the person requesting the hearing for the permit or approval shall pay a fee of $25.

(2m) ADJUSTMENTS IN FEES. (a) The department shall refund a permit or approval fee if the applicant requests a refund before the department determines that the application for the permit or approval is complete. The department may not refund a permit or approval fee after the department determines that the application is complete.

(b) If the applicant applies for a permit or requests an approval after the project is begun or after it is completed, the department shall charge an amount equal to twice the amount of the fee that it would have charged under this section.

(c) If more than one fee under sub. (2) (a) or s. 30.28 (2) (a) or 281.22 is applicable to a project, the department shall charge only the highest fee of those that are applicable.

(d) The department, by rule, may increase any fee specified in sub. (2).

(2r) FEE FOR EXPEDITED SERVICE. (a) The department, by rule, may charge a supplemental fee for a permit or approval that is in addition to the fee charged under this section if all of the following apply:

1. The applicant requests in writing that the permit or approval be issued within a time period that is shorter than the time limit promulgated under par. (b) for that type of permit or approval.

2. The department verifies that it will be able to comply with the request.

(b) If the department promulgates a rule under par. (a), the rule shall contain a time limit for each type of permit or approval classified under sub. (2) (a) for determining whether the department will grant the permit or approval.

(3) EXEMPTIONS. This section does not apply to any federal agency or state agency.

History: 1977 c. 29; 1979 c. 221; 1981 c. 346; 1989 a. 31, 324; 1995 a. 27, 227; 1997 a. 27.

Cross−reference: See also ch. NR 300, Wis. adm. code.

31.99 Parties to a violation. (1) Whoever is concerned in the commission of a violation of this chapter for which a forfeiture is imposed is a principal and may be charged with and convicted of the violation although he or she did not directly commit it and although the person who directly committed it has not been convicted of the violation.

(2) A person is concerned in the commission of the violation if the person:

(a) Directly commits the violation;

(b) Aids and abets the commission of it; or

E.50. Wyoming

STATE OF WYOMING

SAFETY OF DAMS

PROGRAM

The purpose of this brochure is to provide you with information concerning the Wyoming Safety of Dams Program and basic knowledge of the terminology used around dams.

Enclosed for your information is a copy of the Safety of Dams Law, (Wyoming Statutes 41-3-307 through 41-3-318), which authorized the Wyoming Safety of Dams Program and Glossary of Terms accompanied with illustrations. A summary of the Safety of Dams Program is presented below, but we urge you to review the enclosed material and become familiar with all aspects of the Law.

The Safety of Dams Program can be broken into two areas of emphasis:

1) The Safety of Dams Law stipulates that duplicate plans and specifications showing the proposed work on any facility, meeting the criteria of the Safety of Dams Law, shall be prepared by or under the direction of a registered professional engineer licensed in Wyoming and experienced in dam design and construction. These plans and specifications must be submitted to the State Engineer for review and approval. No work shall begin until the submitted plans and specifications are approved by the State Engineer. The term "work" includes the following activities, among others: construction of a new facility and any repair, alteration, or rehabilitation which may affect the safety or size of an existing facility.

Once the plans and specifications have been approved by the State Engineer, a qualified engineer shall be in charge of and responsible for the proposed work. The engineer in charge shall inspect the work and submit reports to the Safety of Dams office detailing the information obtained during the inspection and on the progress of the work.

2) Periodic Safety Inspections of existing facilities, meeting certain criteria, are authorized and required by the Safety of Dams Law. If the facility is found to be defective or, in the judgement of the State Engineer, the facility constitutes a menace to the public, the State Engineer may place restrictions on the use of the facility until the owner returns the facility to a safe condition, as approved by the State Engineer.

In case of an emergency, the State Engineer may order breaching of a facility or any repairs deemed necessary to safeguard life and property.

The owner is responsible for safe operation and maintenance of a facility. No aspect of the Safety of Dams Program shall be construed to relieve the owner of a facility of any legal duties, obligations, or liabilities incident to their ownership or operation of it. The owner is solely liable for any damages resulting from the leakage or overflow of water or for floods resulting from failure or rupture of the fill or structure for such works.

If you discover conditions, which you feel are undesirable and could lead to failure of a facility, please promptly contact this office at the address or phone number listed below and/or your local Water Commissioner or Superintendent. We will promptly send someone to access the situation.

In the event of an emergency, where flooding is expected due to either failure of a dam or large releases of water from a reservoir, you must contact one of the following agencies:

1. Your local law enforcement agency;

2. Wyoming Highway Patrol - 1-307-777-4321 (24 Hours)
   or
   1-800-442-9090;

3. Wyoming Emergency Management Agency
   1-307-777-4900 (Days) or the Wyoming Highway Patrol 1-307-777-4321 (evenings, weekends and holidays)

4. State Engineer's Office
   Herschler Building - 4th Floor East
   Cheyenne, Wyoming 82002
   Phone Number - 1-307-777-6153 or 6154 (Days)

STATE OF WYOMING

SAFETY OF DAMS - STATE STATUTES

41-3-307 through 41-3-318, 1992

41-3-307. Definitions.

(a) As used in this act unless the context otherwise requires:

(i) "Alterations" or "repairs" means only such alterations or repairs as may directly affect the safety of the dam or DIVERSION SYSTEM, as determined by the state engineer or his designated representative;

(ii) "Appurtenant works" include, but are not limited to, such structures as spillways, either in the dam or separate therefrom, the reservoir and its rim, low level outlet works, and water conduits such as tunnels, pipelines or penstocks, either through the dam or its abutments;

(iii) "Dam" means any artificial barrier, including appurtenant works, used to impound or divert water and which is or will be greater than twenty (20) feet in height or with an impounding capacity of fifty (50) acre-feet or greater. "DAM" SHALL NOT INCLUDE ARTIFICIAL BARRIERS INCLUDING APPURTENANT WORKS:

(A) SIX (6) FEET IN HEIGHT OR LESS, REGARDLESS OF STORAGE CAPACITY; OR

(B) WHICH IMPOUND LESS THAN FIFTEEN (15) ACRE-FEET, REGARDLESS OF HEIGHT.

(iv) "Days" used in establishing deadlines means calendar days, including Sundays and holidays;

(v) "Diversion system" means any CHANNEL DIVERSION, HEADGATE or DIVERSION STRUCTURE with a carrying capacity in excess of fifty (50) cubic feet of water per second of time;

(vi) "Emergency" means any threat to life or property caused by the condition of any dam, reservoir or diversion system, or by present or imminent floods which threaten the safety or structural integrity of any dam or diversion system;

(vii) "EMERGENCY RESPONSE AGENCY" MEANS ANY AGENCY WHICH THE DAM OWNER MAY BE REQUIRED TO NOTIFY IN CASE OF AN EMERGENCY, SUCH AS SHERIFF'S OFFICE, HIGHWAY PATROL OR LOCAL EMERGENCY COORDINATOR;

(viii) "Enlargement" means any change in or addition to an existing dam or reservoir which raises or may raise the water storage elevation of the water impounded by the dam;

(ix) "Inspection" means visual or mechanical checks, measures, borings and any other methods necessary for determination of the adequacy of construction techniques, conformity of work with approved plans and specifications, and the safety and operating performance of a dam or diversion system and appurtenant works;

(x) "Owner" includes any of the following who own, control, operate, maintain, manage or propose to construct a dam or reservoir:

(A) The state and its departments, institutions, agencies and political subdivisions;

(B) Every municipal or quasi-municipal corporation;

(C) Every public utility;

(D) Every district;

(E) Every person;

(F) THE FEDERAL GOVERNMENT AND ITS DEPARTMENTS, INSTITUTIONS, AGENCIES AND POLITICAL SUBDIVISIONS;

(G) The duly authorized agents, lessees or trustees of any of the foregoing; and

(H) Receivers or trustees appointed by any court for any of the foregoing.

(xi) "Person" means any person, firm, association, organization, partnership, business trust, corporation or company;

(xii) "Reservoir" means any basin which contains or will contain impounded water;

(xiii) "This act" means W.S. 41-3-307 through 41-3-317.

41-3-308. Plans to be prepared by professional engineer; approval of plans and specifications by state engineer; industrial siting permits.

(a) Plans and specifications of any proposed construction, enlargement, MAJOR repair, alteration or removal of a dam or diversion system shall be prepared by or under the direction of a registered professional engineer licensed to practice in the state of Wyoming and experienced in dam design and construction, and shall be submitted to the state engineer for approval. It is unlawful to commence construction, enlargement, repair, alteration or removal until the plans and specifications have been approved by the state engineer. At the request of the state engineer, the professional engineer responsible for the plans and specifications shall carry out any revisions of the plans and specifications or provide such additional information as is necessary to justify or clarify the design.

(b) A copy of all plans and specifications submitted under this section shall be kept on file in the state engineer's office.

(c) In the event that a proposed dam or diversion system is related to a facility which requires an industrial siting permit pursuant to W.S. 35-12-106:

(i) The plans and specifications of the proposed dam or diversion system shall be submitted to the state engineer at the same time that the application for an industrial siting permit is submitted to the industrial siting administration pursuant to W.S. 35-12-108;

(ii) The state engineer shall approve or reject the plans and specifications of the proposed dam or diversion system prior to the public hearing conducted pursuant to W.S. 35-12-109 (b) (i);

(iii) The approval or rejection of the plans and specifications of the proposed dam or diversion system shall be binding on the industrial siting council for the purposes of issuing an industrial siting permit. Source: Laws 1977, ch. 120, 1.

(d) THE STATE ENGINEER SHALL PROVIDE FOR THE REGULATION AND SUPERVISION OF ALL DAMS, DIVERSION SYSTEMS AND RESERVOIRS BY THE STATE TO THE EXTENT REQUIRED TO PROTECT THE PUBLIC SAFETY AND PROPERTY. THE STATE ENGINEER IS AUTHORIZED AND DIRECTED TO PROMULGATE REGULATIONS AND STANDARDS FOR THE DESIGN, CONSTRUCTION, ENLARGEMENT, ALTERATION, ABANDONMENT, MAINTENANCE, MONITORING, OPERATION, REPAIR AND REMOVAL OF DAMS, RESERVOIRS, AND DIVERSION SYSTEMS AS ARE NECESSARY AND PROPER TO CARRY OUT THE PURPOSES OF THIS ACT. THE STATE ENGINEER MAY WAIVE ANY OR ALL OF THE REQUIREMENTS OF THIS ACT IN INSTANCES WHERE THE DAM OR DIVERSION SYSTEM IS LOCATED IN A REMOTE AREA WHERE THERE IS NO THREAT TO THE PUBLIC SAFETY OR PROPERTY.

41-3-309. Inspections performed and reports submitted to state engineer by professional engineer.

(a) A registered professional engineer licensed to practice in the state of Wyoming shall be in charge of and responsible for the construction, enlargement, repair, alteration or removal of any dam or diversion system.

(b) The engineer in charge shall provide for inspections at such intervals as deemed necessary to insure conformity with the approved plans and specifications, either by himself or by a person qualified to perform the inspections and for whose work the engineer stands personally responsible.

(c) All information obtained from, during or as the result of such inspection shall be made part of a report, certified to by the engineer in charge, which shall be submitted to the state engineer at such time or times as may be set by the state engineer.

(d) All reports submitted under this section shall be FILED in the state engineer's office.

41-3-310. Inspections by state engineer or assistant engineer; cost.

(a) If the state engineer believes that inspections carried out under W.S. 41-3-309 are inadequate or that additional inspections are necessary, the state engineer may inspect personally or appoint an assistant engineer to inspect the construction, enlargement, repair, alteration or removal of any dam or diversion system. If after any inspection the state engineer or his representative finds that amendments, modifications or changes are necessary in order to insure the security and integrity of the work and structure, the protection of property or the public safety, the state engineer may order the owner or owners of the dam or diversion system to revise the plans and specifications, or order work stopped. It is unlawful to proceed with or continue THE work until any revisions have been approved by the state engineer.

(b) Any inspections required by this section shall be made at state expense, provided the assistant engineer performing such inspections is an employee of the state of Wyoming.

(c) If the assistant engineer is not a regular employee of the state of Wyoming, inspections shall be made at the expense of the owner. The owner shall be furnished with an estimate of the cost prior to performance of any inspections, but the state engineer is not precluded from collecting any or all additional costs which result from performance of THE inspections. Costs to be paid by the owner shall include, but are not limited to, ALL work or tests as are necessary to fully provide any information and data required by the state engineer or his appointed representative. IF THE OWNER REFUSES OR NEGLECTS TO TURN OVER THE FUNDS WITHIN THIRTY (30) DAYS, AFTER THE PRESENTATION OF THE BILL OF COSTS, THE COSTS SHALL

CONSTITUTE A LIEN UPON THE WORKS OR OTHER PROPERTIES OF THE OWNER OR OWNERS AND MAY BE COLLECTED BY APPROPRIATE ACTION IN ANY COURT OF COMPETENT JURISDICTION. IN ORDER TO HAVE A VALID, ENFORCEABLE LIEN UNDER THIS SECTION, A LIEN STATEMENT SWORN TO BEFORE A NOTARY PUBLIC SHALL BE FILED BY THE CLAIMANT WITH THE COUNTY CLERK OF THE COUNTY IN WHICH THE PROPERTY IS LOCATED. THE COUNTY CLERK SHALL FILE THE STATEMENT AND INDEX BY DATE, NAME OF CLAIMANT AND PROPERTY OWNER, AND BY LEGAL DESCRIPTION. THE LIEN STATEMENT SHALL CONTAIN THE FOLLOWING:

(i) THE NAME AND ADDRESS OF THE GOVERNING BODY SEEKING TO ENFORCE THE LIEN;

(ii) THE NAME AND ADDRESS OF THE PERSON AGAINST WHOSE PROPERTY THE LIEN IS FILED; AND

(iii) THE LEGAL DESCRIPTION OF THE PROPERTY TO WHICH THE LIEN ATTACHES.

(d) All funds paid by the owner to the state engineer shall be deposited in the state engineer's HOLDING account from which account the costs incurred as a result of any inspections or other work deemed necessary under this section SHALL BE PAID. Any funds not so expended shall be returned to the person or persons advancing the funds.

41-3-311. Periodic inspections.

(a) Any dam subject to the terms of this act shall be inspected at least once every TEN (10) years or as often as deemed necessary BASED ON THE HAZARDS OF THE DAM to insure the continued PROTECTION of PUBLIC SAFETY AND PROPERTY.

(b) Inspections referred to in subsection (a) of this section shall be performed by the state engineer or his appointed representative WHO SHALL HAVE RIGHT OF ENTRY UPON PRIVATE OR GOVERNMENT LANDS AND IS AUTHORIZED TO INSPECT THE OWNER'S TECHNICAL DATA AND OTHER DOCUMENTATION AS MAY BE NECESSARY TO PERFORM THESE INSPECTIONS. All information obtained as a result of THE inspections shall be FILED IN the state engineer's office.

(c) Inspections required under this section shall be made at state expense except as provided in W.S. 41-3-312 when a dam, reservoir or diversion system is found to be unsafe by the state engineer. Source: Laws 1977, ch. 120, 1.

(d) IF INSPECTIONS PERFORMED UNDER THIS SECTION DISCLOSE DEFECTS IN THE WORKS WHICH IN THE JUDGMENT OF THE STATE ENGINEER OR HIS AUTHORIZED AGENT CONSTITUTE A THREAT TO LIFE OR PROPERTY, THE STATE ENGINEER MAY, WITHOUT INCURRING ANY LIABILITY, ORDER THE DRAINING OF ANY RESERVOIR INVOLVED, OR THE LIMITATION OR CESSATION OF ITS

USE OR THE USE OF ANY DEFECTIVE WORKS UNTIL SUCH TIME AS THE OWNER OF THE RESERVOIR OR OTHER WORKS RETURNS THE WORKS TO A SAFE CONDITION AS APPROVED BY THE STATE ENGINEER.

41-3-312. Inspections at any time or at request of other party or parties; cost; limitation against unsafe structures.

(a) The state engineer may, or upon written request from any person or persons residing on or owning land near any dam, reservoir or diversion system, shall order an inspection of THOSE works at any time other than the time set for regular inspections as provided for in W.S. 41-3-311(a). Before ordering AN inspection, the state engineer may require any person or persons requesting THE inspection to deposit a sum of money sufficient to pay the expenses of the inspection into the state engineer's HOLDING ACCOUNT. If after THE inspection the dam, reservoir or diversion system is determined to be in a safe and usable condition, the state engineer may cause the whole or part of the expenses of THE inspection to be paid out of the state engineer's HOLDING account. ANY EXCESS FUNDS SHALL BE RETURNED TO THE PERSON OR PERSONS ADVANCING THE FUNDS.

(b) If the dam, reservoir or diversion system is found to be defective, ANY FUNDS DEPOSITED BY THE PERSON OR PERSONS REQUESTING THE INSPECTION SHALL BE RETURNED AND the state engineer may require the person or persons owning the dam, reservoir or diversion system in question to pay the whole or any part of the expenses of inspection. If the state engineer requires A payment, he shall present a bill of costs to the owner or owners, and if the owner or owners refuse or neglect to pay the costs within thirty (30) days after the presentation of THE bill of costs, the costs shall constitute a lien upon the works or other properties of the owner or owners and may be collected by appropriate action in any court of competent jurisdiction. If the inspection discloses defects in the works which in the judgment of the state engineer or his authorized agent constitute a THREAT to life or property, the state engineer may, without incurring any liability, order the draining of any reservoir involved, or the limitation or cessation of its use or the use of any defective works until such time as the owner of the reservoir or other works returns the works to a safe condition as approved by the state engineer. THE LIEN SHALL BE FILED AS PROVIDED BY W.S. 41-3-310(c).

41-3-313. Outlets; maintenance; draining by breaching.

(a) All dams AND reservoirs hereafter constructed, with or without a controlled inlet, shall contain an outlet controlled by a HEADGATE or other control works. The HEADGATE or control works shall be maintained in an operable condition at all times and in A manner that water impounded by or within a dam OR reservoir may be

evacuated or maintained at any water level which may be required by the state engineer.

(b) All dams constructed prior to the effective date of this act which have no outlet or means for lowering the reservoir water level in an expeditious manner, may be drained by breaching at the owner's expense when the public safety so requires.

(c) The state engineer and anyone working under his direction and control shall not be held liable for any damages or loss of water resulting from the draining or imposed restrictions as to the use of a reservoir, DAM or diversion system.

(d) If within thirty (30) days after presentation of an itemized statement the owner fails to reimburse the state engineer for expenses incurred under this section, any unpaid balance of such expense shall automatically constitute a lien upon lands or other properties of the owner. Source: Laws 1977, ch. 120, 1.

41-3-314. Emergency repairs or breaching.

(a) In case of an emergency where the state engineer or his authorized representative declares that repairs or breaching of a dam or diversion system are immediately necessary to safeguard life and property, the necessary repairs or breaching shall be started immediately by the owner or by the state engineer or his representative at the owner's expense, if the owner fails to do so. The state engineer AND EMERGENCY RESPONSE AGENCIES shall be notified at once of any CHANGES IN THE PHYSICAL CONDITIONS OF THE DAM, DIVERSION SYSTEM, OR RESERVOIR WHICH SIGNIFICANTLY INCREASE THE PROBABILITY OF FAILURE OF THE DAM OR DIVERSION WORKS OR THE DANGER TO LIFE OR PROPERTY, proposed emergency repairs or breaching to be instituted by the owner. THESE REPORTING REQUIREMENTS SHALL APPLY ONLY TO CASES IN WHICH AN EMERGENCY HAS BEEN DECLARED PURSUANT TO THIS SUBSECTION.

(b) If emergency repairs have been made and the emergency situation has passed, the owner shall commence all repairs necessary to return the dam or diversion system to a safe and usable condition, as provided in W.S. 41-3-308 through 41-3-310.

(c) All costs incurred by the state engineer during an emergency shall be payable by the owner or owners on receipt of the bill of costs from the state engineer. Costs not paid within thirty (30) days after presentation of the bill shall constitute a lien upon the dam or diversion system or other properties of the owner or owners and may be collected by appropriate action in any court of competent jurisdiction. THE LIEN SHALL BE FILED AS PROVIDED BY W.S. 41-3-310 (c).

41-3-315. Other reservoirs; enforcement reservoirs 20 feet or less in height or impounding less than 50 acre-feet.

FOR ANY RESERVOIR the state engineer may enforce any sections of this act in such manner and by such means as may be necessary to insure the safety of the public and protection of property.

41-3-316. Actions brought against state, state engineer or employees prohibited.

(a) No action shall be brought against the state or the state engineer or any of his agents or employees for the recovery of damages caused by the partial or total failure of any dam, reservoir OR DIVERSION SYSTEM or damages caused by virtue of the operation of any dam, reservoir OR DIVERSION SYSTEM upon the ground that such defendants are liable by virtue of any of the following:

(i) The approval of the dam, reservoir OR DIVERSION SYSTEM or approval of flood handling plans during construction;

(ii) The issuance or enforcement of orders relative to maintenance or operation of any dam or reservoir;

(iii) Control and regulation of any dam, reservoir OR DIVERSION SYSTEM;

(iv) Measures taken to protect against failure during an emergency; or

(v) Failure to take an action required by the provisions of this act. Source: Laws 1977, ch. 120, 1.

41-3-317. Liability of reservoir owners.

Nothing in this act shall be construed to relieve an owner or owners of any reservoir, dam or diversion system of any legal duties, obligations or liabilities incident to their ownership or operation of or any damages resulting from the leakage or overflow of water or for floods resulting from the failure or rupture of the fill or
structure for such works. Source: Laws 1977, ch. 120, 1.

41-3-318. Penalties; cancellation of permit for failure to comply with sections 41-3-308 through 41-3-314.

Failure to comply with the provisions of W.S. 41-3-308 THROUGH 41-3-314 shall subject the permit to cancellation at any time. FAILURE TO COMPLY WITH ANY VALID ORDER ISSUED BY THE STATE ENGINEER PURSUANT TO W.S. 41-3-308 THROUGH 41-3-314, SHALL SUBJECT THE

PERMIT HOLDER TO A PENALTY NOT TO EXCEED FIVE HUNDRED DOLLARS ($500.000) PER DAY FOR EACH DAY THE VIOLATION CONTINUES. The state engineer is authorized to cancel any permit wherein the provisions of the above sections have not been, or are not being, complied with, and the cancellation shall operate as a forfeiture of all rights acquired under and by virtue of any permit theretofore approved by the state engineer. An appeal from any decision of the state engineer may be made to the board of control, and from the decision of the board of control appeal may be taken to the district court. Source: Laws 1903, ch. 69, 6; C.S. 1910, 748; C.S. 1920, 869; R.S. 1931, 122-1507; C.S. 1945, 71-607; W.S. 1957, 41-32; Laws 1977, ch. 120, 2.

CHAPTER 2

GLOSSARY

i. Definitions

This chapter provides basic terminology used in this guidebook. It is not a complete list but is meant to introduce some basic terminology. Other terminology may be obtained from dam safety books.

Abutment - That part of the valley side or concrete walls against which the dam is constructed. See Page 15. Right and left abutments are those on respective sides of an observer when viewed looking downstream.

Alterations - Such changes in the design of the dam as may directly affect the integrity of the dam and thereby affect the safety of persons, property or natural resources.

Appurtenant Works - The structures or machinery auxiliary to dams which are built to operate and maintain dams; such as outlet works, spillway, powerhouse, tunnels, etc.

Berm - A horizontal step or bench in the sloping profile of an embankment dam. See Pages 15 and 17.

Breach - A break, gap or opening (failure) in a dam which releases impoundment water. See Page 17.

Core - A zone of material of low permeability in an embankment dam. See Page 17.

Dam - A barrier built for impounding or diverting the flow of water.

Dike (Levee) - An embankment,, usually applied to embankments or structures built to protect land from flooding. See Page 17.

Drain, Layer or Blanket - A layer of pervious material in a dam to facilitate drainage. Includes toe drain, seephole and chimney drain. See Page 15.

Drawdown - The resultant lowering of water surface level due to release of water from the impoundment.

Embankment - Fill material, usually earth or rock, placed with sloping sides. See also Embankment Dam and Page 17.

Embankment Dam (Fill Dam) - Any dam constructed of excavated natural materials or of industrial waste materials. See Page 17.

Homogeneous Earth Fill Dam - An embankment constructed of similar earth material throughout, except for possible inclusion of drains. Used to differentiate from a zoned earth fill dam.

Zoned Embankment Dam - An embankment dam is composed of zones of selected materials having different degrees of porosity, permeability and density.

Emergency Action Plan - A predetermined plan of action to be taken to reduce the potential for property damage and loss of lives.

Engineer - A licensed or registered engineer in a given state; offers experience and expertise in the design and inspection of dams.

Failure - An incident resulting in the uncontrolled release of water from a dam.

Freeboard - The vertical distance between a stated water level and the top of a dam. See Page 15.

Gate or Valve - In general, a device in which a leaf or member is moved across the waterway to control or stop the flow.

Impoundment - Water or wastewater held back by a dam.

Instrumentation - Permanent devices which are installed in/near a dam to allow monitoring of the dam and impoundment. These devices may include a staff gage (to measure impoundment levels), piezometers, observation wells, settlement or alignment points, rain gage, etc. See Page 16.

Maintenance - The upkeep necessary for efficient operation of dams and their appurtenant works. It involves labor and materials, but is not to be confused with alterations or repairs.

Operator - The owner, or an agent or employee of the owner.

Outlet - An opening through which water can freely discharge for a particular purpose from an impoundment. See Page 15.

Owner - Any person who owns, leases, controls, operates, maintains or manages a dam or impoundment.

Phreatic Surface - The upper surface of saturation in an embankment. See Page 15.

Piping - The progressive development of internal erosion by seepage, appearing downstream as a hole or seam discharging water that contains soil particles.

Plunge Pool - A natural or sometimes artificially created pool that dissipates the energy of free-falling water. The pool is

located a safe distance downstream of the structure from which water is being released. See Stilling Basin and Page 15.

Repair - To essentially restore a dam to its approved design condition.

Riprap - A layer of large stones, broken rock or precast blocks placed in a random fashion on the upstream slope of an embankment dam, on a reservoir shore, or on the sides of a channel as a protection against wave and ice action. See Page 15.

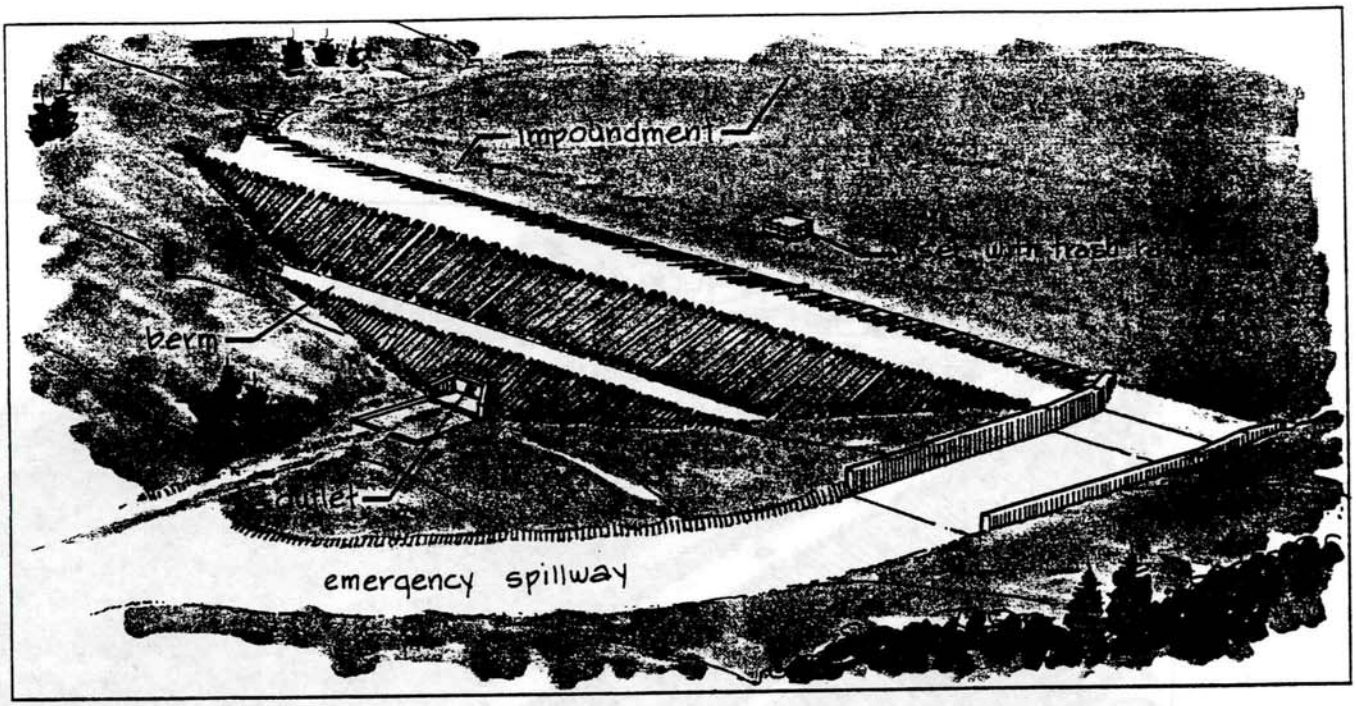
Silt/Sediment - Soil particles and debris in an impoundment.

Slump Area - A portion of earth embankment which moves downslope, sometimes suddenly, often with cracks developing. See Page 17.

Spillway System - A structure over or through which flows are discharged. If the flow is controlled by gates, it is considered a controlled spillway; if the elevation of the spillway crest is the only control, it is considered an uncontrolled spillway. See Pages 15 and 17.

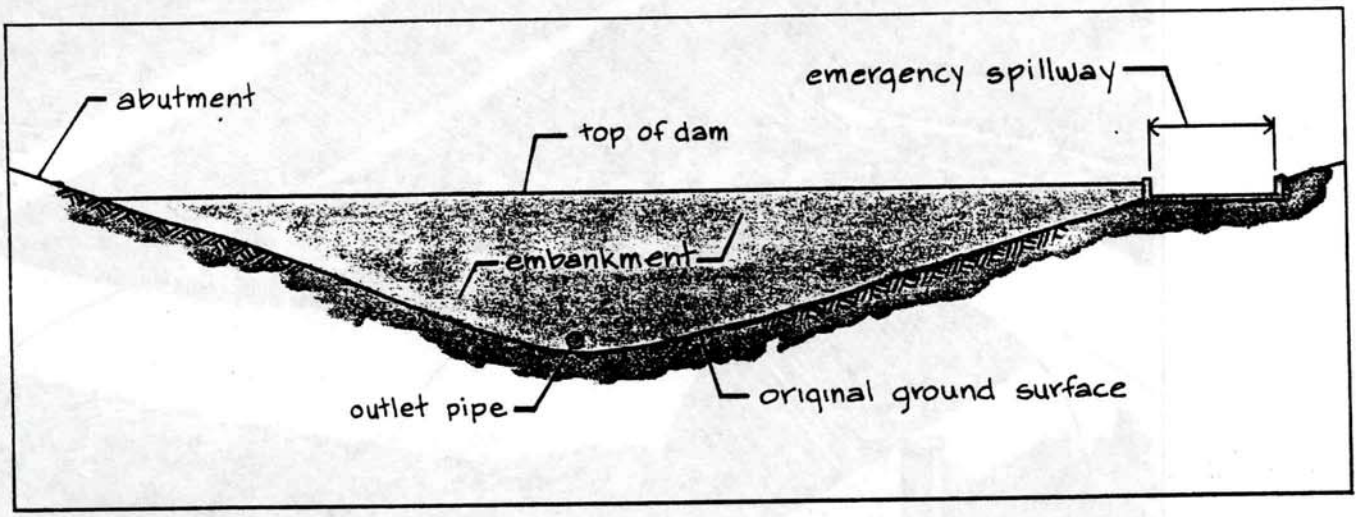
> **Emergency Spillway** - A secondary spillway designed to operate only during exceptionally large floods.
>
> **Principal spillway** - The main spillway for normal and flood flows.

Stilling Basin - A basin constructed to dissipate the energy of fast-flowing water, eg. from a spillway or bottom outlet, and to protect the river bed from erosion. See Plunge Pool. See Page 15.



Stoplogs - Logs or timbers, steel or concrete beams placed on top of each other with their ends held in guides on each side of a channel or conduit.

Toe of Embankment - The junction of the face of the dam with the ground surface.



Trash Rack - A structure of metal or concrete bars located in the waterway at an intake to prevent the entry of floating or submerged debris.

ARTICLE 3 - RESERVOIRS

41-3-301. Application for reservoir construction permit; contents; procedure.

(a) Any person, corporation, association, or organization, of any nature whatsoever, hereafter intending to store or impound, for beneficial uses, any of the unappropriated waters of the state of Wyoming, shall, before commencing construction of any works for such purpose, or performing any work in connection with said proposed construction, make an application to the state engineer, for a permit to construct a reservoir. The application must set forth the name and post office address of the applicant; the source of the water supply; the nature of the proposed use; the location and description of the proposed work; the time within which it is proposed to begin construction, and the time required for the completion of construction. Maps and plans shall conform with the provisions of W.S. 41-4-510. In case of reservoirs where the storage is for stock purposes only and the capacity does not exceed twenty (20) acre-feet and the height of dam does not exceed twenty (20) feet, the state engineer may issue a permit without the filing of a map; however the state engineer may require certain information be submitted on special forms to be furnished or designated by him. Any violation of subsection (a) of this section shall be punishable pursuant to W.S. 41-3-616 with the exception that the owner of any unpermitted reservoir with a capacity of twenty (20) acre-feet or less and a dam height of twenty (20) feet or less shall have forty-five (45) days after receipt of the written notice of violation pursuant to W.S. 41-3-616(a), to submit an application for a permit. The application shall meet the requirements of the state engineer's office. Each day of the forty-five (45) days shall not be counted as a separate violation if the application for a reservoir permit is received during this forty-five (45) day period.

(b) For reservoir permits issued in conjunction with the national pollutant discharge elimination system (NPDES) for mining operations, the state engineer shall promptly review the application and advise the applicant in writing if it is complete, within thirty (30) days. If the application is complete, or is resubmitted to the satisfaction of the state engineer, it shall be approved or denied within forty-five (45) days of this determination:

(i) For the purpose of this subsection "complete" means that the application contains all the essential and necessary elements and is acceptable for further review for substance and compliance with the provisions of this chapter.

41-3-302. Application for construction permit; conditions; secondary permit; certificate of appropriation.

All applications under this article shall be subject to the provisions of W.S. 41-4-502 through 41-4-510, 41-4-517 and 41-3-615, which set forth the duties and authority of the state engineer and provide for the protection of the rights of applicants; provided that an enumeration of any lands proposed to be irrigated under this article shall not be required in the primary permit, provided, further, that any party or parties desiring to appropriate such stored water to particular lands may file with the state engineer an application for permit to be known herein as the secondary permit, in compliance with the provisions of W.S. 41-4-501 through 41-4-510 and 41-4-517. In the event secondary permit may be desired, said application shall refer to such reservoir for a supply of water and the state engineer shall not approve of said application and issue secondary permit until the applicant thereunder shall show to such state engineer by documentary evidence that he has entered into an agreement with the owners of the reservoir for a permanent and sufficient interest in said reservoir to impound enough water for the purposes set forth in said application. When beneficial use has been completed and perfected under the said secondary permit the division superintendent shall take the proof of the water user under such permit and the final certificate of appropriations shall refer to both the ditch described in the secondary permit and the reservoir described in the primary permit.

41-3-303. Use of stored water.

The use of water stored under the provisions of this chapter may be acquired under such terms as shall be agreed upon by and between the parties in interest. Lands entitled to the use of water in any reservoir may use the water stored therein, and to which they are entitled, at such times and in such amounts as the water users may elect, provided that a beneficial use of water is made at all times.

41-3-304. Use of bed of stream.

Whenever the owner, manager or lessee of a reservoir, constructed under the provisions of this act, shall desire the use of the bed of the stream, or other water course, for the purpose of carrying stored or impounded water from the reservoir to the consumer, or shall desire the use of any ditch to carry, convey or transmit any of the stored or impounded water for the benefit of any person having the right to have the reservoir water carried, conveyed or transmitted through the ditch under the laws of this state, he shall, in writing notify the water commissioner of the district in which the stored or impounded water is to be used, giving the date when it is proposed to discharge water from the reservoir, its volume in acre feet and the names of all persons and ditches entitled to its use, and other

matters as may be necessary to properly distribute the water. It shall then be the duty of the water commissioner to so adjust the headgates of all ditches of ditch companies or appropriators from the stream or water course, and the division boxes of individual consumers of water, not entitled to the use of the stored water, as will enable those having the right to secure the volume of water to which they are entitled. The commissioner shall not in any other manner interfere with the headgates or division boxes, except as otherwise provided by law. The water commissioner shall keep a true and just account of the time spent by him in the discharge of his duties as defined in this section, and it shall be the duty of the water commissioner or division superintendent to present a bill of one-half (1/2) the expense so incurred to the reservoir owner, manager or lessee, and if the owner, manager, or lessee shall neglect for three (3) days, after the presentation of the bills of costs, to pay the costs, the costs shall be made a charge upon the reservoir and shall be collected as delinquent taxes until the complete payment of the bill of costs has been made. Costs recovered under this section shall be paid into the general fund.

41-3-305. Direct flow storage.

The holder or owner of an adjudicated water right to the direct use of the natural unstored flow of any surface stream of the state may store such direct flow so long as no other Wyoming appropriator or user is injured or affected thereby. Prior to the commencement of the storage of water under a direct flow water right, the appropriator shall submit a request for such storage in writing to the state engineer and shall obtain the approval of the state board of control. The state board of control may permit storage at any time so long as there is no interference with existing water rights or uses. The state engineer is authorized and empowered to prescribe such rules and regulations as may be necessary or desirable to enable him to effectively administer the provisions of this section.

41-3-306. Instream stock use.

In the administration of water rights on any stream and in the consideration of any applications for permits, the state engineer may require that water be provided to meet reasonable demands for instream stock use.

41-3-307. Alterations or repairs of dams or diversion systems; definitions.

(a) As used in this act unless the context otherwise requires:

(i) "Alterations" or "repairs" means only such alterations or repairs as may directly affect the safety of the dam or diversion system, as determined by the state engineer or his designated representative;

(ii) "Appurtenant works" include, but are not limited to, such structures as spillways, either in the dam or separate therefrom, the reservoir and its rim, low level outlet works, and water conduits such as tunnels, pipelines or penstocks, either through the dam or its abutments;

(iii) "Dam" means any artificial barrier, including appurtenant works, used to impound or divert water and which is or will be greater than twenty (20) feet in height or with an impounding capacity of fifty (50) acre-feet or greater. "Dam" shall not include artificial barriers including appurtenant works:

(A) Six (6) feet in height or less, regardless of storage capacity; or

(B) Which impound less than fifteen (15) acre-feet, regardless of height.

(iv) "Days" used in establishing deadlines means calendar days, including Sundays and holidays;

(v) "Diversion system" means any channel diversion, headgate or diversion structure with a carrying capacity in excess of fifty (50) cubic feet of water per second of time;

(vi) "Emergency" means any threat to life or property caused by the condition of any dam, reservoir or diversion system, or by present or imminent floods which threaten the safety or structural integrity of any dam or diversion system;

(vii) "Emergency response agency" means any agency which the dam owner may be required to notify in case of an emergency, such as sheriff's office, highway patrol or local emergency coordinator;

(viii) "Enlargement" means any change in or addition to an existing dam or reservoir which raises or may raise the water storage elevation of the water impounded by the dam;

(ix) "Inspection" means visual or mechanical checks, measures, borings and any other methods necessary for determination of the adequacy of construction techniques, conformity of work with approved plans and specifications, and the safety and operating performance of a dam or diversion system and appurtenant works;

(x) "Owner" includes any of the following who own, control, operate, maintain, manage or propose to construct a dam or reservoir:

(A) The state and its departments, institutions, agencies and political subdivisions;

(B) Every municipal or quasi-municipal corporation;

(C) Every public utility;

(D) Every district;

(E) Every person;

(F) The federal government and its departments, institutions, agencies and political subdivisions;

(G) The duly authorized agents, lessees or trustees of any of the foregoing; and

(H) Receivers or trustees appointed by any court for any of the foregoing.

(xi) "Person" means any person, firm, association, organization, partnership, business trust, corporation or company;

(xii) "Reservoir" means any basin which contains or will contain impounded water;

(xiii) "This act" means W.S. 41-3-307 through 41-3-317.

41-3-308. Alterations or repairs of dams or diversion systems; plans and specifications; duties of state engineer.

(a) Plans and specifications of any proposed construction, enlargement, major repair, alteration or removal of a dam or diversion system shall be prepared by or under the direction of a registered professional engineer licensed to practice in the state of Wyoming and experienced in dam design and construction, and shall be submitted to the state engineer for approval. It is unlawful to commence construction, enlargement, major repair, alteration or removal until the plans and specifications have been approved by the state engineer. At the request of the state engineer, the professional engineer responsible for the plans and specifications shall carry out any revisions of the plans and specifications or provide such additional information as is necessary to justify or clarify the design.

(b) A copy of all plans and specifications submitted under this section shall be kept on file in the state engineer's office.

(c) In the event that a proposed dam or diversion system is related to a facility which requires an industrial siting permit pursuant to W.S. 35-12-106:

(i) The plans and specifications of the proposed dam or diversion system shall be submitted to the state engineer at the same time that the application for an industrial siting permit is submitted to the industrial siting administration [industrial siting council] pursuant to W.S. 35-12-108;

(ii) The state engineer shall approve or reject the plans and specifications of the proposed dam or diversion system prior to the public hearing conducted pursuant to W.S. 35-12-110(f)(i);

(iii) The approval or rejection of the plans and specifications of the proposed dam or diversion system shall be binding on the industrial siting council for the purposes of issuing an industrial siting permit.

(d) The state engineer shall provide for the regulation and supervision of all dams, diversion systems and reservoirs by the state to the extent required to protect the public safety and property. The state engineer is authorized and directed to promulgate regulations and standards for the design, construction, enlargement, alteration, abandonment, maintenance, monitoring, operation, repair and removal of dams, reservoirs, and diversion systems as are necessary and proper to carry out the purposes of this act. The state engineer may waive any or all of the requirements of this act in instances where the dam or diversion system is located in a remote area where there is no threat to the public safety or property.

41-3-309. Alterations or repairs of dams or diversion systems; inspections performed and reports submitted to state engineer by professional engineer.

(a) A registered professional engineer licensed to practice in the state of Wyoming shall be in charge of and responsible for the construction, enlargement, major repair, alteration or removal of any dam or diversion system.

(b) The engineer in charge shall provide for inspections at such intervals as deemed necessary to insure conformity with the approved plans and specifications, either by himself or by a person qualified to perform the inspections and for whose work the engineer stands personally responsible.

(c) All information obtained from, during or as the result of such inspection shall be made part of a report, certified to by the engineer in charge, which shall be submitted to the state engineer at such time or times as may be set by the state engineer.

(d) All reports submitted under this section shall be filed in the state engineer's office.

41-3-310. Alterations or repairs of dams or diversion systems; inspections by state engineer or assistant engineer; cost.

(a) If the state engineer believes that inspections carried out under W.S. 41-3-309 are inadequate or that additional inspections are necessary, the state engineer may inspect personally or appoint an assistant engineer to inspect the construction, enlargement, repair, alteration or removal of any dam or diversion system. If after any inspection the state engineer or his representative finds that amendments, modifications or changes are necessary in order to insure the security and integrity of the work and structure, the protection of property or the public safety, the state engineer may order the owner or owners of the dam or diversion system to revise the plans and specifications, or order work stopped. It is unlawful to proceed with or continue the work until any revisions have been approved by the state engineer.

(b) Any inspections required by this section shall be made at state expense, provided the assistant engineer performing such inspections is an employee of the state of Wyoming.

(c) If the assistant engineer is not a regular employee of the state of Wyoming, inspections shall be made at the expense of the owner. The owner shall be furnished with an estimate of the cost prior to performance of any inspections, but the state engineer is not precluded from collecting any or all additional costs which result from performance of the inspections. Costs to be paid by the owner shall include, but are not limited to, all work or tests as are necessary to fully provide any information and data required by the state engineer or his appointed representative. If the owner refuses or neglects to turn over the funds within thirty (30) days, after the presentation of the bill of costs, the costs shall constitute a lien upon the works or other properties of the owner or owners and may be collected by appropriate action in any court of competent jurisdiction. In order to have a valid, enforceable lien under this section, a lien statement sworn to before a notarial officer shall be filed by the claimant with the county clerk of the county in which the property is located. The county clerk shall file the statement and index by date, name of claimant and property owner, and by legal description. The lien statement shall contain the following:

(i) The name and address of the governing body seeking to enforce the lien;

(ii) The name and address of the person against whose property the lien is filed; and

(iii) The legal description of the property to which the lien attaches.

(d) All funds paid by the owner to the state engineer shall be deposited in the state engineer's holding account from which account the costs incurred as a result of any inspections or other work deemed necessary under this section shall be paid. Any funds not so expended shall be returned to the person or persons advancing the funds.

41-3-311. Alterations or repairs of dams or diversion systems; periodic inspections.

(a) Any dam subject to the terms of this act shall be inspected at least once every ten (10) years or as often as deemed necessary based on the hazards of the dam to insure the continued protection of public safety and property.

(b) Inspections referred to in subsection (a) of this section shall be performed by the state engineer or his appointed representative who shall have right of entry upon private or government lands and is authorized to inspect the owner's technical data and other documentation as may be necessary to perform these inspections. All information obtained as a result of the inspections shall be filed in the state engineer's office.

(c) Inspections required under this section shall be made at state expense except as provided in W.S. 41-3-312 when a dam, reservoir or diversion system is found to be unsafe by the state engineer.

(d) If inspections performed under this section disclose defects in the works which in the judgment of the state engineer or his authorized agent constitute a threat to life or property, the state engineer may, without incurring any liability, order the draining of any reservoir involved, or the limitation or cessation of its use or the use of any defective works until such time as the owner of the reservoir or other works returns the works to a safe condition as approved by the state engineer.

41-3-312. Alterations or repairs of dams or diversion systems;

inspections at other than regular times; cost; unsafe structures.

(a) The state engineer may, or upon written request from any person or persons residing on or owning land near any dam, reservoir or diversion system shall, order an inspection of those works at any time other than the time set for regular inspections as provided for in W.S. 41-3-311(a). Before ordering an inspection, the state engineer may require any person or persons requesting the inspection to deposit a sum of money sufficient to pay the expenses of the inspection into the state engineer's holding account. If after the inspection the dam, reservoir or diversion system is determined to be in a safe and usable condition, the state engineer may cause the whole or part of the expenses of the inspection to be paid out of the state engineer's holding account. Any excess funds shall be returned to the person or persons advancing the funds.

(b) If the dam, reservoir or diversion system is found to be defective, any funds deposited by the person or persons requesting the inspection shall be returned and the state engineer may require the person or persons owning the dam, reservoir or diversion system in question to pay the whole or any part of the expenses of inspection. If the state engineer requires a payment, he shall present a bill of costs to the owner or owners, and if the owner or owners refuse or neglect to pay the costs within thirty (30) days after the presentation of the bill of costs, the costs shall constitute a lien upon the works or other properties of the owner or owners and may be collected by appropriate action in any court of competent jurisdiction. If the inspection discloses defects in the works which in the judgment of the state engineer or his authorized agent constitute a threat to life or property, the state engineer may, without incurring any liability, order the draining of any reservoir involved, or the limitation or cessation of its use or the use of any defective works until such time as the owner of the reservoir or other works returns the works to a safe condition as approved by the state engineer. The lien shall be filed as provided by W.S. 41-3-310(c).

41-3-313. Alterations or repairs of dams or diversion systems; outlets; maintenance; draining by breaching.

(a) All dams and reservoirs hereafter constructed, with or without a controlled inlet, shall contain an outlet controlled by a headgate or other control works. The headgate or control works shall be maintained in an operable condition at all times and in a manner that water impounded by or within a dam or reservoir may be evacuated or maintained at any water level which may be required by the state engineer.

(b) All dams constructed prior to the effective date of this act which have no outlet or means for lowering the reservoir water level in an expeditious manner, may be drained by breaching at the owner's expense when the public safety so requires.

(c) The state engineer and anyone working under his direction and control shall not be held liable for any damages or loss of water resulting from the draining or imposed restrictions as to the use of a reservoir, dam or diversion system.

(d) If within thirty (30) days after presentation of an itemized statement the owner fails to reimburse the state engineer for expenses incurred under this section, any unpaid balance of such expense shall automatically constitute a lien upon lands or other properties of the owner.

41-3-314. Alterations or repairs of dams or diversion systems; emergency repairs or breaching.

(a) In case of an emergency where the state engineer or his authorized representative declares that repairs or breaching of a dam or diversion system are immediately necessary to safeguard life and property, the necessary repairs or breaching shall be started immediately by the owner or by the state engineer or his representative at the owner's expense, if the owner fails to do so. The state engineer and emergency response agencies shall be notified at once of any changes in the physical conditions of the dam, diversion system, or reservoir which significantly increase the probability of failure of the dam or diversion works or the danger to life or property, proposed emergency repairs or breaching to be instituted by the owner. These reporting requirements shall apply only to cases in which an emergency has been declared pursuant to this subsection.

(b) If emergency repairs have been made and the emergency situation has passed, the owner shall commence all repairs necessary to return the dam or diversion system to a safe and usable condition, as provided in W.S. 41-3-308 through 41-3-310.

(c) All costs incurred by the state engineer during an emergency shall be payable by the owner or owners on receipt of the bill of costs from the state engineer. Costs not paid within thirty (30) days after presentation of the bill shall constitute a lien upon the dam or diversion system or other properties of the owner or owners and may be collected by appropriate action in any court of competent jurisdiction. The lien shall be filed as provided by W.S. 41-3-310 (c).

41-3-315. Alterations or repairs of dams or diversion systems; enforcement of provisions.

For any reservoir the state engineer may enforce any sections of this act in such manner and by such means as may be necessary to insure the safety of the public and protection of property.

41-3-316. Alterations or repairs of dams or diversion systems; actions brought against state, state engineer or employees prohibited.

(a) No action shall be brought against the state or the state engineer or any of his agents or employees for the recovery of damages caused by the partial or total failure of any dam, reservoir or diversion system or damages caused by virtue of the operation of any dam, reservoir or diversion system upon the ground that such defendants are liable by virtue of any of the following:

(i) The approval of the dam, reservoir or diversion system or approval of flood handling plans during construction;

(ii) The issuance or enforcement of orders relative to maintenance or operation of any dam or reservoir;

(iii) Control and regulation of any dam, reservoir or diversion system;

(iv) Measures taken to protect against failure during an emergency; or

(v) Failure to take an action required by the provisions of this act.

41-3-317. Alterations or repairs of dams or diversion systems; liability of owners.

Nothing in this act shall be construed to relieve an owner or owners of any reservoir, dam or diversion system of any legal duties, obligations or liabilities incident to their ownership or operation of or any damages resulting from the leakage or overflow of water or for floods resulting from the failure or rupture of the fill or structure for such works.

41-3-318. Penalties, cancellation of permit, for failure to comply with W.S. 41-3-308 through 41-3-314.

Failure to comply with the provisions of W.S. 41-3-308 through 41-3-314 shall subject the permit to cancellation at any time pursuant to W.S. 41-3-616(c). Failure to comply with any valid order issued by the state engineer pursuant to W.S. 41-3-308 through 41-3-314, shall subject the permit holder to penalty pursuant to W.S. 41-3-616(b).

41-3-319. Owners of ditches and reservoirs; general rights.

Each owner of a share or shares of the capital stock in an incorporated ditch company existing for the purpose of distributing water through such company's ditch to the owners of such stock, shall have the right to carry, convey and transmit reservoir water, supplementing other water rights he may possess, through the ditch of such ditch company in which he may have such stock, to the full extent of the carrying capacity represented by such stock, but no greater. Each partner in a partnership ditch owned or used for a like purpose, shall have the right to carry, convey and transmit reservoir water, supplementing other water rights he may possess, through such partnership ditch, to the full extent of the carrying capacity represented by his interest, as a partner, in such ditch, but no greater. Every such person carrying, conveying and transmitting water through such ditch, or having the same done for his benefit, shall pay all expenses incurred by reason of all extra labor in cleaning such ditch, change of division boxes, and other additional expenses made necessary by reason of carrying such reservoir water through any such ditch. The right herein granted to any person, shall also extend to the owner, manager or lessee of a reservoir, who desires to use any such ditch to carry, convey or transmit water through such ditch for the benefit of any such person to whom the right herein mentioned has been granted as aforesaid.

41-3-320. Owners of ditches and reservoirs; sale or lease of impounded water.

Except as otherwise provided by deed or other written instruments of the owner or owners of the right to impound water in any reservoir, such reservoir owner or owners shall, after the completion of the works in connection with such reservoir, be held to be the owner of the right to impound the water, and the right to sell or lease a portion or all his right to the impounded waters; provided, that the sale of any portion of the capacity of any reservoir shall carry with it an interest in the reservoir and works appurtenant thereto of such proportion as the portion sold bears to the total capacity of the reservoir; and provided, further, that the water stored in any reservoir cannot be used outside the boundaries of the state of Wyoming without special permit from the state engineer; and provided, further, that the state engineer may deny any use of water from any reservoir that would be detrimental to the public interest.

41-3-321. Owners of ditches and reservoirs; priority of right to store or impound.

The priority of right to store or impound water under this act shall date from the filing of the application in the state engineer's office.

41-3-322. Owner's report of persons entitled to use water; superintendent's report of use of water.

The owner of each reservoir shall annually, in writing, before or during the irrigating season and before the releasing of the water from the reservoir, deliver to the water commissioner having jurisdiction over such reservoir a list or lists of parties entitled to use water from such reservoir during the irrigating season of such year, and also a list as near as may be of the lands proposed to be irrigated, and shall immediately notify such water commissioner of any changes in such list or lists. The superintendent of the water division in which such reservoir is situated shall annually on or before the first day of December in each year make a written report to the state engineer of the state, enumerating in detail the person or persons who during the irrigating season immediately preceding use any part of such reservoir water, and shall also enumerate therein the lands upon or uses for which said water was applied during such irrigating season so that the state engineer may be kept at all times advised as to whether or not such water has been applied to beneficial uses.

41-3-323. Deeds for water rights; attaching of rights to land; sale, lease, transfer or use.

The reservoir water and rights acquired under reservoir permits and adjudications shall not attach to any particular lands except by deed, or other sufficient instrument conveying such water or water rights, executed by the owner or owners of such reservoir, and such water and water rights, except when attached to particular lands as aforesaid, may be sold, leased, transferred and used in such manner and upon such lands as the owner of such rights or partial rights may desire, provided, that such water must be used for beneficial purposes.

41-3-324. Deeds and leases for water rights; execution and recording.

All deeds for reservoir water and water rights and all leases of the same for periods of three (3) years or more shall be executed and acknowledged as deeds are executed, and shall be recorded in the

office of the county clerk of the county in which the reservoir is situated and also filed in the office of the state engineer. All leases of such water and water rights for a period less than three (3) years shall be in writing and filed in the office of the state engineer.

41-3-325. Excess stored water to be furnished applicants; preferences; rates.

The owner or owners of a reservoir impounding a greater quantity of water than the owner or owners thereof necessarily use for irrigation and other beneficial purposes in connection with their own lands shall, when application is made to them for that purpose, furnish such surplus water at reasonable rates to the owners of lands lying under and capable of being irrigated from such reservoir for the purpose of irrigating and rendering the same productive, and maintaining their productiveness, and in case of refusal so to do, the owner or owners of such reservoir may be compelled by proper proceedings to furnish such water on such reasonable terms as to the court may seem meet and proper. The water user who may have used any water from such reservoir for any particular year shall have the preference as to the use of the same water for the next ensuing year. The state engineer, the water commissioner of the particular district and the water superintendent having jurisdiction over the region of any reservoir, shall together constitute a board of special commissioners, and shall have power, when application is made to them by either party interested, to establish reasonable maximum rates to be charged for the use of water from any reservoir, whether furnished by individuals or a corporation. The establishment of such rate shall be made only after notice given and public hearing had, at which hearing the applicants may produce witnesses and evidence, and such witnesses must be sworn and may be cross-examined. No commissioner shall sit upon such board and determine such rate who is employed by one (1) of the applicants or if the relationship of debtor or creditor exists between him and one (1) of the applicants. Nothing contained in this section shall be construed to deny the right to store water for use for more than one (1) year.

41-3-326. Applicability of ownership provisions.

The provisions of this act shall apply to reservoirs heretofore lawfully constructed as well as to all reservoirs hereafter lawfully constructed.

41-3-327. Carey Act lands.

This act shall not apply to Carey Act lands or reservoirs for their

irrigation, nor to any water right or rights to the use of waters of natural streams of this state, initiated from such streams and used through any such reservoir. All acts and parts of acts in conflict herewith, excepting such as relate to Carey Act lands, are hereby repealed.

41-3-328. Witnesses' fees and mileage.

Every witness who shall attend before the court, or the judge thereof in vacation, or before the person appointed to take testimony in causes relating to water rights, under subpoena, by request of any party, shall be entitled to the same fees and mileage as witnesses in civil cases in the district court, and shall be paid by the party requiring the testimony.

41-3-329. Change in point of diversion.

(a) The storage of water by means of a reservoir is a diversion, and the point of diversion is the point defined in the permit where the longitudinal axis of the dam crosses the center of the streambed.

(b) A change in point of diversion of a reservoir may be granted pursuant to W.S. 41-3-114 by the state engineer if the water right is unadjudicated, or by the state board of control if the water right has been adjudicated. No petition shall be granted if the rights of other appropriators shall be injuriously affected thereby or if the change is not within the original project concept. In deciding whether to grant or deny a proposed change in point of diversion of a reservoir within the original project concept, the state engineer or the board of control shall consider:

(i) The distance between the old point of diversion and the new point of diversion;

(ii) The water administration problems which may be created by granting the change in the point of diversion;

(iii) The effect of the petition upon Wyoming's entitlement to water under compacts, court decrees and treaties;

(iv) The rights of other appropriators; and

(v) The safety aspects of the new point of diversion.

STATE DAM SAFETY SIZE CLASSIFICATION SCHEMES
Association of State Dam Safety Officials - www.damsafety.org
Compiled September 2010

	Very Large	Large	Intermediate	Small	Minor	Notes
AL						*Not defined; Alabama currently has no dam safety legislation or formal dam safety program. Source: Dam Safety Model Program Jurisdictional definition: Section 6. (a) The following low hazard potential dams are not required to be included in the inventory of dams maintained pursuant to this act: (1) Any dam which is less than six feet in height, regardless of its storage capacity. (2) Any dam which has an impounding storage capacity at maximum water storage elevation of less than 15 acre-feet, regardless of its height.
AK						Source: Dam Safety Model Program To determine if a dam is under state jurisdiction, AS 46.17.900(3) defines a dam as an "artificial barrier and its appurtenant works, which may impound or divert water" and which meets at least one of the following three descriptions "(A) Has or will have an impounding capacity at maximum water storage elevation of 50 ac-ft and is at least 10 ft in height measured from the lowest point at either the upstream or downstream toe of the dam to the crest of the dam." A dam with a jurisdictional height (H) of 10 feet or taller and that stores 50 acre-feet or more of water meets this description, as illustrated in figure 2-1. "(B) is at least 20 feet in height measured from the lowest point at either the upstream or downstream toe of the dam to the crest of the dam." A dam that is 20 ft or more in height meets this dexcription regardless of its storage capacity, as illustrated in figure 2-2. "(C) Poses a threat to lives and property as determined by the department after an inspection." In other words, a barrier with a Class I (high) or Class II (significant) hazard potential classification is considered a dam, even if it does not meet the geometric criteria of A or B, above. See section 2.4 for guidance in determining the hazard potential classification.
AZ	N/A	"Large Dam"- Maximum storage greater than or equal to 50,000 ac-ft; height greater than or equal to 100 ft.	"Intermediate Dam"- Maximum storage between 1,001 and 50,000 ac-ft; height between 41 and 100 ft.	"Small dam"- Maximum storage between 50 and 1,000 ac-ft; height between 25 and 40 ft.	N/A	Source:http://www.azwater.gov/AzDWR/SurfaceWater/DamSafety/HazardandSizeClassifications.htm Owner or engineer determines size by storage capacity or height, whichever results in the larger size.
AR	N/A	"Large Dam"- Maximum storage greater than or equal to 50,000 ac-ft; height greater than or equal to 100 ft.	"Intermediate Dam"- Maximum storage between 1,000 and 50,000 ac-ft; height between 40 and 100 ft.	"Small dam"- Maximum storage between 50 and 1,000 ac-ft; height between 25 and 40 ft. STATE DAM SAFETY SIZE CLASSIFICATION SCHEMES
Association of State Dam Safety Officials - www.damsafety.org
Compiled September 2010

CA						Source: Dam Safety Model Program “Dam means any artificial barrier, together with appurtenant works, which does or may impound or divert water, and which either a) os pr will be 25 feet or more in height from the natural bed of the stream or watercourse at the downstream toe of the barrier, as determined by the department, or from the lowest department, if it is not across a stream channel or watercourse, to the maximum possible water storage elevation or b) has or will have an impounding capacity of 50 acre-feet or more.” A chart indicating jurisdictional and non-jurisdictional dam and reservoir sizes can be found at http://www.water.ca.gov/damsafety/images/JurisChart5.jpg
CO	N/A	"Large Dam" is a dam greater than 50 feet in jurisdictional height, and/or greater than 4,000 acre-feet in capacity.	N/A	“Small Dam" is a dam with a jurisdictional height greater than 20 feet but less than or equal to 50 feet and/or a reservoir capacity greater than 100 acre-feet, but less than 4,000 acre-feet.	"Minor Dam" is a jurisdictional size dam that does not exceed 20 feet in jurisdictional height and/or 100 acre-feet in capacity.	Source: http://water.state.co.us/pubs/rule_reg/ds_rules07.pdf Rules and Regulations for Dam Safety and Dam Construction, Rule 4. Jurisdictional height is defined in Rule 4.2.19. The State Engineer shall have final authority over determination of the jurisdictional height of the dam.
CT						Not defined Source: Dam Safety Model Program Jurisdictional definition: Any barrier of any kind whatsoever capable of impounding or controlling the flow of water, including but not limited to storm water retention or detention dams, flood control structures, dikes, & incompletely breached dams.
DE						Not defined Source: Dam Safety Model Program Jurisdictional definition: "Dam" shall mean any artificial barrier, including appurtenant works, with the ability to impound or divert water, wastewater, or liquid-borne materials. No obstruction in a canal used to raise or lower water shall be considered a dam. A fill or structure for highway or railroad use, or for any other purpose that may impound water, may be subject to review by the Department and shall be considered a dam if the criteria in these Regulations are found applicable and if it is classified as a high hazard potential or significant hazard potential dam.
FL						Source: http://www.damsafety.org/map/state.aspx?s=9 A dam is "any artificial or natural barrier, with appurtenant works, raised to obstruct or impound, or which does obstruct or impound, any of the surface waters of the state." There was nothing is the legislation concerning height and volume definitions. Dam height is not defined in the laws. Dams are not classified by any type of criteria in the laws.

KY						Not defined Source: Dam Safety Model Program Jurisdictional definition: Kentucky statutes (KRS 150.100) defines a dam as any artificial barrier (including appurtenant works) which does, or can, impound or divert water and is, or will be 1) 25 feet or more high from the natural bed of the stream or watercourse at the downstream tow of the barrier, as determined by the Department for Environmental Protection, or 2) has, or will have an impounding capacity of fifty acre-feet or more at the maximum water storage elevation.
LA						Correlated with hazard classification Source: Dam Safety Model Program Jurisdictional definition: For the purposes of this Chapter, a dam is any artificial barrier, including appurtenant works, which does or will impound or divert water or any other liquid substance and which (1) is or will be twenty-five feet or more in height from the bed of the watercourse measured at the downstream toe of the barrier or from the lowest elevation of the outside limit of the barrier, if it is not across a stream channel or watercourse, to the maximum water storage elevation or (2) has or will have an impounding capacity at maximum water storage elevation of fifty acre-feet or more. This definition does not include any dam or barrier that is not or will not be in excess of six feet in height, regardless of storage capacity or which has or will have a storage capacity of maximum water storage elevation not in excess of fifteen acre-feet, regardless of height.
ME						Not listed Source: Dam Safety Model Program Jurisdictional definition: "Dam" means any artificial barrier, including appurtenant works, the site on which it is located and appurtenant rights of flowage and access, that impounds or diverts water, and that: A. Is 25 feet or more in height from the natural bed of the watercourse measured at the downstream toe of the barrier or from the lowest elevation of the outside limit of the barrier to the maximum water storage elevation and impounds at least 15 acre-feet of water; or [2001, c. 460, §3 (NEW).] B. Is 6 feet or more in height from the natural bed of the watercourse measured at the downstream toe of the barrier or from the lowest elevation of the outside limit of the barrier to the maximum water storage elevation and has an impounding capacity at maximum water storage elevation of 50 acre-feet or more. [2001, c. 460, §3 (NEW).]

		dam with a normal pool storage of 20,000 ac-ft or more, a normal vol. depth of 50 ft or more, probable loss of life, and potential for serious damage to residential, industrial, or commercial buildings, public roads, or RR.	dam with a normal pool storage greater than 1000 ac-ft and less than 20,000 ac-ft, a normal vol. depth greater than 25 ft and less than 50 ft, small possibility for loss of life, and located in predominately rural or agricultural areas where failure may cause damage to isolated residence or cause interruption of use or service of public utilities or roads. Damage is within financial capability of owner to repair.	a dam with a normal pool storage less than 1000 ac-ft, a normal vol. depth less than 25 ft, and potential loss of life is very unlikely. Damage is of same magnitude as cost of dam and within financial capability of owner to repair.		
MA	N/A	"Large Dam"- 1000 ac-ft of storage or greater; height greater than or equal to 40 ft.	"Intermediate Dam"- Storage of at least 50 ac-ft, but not exceeding 1000 ac-ft; height of at least 15 ft but not greater than 40 ft.	"Small Dam"- Storage of at least 15 ac-ft but not exceeding 50 ac-ft; height of at least 6 ft but not greater than 15 ft.	"Non-jurisdictional Dam"- Storage not in excess of 15 ac-ft regardless of height; height not in excess of 6 ft, regardless of storage capacity.	Source:http://www.mass.gov/dcr/pe/damSafety/downloads/DCR%20Dam%20Safety%20Regulations.pdf For dams not in excess of 25 feet in height or having maximum impounding capacity not in excess of 50 acre-feet, the Commissioner shall make jurisdictional determination by taking into consideration factors or combination of factors such as height, type of structure, volume of the impoundment, extent of downstream development, and other factors deemed appropriate by the Commissioner.
MI						Not defined Source: Dam Safety Model Program Jurisdictional definition: Dams are regulated by Part 315 when they are over 6 feet in height and over 5 acres are impounded during the design flood. Dams are regulated by Part 307 when a circuit court issues an order establishing the level at which the lake is to be maintained.
MN						Source: Dam Safety Model Program

STATE DAM SAFETY SIZE CLASSIFICATION SCHEMES
Association of State Dam Safety Officials - www.damsafety.org
Compiled September 2010

						Jurisdictional definition: State dam safety regulations apply only to structures that pose a potential threat to public safety or property. The potential for damage downstream if a dam fails increases as the height of the dam and the volume of impounded water increases. State dam safety rules do not apply to dams that are so low or retain so little water as to not pose a threat to public safety or property. Dams 6 feet high or less, regardless of the quantity of water they impound, and dams that impound 15 acre-feet of water or less, regardless of their height, are exempt from state dam safety rules. Dams that are less than 25 feet high and impound less than 50 acre-feet are also exempt from state dam safety rules unless there is a potential for loss of life due to failure or misoperation. Figure 1 shows these criteria in a graphical form.  About 900 dams in Minnesota are subject to dam safety regulations.
MS		Large dams are greater than 50 feet in height. and Large lakes are greater than 1,000 acre-feet maximum storage.	Medium dams are greater than 25 feet and less than 50 feet in height. Medium lakes are greater than 150 acre-feet maximum storage and less than 1,000 acre-feet maximum storage.	Small dams are those less than 25 feet in height. Small lakes are less than 150 acre-feet maximum storage.		Source: MS DEQ, Sept. 2010 Size classification found in design guidelines. Requirements depend on hazard classification (Low, Significant or High), the dam height (Small dams are those less than 25 feet in height, Medium dams are greater than 25 feet and less than 50 feet in height and Large dams are greater than 50 feet in height), and the storage volume (Small lakes are less than 150 acre-feet maximum storage, Medium lakes are greater than 150 acre-feet maximum storage and less than 1,000 acre-feet maximum storage and Large lakes are greater than 1,000 acre-feet maximum storage). Size and hazard classifications shown dictate requirements for plans and engineering reports. Jurisdictional definition: Dam—Any artificial barrier, including appurtenant works, constructed to impound or divert water, waste-water, liquid borne materials, or solids that may flow if saturated. All structures necessary to maintain the water level in an impoundment or to divert a stream from its course will be considered one dam.

STATE DAM SAFETY SIZE CLASSIFICATION SCHEMES
Association of State Dam Safety Officials - www.damsafety.org
Compiled September 2010

NV	N/A	"Large Dam" - has an embankment height greater than 50 feet or a reservoir capacity greater than 10,000 acre-feet.	"Medium Dam" is any dam that is neither small nor large.	"Small Dam" has an embankment less than 20 feet in height and reservoir capacity less than 100 acre-feet.	N/A	Source: http://water.nv.gov/Engineering/Dams/dam_size.cfm ; **Please note** that if an embankment height dictates one size dam and the reservoir capacity dictates a different size dam, the larger of the two designations shall apply, e.g. a dam that has an embankment height of 2 feet and a reservoir capacity of 9,000 acre-feet shall be designated a medium size dam.
NH	N/A	"Class C Structure" means a dam that has a high hazard potential because it is in a location and of a size that failure or misoperation of the dam would result in probable loss of human life as a result of: (a) Water levels and velocities causing the structural failure of a foundation of a habitable residential structure or a commercial or industrial structure which is occupied under normal conditions; (b) Water levels rising above the first floor elevation of a habitable residential structure or a commercial or industrial	"Class B structure" means a dam that has a significant hazard potential because it is in a location and of a size that failure or misoperation of the dam would result in any of the following: (a) No probable loss of life; (b) Major economic loss to structures or property; (c) Structural damage to a Class I or II road which could render the road impassable or otherwise interrupt public safety services; (d) Major environmental or public health losses, including: (1) Damage to a public water system, as defined by RSA	"Class A structure" means a dam that has a low hazard potential because it is in a location and of a size that failure or misoperation of the dam would result in any of the following: (a) No probable loss of life; (b) Low economic loss to structures or property; (c) Structural damage to a town or city road or private road accessing property other than the dam owner's which could render the road impassable or otherwise interrupt public safety services; (d) The release of liquid industrial, agricultural, or commercial wastes, septage,	"Class AA structure" means a dam that is not a menace because it is in a location and of a size that failure or misoperation of the dam would not result in probable loss of life or loss to property, provided the dam is: (a) Less than 6 feet in height if it has a storage capacity greater than 50 acre-feet; or (b) Less than 25 feet in height if it has a storage capacity of 15 to 50 acre-feet.	Source: Dam Safety Model Program; http://www.damsafety.org/map/state.aspx?s=29 Hazard classification included with size classifications. Jurisdictional definition: RSA chapter 482 defines the term *dam* as "(a) any artificial barrier, including appurtenant works, which impounds or diverts water, and which has a height of 4 feet or more, or a storage capacity of 2 acre-feet or more, or is located at the outlet of a great pond. A roadway culvert shall not be considered a dam if its invert is at the natural bed of the water course, it has adequate discharge capacity, and it does not impound water under normal circumstances. Artificial barriers which create surface impoundments for liquid industrial or liquid commercial wastes, septage or sewage, regardless of height or storage capacity, shall be considered dams. (b) An artificial barrier at a storm water detention basin, which impounds 0.5 acre-feet or less of water during normal conditions, shall not be considered a dam unless its height is 10 feet or greater or its maximum storage is 6 acre-feet or greater." Part ENV-WR 101 of the Administrative Code (regulations) contains definitions for the terms *great pond*, which is a "water body of more than 10 acres in its natural condition", and *height of dam*, which means the "vertical distance from the lowest point of natural ground on the downstream side of the dam to the highest part of the dam which would impound water". Part ENV-WR 301 further defines "a roadway embankment whose culvert is set at the natural streambed shall be considered a dam if during the 25 year storm; (1) the water surface elevation at the culvert inlet is 6 feet or more above the water surface elevation at the culvert outlet; and (2) it impounds 2 acre-feet or more of water over the crown, or top of the culvert." RSA Chapter 482 lists the classifications of dams as "non-menace", "low hazard potential", "significant hazard potential", or "high hazard potential". The determination of hazard classification of structures is based on the potential threat to life and extent of property damage, and is further explained in part ENV-WR 101 of the regulations.

		structure which is occupied under normal conditions when the rise due to dam failure is greater than one foot; (c) Structural damage to an interstate highway which could render the roadway impassable or otherwise interrupt public safety services; (d) The release of a quantity and concentration of materials which qualify as "hazardous waste" as defined by RSA 471-A:2 VI; or (e) Any other circumstance which would more likely than not cause one or more deaths.	485:1-a, XV, which will take longer than 48 hours to repair; or (2) The release of liquid industrial, agricultural, or commercial wastes, septage, sewage, or contaminated sediments if the storage capacity is 2 acre-feet or more; or (3) Damage to an environmentally-sensitive site that does not meet the definition of reversible environmental losses.	or contaminated sediment if the storage capacity is less than 2 acre-feet and is located more than 250 feet from a water body or water course; or (e) Reversible environmental losses to environmentally-sensitive sites.		
NJ		"Large dams": Dams that raise the waters of any stream more than 70 feet above its usual mean low water height or which impound more than 10,000 acre feet of water.			A "Class IV" dam is any project which impounds less than 15 ac-ft of water to the top of the dam, and has less than 15 feet height-of-dam (as measured to the top of the dam) and which ahs a drainage area above the	Source: http://www.state.nj.us/dep/damsafety/standard.pdf ; http://www.state.nj.us/dep/damsafety/dampres1/index.htm Jurisdictional definition: "Dam" means any artificial dike, levee or other barrier, together with appurtenant works, which is constructed for the purpose of impounding water on a permanent or temporary basis, that raises the water level five feet or more above the usual, mean, low water height when measured from the downstream toe-of-dam to the emergency spillway crest or, in the absence of an emergency spillway, the top-of dam.

		50,000 ac-ft or greater; height of 100 ft or greater.	1,000 and 49,999 ac-ft; height between 50 and 99 ft.	30 and 99 ac-ft; height between 20 and 49 ft.		the maximum water storage elevation measured from the natural bed of the stream or watercourse at the downstream toe of the barrier, or if it is not across a stream or watercourse, the height from the lowest elevation of the outside limit of the barrier, to the maximum water storage elevation. For the purpose of determining project size, the maximum storage elevation will be considered equal to the top of dam elevation as defined in Rule 1200-5-7-.02(26). Size classification will be determined by either storage or height, whichever gives the larger size category. For size classification purposes, fractions of heights and storages shall be rounded down to the nearest whole number, e.g., 49.9 feet would be classified in the 20 to 49 feet category.
TX	N/A	A “large dam” will have an impoundment storage equal to or greater than 50,000 ac-ft; height equal to or greater than 100 ft.	An “intermediate dam” will have an impoundment storage equal to or greater than 1,000 ac-ft and less than 50,000 ac-ft; height equal to or greater than 40 ft and less than 100 ft.	A “small dam” will have an impoundment storage equal to or greater than 50 ac-ft and less than 1,000 ac-ft; height greater than 6 ft and less than 40 ft OR an impoundment storage equal to or greater than 15 ac-ft and less than 1,000 ac-ft; height equal to or greater than 25 ft and less than 40 ft.	N/A	Source: http://www.tceq.state.tx.us/assets/public/legal/rules/rules/pdflib/299b.pdf The executive director shall classify dams for size based on the larger of the height of the dam or the maximum storage capacity.
UT						Not defined Source: Dam Safety Model Program Jurisdictional definition: DAM is any artificial barrier or obstruction, together with appurtenant works, if any, which impounds or diverts water.
VT	N/A	A “large dam” will have a storage of 50,000 ac-ft or greater; height of 100 ft or greater.	A “medium dam” will have a storage equal to or greater than 1,000 ac-ft and less than 50,000 ac-ft; height equal to or greater than 40 ft and less than 100 ft.	A “small dam” will have a storage less than 1,000 ac-ft; height less than 40 ft.	N/A	Source: http://psb.vermont.gov/sites/psb/files/rules/OfficialAdoptedRules/4500_Dam_Safety.pdf (4.500 Safety of Hydroelectric Dams,1990) 4.510 Dams shall be categorized by size. The size category shall be determined by height or storage, whichever gives the larger size category. The height of a dam and its storage shall both be established with respect to its maximum storage potential, measured from the natural bed of the water course to the maximum water storage elevation. For the purpose of determining size category, the maximum water storage elevation shall be considered to be the height above streambed as defined in section 4.521(B).

		impounding structure" will have an impounding capacity greater than or equal to 50,000 ac-ft; height greater than or equal to 100 ft.	impounding structure" will have an impounding capacity greater than or equal to 1,000 ac-ft and less than 50,000 ac-ft; height greater than or equal to 40 ft and less than 100 ft.	impounding structure" will have an impounding capacity greater than or equal to 15 ac-ft, and less than 1,000 ac-ft; height greater than or equal to 6 ft and less than 40 ft.		For the purposes of categorizing and reporting information to national and other dam safety databases, impounding structure size shall be classified as noted.
WA	N/A	A "large dam" is 50 ft or greater in height.	An "intermediate dam" is 15 ft or greater but less than 50 ft.	A "small dam" is less than 15 ft.	N/A	Source: http://www.ecy.wa.gov/pubs/9255b.pdf The size classification and reservoir operation classification of the proposed project should be listed as defined by Tables 2 and 3. These classifications are used throughout *Part IV of the Dam Safety Guidelines* for determining the degree of conservatism of design, and the sophistication of the methodologies to be used in analyses.
WV						Not defined Source: Dam Safety Model Program Jurisdictional definition: *"Dam" means an artificial barrier or obstruction --including any works appurtenant to it and any reservoir created by it -- which is or will be placed, constructed, enlarged, altered, or repaired so that it does or will impound or divert water and is or will be twenty-five (25) feet or more in height from the natural bed of a stream or watercourse measured at the downstream toe of the barrier and which does or can impound fifteen (15) acre-feet or more of water or is or will be six (6) feet or more in height from the natural bed of such stream or watercourse measured at the downstream toe of the barrier and which does or can impound fifty (50) acre-feet or more of water. (List is given of items that are NOT dams as well) The "**coal related** dam safety" rule is as follows: "Dam" means an artificial barrier or obstruction including works appurtenant to it and be placed, constructed, enlarged, altered or repaired so that it does or will impound or divert water and is or will be twenty-five (25) feet or more in height from the natural bed of a stream or watercourse measured at the downstream toe of the barrier and which does or can impound fifteen (15) acre-feet or more of water or is or will be six (6) feet or more in height from the natural bed of such stream or watercourse measured at the downstream toe of the barrier and which does or can impound fifty (50) acre-feet or more of water.
WI		A dam is considered to be a "large dam" if either of the following applies:				Source: http://www.legis.state.wi.us/statutes/Stat0031.pdf ; http://www.damsafety.org/media/Documents/PDF/WI.pdf Jurisdictional definition: Dam is defined in Chapters NR 333 as "any artificial barrier, together with appurtenant works, built across a waterway that has the primary purpose of impounding or diverting water". Jurisdiction for the dam inspection program described in Chapter NR 333 is established by defining large dams as those with 1) a structural

		(a) It has a structural height of 25 feet or more and impounds more than 15 acre−feet of water. (b) It has a structural height of more than 6 feet and impounds 50 acre−feet or more of water.				height of 25 feet or more and that can impound more than 15 acre-feet of water or, 2) structural height of more than 6 feet and that can impound more than 50 acre feet of water. Source: Dam Safety Model Program All large dams in the state, except those owned by the US Government or inspected, approved and licensed by a federal agency, are under Department of Natural Resources jurisdiction and must conform to Chapter NR 333 "Dam Design and Construction Standards".
WY						Source: http://www.damsafety.org/media/Documents/PDF/WY.pdf Jurisdictional definition: Section 41-3-307 of the statutes defines the term dam as any artificial barrier, including appurtenant works, used to impound or divert water and which is or will be greater than twenty (20) feet in height or with an impounding capacity of fifty (50) acre-feet or greater. Dams less than 15 acre-feet in capacity or 6 feet or less in height are excluded. No system of dam classification is provided for in either the laws or the regulations.

F.2. Hazard Classification Schemes

STATE DAM SAFETY HAZARD POTENTIAL CLASSIFICATION
Association of State Dam Safety Officials - www.damsafety.org
Compiled September 2010

	Extreme	High	Significant	Low	Very Low	Citation/ Notes
AL	NA	High-Hazard Potential	Moderate-Hazard Potential	Low-Hazard Potential	NA	Source: Alabama Dam Inventory and Classification Act, Section 5 (a). The office may gather necessary updated information regarding the characteristics of a dam and its surroundings in order to verify classification. The office may use information furnished to it by other persons to accomplish the purpose of this act and this section including, but not limited to, the classification of dams as set forth in subsection (a).
AK	NA	Class I (high) hazard potential classification, if the department determines that the failure or improper operation of the barrier will result in probable loss of human life.	Class II (significant) hazard potential classification, if the department determines that the failure or improper operation of the barrier will result in(A) a significant danger to public health; (B) the probable loss of or probable significant damage to homes, occupied structures, commercial property, high-value property, major highways, primary roads, railroads, or public utilities, other than losses described in (3)(B) of this subsection; (C) other probable significant property losses or damage, other than losses described in (3)(B) of this subsection; or (D) probable loss of or significant damage to waters identified under 5 AAC 95.011(a) as important for the spawning, rearing, or migration of anadromous fis	Class III (low) hazard potential classification if the department determines that the failure or improper operation of the barrier will result in (A) limited impacts to rural or undeveloped land, rural or secondary roads, and structures; (B) property losses or damage limited to the owner of the barrier; or (C) insignificant danger to public health.	NA	Source: 11 AAC 93.157. Hazard classification
AZ	NA	High Hazard Potential. Failure or improper operation of a dam would be likely to cause loss of human life because of residential, commercial, or industrial development. Intangible losses may	Significant Hazard Potential. Failure or improper operation of a dam would be unlikely to result in loss of human life but may cause significant or high economic loss, intangible damage requiring major mitigation, and disruption or impact on lifeline facilities.	Low Hazard Potential. Failure or improper operation of a dam would be unlikely to result in loss of human life, but would produce low economic and intangible losses, and result in no disruption of	Very Low Hazard Potential. Failure or improper operation of a dam would be unlikely to result in loss of human life and would produce no lifeline losses and very low economic and intangible losses. Losses	Source: AZ DWR, Sept. 2010 Hazard classification based on evaluation of probable present & future incremental adverse consequences of failure or improper operation of the dam or appurtenances regardless of the condition of the dam or appurtenances. Evaluation includes land use zoning & projected development over 10 years following classification. All of the following are considered: probable loss of human life, economic/ lifeline losses, & intangible losses identified & evaluated by a public resource management or protection agency. -Probable incremental loss of human life determined primarily on the number of permanent structures for human

STATE DAM SAFETY HAZARD POTENTIAL CLASSIFICATION
Association of State Dam Safety Officials - www.damsafety.org
Compiled September 2010

		be major and potentially impossible to mitigate, critical lifeline services may be significantly disrupted, and property losses may be extensive. (Loss of human life is probable, with one or more expected. Economic, lifeline & intangible losses can range from low to high; they are not necessary for this classification.)	Property losses would occur in a predominantly rural or agricultural area with a transient population but significant infrastructure.	lifeline services that require more than cosmetic repair. Property losses would be limited to rural or agricultural property, including equipment, and isolated buildings.	would be limited to the 100 year floodplain or property owned or controlled by the dam owner under long-term lease. The Department considers loss of life unlikely because there are no residences or overnight camp sites.	habitation impacted in the event of failure or improper operation of a dam. Loss of human life considered unlikely if: Persons are only temporarily in the potential inundation area; There are no residences or overnight campsites; & the owner has control of access to the potential inundation area & provides an EAP with a process for warning in the event of failure or improper operation. -Probable economic, lifeline & intangible loss determined by property losses, interruptions of services, & intangible losses likely to result from failure or improper operation of a dam. -Hazard class evaluated during each inspection & revised in accordance with current conditions.
AR	NA	Loss of human life expected. Excessive economic loss (extensive public, industrial, commercial, or agricultural development); over $500,000	No loss of life expected. Appreciable economic loss (significant structures, industrial, or commercial development, or cropland); $100,000 to $500,000	No loss of life expected. Minimal economic loss (No significant structures, pastures, woodland, or largely undeveloped land); less than $100,000	NA	Section 705.4. All dams will be classified or reclassified as required to assure appropriate safety considerations. Hazard classification shall be based on the more stringent of either potential loss of human life or economic loss. If doubt exists concerning classification, the more hazardous category must be selected. Loss of human life is based on presence of habitable structures.
CA	Extreme	High	Moderate	Low	NA	Dams are classified as to damage potential (hazard) and condition. This classification is used to determine frequency of inspection and for selection of the return period for hydrology studies. A weighted point system is used to divide the damage potential into four classifications: extreme, high, moderate, and low. Reservoir capacity, dam height, estimated evacuation and potential damage are the factors used to classify the damage potential. A similar point system is used to classify the condition of the dam as: poor, fair, good, and excellent. Age, general condition, geologic, and seismic setting are the factors evaluated to classify the condition of the dam. Hazard classification is reevaluated when development occurs downstream and when the condition of the dam changes, either by identifying deficiencies or when alteration/repair work is completed.
CO	NA	High Hazard - Loss of human life is expected to result from failure of the dam. Designated recreational sites located downstream within the bounds of possible inundation	Significant Hazard - Significant damage is expected to occur, but no loss of human life is expected from failure of the dam. Significant damage is defined as damage to structures where people generally live, work, or	Low Hazard - Loss of human life is not expected, and significant damage to structures and public facilities as defined for a "Significant Hazard" dam is not expected to	No Public Hazard (NPH) - A dam for which no loss of human life is expected, and which damage only to the dam owner's property will result from failure of the dam.	Rule 5.4. Hazard potential is derived from an evaluation of the probable incremental adverse consequences due to failure or improper operation of the dam. Conditions for evaluation are absent flooding, and the reservoir is assumed to be full to the high water line. Classification does not reflect the current condition of the dam with regard to safety, structural integrity, or flood routing capacity. The Hazard Classification evaluation method must be approved by the State Engineer.

STATE DAM SAFETY HAZARD POTENTIAL CLASSIFICATION

Compiled September 2010

		should also be evaluated for potential loss of human life.	recreate, or public or private facilities. Significant damage is determined to be damage sufficient to render structures or facilities uninhabitable or inoperable.	result from failure of the dam.		
CT	Class C - A high hazard potential dam which, if it were to fail, would result in any of the following: (i) probable loss of life; (ii) major damage to habitable structures, residences, hospitals, convalescent homes, schools, etc.; (iii) damage to main highways (greater than 1500 ADT); or(iv) great economic loss.	Class B - A significant hazard potential dam which, if it wee to fail, would result in any of the following: (i) possible loss of life; (ii) minor damage to habitable structures, residences, hospitals, convalescent homes, schools, etc.; (iii) damage to or interruption of the use of service of utilities; (iv) damage to primary roadways (less than 1500 ADT) and railroads; or (v) significant economic loss.	Class BB - A moderate hazard potential dam which, if it were to fail, would result in any of the following: (i) damage to normally unoccupied storage structures; (ii) damage to low volume roadways (less than 500 ADT); or (iii) moderate economic loss.	Class A - A low hazard potential dam which, if it were to fail, would result in any of the following: (i) damage to agricultural land; (ii) damage to unimproved roadways (less than 100 ADT); (iii) minimal economic loss.	Class AA - A negligible hazard potential dam which, if it were to fail, would result in the following: (i) no measurable damage to roadways; (ii) no measurable damage to land and structures; and (iii) negligible economic loss.	The Commissioner shall assign each dam to one of five classes according to its hazard potential. Such classification shall be determined by the Commissioner during the initial periodic inspection. Source: Guidelines for Inspection and Maintenance of Dams
DE	NA	Class I - "High Hazard Potential Dam" shall mean any dam whose failure or misoperation will cause probable loss of human life.	"Significant Hazard Potential Dam " shall mean any dam whose failure or mis-operation will cause possible loss of life, economic loss, environmental damage, disruption of lifeline facilities, or can impact other concerns.	"Low-hazard potential dam" means any dam whose failure or misoperation is unlikely to cause loss of human life but may cause minor economic and/or environmental losses.	NA	
FL	NA	Direct loss of life: Certain (one or more extensive residential, commercial or industrial development) Lifeline losses: Disruption of critical facilities and access Property Losses:	Direct loss of life: Uncertain (rural location with few residences & only transient or industrial development) Lifeline losses: Disruption of essential services & access Property Losses: Major public and private facilities Environmental losses: Major	Direct loss of life: None expected (due to rural location with no permanent structures for human habitation) Lifeline losses: No disruption of services Property Losses: Private agricultural lands,	NA	Source: Design Criteria Memorandum: DCM-1 and “Final Hazard Potential Memorandum” by URS (August 2007)

		Extensive public and private facilities Environmental losses: Extensive mitigation cost or impossible to mitigate	mitigation required	equipment, & isolated buildings Environmental losses: Minimal incremental damage		
GA	NA	Category I – Improper operation or dam failure would result in probable loss of human life. Situations constituting 'probable loss of life' are those situations involving frequently occupied structures or facilities, including but not limited to, residences, commercial and manufacturing facilities, schools, and churches."	NA	Category II - Improper operation or dam failure would not be expected to result in probable loss of human life."	NA	391-3-8-.03 When an existing Category II dam may be reclassified to a Category I dam because of proposed development, the governing authority issuing the permit for the development shall provide for review by the Safe Dams Programs: (a) location of the Category II dam and the proposed development; (b) a surveyed cross-section of the stream valley at the proposed development location, including proposed finished floor elevations; (c) a dam breach analysis to establish the height of the flood wave in the floodplain. If reclassification is deemed appropriate, the owner of the existing Category II dam may request an inspection from the Director within 10 days of notification of the proposed development. Detailed surveys, hydrologic and hydraulic analyses will not be performed, but the Director may provide an opinion on the hydraulic adequacy of the dam. A written evaluation of the existing Category II dam's compliance with Category I requirements will be provided to the owner of the dam and the local governing authority based on preliminary visual inspection by the Safe Dams Program.
HI	NA	High Hazard: Loss of life: Probable, one or more expected Economic/ Environmental Losses: Yes, but not necessary for this classification	Significant: Loss of life: None expected Economic/ Environmental Losses: Yes	Low: Loss of life: None expected Economic/ Environmental Losses: Low and generally limited to owner property	NA	Rules S.13-190-2
ID	NA	High-Hazard Dams: Catastrophic failure and sudden release of water likely would result in direct loss of human life.	Significant Hazard Dams: Failure would cause significant economic damage to existing infrastructure, or may contribute to the indirect loss of life.	Low Hazard Dams: No permanent habitable structures within inundation zone; failure would cause only minor damage to infrastructure, with low probability for loss of life.	NA	Provided by ID Program, 9/3/2010.
IL	NA	Class I - Failure has a high probability of causing loss of life or substantial economic loss, similar to that of	Class II - Failure has a moderate probability for causing loss of life or substantial economic loss, similar to USACE Significant	Class III - failure has a low probability for causing loss of life or substantial economic loss, similar to USACE	NA

Compiled September 2010

		properties, major public utilities, or serious direct or indirect economic loss	limited direct or indirect economic loss to the public other than that described in Class III	are an essential part of the rural transportation system serving the area involved		
MS	NA	High Hazard–A class of dam in which failure may cause loss of life, serious damage to residential, industrial, or commercial buildings; or damage to, or disruption of, important public utilities or transportation facilities such as major highways or railroads. Dams which meet the statutory thresholds for regulation that are proposed for construction in established or proposed residential, commercial, or industrial areas will be assigned this classification, unless the applicant provides convincing evidence to the contrary.	Significant Hazard—A class of dam in which failure poses no threat to life, but may cause significant damage to main roads, minor railroads, or cause interruption of use or service of public utilities.	Low Hazard—A class of dam in which failure would at the most result in damage to agricultural land, farm buildings (excluding residences), or minor roads.	NA	
MO	NA	Class 1 – Downstream of the dam contains at least 10 or more permanent dwellings or any public building.	Class 2 – Downstream of the dam contains 1 to 9 public dwellings or 1 or more campgrounds with permanent water, sewer and electrical services or 1 or more industrial building.	Class 3 – No lives, campgrounds, public dwellings, public buildings or industrial buildings are threatened from a dam failure.	NA	
MT	Dams in Series - (1) The worst case scenario shall govern for determining the hazard classification of	High-hazard - Impoundment capacity is 50 acre-feet or larger and loss of human life is likely to occur within the breach flooded area as a result of failure of	NA	NA	NA	(History: Sec. 85-15-110 , MCA; IMP , Sec. 85-15-209 , MCA; NEW , 1988 MAR p. 2489, Eff. 11/24/88.)

	dams in series where more than one mode of failure is possible among the dams. Classification shall be based on potential for failure under combined and, if applicable, individual dam breach scenarios. (2) If an upstream dam has the capability to create failure in a downstream high-hazard dam because of its failure flood wave, the upstream dam must be classified as a high-hazard dam. (3) If the failure flood wave of the upstream dam will cause failure of the downstream dam, and the combined flows will likely cause a loss of life, the upstream dam must be classified as a high-hazard dam.	the dam. The breach flooded area, for the purpose of this classification only, is the flooded area caused by a breach of the dam with the reservoir full to the crest of the emergency spillway. The evaluation of the effects of flood inundation, for the purpose of classification, will continue downstream until the flood stage is equal to that of the 100-year floodplain. The breach flow hydrograph and downstream routing of the breach flows, for the purpose of classification, will be estimated by the department either by visual determination or dam breach modeling techniques. Loss of life is assumed to occur if the following structures are present or planned for as a matter of public record or notice in the breach flooded area: occupied houses and farm buildings, stores, gas stations, parks, golf courses, stadiums, ball parks, interstate, principal, and other paved highways, and including railroads, highway rest areas, RV areas, developed campgrounds; and excluding unpaved

		county roads and all private roads.				
NE	NA	High hazard - Failure or misoperation of the dam resulting in loss of human life is probable.	Significant hazard - Failure or misoperation of the dam would result in no probable loss of human life but could result in major economic loss, environmental damage, or disruption of lifeline facilities.	Low hazard potential - Failure or misoperation of the dam would result in no probable loss of human life and in low economic loss.	NA	Laws 2005, LB 335, § 19, § 32, § 21. Effective Sept 4, 2005. ~ Revised Statutes Supplement 2005, Sections 46-1632, 46-1621
NV	NA	High hazard – when there is reasonable potential for loss of life and/or extreme economic loss.	Significant hazard designation is assigned to a dam if there is a low potential for loss of life but an appreciable economic loss.	Low hazard designation is assigned to a dam if there is a vanishingly small potential for loss of life and the economic loss is minor or confined entirely to the dam owner's own property.	NA	http://water.nv.gov/Engineering/Dams/hazard_designations.cfm NAC 535.140
NH		"**Class C Structure**" means a dam that has a high hazard potential because it is in a location and of a size that failure or misoperation of the dam would result in probable loss of human life as a result of: (a) Water levels and velocities causing the structural failure of a foundation of a habitable residential structure or a commercial or industrial structure which is occupied under normal conditions; (b) Water levels rising above the first floor elevation of a habitable residential structure or a commercial or industrial structure which is occupied	"**Class B structure**" means a dam that has a significant hazard potential because it is in a location and of a size that failure or misoperation of the dam would result in any of the following: (a) No probable loss of life; (b) Major economic loss to structures or property; (c) Structural damage to a Class I or II road which could render the road impassable or otherwise interrupt public safety services; (d) Major environmental or public health losses, including: (1) Damage to a public water system, as defined by RSA 485:1-a, XV, which will take longer than 48 hours to repair; or (2) The release of liquid industrial, agricultural, or	"**Class A structure**" means a dam that has a low hazard potential because it is in a location and of a size that failure or misoperation of the dam would result in any of the following: (a) No probable loss of life; (b) Low economic loss to structures or property; (c) Structural damage to a town or city road or private road accessing property other than the dam owner's which could render the road impassable or otherwise interrupt public safety services; (d) The release of liquid industrial, agricultural, or commercial wastes, septage, or contaminated sediment	"**Class AA structure**" means a dam that is not a menace because it is in a location and of a size that failure or misoperation of the dam would not result in probable loss of life or loss to property, provided the dam is: (a) Less than 6 feet in height if it has a storage capacity greater than 50 acre-feet; or (b) Less than 25 feet in height if it has a storage capacity of 15 to 50 acre-feet.	NHCAR, Env-Wr 100-800

STATE DAM SAFETY HAZARD POTENTIAL CLASSIFICATION
Association of State Dam Safety Officials - www.damsafety.org
Compiled September 2010

		under normal conditions when the rise due to dam failure is greater than one foot; (c) Structural damage to an interstate highway which could render the roadway impassable or otherwise interrupt public safety services; (d) The release of a quantity and concentration of materials which qualify as “hazardous waste” as defined by RSA 471-A:2 VI; or (e) Any other circumstance which would more likely than not cause one or more deaths	commercial wastes, septage, sewage, or contaminated sediments if the storage capacity is 2 acre-feet or more; or (3) Damage to an environmentally-sensitive site that does not meet the definition of reversible environmental losses.	if the storage capacity is less than 2 acre-feet and is located more than 250 feet from a water body or water course; or (e) Reversible environmental losses to environmentally-sensitive sites.		
NJ	NA	Class I - High Hazard Potential - Dams, the failure of which may cause probable loss of life or extensive property damage.	Class II - Significant Hazard Potential - Dams, the failure of which may cause significant damage to property and project operation, but loss of human life is not envisioned..	Class III - Low Hazard Potential - Dams, the failure of which would cause loss of the dam itself but little or no additional damage to other property.	Class IV - Small Dams - Any project which impounds less than 15 acre-feet of water, is less than 15 feet in height, and has a drainage area above the dam of less than 150 acres.	N.J.A.C. 7:20-1.8.
NM	NA	High hazard potential: Dams where failure or misoperation will probably cause loss of human life.	Significant hazard potential: Dams where failure or misoperation results in no probable loss of human life but can cause economic loss, environmental damage, disruption of lifeline facilities, or can impact other concerns. Significant hazard potential classification dams are often located in predominantly rural or agricultural areas but could be located in populated areas with significant infrastructure.	Low hazard potential: Dams where failure or misoperation results in no probable loss of life and low economic or environmental losses. Losses are principally limited to the dam owner’s property.	NA	[19.25.12.10 NMAC - N, 3/31/2005] Rating is based on loss of life, damage to property and environmental damage that is likely to occur in the event of dam failure. No allowances for evacuation or other emergency actions by the population should be considered.

STATE DAM SAFETY HAZARD POTENTIAL CLASSIFICATION
Association of State Dam Safety Officials - www.damsafety.org
Compiled September 2010

NY	NA	Class "C" or "High Hazard" dam: A dam failure may result in widespread or serious damage to home(s); damage to main highways, industrial or commercial buildings, railroads, and/or important utilities, including water supply, sewage treatment, fuel, power, cable or telephone infrastructure; or substantial environmental damage; such that the loss of human life or widespread substantial economic loss is likely.	Class "B" or "Intermediate Hazard" dam: A dam failure may result in damage to isolated homes, main highways, and minor railroads; may result in the interruption of important utilities, including water supply, sewage treatment, fuel, power, cable or telephone infrastructure; and/or is otherwise likely to pose the threat of personal injury and/or substantial economic loss or substantial environmental damage. Loss of human life is not expected.	Class "A" or "Low Hazard" dam: A dam failure is unlikely to result in damage to anything more than isolated or unoccupied buildings, undeveloped lands, minor roads such as town or county roads; is unlikely to result in the interruption of important utilities, including water supply, sewage treatment, fuel, power, cable or telephone infrastructure; and/or is otherwise unlikely to pose the threat of personal injury, substantial economic loss or substantial environmental damage.	NA	Source: NY DEC, Sept. 2010 673.5 Hazard Classifications (2009) Revises language related to the hazard classifications that may be assigned to a dam, and the factors that the Department may consider in assigning a hazard classification, for clarity. Requires that the Department must notify a dam owner when it changes the hazard classification, and that the Department will make available a list of dams and the hazard classifications assigned to them. Provides a process for appealing a hazard classification. Also includes Class "D" or "Negligible or No Hazard" dam: A dam that has been breached or removed, or has failed or otherwise no longer materially impounds waters, or a dam that was planned but never constructed. Class "D" dams are considered to be defunct dams posing negligible or no hazard. The department may retain pertinent records regarding such dams.
NC	NA	Class C – High-hazard: Dams located where failure will likely cause loss of life or serious damage to homes, industrial and commercial buildings, important public utilities, primary highways, or major railroads.	Class B – Intermediate-hazard: Dams located where failure may damage highways or secondary railroads, cause interruption of use or service of public utilities, cause minor damage to isolated homes, or cause minor damage to commercial and industrial buildings. Damage to these structures will be considered minor only when they are located in back water areas not subjected to the direct path of the breach flood wave; and they will experience no more than 1.5 feet of flood rise due to breaching above the lowest ground elevation adjacent to the outside foundation walls or no more than 1.5 feet of flood rise due to breaching above the	Class A – Low-hazard: Dams located where failure may damage uninhabited low value non residential buildings, agricultural land, or low volume roads.	NA	Rule .0105

			property. (d) Damage or disruption to major roads including but not limited to interstate and state highways, and the only access to residential or other critical areas such as hospitals, nursing homes, or correctional facilities as determined by the chief. (e) Damage or disruption to railroads, or public utilities. (f) Damage to downstream class I, II or III dams or levees, or other dams or levees of high value.	property in paragraph A of this rule. At the request of the dam owner, the chief may exempt dams from the criterion of this paragraph if the dam owner owns the potentially affected property. (b)Damage or disruption to local roads including but not limited to roads not otherwise listed as major roads in paragraph A of this rule.		
OK	NA	High hazard: One or more habitable structures with loss of life due to dam failure likely. Excessive economic loss/property damage (extensive community, industrial or agriculture)	Significant hazard: No loss of life Potential for future development exists, habitable structures may exist in inflow design flood floodplain, but dam failure would not endanger lives that would not be endangered if structure did not exist. Appreciable economic loss/ property damage (notable agriculture, industrial or structural)	Low hazard: None (no probable future development; may be zoned to prevent future development).	Minimal economic/property loss (undeveloped to occasional structure or agriculture)	785:25-3-3. Hazard classification subject to regulation and change. (A) For dams inventoried in the National Safety of Dams program authorized under 33 USC 467, hazard classifications set forth in Phase I reports is presumed accurate. If the dam owner disagrees, he has the burden to show that hazard class should be changed. (B) At the discretion of the Board, any proposed or existing dam considered to have classification of a high hazard potential may be subject to regulation regardless of size or impounding capacity. (C) The hazard potential classification may change as the area downstream from a dam develops and the dam may be reclassified from time to time.
OR	N/A	High Hazard: This rating indicates that if the dam fails there is a strong plausibility for loss of life. The plausibility is established because of inhabited infrastructure (such as homes and business) downstream that would be inundated to such a degree see 690-020-0100(2)(d) for specific criteria that it would put the person	Significant Hazard: This rating indicates that if a dam fails, infrastructure (such as roads, power lines or other largely uninhabited buildings) would be damaged or destroyed due to inundation and flooding. The department shall endeavor to inspect this class of dams at least once every three years.	Low Hazard: This rating indicates that if the dam fails there is little plausibility for loss of life, and human infrastructure that could be affected by inundation downstream is minor or non-existent. The department shall endeavor to inspect this class of dams at least once every six years.	NA	http://arcweb.sos.state.or.us/rules/OARS_600/OAR_690/690_020.html

		who inhabits the structure in jeopardy. Any factor that puts a strong probability of people being downstream in an inundation area of a dam failure shall be considered. The department shall endeavor to inspect this class of dams on an annual basis.				
PA	NA	High Hazard: A dam so located as to endanger populated areas downstream by its failure. Category 1: Substantial loss of life. Excessive economic loss (extensive residential, commercial, agricultural and substantial public inconvenience). Failure would impact two or more habitable structures. Category 2 - High Hazard: Breach inundation area impacts one habitable structure.	Category 2 - Non High Hazard: No habitable structures are impacted (appreciable economic loss only). Category 2: Few fatalities (no rural communities or urban developments and no more than a small number of habitable structures). Appreciable economic loss (Damage to private or public property and short duration public inconvenience).	Category 3: No loss of life expected (no permanent structure for human habitation). Minimal economic loss (undeveloped or occasional structures with no significant effect on public inconvenience).	NA	Source: PA DEP, Sept. 2010
PR	NA	High Hazard - Structures for which failure would cause more than very little loss of life and serious damage to communities, industry and agriculture.	Intermediate Hazard - Structures for which failure would cause very little loss of life and significant damage to property and project operation,	Low Hazard - Structures for which failure would result in loss of the structure itself, but little or no additional damage to other property.	NA	

STATE DAM SAFETY HAZARD POTENTIAL CLASSIFICATION
Association of State Dam Safety Officials - www.damsafety.org
Compiled September 2010

RI	NA	High hazard: Failure or mis-operation results in a probable loss of human life.	Significant hazard: Failure or mis-operation results in no probable loss of human life but can cause major economic loss, disruption of lifeline facilities or impact other concerns detrimental to the public's health, safety or welfare.	Low hazard: Failure or mis-operation results in no probable loss of human life and low economic losses.	NA	In regulations effected December 2007, each dam has a hazard classification of high, significant or low, which is a determination made by the Director relating to the following probable consequences of failure or misoperation of the dam:
SC	NA	Class I - High Hazard: Dams located where failure will likely cause loss of life or serious damage	Class II - Significant Hazard: Dams located where failure will not likely cause loss of life but may damage property.	Class III - Low Hazard: Dams located where failure may cause minimal property damage	NA	
SD	NA	Category 1: Potential loss of life;	Category 2: No loss of life expected: Extensive economic loss potential (community or industry)	Category 3: No loss of life expected: minimal economic loss potential (undeveloped to occasional structures)	NA	http://legis.state.sd.us/rules/DisplayRule.aspx?Rule=74:02:08:05
TN	NA	Category 1: Failure would probably result in any of the following: loss of human life; excessive economic loss due to damage of downstream properties; excessive economic loss, public hazard, or public inconvenience due to loss of impoundment and/or damage to roads or any public or private utilities.	Category 2: Failure may damage downstream private or public property, but such damage would be relatively minor and within the general financial capabilities of the dam owner. Public hazard or inconvenience due to loss of roads or any public or private utilities would be minor and of short duration. Chances of loss of life would be possible but remote.	Category 3: Failure may damage uninhabitable structures or land but such damage would probably be confined to the dam owner's property. No loss of human life would be expected.	NA	Regulations state that dams will be re-evaluated for hazard potential every 5 years (1200-5-7-.05).
TX	NA	A dam in the high-hazard potential category has: (A) loss of life expected (seven or more lives or three or more habitable structures in the breach inundation area downstream of the	A dam in the significant-hazard potential category has: (A) loss of human life possible (one to six lives or one or two habitable structures in the breach inundation area downstream of the dam); or (B) appreciable economic loss, located primarily in rural areas where	A dam in the low-hazard potential category has: (A) no loss of human life expected (no permanent habitable structures in the breach inundation area downstream of the dam); and (B) minimal economic loss (located	NA	Definitions provided by TX Program, 9/3/2010.

		Dams are those, the failure of which could result in more than a few deaths and excessive economic loss.	Dams, are those, the failure of which could result in a few deaths and appreciable economic loss.	Dams are those, the failure of which is not expected to result in either loss of life or any economic loss.		the Downstream Hazard Classification system recommended by the US Army Corps of Engineers.
VA	NA	High Hazard Potential is defined where an impounding structure failure will cause probable loss of life or serious economic damage. "Probable loss of life" means that impacts will occur that are likely to cause a loss of human life, including but not limited to impacts to residences, businesses, other occupied structures, or major roadways. Economic damage may occur to, but not be limited to, building(s), industrial or commercial facilities, public utilities, major roadways, railroads, personal property, and agricultural interests. "Major roadways" include, but are not limited to, interstates, primary highways, high-volume urban streets, or other high-volume roadways.	Significant Hazard Potential is defined where an impounding structure failure may cause the loss of life or appreciable economic damage. "May cause loss of life" means that impacts will occur that could cause a loss of human life, including but not limited to impacts to facilities that are frequently utilized by humans other than residences, businesses, or other occupied structures, or to secondary roadways. Economic damage may occur to, but not be limited to, building(s), industrial or commercial facilities, public utilities, secondary roadways, railroads, personal property, and agricultural interests. "Secondary roadways" include, but are not limited to, secondary highways, low-volume urban streets, service roads, or other low-volume roadways.	Low Hazard Potential is defined where an impounding structure failure would result in no expected loss of life and would cause no more than minimal economic damage. "No expected loss of life" means no loss of human life is anticipated.		4VAC50-20-40. Hazard potential classifications of impounding structures (2008) www.dcr.virginia.gov/documents/dsfinregs092608.pdf The hazard potential classification shall be proposed by the owner and shall be subject to approval by the board. To support the appropriate hazard classification, dam break analysis shall be conducted by the owner's engineer. Present and planned land-use for which a development plan has been officially approved by the locality in the dam break inundation zones downstream from the impounding structure shall be considered in determining the classification. Impounding structures shall be subject to reclassification by the board as necessary.

STATE DAM SAFETY HAZARD POTENTIAL CLASSIFICATION
Association of State Dam Safety Officials - www.damsafety.org
Compiled September 2010

	1a: -PAR*: More than 300 -Economic loss: Extreme. More than 100 inhabited structures. Highly developed, densely populated suburban or urban area with associated industry, property, transportation and community life line features.	-PAR*: 31-300 -Economic loss: Extreme. 11 to 100 inhabited structures. Medium density suburban or urban area with associated industry, property and transportation features. -Environmental damages: Severe water quality degradation potential from reservoir contents and long term effects on aquatic and human life.	-PAR*: 7-30 -Economic loss: Major. 3 to 10 inhabited structures. Low density suburban area with some industry and work sites. Primary highways and rail lines.	Class 2: -PAR*: 1-6 -Economic loss: Appreciable. 1 or 2 inhabited structures. Notable agriculture or work sites. Secondary highway and/or rail lines. -Environmental damages: Limited water quality degradation from reservoir contents and only short term consequences.	-PAR*: 0 -Economic loss: Minimal. No inhabited structures. Limited agricultural development. Environmental damages: No deleterious materials in reservoir contents.	areas. The most serious potential consequences of failure of PAR, economic loss, and environmental damages are used to establish hazard classification. **PAR = Population at Risk*
WV	NA	Class 1 (High Hazard): Dams located where failure may cause loss of human life or major damage to dwellings, commercial or industrial buildings, main railroads, important public utilities, or where a high risk highway may be affected or damaged. This classification must be used if failure may result in the loss of human life.	Class 2 (Significant Hazard): Dams located where failure may cause minor damage to dwellings, commercial or industrial buildings, important public utilities, main railroads, or cause major damage to unoccupied buildings, or where a low risk highway may be affected or damaged. The potential for loss of human life resulting from failure of a Class 2 dam must be unlikely.	Class 3 (Low Hazard): Dams located in rural or agricultural areas where failure may cause minor damage to nonresidential and normally unoccupied buildings, or rural or agricultural land. Failure of a Class 3 dam would cause only a loss of the dam itself and a loss of property use, such as use of related roads, with little additional damage to adjacent property. The potential for loss of human life resulting from failure of a Class 3 dam must be unlikely. An impoundment exceeding 40 ft in height or 400 acre-ft storage volume shall not be classified as a Class 3 dam. A waste disposal dam, the failure of which may cause significant harm to the	Class 4 (Negligible Hazard): Dams where failure is expected to have no potential for loss of human life, no potential for property damage and no potential for significant harm to the environment. Examples: dams across rivers, failure of which under any conditions will not flood areas above normal streambank elevations; dams located in the reservoir of another dam which, under any conditions, can contain water released by failure of the Class 4 dam; and dams in series where the toe of the Class 4 dam(s) is in close proximity to the reservoir of a dam which can contain failure of the Class 4 dam(s) under any condition. In considering a request for a Class 4 designation, the director may require written	

STATE DAM SAFETY HAZARD POTENTIAL CLASSIFICATION

Compiled September 2010

				environment, shall not be classified as a Class 3 dam.	concurrence from the owner(s) of downstream dams that may be affected by failure of the Class 4 dam. Approval is vested in the director, and will be based on engineering evaluation of the dam(s) and downstream areas in question.	
WI	N/A	High hazard: A high hazard rating shall be assigned to those dams that have existing development in the hydraulic shadow that will be inundated to a depth greater than 2 feet or do not have land use controls in place to restrict future development in the hydraulic shadow. This rating must be assigned if loss of human life during failure or mis-operation of the dam is probable.	Significant hazard: A significant hazard rating shall be assigned to those dams that have no existing development in the hydraulic shadow that would be inundated to a depth greater than 2 feet and have land use controls in place to restrict future development in the hydraulic shadow. Potential for loss of life during failure must be unlikely. Failure or mis-operation of the dam would result in no probable loss of human life but can cause economic loss, environmental damage, or disruption of lifeline facilities.	Low hazard: A low hazard rating shall be assigned to those dams that have no development unrelated to allowable open space use in the hydraulic shadow where the failure or mis-operation of the dam would result in no probable loss of human life, low economic losses (losses are principally limited to the owners property), low environmental damage, no significant disruption of lifeline facilities, and have land use controls in place to restrict future developments in the hydraulic shadow.	N/A	Source: Page 63 of Dam Design and Construction
WY	NA	High hazard dams would, in case of failure of the dam, likely cause loss of life.	Significant hazard dams would, in case of failure, likely cause significant property damage, but no loss of life.	Failure of a low hazard dam would likely cause only minimal property damage.
